Francisco de Goya, trained in the foreign traditions fashionable in 18th-century Spain, became one of the most characteristically Spanish artists of all times and a major figure in the history of European art. His enormous and varied production of paintings, drawings, and engravings, relating to nearly every aspect of contemporary life, reflects the period of political and social upheavals in which he lived. He had no immediate followers, but his many original achievements profoundly impressed later 19th-century French artists—Eugène Delacroix was one of his great admirers—who were the leaders of new European movements, from Romanticism and Realism to Impressionism; and his works continued to be admired and studied by the Expressionists and Surrealists in the 20th century.

Early training and career. Francisco José de Goya y Lucientes was born on March 30, 1746, at Fuendetodos, near Saragossa. He began his studies in Saragossa under José Luzán y Martínez, a local artist trained in Naples, and was later a pupil, in Madrid, of the court painter Francisco Bayeu, whose sister he married in 1773. He went to Italy to continue his studies and was in Rome in 1771. In the same year he returned to Saragossa, where he obtained his first important commission for frescoes in the cathedral, which he executed at intervals during the next ten years. These and other early religious paintings made in Saragossa are in the Baroque–Rococo style then current in Spain and are influenced in particular by the great Venetian painter Giovanni Battista Tiepolo, who spent the last years of his life in Madrid (1762–70), where he was invited to paint ceilings in the royal palace.

Francisco de Goya, self-portrait from "Los caprichos" series, etching, c. 1798.

Goya's career at court began in 1775, when he painted the first of a series of over 60 cartoons (preparatory paintings; mostly preserved in the Prado, Madrid), on which he was engaged until 1792, for the Royal Tapestry Factory of Santa Bárbara. These paintings of scenes of contemporary life, of aristocratic and popular pastimes, were begun under the direction of the German artist Anton Raphael Mengs, a great exponent of Neoclassicism who, after Tiepolo's death, had become undisputed art dictator at the Spanish court. In Goya's early cartoons the influence of Tiepolo's decorative style is modified by the teachings of Mengs, particularly his insistence on simplicity. The later cartoons reflect his growing independence of foreign traditions and the development of an individual style, which began to emerge through his study of the paintings of the 17th-century court painter Diego Velázquez in the royal collection, many of which he copied in etchings (*c.* 1778). Later in life he is said to have acknowledged three masters: Velázquez, Rembrandt, and, above all, nature. Rembrandt's etchings were doubtless a source of inspiration for his later drawings and engravings, while the paintings of Velázquez directed him to the study of nature and taught him the language of realism.

First cartoons

In 1780 Goya was elected a member of the Royal Academy of San Fernando, Madrid, his admission piece being a "Christ on the Cross," a conventional composition in the manner of Mengs but painted in the naturalistic style of Velázquez' "Christ on the Cross," which he doubtless knew. In 1785 he was appointed deputy director of painting at the Academy and in the following year painter to the king, Charles III. To this decade belong his earliest known portraits of court officials and members of the aristocracy, whom he represented in conventional 18th-century poses. The stiff elegance of the figures in full-length portraits of society ladies, such as "The Marquesa de Pontejos," and the fluent painting of their elaborate costumes also relates them to Velázquez' court portraits; and his representation of "Charles III as Huntsman" (private collection) is based directly on Velázquez' royal huntsmen.

Period under Charles IV. The death of Charles III in 1788, a few months before the outbreak of the French Revolution, brought to an end the period of comparative prosperity and enlightenment in which Goya reached maturity. The rule of reaction and political and social corruption that followed—under the weak and stupid Charles IV and his clever, unscrupulous queen, Maria Luisa—ended with the Napoleonic invasion of Spain. It was under the patronage of the new king, who raised him at once to the rank of court painter, that Goya became the most successful and fashionable artist in Spain; he was made director of the Academy in 1795 (but resigned two years later for reasons of health) and first court painter in 1799. Though he welcomed official honours and worldly success with undisguised enthusiasm, the record that he left of his patrons and of the society in which he lived is ruthlessly penetrating. After an illness in 1792 that left him permanently deaf, his art began to take on a new character, which gave free expression to the observations of his searching eye and critical mind and to his newly developed faculty of imagination. During his convalescence, he painted a set of cabinet pictures said to represent "national diversions," which he submitted to the Vice Protector of the Academy with a

covering letter (1794), saying, "I have succeeded in making observations for which there is normally no opportunity in commissioned works, which give no scope for fantasy and invention." The set was completed by "The Madhouse" in 1794, a scene that Goya had witnessed in Saragossa, painted in a broad, sketchy manner, with an effect of exaggerated realism that borders on caricature. For his more purposeful and serious satires, however, he now began to use the more intimate mediums of drawing and engraving. In "Los caprichos," a series of 80 etchings published in 1799, he attacked political, social, and religious abuses, adopting the popular imagery of caricature, which he enriched with highly original qualities of invention. Goya's masterly use of the recently developed technique of aquatint for tonal effects gives "Los caprichos" astonishing dramatic vitality and makes them a major achievement in the history of engraving. Despite the veiled language of designs and captions and Goya's announcement that his themes were from the "extravagances and follies common to all society," they were probably recognized as references to well-known persons and were withdrawn from sale after a few days. A few months later, however, Goya was made first court painter. Later he was apparently threatened by the Inquisition, and in 1803 he presented the plates of "Los caprichos" to the King in return for a pension for his son.

Etchings attacking abuses of society

While uncommissioned works gave full scope for "observations," "fantasy," and "invention," in his commissioned paintings Goya continued to use conventional formulas. His decoration of the church of San Antonio de la Florida, Madrid (1798), is still in the tradition of Tiepolo; but the bold, free execution and the expressive realism of the popular types used for religious and secular figures are unprecedented. In his numerous portraits of friends and officials a broader technique is combined with a new emphasis on characterization. The faces of his sitters reveal his lively discernment of personality, which is sometimes appreciative, particularly in his portraits of women, such as that of "Doña Isabel de Porcel," but which is often far from flattering, as in his royal portraits. In the group of "The Family of Charles IV," Goya, despite his position as court painter, has portrayed the ugliness and vulgarity of the principal figures so vividly as to produce the effect of caricature.

The Napoleonic invasion and period after the restoration. In 1808 Goya was at the height of his official career when Charles IV and his son Ferdinand were forced to abdicate in quick succession, Napoleon's armies entered Spain, and Napoleon's brother Joseph was placed on the throne. Goya, retained his position as court painter, but in the course of the war he portrayed Spanish as well as French generals, and in 1812 he painted a portrait of "The Duke of Wellington." It was, however, in a series of etchings, "Los desastres de la guerra" ("The Disasters of War"; first published 1863), for which he made drawings during the war, that he recorded his reactions to the invasion and to the horrors and disastrous consequences of the war. The violent and tragic events, which he doubtless witnessed, are represented not with documentary realism but in dramatic compositions—in line and aquatint—with brutal details that create a vivid effect of authenticity.

Depiction of the horrors of war

On the restoration of Ferdinand VII in 1814, after the expulsion of the invaders, Goya was pardoned for having served the French king and reinstated as first court painter. "The 2nd of May 1808: The Charge of the Mamelukes" and "The 3rd of May 1808: The Execution of the Defenders of Madrid" were painted to commemorate the popular insurrection in Madrid. Like "Los desastres," they are compositions of dramatic realism, and their monumental scale makes them even more moving. The Impressionistic style in which they are painted foreshadowed and influenced later 19th-century French artists, particularly Manet, who was also inspired by the composition of "The 3rd of May." In several portraits of Ferdinand VII, painted after his restoration, Goya evoked—more forcefully than any description—the personality of the cruel tyrant, whose oppressive rule drove most of his friends and eventually Goya himself into exile. He painted few other official portraits, but those of his friends and relations and his "Self-Portraits" (1815) are equally subjective. Some of his religious compositions of this period, the "Agony in the Garden" and "The Last Communion of St. Joseph of Calasanz" (1819), are more suggestive of sincere devotion than any of his earlier church paintings. The enigmatic "black paintings," with which he decorated the walls of his country house, the "Quinta del Sordo" (1820–23, now in the Prado) and "Los proverbios" or "Los disparates," a series of etchings made at about the same time (though not published until 1864), are, on the other hand, nightmare visions in expressionist language that seem to reflect cynicism, pessimism, and despair.

Later religious paintings

Last years. In 1824, when the failure of an attempt to establish a liberal government had led to renewed persecution, Goya applied for permission to go to France for reasons of health. After visiting Paris he settled in voluntary exile in Bordeaux, where he remained, apart from a brief trip to Madrid, until his death. There, in spite of old age and infirmity, he continued to record his impressions of the world around him in paintings, drawings, and the new technique of lithography, which he had begun to use in Spain. His last paintings include genre subjects and several portraits of friends in exile: "Don Juan Bautista de Muguiro," "Leandro Fernández de Moratín," and "Don José Pío de Molina," which show the final development of his style toward a synthesis of form and character in terms of light and shade, without outline or detail and with a minimum of colour. He died on April 16, 1828. Though there is little evidence for the legends of Goya's rebellious character and violent actions, he was undoubtedly a revolutionary artist.

MAJOR WORKS

PAINTINGS (RELIGIOUS): "The Adoration of the Name of God" (1772; Cathedral of Nuestra Señora del Pilar, Saragossa); "Christ on the Cross" (1780; Prado, Madrid); "The Queen of Martyrs" (1780–81; Cathedral of Nuestra Señora del Pilar, Saragossa); "St. Bernardino of Siena" (1782–83; San Francisco el Grande, Madrid); "The Annunciation" (1785; private collection, Spain); "The Taking of Christ" (1798; Cathedral, Toledo); "A Miracle of St. Anthony of Padua" and other scenes (1798; San Antonio de la Florida, Madrid); "SS. Justa and Rufina" (1817; Cathedral, Seville); "The Last Communion of St. Joseph of Calasanz" (1819; Escuelas Pías de San Antón, Madrid); "Agony in the Garden" (1819; Escuelas Pías de San Antón, Madrid). (PORTRAITS): "The Count of Floridablanca and Goya" (1783; Banco Urquijo, Madrid); "The Marquesa de Pontejos" (*c.* 1786; National Gallery of Art, Washington, D.C.); "Manuel Osorio de Zúñiga" (1788; Metropolitan Museum of Art, New York); "Family of the Duke of Osuna" (1788; Prado); "The Marquesa de la Solana" (*c.* 1794–95; Louvre, Paris); "The Duchess of Alba" (1797; Hispanic Society of America, New York); "Ferdinand Guillemardet" (1798; Louvre); "La Tirana" (1799; Academy of San Fernando, Madrid); "Queen Maria Luisa, on Horseback" (1799; Prado); "The Family of Charles IV" (1800; Prado); "The Naked Maja" and "The Clothed Maja" (*c.* 1800–05; Prado); "Doña Isabel de Porcel" (*c.* 1806; National Gallery, London); "General Manuel Romero" (*c.* 1810; private collection, Chicago); "The Duke of Wellington" (1812; National Gallery, London); "Mariano Goya" (*c.* 1812–14; private collection, Madrid); "Ferdinand VII in an Encampment" (*c.* 1814; Prado); "Self-Portrait" (1815; Academy of San Fernando, Madrid); "Portrait of Don Juan Antonio Cuervo" (1819; Cleveland Museum of Art); "Self-Portrait with Doctor Arrieta" (1820; Minneapolis Institute of Arts); "Leandro Fernández de Moratín" (1824; Museo de Bellas Artes, Bilboa); "The Milkmaid of Bordeaux" (1825–27; Prado); "Don Juan Bautista de Muguiro" (1827; Prado); "Don José Pío de Molina" (1827–28; Reinhart Collection, Winterthur). (HISTORY, ALLEGORY, AND GENRE): "Tapestry Cartoons" (1775–92; Prado); "The Madhouse" (1794; Virginia Meadows Museum and Elizabeth Meadows Sculpture Court, Dallas); "Allegory of the City of Madrid" (1810; Casa del Ayuntamiento, Madrid); "The Colossus" ("The Panic," *c.* 1810–12; Prado); "Time and the Old Women" (*c.* 1810–12; Musée des Beaux-Arts, Lille); "The Majas on the Balcony" (*c.* 1812; Metropolitan Museum of Art, New York); "Young Women with a Letter" (*c.* 1814–18; Musée des Beaux-Arts, Lille); "The 2nd of May 1808 in Madrid: The Charge of the Mamelukes" (1814; Prado); "The 3rd of May 1808: The Execution of the Defenders of Madrid" (1814; Prado); "The Forge" (*c.* 1819; Frick Collection,

New York); "The Black Paintings from the Quinta del Sordo" (1820–23; Prado).

DRAWINGS, ENGRAVINGS, AND LITHOGRAPHS: The largest and most important collection of drawings of all periods is in the Prado, Madrid.

ETCHINGS: "Los caprichos" (1797–98); "Los desastres de la guerra" (1810–14); "La tauromaquia" (1815–16); "Los disparates" or "Los proverbios" (*c.* 1820–24).

LITHOGRAPHS: "The Bulls of Bordeaux" (1824–25).

BIBLIOGRAPHY

General works: LAURENT MATHERON, *Goya* (1858), the first monograph (in French) on Goya, dedicated to Delacroix —contains interesting data on the artist's last years in Bordeaux; FRANCISCO ZAPATER Y GOMEZ, *Goya. Noticias biográficas* (1868; new ed., 1924), important biographical notes by the son of Goya's intimate friend, Martín Zapater, with extracts from his correspondence; CONDE DE LA VINAZA, *Goya: su tiempo, su vida, sus obras* (1887), a study of Goya and his times, incorporating many documents, with a catalogue raisonné; F.J. SANCHEZ CANTON, *Vida y obras de Goya* (1951; Eng. trans., *The Life and Works of Goya*, 1964), a well-documented general survey of Goya's life and principal works; F.D. KLINGENDER, *Goya in the Democratic Tradition*, 2nd ed. (1968), a stimulating, if partisan, study of the artist in relation to his political and social background, which is treated in considerable detail; PIERRE GASSIER and JULIET WILSON, *Vie et oeuvre de Francisco Goya* (1970; Eng. trans., *The Life and Complete Work of Francisco Goya*, ed. by FRANCOIS LACHENAL, 1971), of major importance as the most comprehensive monograph on Goya, providing an authoritative account of his life and career, with a catalog and reproductions of all his known paintings, drawings, and engravings and detailed bibliographical references.

Paintings: VALENTIN DE SAMBRICIO, *Tapices de Goya* (1946), the definitive work on Goya's tapestry cartoons, with all the relevant documents, and illustration of all the paintings; ENRIQUE LAFUENTE FERRARI, *The Frescos in San Antonio de la Florida in Madrid* (Eng. trans. 1955), a historical and critical study of the frescoes, illustrated in colour; F.J. SANCHEZ CANTON, *Goya and the Black Paintings*, with an appendix by XAVIER DE SALAS (1964), a well-documented account of Goya's career with a detailed study of the "black paintings" and a history of the "Quinta del Sordo," with large and detailed colour illustrations; JOSEP GUDIOL I RICART, *Goya: Biography, Analytical Study, and Catalogue of His Paintings* (Eng. trans., 1971), a detailed study of Goya's life and work accompanied by a critical catalog of his paintings (fully illustrated).

Drawings and engravings: F.J. SANCHEZ CANTON, *Los dibujos de Goya*, 2 vol. (1954), a catalog with reproductions of Goya's drawings in the Prado; and *Los Caprichos de Goya y sus dibujos preparatorios* (1949), a well-illustrated study of the etchings and their preparatory drawings; JOSE LOPEZ-REY, *A Cycle of Goya's Drawings: The Expression of Truth and Liberty* (1956), an interpretation of the drawings in the light of the political and social background during the liberal struggle in Spain following the defeat of Napoleon; and *Goya's Caprichos: Beauty, Reason and Caricature*, 2 vol. (1953), an interpretive study of the "Caprichos" with a catalog of the etchings and preparatory drawings, all illustrated; ENRIQUE LAFUENTE FERRARI, *Los desastres de la guerra de Goya y sus dibujos preparatorios* (1952); and JOSE CAMON AZNAR, *"Los Disparates" de Goya y sus dibujos preparatorios* (1951), two well-illustrated studies of the etchings and their preparatory drawings; TOMAS HARRIS, *Goya: Engravings and Lithographs*, 2 vol. (1964), the most important and most comprehensive work on the subject, including a study of Goya's techniques and methods of production and a complete illustrated catalog with critical and descriptive analysis of every work from the preparatory drawings and working proofs to all the published impressions.

(E.Ha.)

Gracchi, The

The brothers Tiberius Sempronius and Gaius Sempronius Gracchus, by exploiting the tribunate of the people and the legislative power of the People's Assembly of the Roman Republic, initiated what came to be called the Roman Revolution. Their techniques enabled later political leaders to secure power independently of the Senate, an aristocratic council of state dominated by elder statesmen, which had previously seldom been challenged in its control of public affairs.

Early years. The story of the Gracchi is overlain by partisan bias and invention, both friendly and hostile. The narratives of the historians Appian and Plutarch, composed two centuries after the events, tend to obscure both the motives of the actors and the details of the actions. Tiberius Sempronius Gracchus and his brother Gaius Sempronius, born about 163 and 153 BC, respectively, were the sons of a Roman aristocrat whose family had regularly held the highest offices of state for the past century. They could expect to secure election to the annual praetorships and consulships, the plums of public life, without any special exertions. But, maturing in an age of social and political crisis, they were the first to face its problems, and, by advocating radical changes in the face of entrenched conservatism, they undermined their own position and failed to establish a permanent substitute in populist support. They were born to a nexus of political connections with other leading families that would ensure the regular promotion of their careers—most notably with the Cornelii Scipiones, the most continuously successful of the great Roman houses—through their mother, Cornelia, daughter of the conqueror of Hannibal, and through their sister Sempronia, wife of Scipio Aemilianus, the destroyer of Carthage. They were equally associated with the great rivals of the Scipios, the Claudii Pulchri, through Tiberius' wife, Claudia, daughter of Appius Claudius Pulcher, the contemporary head of the house.

The brothers were educated in the new Greek enlightenment that had been adopted by the more liberal families after the Roman conquest of the Hellenistic kingdoms, and this gave form and clarity to their natural talent for public speaking. The new learning was based on literature, oratory, and philosophy. The Stoic teacher Blossius had special influence with Tiberius, but the central Stoic doctrine of duty merely enhanced his natural determination and obstinacy. Other Greek associates may have instructed him in the democratic theory that later coloured his speeches.

Military service

Career of Tiberius Gracchus. As a Roman aristocrat, Tiberius began a normal military career, serving as a junior officer with distinction under Scipio Aemilianus in the war with Carthage (147–146 BC), and in due course went as quaestor, or paymaster, with the consul Mancinus to the protracted colonial warfare in Spain (137 BC). There his personal integrity and family reputation enabled him to save a Roman army from total destruction at Numantia by an honourable compact with the Spanish tribesmen. But, at the insistence of Aemilianus, the agreement was disavowed by the Senate at Rome, and Mancinus, the defeated consul, though not his staff and his troops, was returned to his captors. This setback alienated Tiberius from the Scipionic faction in the Senate and drew him closer to his Claudian friends.

Distribution of public lands. His military experience had shown him the latent weakness of Rome. Its manpower was stretched to the limit to maintain its hegemony over the Mediterranean world, while its sources in Italy were beginning to contract. The primitive subsistence economy that in past centuries had nourished a large population of poor peasants was being eroded by new factors, notably the development of large estates owned by magnates enriched in the imperialist wars and devoted to cash crops worked by slaves and day labourers. The landowning peasantry, who alone were thought useful for military service, were declining in numbers, while the landless citizenry were increasing. Tiberius sought a solution of the manpower problem in a large-scale revival of the traditional Roman policy, abandoned only in the last 30 years, of settling landless men on the extensive public lands acquired by the Roman state during the former conquest of Italy. Much of this land had fallen irregularly but effectively into the hands of the Roman gentry, who regarded it wrongly as their private property. Tiberius, with the support of a small but powerful group of consular senators, primarily of the Claudian faction, who shared his concern and also looked for political advantage from sponsoring such a scheme, concocted a bill for the redistribution of the public lands to landless labourers in plots of viable size. The novelty lay only in the scale of the scheme, which was not limited to a defined area of land or number of persons, and in the

institution of a permanent executive of land commissioners. Opposition from vested interests was certain, but Tiberius hoped to pacify it by a generous provision allowing the great occupiers of public land to retain from 300 to 600 acres in private ownership, according to the size of their families.

Tribunate. To implement this measure Tiberius secured the legislative office of tribune, for 133 BC, which was not an essential part of a senatorial career. Tribunes at this period normally legislated in the People's Assembly on the advice of the Senate, but more than once in recent years tribunes had passed reformist measures without senatorial approval. Tiberius in 133 had the support of the sole consul in Rome—Publius Mucius Scaevola, who had helped to draft the agrarian bill—and of several other leading senators, mostly of the Claudian faction, whose authority could be expected to deflate opposition while hordes of peasants flocked to Rome to use their votes. When, after lengthy public debate, the bill was presented to the voters, the tribune Octavius used his right of veto to stop the proceedings in the interest of the great occupiers. When he refused to give way, Tiberius vainly sought belated approval from the Senate. That should have been the end of the matter, but Tiberius, obstinately convinced of the necessity of his bill, devised a novel method of bypassing the veto: a vote of the Assembly removed Octavius from office, contrary to all precedent. The bill itself was then passed. But the deposition of Octavius alienated many of Tiberius' supporters, who saw that it undermined the authority of the tribunate itself; they rejected the unfamiliar justification, devised by Tiberius, that tribunes who resisted the will of the people ceased to be tribunes.

Fresh complications arose from the lack of financial provision in the agrarian law for the equipment of the new landholders. Tiberius expected the Senate to make the traditional allocation of funds, but Scipio Nasica, an elderly senator from the Scipionic faction, succeeded in limiting these to a derisory sum. Tiberius countered by a second outrageous proposal, of which he failed to see the implication. The King of Pergamum, a city in Anatolia, on his death in 134 had bequeathed his fortune and his kingdom to the Roman state. Tiberius by a fresh bill claimed these monies in the name of the people and assigned them to the land commissioners, thus interfering with the Senate's traditional control of public finance and foreign affairs. The storm over Tiberius' methods continued to rage. He was threatened with prosecution after the end of his tribunate, when he would have no formal means of protecting his law and would be liable to prosecution before the Centuriate Assembly, in which the wealthier classes had a voting advantage. The charge would have been violation of the immunity of the tribune Octavius. Lacking the self-assurance to realize that the people were unlikely either to repeal the agrarian law or to pass sentence against its champion, Tiberius sought refuge in yet another impropriety. He proposed to stand for election to a second tribunate in 132, but re-election had not been practiced for 300 years and was widely believed to have been barred by an ambiguous statute. In the Senate the embittered opposition, again led by Nasica, tried to induce the consul Scaevola to stop the elections by force. Scaevola replied evasively that he would see that nothing illegal was done. Meanwhile, in the Assembly, Tiberius and the other tribunes were at loggerheads over the conduct of the election. An abortive vote had shown that the success of Tiberius was assured if only the election could be completed. He expected no violence and made no preparations against it. Enraged by the attitude of the Consul, Nasica and his associates stormed out of the Senate, equally unarmed. Seizing sticks and staves they precipitated a riot. It may well have begun as an attempt to disperse the electoral meeting, but it ended with the clubbing to death of Tiberius and the indiscriminate killing of some scores of citizens.

Threat of impeachment

The political fault lay with Tiberius. After presentation of the agrarian bill, he failed to act in prudent collaboration with his senatorial supporters, and he added to his troubles by dubious initiatives that were bound to offend the bulk of senatorial opinion. So Scaevola and the others abandoned him and effected a compromise. The Senate recommended that the land commission should continue, and, though in 132 it set up a political court that punished many of the lesser followers of Tiberius, it also encouraged Nasica, who barely escaped prosecution, to leave Italy.

Career of Gaius Gracchus. Gaius Gracchus was not long deterred from politics by his brother's disaster. Though barely 22 years old, he joined in the immediate outcry against Nasica, and he acted energetically as land commissioner in executing his brother's law. He became quaestor, a magistrate usually concerned with finance, in 126 at the normal age, after lengthy military service. When in 124 an intrigue against him at Rome delayed his already overdue recall from Sardinia, he asserted his independence by returning unsummoned and counterattacked his critics by underlining the honesty of his administration: "The purses that I took out to my province full of silver I have brought back empty, while others take out casks of wine and bring them back stuffed with loot."

First tribunate. The contentious tone forecast a vigorous politician, and his candidacy for the tribunate of 123 brought out great crowds of voters, though the opposition of family enemies prevented him from receiving the highest number of votes. He soon showed himself bent on exploiting his legislative power to the maximum. Cooler and more astute than his brother, he planned a complex program, of a sort never before proposed at Rome, and the means to carry it out.

Gaius realized that, by fostering sectional advantages, the influence of the wealthy upper class of landowners and businessmen outside the Senate—later known as Roman knights because of their liability to cavalry service—could be largely detached from its traditional support of the senatorial aristocracy and combined with the votes of the poorer citizens to carry radical reforms that no single group could manage by itself. Unlike his brother, he acted without significant senatorial support. Of the former family connections only Marcus Fulvius Flaccus, consul in 125, stood with Gaius. His other associates were dim and unknown figures. The scope of his proposals is the more remarkable, and the credit is his alone. He diagnosed the weaknesses of the Roman state at that time and proposed effective remedies. But, while the purpose of his particular measures is fairly clear, his general intentions remain obscure. Each of his proposals could be and was interpreted narrowly as a demagogic device for securing a personal predominance in the Assembly or as a direct attack on senatorial authority. Gaius certainly intended to establish an independent popular force in the Assembly, free from the traditional control of the great families. But his purpose was not democratic, for none of his measures intended the permanent replacement of the Senate and the annual officers of state by the popular Assembly. He used the Assembly not as an administrative body but as the source of legislative reform. This is seen clearly in his regulation for the annual assignment of the consular provinces, the most important policy-making moment in the Roman year. By securing passage of this law he ensured that the provinces would be allocated before the consuls were elected. This left the Senate as the policy-making body for war and foreign affairs but corrected an abusive procedure by requiring the Senate to make its decisions for each campaigning season before, instead of after, the election of the consuls who were to conduct affairs, thereby diminishing the opportunity for corruption. As an aristocrat he had no intention, unlike some of his successors, of subordinating the magistrates to the detailed control of the Assembly. He spoke in public as an enlightened, somewhat sardonic aristocrat who cultivated righteousness and despised his enemies, as in this fragment of a speech on foreign affairs:

Use of assembly for legislative reform

> Citizens, none of us men of rank comes before you for nothing, not even I myself. . . . But what I want from you is not money, but a good repute and public distinction.

The true understanding of Gaius is obscured by the un-

certainty of the chronological order of his measures in 123 and 122. But, despite minor confusions, it is clear that Gaius completed the whole of his program that touched the government of the Roman state before he turned to a different problem—the relationship between Rome and her Italian allies—early in his second tribunate and that his bill for the extension of the franchise to the independent peoples of Italy was his last legislative proposal. His preceding measures were criticized by the extreme conservatives as a general attempt to "destroy aristocracy and set up democracy, but they did not satisfy the radicals either." Other writers, while criticizing his methods, conceded the utility of many of his measures. Certainly his laws were "against the Senate," in that they sought to diminish its monopoly of power, and, if he had ended his effort in December 123, he could be dismissed as a statesman who sought personal supremacy by advocating salutary reforms. But the second tribunate, in which he sacrified his career to an unpopular cause, refutes so limited a view.

The measures of 123 were concerned with the abuse of power and with the extension of his brother's economic policy. He began with a demonstration against the enemies of Tiberius: the family vendetta was a regular part of Roman politics. A bill aimed at Octavius denied further office to magistrates deposed by the Assembly. Though Gaius did not press this proposal, it deterred his colleagues from using their vetoes against him. A law forbidding the establishment of political tribunals by the Senate without the sanction of the Assembly was intended to prevent a recurrence of the judicial murders committed by the political court set up to punish the supporters of Tiberius in 132, while providing for the indictment of Popillius Laenas, who had presided over them. This law was reinforced by a measure that penalized any attempt to exert improper influence over the management of tribunals, by the use of an ingenious formula covering "any magistrate or senator who combined or associated to secure the condemnation of a person in a public court."

A third law, concerned with judicial corruption, sought to provide independent juries for the "extortion court." This court had been created only 26 years earlier to curb the malpractices of Roman governors by enabling provincial subjects to sue for the restitution of monies taken improperly from them. Hitherto the jurors of this court had been senators, who had failed to protect the provincials against extortion through their own private interest in the fleecing of provinces. The judiciary law of Gaius excluded senators from the juries altogether and replaced them by Roman knights, who were expected to be more impartial. It is possible that Gaius originally proposed a mixed commission of senators and knights and withdrew that proposal when it became apparent that this scheme would not secure enough support to ensure its passage.

Gaius' judiciary law

Considerable portions survive of the text of what must be either the actual judiciary law of Gaius or a revised version modelled closely upon it. These show the same determination and ingenuity as his laws about special tribunals, to stop corruption and abuse in the working of the court. The exclusion of all magistrates and senators is minutely regulated, and no qualified juror may sit on a case if he and the accused person are members of the same club or confraternity. Lengthy clauses exactly regulated the distribution and collection of voting tablets and the counting of the vote.

This attention to detail is the hallmark of all the work done by Gaius about which there is any substantial information.

Two measures served partisan interests. The first established a beneficial system for the basic food supply of the now overgrown metropolis of Rome, where urban employment and prices were equally irregular. This "corn law" organized a supply of grain to be stored in new public granaries and to be sold to the urban population at a moderate price throughout the year. The second bill transferred the lucrative farming of taxes in the new province of Asia from local businessmen, who farmed the taxes on behalf of the Roman governor, to financial syndicates of Roman knights who dealt directly with the treasury at Rome, thus creating a monopoly for the Roman financiers. Both measures suggest a positive bid for the votes of persons domiciled at Rome. The rural population was wooed by two other measures: one transferred payments for military clothing from the conscript peasantry to the Roman treasury, and the second, modifying the law of Tiberius, proposed the establishment of self-governing communities of colonists instead of isolated individual holdings, not only in Italy but also in provinces overseas. This innovation led in later times to the widespread settlement of Roman colonies that latinized southern Europe.

Food and tax laws

Gaius may have toyed also with two basic constitutional amendments. The first would have enlarged the Senate from a council composed solely of former officials to include a larger number of Roman knights who had not held public office, thus giving the upper bourgeoisie a dominant voice in the formation of policy. The second proposal would have introduced a measure of equality into the complicated structure of the Centuriate Assembly. This body elected the consuls and praetors on the basis of voting groups weighted heavily in favour of the wealthier classes. Apparently Gaius ingeniously proposed to diminish the prepotent effects of the votes of the wealthy by simply changing the order in which they voted.

Second tribunate. Such were the laws proposed or carried by Gaius in 123 in the face of determined opposition. Though in late summer popular enthusiasm swept Gaius into a second tribunate, for which he had not originally intended to stand, his judiciary bill was subsequently passed by the vote of only 18 of the 35 voting groups of the Assembly. In so close a situation his successes are the more remarkable. But he had a yet more difficult project in mind for the next year. The greatest of Roman problems at this time concerned the management of the allies in Italy, who occupied two-thirds of the peninsula. They provided the larger part of the Roman armies that held the world in fee, yet these peoples were treated with increasing disdain and severity by the Roman aristocracy, though they were akin in race, language, and customs.

Gaius proposed a complex solution of the Italian question. The Latin-speaking allies, whose communal life was akin to that of Rome, were to be incorporated into the Roman state as full citizens and organized in locally self-governing municipalities, and the Italic peoples of non-Latin stocks were to have the intermediate status of the Latin allies; in private life the Latin allies shared some privileges of the Romans. This ingenious measure shows the disinterested yet committed character of Gaius as a statesman. Such an enlargement of the Roman state was, however, intensely unpopular with Romans of all classes. Gaius' persistence at once weakened his popular following and in the end wrecked his career. The opposition took heart. The tribune Marcus Livius Drusus undercut the proposal of Gaius with the suggestion that the Latin allies would be satisfied with a minor extension of privilege, while the consul Fannius played on the xenophobia of the masses. The prestige gained from the colonial schemes was undermined by a fictitious proposal of Drusus to found a full dozen such colonies in the name of the Senate. Gaius' position at Rome was not helped by his departure for two months to Africa to manage the foundation of a colony of 6,000 settlers at Carthage. Among the business classes, who had nothing more to gain from Gaius, his support was weakened by the alienation of the numerous corn merchants whose profits had been decreased. On his return Gaius tried by a series of demonstrations to restore his popular following. He moved his residence from an aristocratic quarter down to the plebeian streets around the Forum, insisted on the right of the common people to watch the public games without charge, and tried, though ineffectively, to prevent the execution of a consular decree forbidding Italians to remain in Rome during the vote on the enfranchisement bill. Altogether, opposed by senatorial opinion

Proposals for enfranchising allies

and shorn of his equestrian supporters, Gaius was a more isolated and a more demagogic figure than in 123. The enfranchisement bill was rejected, and Gaius failed to secure a third tribunate at the elections of 122.

In adversity Gaius showed the same stubborn determination as his brother to maintain a good cause at all costs. Like Tiberius he fell defending the agrarian colonization that was the basis of their position. In 121 a tribune proposed the dissolution of the great colony of Carthage. Helped by the remnant of his plebeian supporters, Gaius organized a counterdemonstration in a style that was allowed to no private citizen at Rome, where even a senator could not address a public meeting unless invited by a magistrate. In the fracas one of Gaius' party was killed, and the Gracchans retired uneasily to the Aventine Hill, traditional asylum of the Roman plebeians in an earlier age. Some of them bore arms, but the hostile sources admit that Gaius carried no more than a dagger. The Senate seized the opportunity to pass a novel decree, which urged the consuls to protect the state from any harm. Gaius, appalled, sought a parley. But the consul Lucius Opimius, refusing any negotiations, organized a heavily armed force composed largely of Roman knights and assaulted the Aventine. Massacre followed, as did the suicide of Gaius. But most of his legislation survived, and his unfinished projects were remembered, to become the basis of politics in the next generation. His rejected unification of Italy was finally conceded in 89 BC, after a destructive and unnecessary civil war that came close to destroying the foundations of Roman power. Hardly any substantial reform was proposed in the last century of the republic that did not owe its conception to the political intelligence of Gaius Gracchus. But he had also perfected a method of political organization in the interest of serious policy that proved disastrous in the hands of lesser men. Only too justly did he remark that he had cast into the Forum daggers with which the citizens would destroy themselves.

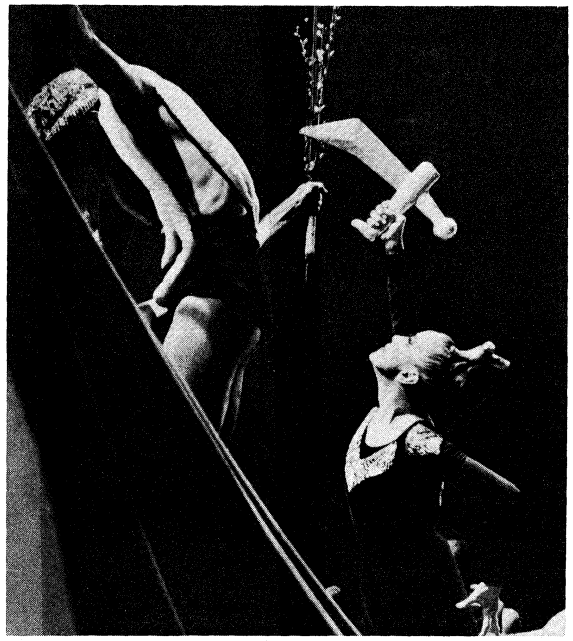
Graham, Martha

One of the most influential dancers, choreographers, teachers, and innovators of modern dance, Martha Graham created a dance technique rooted in the muscular and neuromuscular responses of the body to both inner and outer stimuli. It is a technique requiring both unrelenting discipline and prodigious virtuosity. It is the most highly developed body-training method in the entire field of modern dance. Explaining her art, she said that it was the function of her theatre of dance "to reveal the inner man" or "to give substance to things felt."

Martha Graham was born on May 11, 1893, in Pittsburgh, Pennsylvania, one of three daughters of a physician who was particularly interested in the bodily expression of human behaviour. Her ancestry, on one side, went directly back to Myles Standish and, on the other, to what she herself has called "Black Irish," a combination that resulted in a strict Protestant upbringing but an early exposure to the ritual beauties of the Roman Catholic Church. After some time in the South, her family settled in Santa Barbara, California, where she discovered the rhythm of the sea and made an acquaintance with Oriental art, influences that were to be evident in her choreography throughout her career.



Martha Graham as Clytemnestra. (Choreography and costumes, Martha Graham; music, Halim El-Dabh; decor, Isamu Noguchi.)
Martha Swope

Denishawn

Her professional career had its beginning at Denishawn, the schools and dance company founded by Ruth St. Denis and Ted Shawn, where as a teenager she was introduced to a repertory and curriculum that, for the first time in America, explored the world's dances—folk, classical, experimental, Oriental, Occidental, and American Indian. She was entranced by the religious mysticism of St. Denis, but Shawn was her major teacher; he discovered sources of dramatic power within her and then channelled them into an Aztec ballet, *Xochitl*. A tremendous success in both vaudeville and in concert performance (in the latter Shawn himself was her partner), *Xochitl* made her a Denishawn star.

She remained with Denishawn from 1916 to 1923, and although she ultimately rebelled violently against its eclecticism, she later mirrored in her own works something of the Orientalism that pervaded the school, and she assumed something of Ruth St. Denis' attitude of a priestess when she herself became a senior dancer.

Martha Graham eventually left Denishawn to become a featured dancer in the Greenwich Village Follies revue, where she remained for two years. Independence was not all she wanted, however; she was also searching for a new way of permitting the body to express itself in dance. In 1924 she went to the Eastman School of Music in Rochester, New York, to teach and to experiment.

Martha Graham made her New York debut as an independent artist in 1926. Though some of the fruits of her experiments were discernible from the first, a good many of her dances, such as *Three Gopi Maidens* and *Danse Languide*, echoed her Denishawn past. The critics found her to be very graceful and lyrical. All of that changed with her 1927 concert, and for the next decade and more, her dances were to be referred to as ugly, stark, and obscure. The exotic costumes and rich staging of Denishawn were in the past. Among the dances of her 1927 program was *Revolt*, probably the first dance of protest and social comment staged in the United States, which was set to the avant-garde music of Arthur Honegger. The audience was not impressed; dancers and theatregoers, famous and unknown, made fun of her. Fanny Brice, the popular comedienne, satirized her in a revue. Graham herself later referred to this decade as "my period of long woolens," a reference to the plain jersey dress that she wore almost as a uniform.

A strong and continuing influence in her life was Louis Horst, musical director at Denishawn, who had left the school two years after Graham. He became her musical

director, and often composer, during her first two decades of independence, and remained close to her until his death in 1964. Among his most noted scores for her were those for the now historic *Frontier*, a solo dance, and *Primitive Mysteries*, written for Graham and a company of female dancers.

Frontier (1935) initiated the use of decor in her repertoire and marked the beginning of a long and distinguished collaboration with the noted Japanese-American sculptor Isamu Noguchi, under whose influence she developed one of her most singular stage innovations, the use of sculpture, or three-dimensional set pieces, instead of flats and drops. This production illustrated her concept of dance.

Concept of dance

For Martha Graham the dance, though it is in part a narrative medium, can also, like the spoken drama, explore the spiritual and emotional essence of man. Thus, when in *Frontier* a leg sweeps high, it is not a chorus girl's high kick but an expression of ecstasy, of a willingness to adventure. *Frontier* is not of the American West alone, but rather a distillation of the word's meaning itself; a geographical frontier, the youth facing the post-school frontier of life, the virgin passing into potential motherhood, the citizen choosing between safe conformity and rebellion, the man between comfort and daring. It is a revolution of "the inner man."

In *Night Journey* (1947), a work about the Greek legendary figure Jocasta, the whole dance-drama takes place in the instant when Jocasta learns that she has mated with Oedipus, her own son, and has borne him children. The enormity of the sin is such that there is no cry of remorse from the lips; only a leg sweeping head high and the body falling forward to the floor as the legs slide into a split. The action, was to Graham, "a cry from the loins." Such a monumental exclamation was necessary to distinguish Jocasta's crime from an ordinary one. In *Letter to the World* (1940), a work about the poet Emily Dickinson, there are two Emilys: one who spoke the lines of Dickinson poems, and was restrained, ladylike, New England in deportment; and another whom Graham danced as the inner Emily, a wild, tempestuous, mercurial creature. It was the inner, not the outer, being who wrote the poems, and Graham knew it—this dance was one more example of her concept of the function of a dance, "to reveal the inner man."

For more than ten years, her company consisted solely of girls, but her themes were beginning to call for men and women dancers. She engaged Erick Hawkins, a ballet dancer, to join her company, and he appeared with her in a major work, *American Document* (1938). Though she and Hawkins ultimately were married, the marriage did not last.

In a career spanning more than half a century, Martha Graham created close to 150 works, ranging from solos to large-scale creations of full-program length such as *Clytemnestra* (1958). For her themes she has almost always turned to man, his conflicts and his emotions. The settings and the eras vary, but her great gallery of danced portraits never fails to explore the inner being. She created some dances from American frontier life, the most famous of which is *Appalachian Spring* (1944), with its score by Aaron Copland. Another source was Greek legend, the dances rooted in classical Greek dramas, stories, and myths. *Cave of the Heart* (1946), based on the Medea figure, with music by Samuel Barber, was not a dance version of Medea herself but rather an exposure of the Medea latent in every woman who, out of consuming jealousy, not only destroys those she loves but herself as well. *Errand Into the Maze* (1947), an investigation of hidden fears presented through the symbols of the Minotaur and the labyrinth; *Alcestis* (1960); *Phaedra* (1962); *Circe* (1963); and others followed. Biblical themes and religious figures have also inspired her: *Seraphic Dialogue* (1955; Joan of Arc), *Embattled Garden* (the Garden of Eden), *Legend of Judith* (1962), and such fanciful abstractions as *Diversion of Angels* (1948) or *Acrobats of God* (1960).

Graham, whose stage presence is one of commanding stature and great dynamic force, is, in fact, a tiny woman. An indefatigable worker, quick-tempered, terrifying in her rages, sunny, kind, and humorous when life is smooth, she is generous with her company and her students and friends.

Assessment

She has maintained a position as the foremost figure in U.S. modern dance, for although movements that were once avant-garde have become familiar, her art and her craftsmanship can still startle and surprise. She has instructed, or guided, generations of modern dance teachers both in America and abroad, and has toured Europe, the Orient, and the Middle East with her company. She has strongly influenced succeeding generations of modern dancers, ballet choreographers, stagers of musicals and operas, creators of dance-dramas, and directors of motion pictures and television. In 1970 she announced her retirement as a dancer but continued to create dances. From the "long woolens" of the 1920s, Martha Graham has moved to some of the most opulent productions to be found in modern dance, with an accent on sculptured pieces, brilliant costumes and properties, and she continues to be the recipient of many awards and honours.

(W.T.)

Grammar

Historically, the term grammar has been used in several senses, not all of which need be taken up in detail here.

1. It is the name of a branch of learning that investigates the formal, or abstract, features of a language and the rules that govern their combination, reference, and interpretation. By "features of a language" are understood such matters as sounds, morphemes (the smallest meaningful units), words, and sentences. Morphology, in the narrowest sense, refers to the construction of words from morphemes; syntax has to do with the construction of sentences, often to the exclusion of morphology. A central concern of grammar, then, is syntax, though often also with its phonetic manifestations and representation in writing. A more usual and more manageable meaning of the word grammar, attested in English at least since 1846, is the study of morphology and syntax. Another conception of grammar, particularly current in technical work of the 1930s and 1940s, embraced phonology (the study of the sound patterns that occur within languages) and morphosyntax (the body of rules, taken together, that not only build sentences but also incorporate elements in words and thus predict the formation—morphology—of words along with sentences). This view excluded semantics and phonetics, which such theorists took to involve substantial, nonlinguistic criteria different from the abstract attributes that they supposed to characterize grammar and linguistics proper.

There is a further understanding of the notion of grammar that limits it to those problems that bear on the classification of the parts of speech.

2. "Grammar" also refers to the actual features dealt with abstractly in grammar as it is defined in 1 above and to the rules that unite and relate them; it is in this sense that the term English grammar is used. More formally, a grammar has been called a system of rules that expresses the correspondences between the sounds and meanings of a language. A grammar, then, is a finite theory that specifies the structures of an infinite class of sentence and discourse shapes. A limited version of this sense that has long been current is illustrated by the phrase "English has very little grammar." By this is meant that English has few overt inflections.

3. By "grammar" are understood such features and rules as are sketched in 2 above, or the study of such features and rules as is outlined in 1, when they char-

"Universal grammar"

acterize human language as a whole. When one speaks of "universal grammar," he means grammar in this sense. Such a view could also seek by extension to characterize other creatures' modes of communication.

4. A grammar may also be a book or treatise presenting or formulating those features outlined in 2 above. A special but frequent use of this sense has reference to a handbook for foreign-language learning. Such a grammar for a second language is committed to presenting the grammatical characteristics of one language from the point of view of another. This approach rests upon the accumulation of a body of statements that has been called contrastive grammar, the systematic study of all those features and rules whereby one grammar (of language *A*) differs from another (of language *B*). It is obvious that from such a study two separate formulations may be derived: the divergences of the grammar of *A* with respect to *B* as a base; or the divergences of the grammar of *B* with respect to *A*. Thus, the problem of specifying English for French speakers is not the same as that of specifying French for English speakers. Analogously, the devising of effective teaching materials offers complex and asymmetrical problems in each case.

In contrast to a historical grammar, which sets forth the features and rules of a language and their changes (attested in documents) over a period of time, a comparative grammar presents in manageable form those aspects of grammar (and the supporting evidence) that are recovered by reconstruction for the unattested parent language.

A treatise designed to provide a reasonably exhaustive, technical, formally stated, and parsimonious account of the grammar of a language is called a reference grammar. A handbook that aims to convey in an effective fashion a manageable coverage of the grammar of a language (whether for purposes of information or to impart an active command of the language in writing or in speaking) is called a pedagogical grammar.

5. "Grammar" may also be conceived of as a set of rules or criteria for evaluating sentences or constructions; such a set of criteria might be rather informal. This sense is in a way a subtype of 2 above, although it differs immediately in introducing an element of value judgment. The word grammar is understood in this sense in the locution "He knows his grammar."

6. "Grammar," in colloquial and everyday usage, frequently means the knowledge or employment of preferred or prescribed modes of expression according to some social and regional norm. It also means simply the knowledge or employment of grammatical forms. Both of these allied senses presuppose the establishment of the exact nature of the first three senses indicated above.

Origins of the term grammar

The word "grammar" is descended from the Middle English *gram(m)er(e)*, which in turn was borrowed from the Old French *gramaire*. Until the 16th century this term was used only of the grammar of Latin; in a now obsolete sense "grammar" meant simply "the Latin language." This family of words earlier replaced the Latin term *grammatica*, which in turn was a borrowing by learned Latin scholarship from the Greek term *grammatikē*.

THE STUDY OF GRAMMAR IN THE PAST

Non-Western traditions. Grammatical speculation and investigation, insofar as is known, has gone on in only a small number of societies. To the extent that Mesopotamian, Chinese, and Arabic learning dealt with grammar, their treatments were so enmeshed in the particularities of those languages and so little known to the European world until recently that they have had virtually no impact on Western grammatical tradition. Chinese linguistic and philological scholarship stretches back for more than two millennia, but the interest of those scholars was concentrated largely on phonetics, writing, and lexicography; their consideration of grammatical problems was bound up closely with the study of logic.

Certainly the most interesting non-Western grammatical tradition—and the most original and independent—is that of India, which dates back at least two and one-half millennia and which culminates with the grammar of Pāṇini, of the 5th century BC. There are three major ways in which the Sanskrit tradition has had an impact on modern linguistic scholarship. As soon as Sanskrit became known to the Western learned world the unravelling of comparative Indo-European grammar ensued and the foundations were laid for the whole 19th-century edifice of comparative philology and historical linguistics. But, for this, Sanskrit was simply a part of the data; Indian grammatical learning played almost no direct part. Nineteenth-century workers, however, recognized that the native tradition of phonetics in ancient India was vastly superior to Western knowledge; and this had important consequences for the growth of the science of phonetics in the West. Thirdly, there is in the rules or definitions (sutras) of Pāṇini a remarkably subtle and penetrating account of Sanskrit grammar. The construction of sentences, compound nouns, and the like is explained through ordered rules operating on underlying structures in a manner strikingly similar in part to modes of contemporary theory. As might be imagined, this perceptive Indian grammatical work has held great fascination for 20th-century theoretical linguists. A study of Indian logic in relation to Pāṇinian grammar alongside Aristotelian and Western logic in relation to Greek grammar and its successors could bring illuminating insights.

Sanskrit grammar

Whereas in ancient Chinese learning a separate field of study that might be called grammar scarcely took root, in ancient India a sophisticated version of this discipline developed early alongside the other sciences. Even though the study of Sanskrit grammar may originally have had the practical aim of keeping the sacred Vedic texts and their commentaries pure and intact, the study of grammar in India in the 1st millennium BC had already become an intellectual end in itself.

Classical antiquity. The emergence of grammatical learning in Greece is less clearly known than is sometimes implied, and the subject is more complex than is often supposed; here only the main strands can be sampled. The term *hē grammatikē technē* ("the art of letters") had two senses. It meant the study of the values of the letters and of accentuation and prosody and, in this sense, was an abstract intellectual discipline; and it also meant the skill of literacy and thus embraced applied pedagogy. This side of what was to become "grammatical" learning was distinctly applied, particular, and less exalted by comparison with other pursuits. Most of the developments associated with theoretical grammar grew out of philosophy and criticism; and in these developments a repeated duality of themes crosses and intertwines.

Much of Greek philosophy was occupied with the distinction between that which exists "by nature" and that which exists "by convention." So in language it was natural to account for words and forms as ordained by nature (by onomatopoeia—*i.e.*, by imitation of natural sounds) or as arrived at arbitrarily by a social convention. This dispute regarding the origin of language and meanings paved the way for the development of divergences between the views of the "analogists," who looked on language as possessing an essential regularity as a result of the symmetries that convention can provide, and the views of the "anomalists," who pointed to language's lack of regularity as one facet of the inescapable irregularities of nature. The situation was more complex, however, than this statement would suggest. For example, it seems that the anomalists among the Stoics credited the irrational quality of language precisely to the claim that language did not exactly mirror nature. In any event, the anomalist tradition in the hands of the Stoics brought grammar the benefit of their work in logic and rhetoric. This led to the distinction that, in modern theory, is made with the terms *signifiant* ("what signifies") and *signifié* ("what is signified") or, somewhat differently and more elaborately, with "expression" and "content"; and it laid the groundwork of modern theories of inflection, though by no means with the exhaustiveness and fine-grained analysis reached by the Sanskrit grammarians.

"Analogists" and "anomalists"

The Alexandrians, who were analogists working largely on literary criticism and text philology, completed the development of the classical Greek grammatical tradition. Dionysius Thrax, in the 2nd century BC, produced the

first systematic grammar of Western tradition; it dealt only with word morphology. The study of sentence syntax was to wait for Apollonius Dyscolus, of the 2nd century AD. Dionysius called grammar "the acquaintance with [or observation of] what is uttered by poets and writers," using a word meaning a less general form of knowledge than what might be called "science." His typically Alexandrian literary goal is suggested by the headings in his work: pronunciation, poetic figurative language, difficult words, true and inner meanings of words, exposition of form-classes, literary criticism. Dionysius defined a sentence as a unit of sense or thought, but it is difficult to be sure of his precise meaning.

The Romans, who largely took over, with mild adaptations to their highly similar language, the total work of the Greeks, are important not as originators but as transmitters. Aelius Donatus, of the 4th century AD, and Priscian, an African of the 6th century, and their colleagues were slightly more systematic than their Greek models but were essentially retrospective rather than original. Up to this point a field that was at times called *ars grammatica* was a congeries of investigations, both theoretical and practical, drawn from the work and interests of literacy, scribeship, logic, epistemology, rhetoric, textual philosophy, poetics, and literary criticism. Yet modern specialists in the field still share their concerns and interests. The anomalists, who concentrated on surface irregularity and who looked then for regularities deeper down (as the Stoics sought them in logic) bear a resemblance to contemporary scholars of the transformationalist school. And the philological analogists with their regularizing surface segmentation show striking kinship of spirit with the modern school of structural (or taxonomic or glossematic) grammatical theorists.

The Middle Ages. It is possible that developments in grammar during the Middle Ages constitute one of the most misunderstood areas of the field of linguistics. It is difficult to relate this period coherently to other periods and to modern concerns because surprisingly little is accessible and certain, let alone analyzed with sophistication. In the early 1970s the majority of the known grammatical treatises had not yet been made available in full to modern scholarship, so that not even their true extent could be classified with confidence. These works must be analyzed and studied in the light of medieval learning, especially the learning of the schools of philosophy then current, in order to understand their true value and place.

The field of linguistics has almost completely neglected the achievements of this period. Students of grammar have tended to see as high points in their field the achievements of the Greeks, the Renaissance growth and "rediscovery" of learning (which led directly to modern school traditions), the contemporary flowering of theoretical study (men usually find their own age important and fascinating), and, in recent decades, the astonishing monument of Pāṇini. Many linguists have found uncongenial the combination of medieval Latin learning and premodern philosophy. Yet medieval scholars might reasonably be expected to have bequeathed to modern scholarship the fruits of more than ordinarily refined perceptions of a certain order. These scholars used, wrote in, and studied Latin, a language that, though not their native tongue, was one in which they were very much at home; such scholars in groups must often have represented a highly varied linguistic background.

Use of Latin by medieval scholars

Some of the medieval treatises continue the tradition of grammars of late antiquity; so there are versions based on Donatus and Priscian, often with less incorporation of the classical poets and writers. Another genre of writing involves simultaneous consideration of grammatical distinctions and scholastic logic; modern linguists are probably inadequately trained to deal with these writings.

Certainly the most obviously interesting theorizing to be found in this period is contained in the "speculative grammar" of the *modistae*, who were so called because the titles of their works were often phrased *De modis significandi tractatus* ("Treatise Concerning the Modes of Signifying"). For the development of the Western grammatical tradition, work of this genre was the second great milestone after the crystallization of Greek thought with the Stoics and Alexandrians. The scholastic philosophers were occupied with relating words and things—*i.e.*, the structure of sentences with the nature of the real world—hence their preoccupation with signification. The aim of the grammarians was to explore how a word (an element of language) matched things apprehended by the mind and how it signified reality. Since a word cannot signify the nature of reality directly, it must stand for the thing signified in one of its modes or properties; it is this discrimination of modes that the study of categories and parts of speech is all about. Thus the study of sentences should lead one to the nature of reality by way of the modes of signifying.

The *modistae*

The *modistae* did not innovate in discriminating categories and parts of speech; they accepted those that had come down from the Greeks through Donatus and Priscian. The great contribution of these grammarians, who flourished between the mid-13th and mid-14th century, was their insistence on a grammar to explicate the distinctions found by their forerunners in the languages known to them. Whether they made the best choice in selecting logic, metaphysics, and epistemology (as they knew them) as the fields to be included with grammar as a basis for the grand account of universal knowledge is less important than the breadth of their conception of the place of grammar. Before the *modistae*, grammar had not been viewed as a separate discipline but had been considered in conjunction with other studies or skills (such as criticism, preservation of valued texts, foreign-language learning). The Greek view of grammar was rather narrow and fragmented; the Roman view was largely technical. The speculative medieval grammarians (who dealt with language as a *speculum*, "mirror" of reality) inquired into the fundamentals underlying language and grammar. They wondered whether grammarians or philosophers discovered grammar, whether grammar was the same for all languages, what the fundamental topic of grammar was, and what the basic and irreducible grammatical primes are. Signification was reached by imposition of words on things; *i.e.*, the sign was arbitrary. Those questions sound remarkably like current issues of linguistics, which serves to illustrate how slow and repetitious progress in the field is. While the *modistae* accepted, by modern standards, a restrictive set of categories, the acumen and sweep they brought to their task resulted in numerous subtle and fresh syntactic observations. A thorough study of the medieval period would greatly enrich the discussion of current questions.

The Renaissance. It is customary to think of the Renaissance as a time of great flowering. There is no doubt that linguistic and philological developments of this period are interesting and significant. Two new sets of data that modern linguists tend to take for granted became available to grammarians during this period: (1) the newly recognized vernacular languages of Europe, for the protection and cultivation of which there subsequently arose national academies and learned institutions that live down to the present day; and (2) the exotic languages of Africa, the Orient, the New World, and, later, of Siberia, Inner Asia, Papua, Oceania, the Arctic, and Australia, which the voyages of discovery opened up. Earlier, the only non-Indo-European grammar at all widely accessible was that of the Hebrews (and to some extent Arabic); and Semitic in fact shares many categories with Indo-European in its grammar. Indeed, for many of the exotic languages scholarship barely passed beyond the most rudimentary initial collection of word lists; grammatical analysis was scarcely approached.

New sources of data

In the field of grammar, the Renaissance did not produce notable innovation or advance. Generally speaking, there was a strong rejection of speculative grammar and a relatively uncritical resumption of late Roman views (as stated by Priscian). This was somewhat understandable in the case of Latin or Greek grammars, since here the task was less evidently that of intellectual inquiry and more that of the schools, with the practical aim of gaining access to the newly discovered ancients. But, aside from the fact that, beginning in the 15th century, serious grammars

of European vernaculars were actually written, it is only in particular cases and for specific details (*e.g.*, a mild alteration in the number of parts of speech or cases of nouns) that real departures from Roman grammar can be noted. Likewise, until the end of the 19th century, grammars of the exotic languages, written largely by missionaries and traders, were cast almost entirely in the Roman model, to which the Renaissance had added a limited medieval syntactic ingredient.

From time to time a degree of boldness may be seen in France: Petrus Ramus, a 16th-century logician, worked within a taxonomic framework of the surface shapes of words and inflections, such work entailing some of the attendant trivialities that modern linguistics has experienced (*e.g.*, by dividing up Latin nouns on the basis of equivalence of syllable count among their case forms). In the 17th century, members of the Port-Royal community (a group of hermits who lived in the deserted abbey of Port-Royal in France) produced a grammar that has exerted noteworthy continuing influence, even in contemporary theoretical discussion. Drawing their basic view from scholastic logic as modified by rationalism, these people aimed to produce a philosophical grammar that would capture what was common to the grammars of languages—a general grammar, but not aprioristically universalist. This grammar has attracted recent attention because it employs certain syntactic formulations that resemble in detail contemporary transformational rules, which formulate the relationship between the various elements of a sentence.

The Port-Royal school

Roughly from the 15th century to World War II, however, the version of grammar available to the Western public (together with its colonial expansion) remained basically that of Priscian with only occasional and subsidiary modifications, and the knowledge of new languages brought only minor adjustments to the serious study of grammar. As education has become more broadly disseminated throughout society by the schools, attention has shifted from theoretical or technical grammar as an intellectual preoccupation to prescriptive grammar, which started with Renaissance vernacular nationalism. Grammar increasingly parted company with its older fellow disciplines within philosophy as they moved over to the domain known as natural science, and technical academic grammatical study has increasingly become involved with issues represented by empiricism versus rationalism and their successor manifestations on the academic scene.

Nearly down to the present day, the grammar of the schools has had only tangential connections with the studies pursued by professional linguists; for most people prescriptive grammar has become synonymous with "grammar," and the prevailing view held by educated people regards grammar as an item of folk knowledge open to speculation by all, and in nowise a formal science requiring adequate preparation such as is assumed for chemistry.

19th and early 20th centuries. The past two centuries have witnessed two fundamental changes in the characteristic activities of linguists that must be noted to put grammar in proper perspective. The great triumph of the 19th century was the unfolding of the study of language from a comparative and historical point of view. This had tremendous consequences for linguistics as a whole. It built firmly on the refined text philology developed during the Renaissance and had enormous impact on the field of phonology. It even filtered into some of the popular teaching in the schools, and for this reason linguists are often viewed by the public as essentially etymologists and tracers of the history of old words. The successor field of dialectology has also added to this popular picture. Nineteenth-century comparative philology, however, did not lead to any fundamental questioning of the basic notions of grammar; if anything, scholars increasingly despaired of successfully recovering from the past such abstract structures and their relations in any degree of interesting complexity.

Comparative and historical treatment of grammar

In the late 19th century, however, a series of intellectual earthquakes began to rock the field of linguistics from various directions. Ethnography—the descriptive study of the customs of particular tribes and peoples—contributed new data of a new order of exactitude from exotic aboriginal languages. Certain linguists with typological, rather than comparativist, leanings took a fresh look at what they could then learn of the world's grammar; and formalist literary criticism inspired a fresh analytic attitude from another, and unexpected, angle. These varied points of view converged to provide the direction that grammatical study was to take.

Ethnographers, studying aboriginal cultures in the field, insisted that the student could not truly understand a culture and its values without approaching it through the language; that the language and its grammar must be analyzed in its own terms and not through the lens of Latin or European grammar as had been customary since the voyages of discovery; and that if cultures could differ enormously from what Westerners are accustomed to, as the cultures visibly did, then grammars might, similarly, show infinite variety. Alexandrian and Renaissance scholars drew from literature their textual authority for the data they analyzed, and the product of grammatical analysis was integrated into literary study. It was now the turn of literary study to provide the analytic model for grammatical investigation. The insistence of the formalists on internal analysis of the literary work itself suggested to those of their number working in Moscow at the turn of the century (and later in Prague) who were interested in grammar that a similar internal analysis of oppositions (contrasts) within the language should apply.

Structural grammar

The upshot of all this was the view of grammar prevalent among many theoretical linguists from about 1930 to 1960, a view highly compatible with the emphasis on cultural relativism then current in anthropology. In brief, these linguists held the view that no prediction could be made in advance as to what a given grammar might contain or how it might be structured, that basic categories could vary from language to language indefinitely, and that this relative and arbitrary grammar could in turn serve as a screen through which a society might view the world differently from all other societies. Although some who held these views also had strong positivist or behaviourist leanings that additionally coloured their working methods, such further views were not an essential part of this grammatical outlook. This view of grammar led to a close association between the fields of linguistics and anthropology; at the same time traditional preoccupations of philosophy were not congenial to this view of grammar.

This, in grossly over-simplified terms, is the approach that has been called structural grammar; often in the United States it has been called descriptive grammar. To the extent that such study rigorously excluded evidence from elsewhere on the time axis or from among geographic or social variants, it was called synchronic grammar. Linguists working in a transformational framework often refer to it as taxonomic grammar. The central interest of structural grammar has been to show how the grammar of a given language is unique.

CONTEMPORARY GRAMMAR

During the 1960s, with the striking shift in the field of linguistics to generative-transformational grammar (also called simply transformational grammar or generative grammar), a different emphasis asserted itself. This type of grammar tries to generate, or produce, all of the possible grammatical utterances of a language and only those that are grammatical. In order to accomplish this, a series of rules is posited (some of which are called transformations) that express the relationships among the elements of a sentence. For example, a generative-transformational grammar tries to formulate the relationship between such sentences as "The man is here." "Is the man here?" "Where is the man?" and "Who is here?" It also attempts to produce all of these valid, or grammatical utterances, while excluding such un-English statements as "Man the here is." "Here man the is." and "The man are here."

In the early days of generative-transformational grammar, linguists believed that there was a core of simple

basic sentences in a language from which all of the other sentences in a language could be derived and that there were transformations that applied optionally to different structures. Later these ideas were abandoned, and most linguists advocated the belief that all sentences, even the simplest, are derived by transformations. This derivation of sentences led to the notion of deep structure, the underlying structure of utterances (as opposed to surface structure, what one actually says). It began to appear to workers in this field that the deep structures formulated for various grammars (*i.e.*, the grammars of various languages) came to be more and more alike, thus suggesting that all languages may share to a great extent, or even completely, the same deep structures.

Deep and surface structure in transformational grammar

In the early 1970s there were many linguists who believed that no strict discrimination could be made between "deep" and "surface" structure and that the most fundamental portion of a grammar is a base component consisting simply of abstract semantic structures or configurations. In that case, this source semantic structure would be largely general for all grammars. Regardless of which model is accepted in detail, the important fact was the recognition in the 1960s that all languages may in some sense share a basic facet of grammar. Thus it is evident that a renewed interest in universal grammar has displaced the focus on relativism.

Further conclusions have subsequently been drawn from the claim of a universal base component for all of human language. The existence of such a component would help to explain how a child in any society manages to master to a surprising degree in a few years a large part of the competence that is called "speaking a language." Such theses have important consequences for the study of developmental psychology. The properties of transformational grammars have also been exploited in probing questions of linguistic behaviour that have psychological implications. In brief, a strong and renewed connection has been forged between grammar and the field of psychology; connections of this sort were resolutely rejected by many structural grammarians. Finally, problems of the form of transformational grammars and the nature of the semantic base component have given rise among grammarians to a very active renewed interest in logic; there are indications that philosophers and logicians in turn have a newly developed interest in contemporary grammar, and there are signs, too, that linguistic anthropologists are attempting to bridge their grammatical interests with contemporary psychology and logic. Except in poetics, however, contemporary grammar has as yet had little impact on literary studies; the connections with philology, which were so close during the 19th century, are now rather weak.

Relationships and independence of grammatical study

The Greeks saw an intimate link between questions of philosophy and those of grammar; indeed, they were from one point of view one and the same. Today grammar again enjoys a close relationship with philosophy (and its one-time offshoots, psychology and anthropology); but this time grammar is a well-established field in an autonomous discipline.

THE QUESTION OF GRAMMATICALITY

Older definitions. There has been considerable discussion of what is meant by the notion "grammatical." If grammar is considered to be the art of speaking and writing correctly (as with the ancients), "grammatical" means what the poets use or what the best (*i.e.*, most erudite, tasteful, or socially acceptable) people say. This leads to a normative prescriptive meaning of the term, which is still in use. If grammar formulates what partakes of nature (as with the Stoics), "grammatical" means "physical" or "logical"; if it is concerned with the properties of things (as with the scholastics), it means "real" in their technical sense; if grammar treats of human reason (as with the Port-Royal thinkers), then it means "rational."

If, however, grammar forms part of an autonomous study, then an explicit understanding is needed that may be applied in specific cases; it is difficult to find total agreement on this issue, and much depends in detail on one's particular view of grammar. Glossematic grammar, originated by Louis Hjelmslev, a Danish linguist, views its task as that of partitioning an enormous text (the language); in this sense "grammatical" approaches "attested." Since structural grammar is based on the observation of functional oppositions or contrasts, "grammatical" in one sense means "distinctive"; in another sense it means that the expression in question fits within the outlines sketched by the descriptive grammarian.

If the bias of the grammarian is strongly empirical, positivist, and procedural, he may have limited his grammar to his corpus of data or to one aspect of it; this leaves out of account a very significant aspect of human language—its capacity to produce and predict in any one speaker an indefinite number of sentences. To bridge this gap the notion "potential" has been proposed; *i.e.*, extrapolating from a model, one speaks of certain structures as potentially occurring. Apart from its vagueness, the notion of potentiality is also subject to a kind of indeterminancy or variability. A structural grammar may be specified to varying degrees of completeness. It is clear that as the completeness varies, the amount of room left for potentiality and the degree of restriction in the notion of grammaticality will fluctuate.

Generative views. The introduction of generative grammar has both refined and complicated the question of grammaticality. By "generative" is understood "explicit, complete, precise, and perhaps formal." If a language is taken to be a set of sentences and a grammar is a theory that generates and assigns descriptions to those sentences, then one view is that an adequate and appropriate grammar generates all of and only those sentences; *i.e.*, any other sentences past and future are ungrammatical. This is a demanding requirement.

A refined version of this view clarifies matters in relation to the structuralist position, which would often include in the account lapses or distortions or truncations of various sorts, just as unassimilated loanwords from other languages would be incorporated in the grammar with equivalent status. In such a view the language competence or knowledge of a speaker must be differentiated from his performance amid the accidents of the individual, the temporal, the real, the physical, etc. This distinction bears some relation to the concepts of *langue* (a language system) and *parole* (an individual's use of a language) proposed by a Swiss linguist, Ferdinand de Saussure, in the early 20th century. Thus one may speak of grammaticality in relation to competence.

There is still debate, however, as to how a speaker's knowledge may be tested and determined when individuals differ in minor ways on what they will accept or discriminate or call equivalent (*e.g.*, "He was talked to deliberately." will be accepted by some speakers, but not by others). Despite this variation there is often widespread agreement that an expression is nearly but not quite acceptable or grammatical; a good grammar should not merely rule out such an expression as ungrammatical, but it should characterize it as, and even specify the degree to which it is, deviant. Much poetry and humour are deviant.

Variation and grammaticality. In addition to the problems of acceptability, knowledge, and deviance, there is the complicating fact that no speaking population of consequence is homogeneous; social and regional variation must be not merely recognized but positively provided for and accommodated in the grammar. Otherwise one fails to account for the ability of speakers to communicate readily across some cleavages but not across others; they will both note and evaluate some differences while understanding completely, or they may ignore even greater differences, or they may reject divergences that seem perfectly predictable to an outsider.

Individuals in most societies employ more than one fashion of constructing expressions, depending on the situation and addressee (*e.g.*, "Lug that out of here." "Be so good as to convey that to the efferent system."). Such variant fashions may be called registers. These variations should be clearly distinguished, as they sometimes are not, from style. Style is neither grammar nor a component of a grammar but consists in the introduction, op-

tionally, of values designed to gain a particular effect; it is therefore a complex and cumulative result of semantic choices that the speaker has made.

Diglossia

In some communities (*e.g.*, Baghdad or Greece) two sharply different varieties of the same language are in use under different but well-defined conditions. This special type of bidialectalism, which is quite different from the pervasive phenomenon of register, has been called diglossia. For such situations, it is possible to write a slightly expanded grammar in which the grammatically compatible forms will be correctly selected for the diglossia situation. A similar duplicate marking can accommodate slang, argot, or jargon equivalence (*e.g.*, starboard = right, bulkhead = wall, ladder = stairs, secure = tie, and the special derivations of fore, forward, aft, after, and so on).

In all these cases of register, argot, and code-switching it is clear that the speaker does not make independent choices at every turn, but selects by a single rule the desired set of compatible alternatives. In various ways it is seen that "grammar" and "grammatical" are complex, slightly blurred, flexible, and expandable notions.

MODELS OF GRAMMATICAL DESCRIPTION

Universal grammar. In recent years, as the interests of many students of grammar have shifted from the observation and classification of the facts whereby languages differ on the surface to the more abstract ways in which the broader or "deeper" characteristics of different languages are the same, the empirical investigation of natural human languages has shifted once again to a strong interest in general, or universal, grammar. The object of such study is to distill from the analysis of natural languages what they hold in common; *i.e.*, the grammatical characteristics or rules that hold for all human language.

From a psychological point of view, this holds great interest by potentially stating what is essentially and typically human about language and what types of language are humanly possible or expectable. From a formal point of view, the investigation of this aspect of what has come to be called algebraic linguistics has led to a new rapprochement with certain forms of mathematics, for it is possible to study abstractly selected mathematical structures and relations that have been found to or are believed to resemble those general abstract characteristics called universal grammar. This is more a program for the future than it is a present reality. The universal grammar that may be sifted from empirical language-based study is certain to be a construct of rather complex relations and properties; the mathematical models that have been discussed and proposed to date and that can be manipulated with clarity are not very rich, relatively speaking. Thus there is a considerable gap for scholarship yet to bridge. The false impression is sometimes given that modern grammar has yielded to mathematics; even when the two fields become fully linked, there will always be an empirically based study of natural grammars.

Mathematics and grammar

Taxonomic, or structural, models. A number of models have been proposed for grammars, and several have gained wide currency. In each case they reflect the scholars' intellectual, philosophic, and practical orientation. Among taxonomic, or structural, models, which are strongly (but not necessarily) linked to the search for basic grammatical elements, three versions have been notably cultivated and discussed: Item-and-Arrangement (IA), Item-and-Process (IP), and Word-Paradigm (WP).

Item-and-Arrangement. Item-and-Arrangement stresses the isolation of basic elements (also called primes) and then undertakes to present all arrangements, or juxtapositions, of these elements found in sentences. For example, this type of analysis explains the plural form "dishes" as the juxtaposition of "dish" and the plural element *-es*, the comparative form "older" as "old" and the comparative element *-er*, the participle "drunken" as the juxtaposition of "drunk" (rather than "drink") and *-en*. The items described all occur in actual speech.

Item-and-Process. Item-and-Process isolates primes and then applies processes, or rules, or formulas, that sometimes unite these primes, sometimes adjust their shape or their sequence, and sometimes do both to yield constructions and sentences that are found to occur. For example, it explains the form "dishes" as the result of the process of combining "dish" with the element "plural," and "drunken" as the result of combining "drink" with the function "past participle." One may restrict the processes so that they operate only on some actually occurring surface shape in order to produce the other desired shapes, or one may set up abstract primes that never appear in actual speech but that undergo processes in all instances. Both IA and IP share the characteristic of starting from an inventory of elements and building these up into constructions occurring in observed sentences of the language; in this sense they may be viewed as two devices for assembling language elements. For many grammarians an advantage of the dynamic IP model over the static IA is in the more natural derivation of a form such as "feet" from "foot" + PLURAL.

Word-Paradigm. The grammar is viewed from a different vantage point by the WP model, which observes the relation between the forms that words take and the function of those words in sentences. The various interrelated forms of words are arranged in patterned lists called paradigms; for example, in Latin:

dūcō	"I lead"	*dūcimus*	"we lead"
dūcis	"you lead"	*dūcitis*	"you lead" (plural)
dūcit	"he, she, it, leads"	*dūcunt*	"they lead"
amīcus	"friend"	*amīcī*	"friends"
amīcī	"of the friend"	*amīcōrum*	"of the friends"
amīcō	"to the friend"	*amīcīs*	"to the friends"
amīcum	"friend" (accusative)	*amīcōs*	"friends" (accusative)
amīcō	"with the friend"	*amīcīs*	"with the friends"

Latin paradigms are composed of a fixed set of endings, which can be attached to any stem (or base) belonging to a particular class. In the first example above, the endings are *-ō, -is, -it, -imus, -itis, -unt* and the stem is *dūc-*. The same ending can be used with *cadere* "to fall" (stem: *cad-*), *crēdere* "to believe" (stem: *crēd-*), *īnscrībere* "to inscribe" (stem: *īnscrīb-*), *perdere* "to destroy, lose" (stem: *perd-*), and many other verbs of the same class. Such a grammar prominently depends on and leads to the notion of class. While WP differs markedly in its approach from IA and IP by attaching its primes to the paradigm as a whole, it shares with them an emphasis on class and taxonomy and on the unordered characterization of sentence syntax by relations based on primes of smaller scope.

Transformational models. A transformational grammar, of which the first contemporary exponent was Noam Chomsky, recognizes, essentially, two kinds of rules. One, which may be called an expansion (or phrase-structure) rule, rewrites a unitary element into two or more elements, which themselves may further be rewritten into multiple units by other rules. Such a set of rules yields a branching tree (which may also be displayed as a successive bracketing) with labelled nodes dominating each successive branching. It will be immediately noticed that the starting expressions of such a derivation are the most inclusive (*e.g.*, the sentence, or even some higher unit). The derivation then proceeds through increasingly less inclusive constructions until it reaches all possible terminal strings (*i.e.*, arrangements) of elements for every possible path through the nodes and branches of the tree. A transformational rule, however, may rewrite two (or more) symbols into another expression or, equivalently, may transpose a node in a derivational tree to another position in the same tree; thus a whole phrase or clause may be transformed and rearranged to function differently in the sentence (the arrow in the following examples should be read as "is rewritten as"):

He caused the wine to get to be cool → He chilled the wine.
(The fact) that he chilled the wine improved it → Chilling the wine improved it.

(It should be noted that a great many transformations actually underlie these innocently simple sentences.) The transformational model is able to account for the infinity of sentences that make up a language with a finite (even rather small) set of rules because one can apply the transformational rules over and over again to the original basic sentence and the sentences derived from it.

Debate over form of rules

There is a continuing debate regarding the most appropriate form of the rules of such grammars. This affects not merely the details of their shape, content, and formal composition but also their status and interrelation in the total grammar. A widespread version insists that they should be ordered completely, partially, or by sets in their application; another version would have a rule apply every time a structure appropriate to its input appeared as the output of earlier rule applications. Both these versions require that the output finally be precisely grammatical or acceptable. Still another view would generate many more outputs than those that are grammatical and then pass these through the filters of output restrictions.

FEATURES OF GRAMMATICAL ANALYSIS

There are some properties and topics that have been attributed or implied in one way or another to most types of grammar that have been seriously considered by grammarians.

Distribution. Distribution is the position (or sum of positions) held by an element in a chain, or sequence, of elements; thus it implies "before" and "after." This may be referred to the temporal spoken or written chain ("The bird is seen by the dog."), or to an abstract structure considered to underlie it ("The dog see-s the bird."). These sequential aspects of distribution are referred to as context (or environment). Though it is surely not fruitful to posit context-free grammars for human languages (*e.g.*, the plural *-ren* is found only in the context "child-"), rules may take context into account (*i.e.*, be context sensitive) or may not. Some proponents of taxonomic grammar consider distribution so important that they have claimed that meaning is determined by or is coextensive with the totality of distribution(s) of an element; *i.e.*, the meaning of "optometrist" would mean the sum total of all of its occurrences. This effectively empties "meaning" of any independent standing, and grammar (and indeed language) is then viewed as nothing more than lists and classes of elements and their distributions.

Classes. All grammatical literature recognizes the notion of class in some form but accords it very different status and goals according to the doctrinal view. Any set of elements sharing a property may be said to form a class; some classes, as the parts of speech of traditional grammar, have been set up on multiple criteria and, hence, present inherent problems of overlap (or intersection) and indeterminancy. Items sharing a given distribution form a class; *e.g.*, stems occurring before the plural may be called nouns or, more inclusively, stems that are not compared, thus excluding adjectives, but that follow "the" may be classed as nouns. In traditional grammar, nouns generally were implied to behave in the manner just mentioned and also to name persons, things, and so on. Such mixed criteria yield mixed classes.

Traditional parts of speech

If a form of grammar (*i.e.*, a taxonomic grammar) is much occupied with establishing such classes it rapidly encounters problems of consistency and definition. If all elements that may undergo the same rule in a generative grammar are allotted to a class, the result is a very large number of intersecting classes; there then arises the problem of evolving relevant criteria to choose the important classes that are to be recognized. Proposals have also been made for classes (and matching terminologies) that rest on selected types of criteria; *e.g.*, "nouns" are to be based on criteria of word morphology (plural affixation and the like), and "nominals" on those of phrasal or of sentence syntax (occurrence with "the," as subject of a verb, and so on). Such attempts, however, depend heavily on the theoretician's view of grammar in detail, on idiosyncracies of particular languages (the number of important levels of phrasal or sentence integration), and on a persevering desire to classify regardless of the proliferation in numbers of discriminations.

Though this is an open question in theory, there is a need to recognize some important classes (*e.g.*, stative verbs, verbs of perception, as well as verbs as a whole), while other classes are clearly minor (*e.g.*, "havoc" and "vengeance," which occur with "wreak") or uninteresting (*e.g.*, "bay," "to curry," and other words applying solely to horses). Nevertheless there exist cultures in which it is important to discern features that apply to horses as a diagnostic of that culture—many languages differentiate words for "eat" and "die" according to whether they apply to men or animals. Such a consideration of classes leads naturally to the question of what, in generative grammar, have been called selectional and sub-categorization features and rules.

In much of the discussion concerning distribution, classes, and contextual alternants that depend on distribution and classes, there is a confusion of two independent considerations, the internal constituency or organization of the element in question and the external identity or classification of the adjacent elements that surround it. Many grammarians have regarded these as a procedural means toward the discernment and statement of grammatical elements, classes, and constructions.

Analytical procedures

Levels. The internal organization of a grammar may be viewed as being more or less separable into levels of integration; grammarians differ greatly in this view, since it depends in detail on the doctrine preferred, but all consider it. For almost all schools of thought there is a break between phonology and the other levels. For taxonomists, grammatical (*i.e.*, nonphonological) units are made up of, or constituted by, other grammatical units while they are represented by phonological units; for those who urge more separate levels or strata of grammatical organization, such mapping occurs between each pair of levels. For grammarians who follow J.R. Firth, an English linguist, ranks are discriminated within levels, and rank units are composed of lower rank units. In generative grammar, the phonological component is discriminated from the syntactic (or semantic) component, and these are distinguished by the difference in feature content that is introduced into the rules of each.

Grammatical segmentation. Even though most grammarians today deny that the proper study of grammar is a procedural discipline, certain procedures are well recognized and recur in all discussions. All grammars presuppose a segmentation or partitioning, although only some (proponents of IA analysis) have urged that this is an important aspect of the grammar proper or that all segmentations once made and accorded status must remain undisturbed by later operations governed by the grammar. It is by segmentation that units (elements, primes, and constructions) are recognized. On the basis of provisional segmentations, commutation (*i.e.*, substitutions of replaceable elements within stable frames) is carried out—*e.g.*, "The dog/cat/horse ate his food."

The procedures involved in segmentation of utterances are tolerably well understood and recognized and lead most immediately to the isolation of surface elements. There are procedures being evolved for the recognition of appropriate underlying abstract representations and rule formation, but these are as yet neither well codified nor generally agreed upon. Some of them involve notions familiar from logic and other formalizing disciplines (disjunctive and conjunctive ordering, implication, and so on); others are extensions of intuitive semantic perceptions (including equivalence, paraphrase, ambiguity).

Morphemes and words. The isolation of units by segmentation (and any other means) leads to the ultimate syntactic units, which are called morphemes or formants. A morpheme is generally considered as a single unit in the surface structure, regardless of its underlying sources. For most grammarians "cat-s" has two morphemes, and "book-bind-er-s" has four. The correct partitioning of "men" (:"man") has caused much debate, but everyone agrees that it results from two formants: "man" + PLURAL.

Morphemes as ultimate syntactic units

"Word" is a notion that appears to be useful and applicable in a wide range (probably all) of known languages, but it is very difficult to arrive at a set of criteria applicable to every language to determine exactly which parts of an utterance constitute words. All languages tend to have cohesive units that the speakers normally isolate instinctively and can call words. Such units typically show a large number of specimens with but one element that serves as a nucleus (or root, or base) and that may

in most languages be accompanied by a number of satellite elements. The difficulty is not so much that of finding entities that are obvious "words" (though some languages, such as Eskimo or Oneida, have words that seem very long and complex to speakers of English), as that of finding criteria to segregate all words and not include phrases and the like (*e.g.*, "the king of England's hat"; "of course"). Some morphemes or formants can occur as independent words (*e.g.*, "occur"), while others only occur attached to other morphemes (*e.g.*, *-ence* in "occurrence"). This leads to the recognition of free and bound elements, or morphemes.

This notion, however, does not always lead uniquely to the constructions that one seeks to recognize. In many languages free forms turn out to be roots, or bases (Latin *clam* "secretly"), and in English very many bases may occur as free forms. But in Latin a noun can never stand as a single free form, since a case ending is normally also required; the same is largely true for a Latin verb and certainly for a verb in a declarative sentence. Similarly, some bound elements occasionally turn out to be what might be called separate words in phrases (*e.g.*, "kith" and "kin," "to" and "fro," "wreak havoc"). Therefore the search for a neat universal specification of the "word" is probably illusory; yet the concept is so widespread and easily grasped, apart from being analytically fruitful, that grammarians will probably continue this search.

Prefixes, suffixes, and infixes

Affixes and allomorphs. In those very many instances in which there are words that are not identical with morphemes, one may discriminate the base from its satellites, or affixes. Affixes are conveniently subdivided into prefixes (occurring before the base), suffixes (occurring following the base), and infixes (inserted into the phonetic substance of the base). Infixes are frequent in Indonesian and Southeast Asian languages and are illustrated by the *-n-* in Latin *vi-n-c-ō* "I conquer," as compared to *vic-tum* "conquered," which has the same root *vic-* without an infix.

Among most languages (perhaps excepting a few such as Quechua or some of the Philippines or Oceania) a large portion of the stock of morphemes varies according to context (these are called context-sensitive forms); such systematic (and even irregular or unique) variants have been called allomorphs. Many involve simple widespread adjustments in their sounds (phonetic assimilation and the like), but some languages show large numbers of nonpredictable variants that must be listed or require intricate rules of minor scope. European languages often show such irregularity. An extension of such idiosyncracies turns up in languages of culture such as Japanese, Tamil, or English (usually arising when many forms have been borrowed as stylistic or technical variants from another language). If in English one is justified in stating that a rule relates "go" and the past form "went" ("wen-t" = "slep-t," "learn-t"), one may state a similar relation between "blood" and "hemat-ology" (never "blood-ology" or "blood-lore" as in some languages). Whole words may stand in an allomorphic relation; *e.g.*, among English pronouns, "I" is the variant found immediately before the verb or the auxiliary, even when deleted as in "bigger than I (am)," and "me" in all other contexts.

Distinction between morphology and syntax. The recognition of the widespread notion of "word" leads to the frequent utility of a discrimination between morphology and syntax, the fields of intra-word and inter-word integration, respectively. There are languages (*e.g.*, Chinese and Vietnamese) in which most words are composed of a single morpheme, and in which there is consequently little that can fruitfully be called word morphology. English illustrates this type of structure to a high degree (*e.g.*, in "You see how I can drink cold milk with a straw."), but there are also complex words such as "your," "saw," "could," "drunk(en)," "colder," "milking," "straws," combining more than one morpheme or element of meaning.

Grammarians have sometimes expressed surprise that there exist languages in which many words seem to englobe whole clauses or sentence constituents (*e.g.*, Nootka or Eskimo). This tends to obscure the fact that an English word such as "chilling" is really a surface manifestation for a clause roughly of the form "(the fact) that one causes to get to be cool." One should not be surprised to find words that embrace whole underlying syntaxes; it is rather that in English such cases are comparatively irregular and particular (*i.e.*, apply in idiosyncratic ways to different elements), while in Nootka the process is more regular and pervasive. Moreover, single surface morphemes often represent a complex of underlying grammatical formants; *e.g.*, "bull" = BOVINE + MALE, "calf" = BOVINE + IMMATURE, "veal" = (BOVINE + IMMATURE) + (MEAT + EDIBLE). It is clear that words are surface phenomena, and that their relationships with syntax, sentences, and semantics are complex and intertwined.

Stems and inflections

Stems and bases. For the many languages that show an interesting word morphology, a stem (which may in cases be identical with a base) and its inflections are normally distinguished. Word classes are often discriminated and identified by stems; *e.g.*, "accommodate" is a verb, "friendship," "timeliness," and "politicizationist" are nouns. A stem may comprise a base plus one or more derivative affixes; the last added affix either alters or preserves the class of the stem to which it is added (*e.g.*, the *-ist* ending on "politicizationist" preserves the stem class of noun). A stem may often be composed of a base plus a stem-forming theme; *e.g.*, in Latin, the word *dūcimus* "we lead," with the stem *dūci-*, has *dūc-* as its base and *-i-* as its stem-forming theme, indicating that it is a verb of the third conjugation. Finally, a simple base itself may be specified for class; thus, while most bases in a Semitic language may be viewed as verbs that can be changed into nouns, a restricted number ("father," "dog," "heart") are nouns.

Although the structure of stems, when distinctive, may be a major criterion for the identification of word classes, their use in sentences ultimately determines their class, or part of speech. Thus, while one may argue that "word" is a noun because it can take plural and possessive endings or, conversely, that it is a verb because it can take verbal endings, its function in a sentence like "He worded his argument poorly." indicates "word" to be a member of the verb class; and its function in the sentence "The baby learned three new words." indicates it to be a noun.

Inflection. An important aspect of the morphology of words in many languages is their inflection. This consists in the addition of markers that indicate relations with other words in the sentence or that incorporate into the inflected words abstract formants from elsewhere in the sentence structure. For example, Latin words vary (*i.e.*, are inflected) for case, number, person, tense, mood, and so on. In addition to the variations in the forms of inflectional affixes used in a language, there are also certain widespread types of restrictions concerning the appearance of these affixes. Thus, one element may determine or call forth the form of another; this is called government (or rection). In various European languages a preposition governs a particular case form of its noun or pronoun; *e.g.*, in German, the use of the preposition *mit* "with" determines that the following noun or pronoun be in the dative case (rather than the accusative case)—*Ich ging mit ihm zum Bahnhof* "I went with him to the station."

Concord (or agreement) is the term applied when two or more inflections (on as many words) correspond as to number, gender, case, and other grammatical categories; one is always to be regarded as the head, and the other is said to agree with it. For example, in French, the noun *maison* "house" is classified as a feminine noun; in the phrase *la maison blanche* "the white house" the modifying elements *la* "the" and *blanche* "white" also appear in their feminine forms, in contrast with *le ballon blanc* "the white ball" with the masculine *ballon*. The inflectional property is assigned to the head and thereafter an appropriate mark is transported to the agreeing word or words.

Generative grammarians have proposed that properties analogous to these traditional features of concord and government also apply to the more abstract syntactic (or semantic) structures. Thus there is a type of concord that can be seen by assigning appropriate selectional fea-

tures so that in a single well-formed sentence certain verbs (*e.g.*, compute, parse, pray; eat, give birth) will be prevented from having subjects that are not human or animate, and so forth.

Grammatical categories. The entire subject of categories is a vast one and can only be touched upon here. The term has been applied to very different things, in part confusingly so. Entities such as unit, class, construction, and so on are really frameworks for grammatical relation. Such concepts as noun, verb, and the like have been lumped under this rubric; they are best called form classes or, traditionally, parts of speech. Elements of the sentence such as subject, object, and so on are appropriately referred to as syntactic categories, but their status differs greatly in different theoretical views. For some generative grammarians they are stable basic points of reference in the most abstract representations of a sentence; for others they are categories of syntactic emphasis to which more abstract and basic semantic features are allotted. Then there are typical parameters of word or phrase paradigms: number, gender, definiteness, genericness, case, person, tense, mood, aspect. These are the grammatical categories proper, and they pervade the grammars of most or all known languages, although the list of overt categories will vary somewhat from language to language. It appears that grammatical categories and parts of speech as usually recognized belong to the surface structure of language.

Some form classes (*e.g.*, adjuncts and so-called sentence adverbs) have resisted close definition, sometimes appealing to such a criterion as intonation, and stand on a different footing. Some categories, more abstractly taken, turn out to have very ramified implications; that of person, since it involves and flows from the speaking situation, is bound up with that of deixis, or the kind of pointing that demonstrative pronouns normally carry out (I = this; thou = that (near); 3rd person = yonder). The topic of categories leads naturally to semantic features and to linguistic universals. It is further notable that the notional grammar of the Danish linguist Otto Jespersen also involves extralinguistic categories claimed to be universal but imperfectly expressed in actual languages.

Up to this point the focus has been on those aspects of grammar that are mirrored in overt shapes in the surface structure of sentences. Some grammarians have claimed that true grammar inheres only in such visible or audible "recurrent partials." Yet in their practice all grammarians have been forced to deal with abstract relations, at least in questions of constituency and construction.

Segmentation into immediate and ultimate constituents

Constituents and immediate constituents. When sentences are segmented not all segments are equally revealing or cohesive; thus one seeks to divide spans of speech into immediate constituents, such that the divisions made will show maximal independence (thus "un-gentlemanly" rather than "ungentleman-ly"). The test used to establish relative independence of the constituents is that of their substitutability by other phrases, words, or morphemes. Such divisions, or cuts, usually result in just two constituents, but cases can easily be found in which multiples must be allowed.

This method of reducing a sentence to its ultimate constituents by successive cuts is a useful working procedure; it belongs to the grammarian's kit of field methods, rather than to his body of theory or guides for grammatical formulation. The results, when laid out and studied (with appropriate corrections made) and then formulated, yield the trees (or bracketing or layering) of the phrase-structure (or constituent structure) rules of a transformational grammar. In the strictest taxonomic grammars (exemplified by those of a U.S. linguist, Zellig Harris) the nodes of these trees, constructed from the twigs inward to the root, are unlabelled; in the tagmemic model of the U.S. linguist Kenneth L. Pike and in some work by Firth and his followers, the nodes are labelled, but other types of rules are not provided. In the tagmemic model one inspects all constituents and constitutes (constructions for some grammarians), typologizes these into the most inclusive number of types, and labels the types, each labelling yielding a slot. A tagmeme is a slot together with its list of filler elements, and these lists may have overlapping membership. Thus tagmeme fillers differ from form classes and from constituents, which are mutually exclusive.

The difficulty that arises with immediate constituent (IC) analysis inheres largely in discontinuities that are found (which may additionally be partly ambiguous and idiomatic, thus calling for a unified accounting); *e.g.*, "I *put* a lot of time *in* on it." "I *got* John *up* out of bed." "John *got himself up* out of bed." "John *got himself up* in a new suit." "John *got* the report *up* for the boss." Such discontinuities, as well as some instances of homophony (*i.e.*, ambiguous sentences like "Flying planes can be dangerous."), are symptoms of the shortcomings of a taxonomic constituent-structure approach. While subordination (traditional hypotaxis) generally is amenable to immediate constituent analysis, coordination (parataxis) offers certain problems of detail; *e.g.*, the assignment of conjunctions.

The typologizing of immediate constituents into endocentric constructions (in which an immediate constituent functionally equals the whole—*e.g.*, "barn" in "the red barn" functions the same as the whole phrase) and exocentric constructions (in which no immediate constituent equals the whole—*e.g.*, in "John slept" neither "John" nor "slept" is the equivalent of the whole phrase) is often clarifying but fails to reach a deep understanding of the grammar involved and says nothing of the grammatical source of the constructions.

DEVELOPMENTS IN TRANSFORMATIONAL GRAMMAR

As transformational grammarians have turned to increasingly subtle problems of sentence formation, important changes in the grammatical model have been introduced and opinion among experts has diverged sharply. Within the constituent structure portion of the grammar, in addition to the branching phrase-structure rules, another set called sub-categorization rules had been introduced by 1965. These rules enable the categories that apply to a constituent to be specified and control the selections and concords that restrict the arrangements or conjoining of elements. A notable feature of this model, too, is the provision for insertion of the lexicon (*i.e.*, the individual base and stem morphemes with their characterizing phonetic and semantic features and shapes) along with the constituent structure rules before transformational rules are applied to that structure. In current grammatical scholarship there is a lack of clarity about the nature and structure of the lexicon, its relation to or inclusion in the grammar proper, and the form of a lexical entry and rule.

Sub-categorization rules

Criticism of earlier forms of transformational grammar has been essentially of two sorts: the detection of inadequacies or insufficiencies and the claim that certain functions are misplaced, unnaturally provided for, or unwittingly duplicated since they are really implied by a proper understanding of some other component. The rule structure of a grammar has been explored and refined: the recognition of general rules has bearing for the formalization of universal grammar; the notion of minor rule helps to recognize, clarify, and formalize what is commonly called irregularity. The properties of trees and node structure have been studied and exploited, leading to several fruitful notions.

A highly important characteristic of recent versions of a transformational grammar is the elimination of double-based and of optional transformations. Earlier versions, for example, allowed a sentence to be negated by the introduction of a negative transformation (schematically, I can go → I can not go); this optional application is somewhat related to the rejected doctrine of kernel sentences that are then transformed into more complex structures, a doctrine that had characterized earlier theories. Around 1965 it became clear that all transformations are best viewed as obligatory and called forth by an abstract element in the underlying (constituent) structure. Such elements include provision for an entire sentence, represented as S, which becomes a node to which a whole embedded clause is attached by appropriate transformations. Thus the derivation of a negative now becomes

Obligatory nature of all transformations

schematically: I Neg can go → I can not go. The implications of this view are far-reaching; this means that all the basic information is already in the most abstract phrase structure of a given sentence, and that transformations, instead of introducing information, simply position, delete, or reshape elements correctly when they are triggered off; thus, except for possible optional stylistic rules (whereby style has a formalized different status), transformations never add information; they are meaning preserving.

A further claim of the 1965 grammatical model was that deep structure exists as an abstract integrated level intermediate between an autonomous semantic representation (connected by rules of interpretation) and the surface structure; this view rests on the assumption that the elements and relations of the deep structure are to be characterized as syntactic and distinct from semantic. In the view of many it has become more and more difficult, however, to maintain this distinction; the syntax of "pregnant," for example, is governed by the presence of an element FEMALE, and the subject and object of "marry" is expected to be opposite in sex even in a gender language. Such a line of reasoning leads to the conclusion that the base component, or the most abstract feature structure of a grammar, simply is semantic. The initial rules generating the structures of such a generative semantics would then be a part of or simply be the rules of logic—an interesting but highly refined return to the preoccupations of the Stoics and Scholastics. In this view a separate syntax in a grammar or a level of structure between the abstract semantic feature bundles and the phonological mapping rules would be just a complication, matching nothing real and occluding the clarity of the rule structure of a transformational semantic grammar.

An additional fundamental departure from the 1965 model of transformational grammar has been urged by the abandonment of the structures of traditional sentence parts that the constituent structure of that model generates. Formerly, a sentence, as the starting unit, was expanded in part into Verb + Noun-phrase (*i.e.*, object) and in that sequential order. The newer view would incorporate in the semantic base features associating unordered roles with various nounlike semantic entities (*e.g.*, agent, patient, instrument, and so on), rather than generated strings equivalent to subject + object and the like. These roles would then be assigned sentence values (subject, object, locative, and so forth) or cases (with inflections for Latin, for example, but prepositions for English) by rule, depending upon inherent feature-specified constraints (restrictions) in the elements that co-occur in a particular sentence. For example, the agent may not be committed a priori to be the subject of a verb ("The medicine healed the wound." "The wound healed from the medicine.") but is assigned to it as the result of a subtle choice on the speaker's part. Subject and predicate have even been claimed as surface structures, while agent and patient would be semantic roles associated with passive function. Many languages show a distinction, which has been called ergative, whereby the subject of an intransitive verb is treated differently from that of a transitive verb and may be treated like the object of a transitive verb; here it is possible that ergativity marks the agent, while the English subject is the natural assignment for assumed information. These questions of basic sentence structure and meaning open up vast and complex debates.

Features of the semantic base

As soon as the prominent part that semantics must play in a grammar is focussed upon, numerous questions of meaning arise that equally occupy the interests of philosophers. For example, the function of reference becomes crucial in dealing with grammatical processes as varied as pronominalization, reflexivization, and relativization; in each of these instances one must distinguish whether a noun has a particular reference or not.

Although it has been customary to consider the sentence (from which parts may of course be deleted or truncated by rule) as the basic unit for grammatical derivations, there is ample evidence that an adequate accounting must go beyond the sentence limit in at least three senses. Some languages, such as Classical Greek and Tonkawa, employ linking particles that show the relation of the sentence to the preceding sentence or sentences. Something similar is involved in discourses with measure expressions: "How much butter would you like?" "Two pounds, please." but never seriously: "Two yards (litres, etc.), please." In another sense one goes beyond the audible sentence when one considers the presuppositions that some structures seem to require; *e.g.*, with the adverb "anymore," as in "Do you see Jean anymore?", one presupposes that at one time the hearer did see Jean. Finally, there are restrictions that an entire conversation or situation places upon the internal interpretation of a sentence: "Won't you have another cup of tea?" is not the negative of "Will you have another cup of tea?" nor of "Gosh, will you really have another cup of tea?"

Because of rapid change in modern grammar, it is not feasible to survey all views. The interested reader should seek further information in the bibliographic references and related articles LINGUISTICS and SEMANTICS.

(E.P.H.)

Gran Chaco

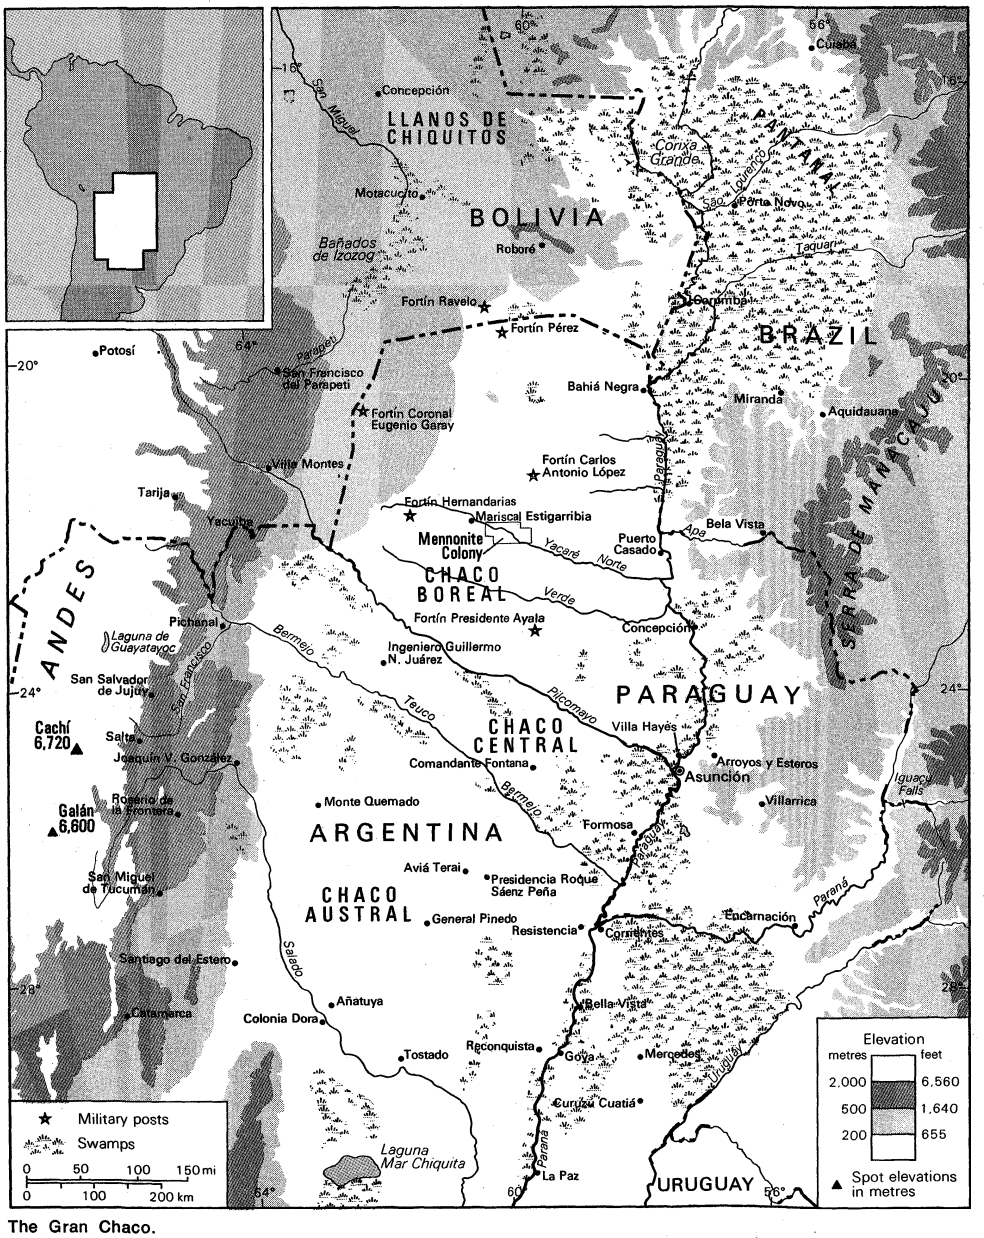
The Gran Chaco is an immense lowland alluvial plain in interior south central South America. The name is of

Quechua origin, meaning "hunting land." Largely uninhabited, the Chaco is an arid subtropical region of low forests and savannas traversed by only two rivers and practically unmarked by roads or rail lines. It is bounded on the west by the Andes mountains and on the east by the Paraguay and Paraná rivers. Its northern and southern boundaries are not as precise: its northern boundary is generally assumed to be the Llanos (high plains) de Chiquitos and Bañados (swamps) de Izozog in Bolivia, and its southern boundary the Río Salado in Argentina. Thus defined, the Gran Chaco covers about 280,000 square miles (730,000 square kilometres), of which slightly more than one-half lies within Argentina, one-third in Paraguay, and the remainder in Bolivia. Two great rivers, the Pilcomayo and the Bermejo, traverse the Chaco from their Andean headwaters to the Paraguay and Paraná rivers in the east. Widely recognized regional divisions are the Chaco Boreal, north of the Pilcomayo; the Chaco Central, between the Pilcomayo and Bermejo; and the Chaco Australⁱ, south of the Bermejo.

Area and boundaries

The natural environment. *Geomorphology.* The Gran Chaco is the alluvial fill of a vast geosynclinal basin formed by downwarping or submergence of the area between the Andean Cordillera on the west and the Brazilian Shield on the east. Because of its alluvial character, the Gran Chaco is nearly stone free and is composed of extremely deep (up to 10,000 feet) unconsolidated sandy and silty sediments. The only rock outcrops of consequence are a few isolated remnants along the Paraguay River (in Paraguay) and some sandstone mesas in northern Paraguay and southern Bolivia.

Rivers and drainage. All but the extreme northwestern sector of the Gran Chaco is drained by west-bank tributaries of the Paraguay and Paraná rivers. The Bermejo (Teuco) and the Pilcomayo, even though they manage to traverse the Chaco, are still typical of most Chaco streams. Their courses are marked by countless sloughs, oxbow lakes, braided channels, sandbars, and vast swamplands; and they sustain such high losses from flooding, seepage, and evaporation that only a meagre portion of their full flow ever reaches the parent stream. Most of the Chaco is so poorly drained that the very shallow, irregular channels on the exceptionally level plain lead to rapid and extensive flooding during the very rainy summers. At the peak of these floods, as much as 42,000 square miles, or 15 percent, of the area of the Chaco may be inundated, although some of this is as much due to improper drainage of the impermeable subsoils as to overflow of the streams. Potable groundwater supplies are poor. Saline water is common in both deep and shallow wells, and the location and maintenance of freshwater supplies is much a matter of chance. The



The Gran Chaco.

problem appears to be greatest in the Chaco Boreal, although some hydrologists feel that large-scale studies might reveal a situation more like that of the remainder of the Chaco or like the Argentine Pampa, where groundwater problems are not now considered to be as severe as early settlers and explorers had postulated.

Climate. With a north–south extent of about 700 miles, the Gran Chaco is subject to climates that vary from tropical in the north to warm temperate in the south. Most of the region is, however, subtropical. Average temperatures vary from 65° to 75° F (18° to 24° C), with an average humidity between 60 and 75 percent. Great temperature contrasts, however, exist. Average maximums are near 80° F (27° C), and absolute maximums may exceed 116° F (47° C). The average minimum is about 57° F (14° C), although freezing winter temperatures are known throughout the region.

The highest average annual rainfall is in the east, with 52 inches, which gradually decreases to about 20 inches in the far west. Although the rainfall would normally be adequate for agriculture, from one-third to one-half the total comes in hot summer. Evaporation losses sharply reduce the effective precipitation and give the Chaco an arid nature lost only in the permanent swamps and forests along the Paraguay River.

Although light breezes are common, outbreaks of cool air from the south, called pamperos in Argentina, bring gusty winds of 32–45 miles per hour that occasionally exceed 60 miles per hour. The windiest season, however, is spring, during the transition from warm to hot weather. In the dry season dust storms are not uncommon.

Soils. Chaco soils range from sandy to heavy clay. Soils in the more humid east have more organic material and lateritic subsoils, whereas in the west are soils with less surface organic material and predominately calcareous subsoils. The local determining factor is drainage, whether a function of soil texture or relative relief. Sometimes elevation differences of less than three feet result in different soil types. Grasslands, or savannas, seem to be associated commonly with sandier soils, bushlands with poorly drained clay soils, and the forestland with better drained clay soils. In many cases the high concentration of dissolved salts in the soil water creates physiologically arid conditions in swampy sites, thus extending the arid appearance even into many areas with an abundance of water.

Vegetation. The vegetation of the Gran Chaco is intimately associated with the pattern of soils and reflects the same general east–west division. The eastern Chaco is called Parque Chaqueño for its parkish landscape of clustered trees and shrubs interspersed with tall herbaceous savannas. To the west, a wide transition zone grades into the *espinal*, a dry forest of spiny, thorny shrubs and low trees. Chaco vegetation is adapted to grow under arid conditions and is highly varied and exceedingly complex. The climax vegetation is considered to be the *quebrachales*, the vast, low hardwood forests of which various species of quebracho tree are dominant and economically important as sources of tannin and lumber. These forests cover extensive areas away from the rivers; nearer the rivers they occupy the higher, better drained sites, giving rise to a landscape in which the forests appear like islands amid a sea of savanna grasses growing as high as a man on horseback. In the more arid western Chaco, thorn forests, the continuity of which is occasionally broken by palm groves, saline steppes, and savannas induced by fire or deforestation, are dominated by another quebracho tree that has a lower tannin content and is used most often for lumber. There is also a marked increase in the number and density of thorny species, among which the notorious vinal (*Prosopis ruscifolia*) was declared a national plague in Argentina because its thorns, up to a foot in length, created a livestock hazard in the agricultural lands it was invading.

Sources of tannin and lumber

Animal life. True to its native name, the Chaco has an abundance of wildlife. Among the larger animals are the jaguar, ocelot, puma, tapir, giant armadillo, spiny anteater, many foxes, numerous small wildcats, the agouti (a large rodent), the capybara (water hog), the red wolf, palustrian deer, the peccary, and the guanaco. It is one of the last major refuges for the South American member of the ostrich family, the rhea, or nandu, and has long been noted for its abundant and varied bird population. The streams are host to more than 400 fish species, among which are the salmon-like dorado and the aggressive piranha. Countless travellers' tales complain of the pestilent insects. Reptiles are also abundant, with numerous lizards and at least 60 known species of snakes, including many pit vipers and constrictors, while at least six species of poisonous tree toads have been identified.

Human ecology. The indigenous tribes of the Chaco were numerous. Because of their subsistence as hunters, gatherers, and fishermen, tribal units were not much larger than extended families. Nevertheless, from among the diverse dialects, anthropologists have described a few major linguistic associations: the Guaicurú, Lengua, Mataco, Vilela, Zamuco, and Tupí. Most of these people lived under extremely primitive conditions, with settlement dictated by the availability of fresh water, making stream courses the most coveted sites. Implements were fashioned largely from wood and bones because of the absence of stones, while the spiny leaves of the pineapple-like groundcover *carraguatas* served as the universal fibre source. The harsh Chaco forest, quite surprisingly, contains more plant sources of human sustenance in the form of edible pods, fruits, berries, and tubers than surrounding areas, and this factor was well exploited by the native tribes. Game was gathered by trapping, netting, clubbing, and spearing, often in conjunction with large group drives. For those Indian groups still living outside the limits of European settlement, conditions are only slightly modified today, although these people now have domesticated animals and metal tools. Most tribes, however, exist as sort of a peasant pioneer fringe and practice some form of shifting subsistence agriculture.

Aside from the scattered, although successful, *reducciones* (agricultural communes) of the Jesuits, the Chaco defied effective European occupancy until well into the 19th century. Hostile Indian tribes, in concert with the forbidding nature of the Chaco itself, limited European influence in the colonial period to a situation much like a state of siege.

Natural resources and their exploitation. The limited early colonization in the Argentine and Bolivian Chaco was based on exploitation of the longhorn criollo cattle that roamed half wild throughout the region. The western Chaco Austral, near Salta, was also exploited as a source of heavy timbers for the mines in the highlands of Bolivia and Peru. In the late 19th century, the Chaco in Argentina and southern Paraguay became a land of great ranches trading in the criollo cattle; and numerous, small, independent camps of woodcutters (*obrajes*) exploited the abundant hardwoods of the Chaco forests for lumber and firewood. Cattle grazing is still the most extensive land use, with few substantial changes from pioneer days. One of the key problems in improving industry is the apparent endemic nature of many serious cattle diseases and pests against which the criollo cattle have developed some immunity, whereas purebred cattle are fully susceptible.

In the eastern Chaco, vast, highly capitalized industrial ventures established large plants to process the great quantities of tannin found in the various quebracho species. Unlike the *obrajes* of the woodcutters, these operations were large, centralized mills adjacent to rivers or rail lines from which the selective cutting of quebracho has proceeded at a systematic pace. The slow growth habits of the quebracho trees, however, may result in the demise of the tannin industry, as the pace of the harvest has greatly exceeded reforestation. It is uncertain if the relatively untouched Bolivian Chaco holds sufficient quebracho timber to offset diminished production in the exploited sectors or if synthetic products will supplant the present demand for quebracho tannin. Other forest products include lumber and heavy timbers from a variety of other species, firewood, and palo santo oil (holywood oil), from the wood of *Bulnesia sarmientii*, a tree found in the more arid portions of the Chaco.

The tannin processing industry

Although wild cotton had been known in much of the Chaco since pre-Columbian times, it had never been raised as more than an agricultural curiosity until the 20th century. During World War I, with cotton prices at a peak, large areas in Chaco province of Argentina were turned over to cotton culture. Despite bad markets, insect plagues, and often poor weather in many years since that time, the crop area has increased to over 1,000,000 acres. Production methods are antiquated, however, with nearly total reliance on thousands of migrant labourers. The crop is used for both fibre and seed-oil production. Lesser quantities are found in the Paraguayan and Bolivian Chaco.

Discovery of oil in the Bolivian piedmont in the 1920s led within a decade to the disastrous Chaco War between Bolivia and Paraguay, whose leaders held hopes of finding more oil in the neighbouring Chaco Boreal. Paraguayan claims were eventually honoured but did not include any part of the oil-rich piedmont. Subsequent explorations have been disappointing, but hopes still exist for future discovery.

Future prospects. Since World War II, efforts have been made by the respective governments to spur colonization and settlement of the Chaco. Argentine efforts have concentrated along the railways out of Resistencia and Formosa, with pioneer settlements composed mainly of eastern European immigrants and based on cotton production. In the central Paraguayan Chaco, where the Trans-Chaco Road from Villa Hayes to Fortín Coronel Eugenio Garay was completed only in 1965, Mennonite immigrants from Canada had settled in the 1920s and were joined by co-religionists from the Soviet Union in the 1930s. These settlers established self-sufficient colonies and were joined by another large contingent of refugees from the Soviet Union after World War II. These colonies support a population of about 30,000. The primary land use in the Bolivian Chaco is still open cattle range. With nearby supplies of oil and gas in addition to hydroelectric and water storage on the fast-flowing piedmont streams such as the Pilcomayo, future development of the Bolivian Chaco may be more feasible than in some other parts of the Chaco.

The Mennonite colonies

In each of the various countries, the Gran Chaco is viewed as a region with immense yet untapped potential. Notwithstanding this optimism, there exist severe inherent limitations on its development, among which are its isolation from markets due to poor transportation capabilities; extreme climatic variability, with both severe flooding and extended drought; serious endemic pests posing threats to humans, cattle, and crops; saline soils; and poor groundwater supplies. Any large-scale settlement effort must have great financial and technical capacities if it is to overcome these obstacles.

BIBLIOGRAPHY. PRESTON E. JAMES, *Latin America*, 4th ed. (1969); and OSCAR SCHMEIDER, *Geografía de América Latina* (1965), are two complementary works; James focusses on the political units and land use, while Schmeider discusses physiographic regions. "The Indians of the Gran Chaco," in JULIAN STEWARD (ed.), *Handbook of South American Indians*, vol. 1, pt. 2 (1946), consists of two chapters by ALFRED METRAUX and JUAN BELAIEFF. SIR CHRISTOPHER HERBERT GIBSON, *Enchanted Trails* (1948), is the tale of the life of a cattle rancher in the Gran Chaco in the mid-20th century. SIR JOHN GRAHAM KERR, *A Naturalist in the Gran Chaco* (1950, reprinted 1968), is an account of expeditions along the Bermejo, Pilcomayo, and Paraguay rivers in 1889–97.

(G.E.Ma./M.D.H.M.)

Grand Canyon

Cut by the Colorado River, the Grand Canyon, the world's most intricate and complex system of canyons, gorges, and ravines, is part of the Colorado Plateau, an upthrust area generally circular, located mainly in northwestern Arizona in the southwestern United States. The plateau, about 140,000 square miles (360,000 square kilometres) in area, comprises essentially horizontal, layered rocks and lava flows. The trunk gorge, the unifying link for all canyons and gorges, is the continuous canyon cut by the Colorado River, the Grand Canyon. This deepest and most spectacular of all the Colorado Plateau canyons, frequently called the awesome abyss, is about 5,300 feet (1,620 metres) deep.

Location, dimensions, and colouring

The Grand Canyon is a broad, intricately sculptured chasm that contains between its outer walls many imposing peaks, buttes, and canyons. It ranges in width from 4 to 18 miles (6 to 29 kilometres) and extends in a winding course from the head of Marble Gorge, near the northern boundary of Arizona, to Grand Wash Cliffs, near the Nevada line, a distance of about 217 miles. The deepest and most impressively beautiful section, 56 miles long, is within Grand Canyon National Park, through which the river winds for 105 miles. In its general colour, the canyon is a red, but each stratum or group of strata has a distinctive hue—buff and gray, delicate green and pink, and, in its depths, brown, slate-gray, and violet. At 8,200 feet (2,500 metres) above sea level, the North Rim is 1,200 feet higher than the South Rim.

The first sighting of the Grand Canyon is credited to the Coronado expedition of 1540 and subsequent discovery to two Spanish priests, Francisco Garcés and Silvestre Vélez de Escalante, in 1776. In the early 1800s trappers examined it, and sundry government expeditions exploring and mapping the West began to record information about the canyon. In May 1869 the explorer-scientist John Wesley Powell descended the Green River and on August 10, 1869, the party arrived at the mouth of the Little Colorado River at the northeast edge, the upstream entry point to the Grand Canyon. In 1870 reports on the geography, geology, botany, and ethnology of the area were published, and mineral exploration in the most accessible parts of the canyon was begun.

Grand Canyon National Park, containing 673,575 acres (272,586 hectares), was created in 1919. The North and South rims are connected by a paved road and by a transcanyon trail. Scenic drives and trails lead to all important features. There are about 2,000,000 visitors annually. Mule-pack trips and adventuresome scenic rides down the river in rafts and power-driven craft are intensively sought-after ways of viewing and experiencing the vast beauty of the canyon. Many pueblo and cliff-dweller ruins, with accompanying artifacts, indicate prehistoric occupation. There are five Indian tribes living on nearby reservations.

Geological history. Although the awesomeness and grandeur of its beauty are major attractions of the Grand Canyon, probably the most vital and valuable aspect of the canyon lies in the time scale of Earth history that is revealed in the exposed rocks of the canyon walls. No other place on Earth displays such an extensive and profound record of Earth events for analysis, dating, and study. Three aspects of Earth processes are superlatively, if not always clearly, presented: first, the building materials of the Earth's crust, the composition, kind, origin, and age of the exposed rocks; second, the destructive processes, the cutting of the canyon, erosion; and, third, the Earth-building processes, submergence, deposition, uplift, folding, faulting, and volcanism. Extending north from the Colorado River to Bryce Canyon, a 23,000-foot section of rocks is exposed in normal sequence from old to recent. The record, however, is far from continuous and complete. There are immense time gaps; probably several million years are unaccounted for by an unconformity in which vast quantities of Earth materials were either removed by erosion or there was little or no deposition of Earth materials. Thus rock formations of vastly different ages are separated only by a thin, distinct surface that reveals the vast unconformity in time.

The rock strata of the canyon walls are mostly limestones, freshwater shales, and cemented sandstones of windblown origin, the result of limey ooze, mud, and sand laid down in water and later hardened into rock by the great weight of the overlying layers. The crystallized, twisted, and contorted unstratified rocks of the inner gorge are granite and schist about 4,000,000,000 years old. They constitute the roots of lofty mountains, their tops eroded away. Overlying the canyon rocks are the precipitous butte remnants from the Mesozoic Era (225,000,000 to 65,000,000 years ago) and the vermilion,

white, and pink cliff terraces of southern Utah, which have been entirely eroded away in the south. Of relatively recent origin are sheets of black lava and volcanic cones covering portions of the plateau tops, some estimated to have been active within the past 1,000 years.

The cutting of the mile-deep Grand Canyon by the Colorado River is one of the greatest events of Earth history. River velocity, volume, stream gradient, and cutting tools (mud, sand, and gravel) account for the incredible cutting capacity of the river. Sediments carried by the Colorado have been measured at an average of 500,000 tons per day. The canyon actually was cut by a reverse process, for the river remained in place and cut as the land moved slowly upward against it. Only thus can be explained the canyon's east-to-west course across a south-facing slope and the presence of plateaus that stand across the river's course without having deflected it.

Inevitably, questions arise not only as to how the Grand Canyon was formed but also as to how its magnificent features, once formed, have persisted. The most significant aspect of the environment that is responsible for the canyon is frequently overlooked or not recognized. Were it not for aridity, there would be no Grand Canyon. Slope wash would have removed the canyon walls, the stair-step topography would long ago have been excavated, the distinctive sculpturing and the multicoloured rock structures could not exist, the Painted Desert would be gone, and the picturesque Monument Valley would have only a few rounded hillocks.

Biological past and present. Plant and animal fossils are abundant in the sedimentary rocks, ranging from primitive algae in the lower strata to trees in the upper strata and from seashells and trilobites to the remains of dinosaurs (both bones and footprints), camels, horses, ground sloths, and elephants. These fossils suggest the evolution of life through the ages.

Fossil and living plant and animal life

Because of the location and vast scale of the Colorado Plateau and the Grand Canyon, noticeable differences exist in soil types, temperatures, moisture distribution, slope exposure, and elevation. All of these are reflected in the plant and animal life of the canyon.

In the bottom of the canyons are the hydrophytes, plants that require abundant water during the growing season. This plant association grows along the riverbanks of the main stem Colorado and along the tributary streams on low sand and gravel bars. Willows and cottonwoods are prominent examples of the hydrophytes.

At the other end of the moisture scale are the xerophytes, the desert, drought-resistant plants with a wide diversity of adaptations. Most are perennials, widely spaced with well-developed lateral root systems. Common among the xerophytes are the yucca, agave, and numerous species of cactus.

The phreatophytes, a pestiferous group of bush and tree vegetation, grow near the streams in canyon bottoms. They have very deep root penetration, up to 50 feet, and consume immense quantities of precious water, diminishing the discharge of all streams. Mesquite, acacia, tamarix, and cottonwood are common phreatophytes.

On the canyon rims, north and south, there is a wide assortment of plant life. Typical of the South Rim is a well-developed ponderosa pine forest, with scattered stands of piñon pine and juniper. Bush vegetation consists mainly of scrub oak, mountain mahogany, and large sagebrush.

On the North Rim, in the areas of moist and deep soil are magnificent forest communities of ponderosa pine, white and Douglas fir, and aspen. Under less optimum conditions the plant life reverts to the desert varieties.

Animal life in the Grand Canyon area is both varied and abundant. In some instances it is confined to a specific area and habitat because of the extremely difficult terrain that limits movements. The common animals are the many varieties of squirrels, coyotes, foxes, deer, badgers, bobcats, rabbits, chipmunks, and kangaroo rats.

BIBLIOGRAPHY. W. KENNETH HAMBLIN and JOSEPH R. MURPHY, *Grand Canyon Perspectives* (1969), is a systematic division of the Grand Canyon into subregions and panoramas. For each panorama there is a lucid description of the rock outcrops and their colour, the canyon profile, the nature of the Colorado River, and the related plant and animal ecology. The FOUR CORNERS GEOLOGICAL SOCIETY, *Geology and Natural History of the Grand Canyon Region* (1969), the record of the Fifth Field Conference of the Powell Centennial River Expedition, accounts for, in a very comprehensive manner, the main structural features of the Grand Canyon and the major rock formations with age description and location. A brief resumé of the Powell party, its members, and the exploration of the Grand Canyon serves as the introduction to the main work.

(M.J.Lo.)

Grant, Ulysses S.

Ulysses S. Grant was a U.S. soldier and the 18th president of the United States. During the Civil War (1861–65) he commanded the Federal forces and led the Union to victory over the Confederacy. He was elected president in 1868 and served two full terms (1869–77).

Grant.

Grant was born Hiram Ulysses Grant at Point Pleasant, Clermont County, Ohio, on April 27, 1822, the son of Jesse Root Grant, a tanner, and Hannah Simpson Grant. Detesting the work around his father's tannery, Ulysses performed his share of chores on farmland owned by his father, developing considerable skill in handling horses. Ulysses' boyhood appears normal for the time and place.

Early life

Jesse secured for Ulysses an appointment to the United States Military Academy at West Point, New York, in 1839. Ulysses had no interest in military life but accepted the appointment, realizing that the alternative was no further education. Ulysses decided to reverse his original name and enroll as Ulysses Hiram; his appointment to West Point was erroneously made in the name Ulysses S. Grant, the name he eventually accepted, maintaining that the middle initial did not stand for anything.

At West Point, Grant ranked 21st in a class of 39 but distinguished himself in horsemanship and showed considerable ability in mathematics. Upon graduation in 1843, he was assigned as a brevet second lieutenant to the 4th U.S. Infantry, stationed near St. Louis. There he fell in love with Julia Boggs Dent, whom he married in 1848. They had four children.

During the Mexican War (1846–48) Grant showed gallantry in campaigns under Gen. Zachary Taylor, then was transferred to Gen. Winfield Scott's army, where he first served as regimental quartermaster and commissary, which gave him invaluable knowledge of army supply but galled the young officer who wanted action, and later distinguished himself in battle, earning brevet commissions as first lieutenant and captain, though his permanent rank was first lieutenant.

On July 5, 1852, when the 4th Infantry sailed from

New York for the Pacific coast, Grant left his family behind, unwilling to endanger them on a dangerous crossing of the Isthmus of Panama. Assigned to Ft. Vancouver, Oregon (later Washington) Territory, he entered unsuccessful business ventures to supplement his army pay, but he could not reunite his family. A promotion to captain in August 1853 brought an assignment to Ft. Humboldt, California, a dreary post with an unpleasant commanding officer. On April 11, 1854, Grant resigned from the army. Allegations that he found consolation in drink during the lonely years on the Pacific coast and in later life were never proved, yet they affected his reputation nonetheless. There were many reasons for his resignation, and it was submitted by his own choice.

Grant settled on the Dent estate of White Haven, in Missouri, and began to farm 80 acres (30 hectares) given to Julia by her father. Grant's farming venture and a real estate partnership in St. Louis in 1859 were both unsuccessful. In 1860 Grant took a post in a leather goods business, owned by his father and operated by his brothers, in Galena, Illinois.

The Civil War

At the outbreak of the Civil War, Grant helped recruit, equip, and drill troops in Galena, then accompanied them to Springfield, where Gov. Richard Yates appointed him an aide and assigned him to the state adjutant general's office. Yates appointed him colonel of an unruly regiment (later named the 21st Illinois Volunteers) in June 1861. Before he had even engaged the enemy, Grant was appointed brigadier general through the influence of Elihu B. Washburne, U.S. congressman from Galena. He soon gained command of the District of Southeast Missouri, headquartered at Cairo, Illinois.

In January 1862, dissatisfied with the use of his force for defensive and diversionary purposes, Grant received permission from Gen. Henry Wager Halleck to begin an offensive campaign. On February 16 he won the first major Union victory of the war, when Fort Donelson, on the Cumberland River in Tennessee, surrendered with about 15,000 troops.

Now a major general, Grant drove off an unexpected Confederate attack on April 6–7 at Shiloh Church, near Pittsburg Landing, Tennessee, but outcry over heavy Union losses (1,754 killed) hurt Grant's reputation, and Halleck took personal command of the army. When Halleck was called to Washington as general in chief in July, Grant regained command. Before the end of the year, Grant began his advance toward Vicksburg, the last major Confederate stronghold on the Mississippi River. Grant displayed the qualities of aggressiveness, resilience, independence, and determination that led to final victory on July 4, 1863. When Port Hudson, Louisiana, the last Confederate post on the Mississippi, fell a few days later, the Confederacy was cut in half.

Command over Union armies

Grant was appointed lieutenant general in March 1864 and was given command over all the armies of the United States. His basic plan for the 1864 campaign—to immobilize Gen. Robert E. Lee near the Confederate capital at Richmond, Virginia, while Gen. William Tecumseh Sherman led the western Union army through Georgia—was successful. By mid-June Lee was pinned down at Petersburg, near Richmond, while Sherman's army cut through Georgia, and cavalry forces under Gen. Philip Sheridan destroyed railroads and supplies in Virginia. On April 2, 1865, Lee was forced to abandon his Petersburg line, and the inevitable surrender followed on April 9 at Appomattox Court House.

That Grant's army vastly outnumbered Lee's at the close of the conflict should not obscure Grant's achievements; the Union had had numerical superiority in Virginia throughout the war, yet Grant was the first to make these numbers count. Grant had rebounded from initial defeat at Shiloh; his success was due in large measure to administrative ability, receptiveness to innovation, versatility, and capacity for growth.

In late 1865 Grant toured the South at Pres. Andrew Johnson's request, was greeted with surprising friendliness, and submitted a report recommending a lenient Reconstruction policy. In 1866 Grant was appointed to the newly established rank of general of the armies of the United States. In 1867 Johnson removed Secretary of War Edwin M. Stanton in order to test the constitutionality of the Tenure of Office Act, which required the assent of Congress to removals from office, and in August he appointed Grant secretary of war ad interim. When Congress insisted upon Stanton's reinstatement, Grant resigned his secretaryship (January 1868), thus infuriating Johnson, who believed that Grant had promised to remain in office to provoke a court decision. Johnson's angry charges brought an open break and strengthened Grant's Republican ties, leading to his nomination for president in 1868. The last line of his letter of acceptance, "Let us have peace," became the Republican campaign slogan. Grant was elected with a small popular margin over his Democratic opponent, Horatio Seymour, former governor of New York.

Grant's presidency

Grant entered the White House on March 4, 1869, politically inexperienced and, at age 46, the youngest man yet elected president. His appointments to office were uneven in quality but sometimes refreshing, as when he appointed a Seneca Indian, Ely S. Parker, his former staff officer, as commissioner of Indian affairs.

On March 18 Grant signed his first law, pledging to redeem in gold the greenback currency issued during the Civil War, thus placing himself with the financial conservatives of the day. During his first term he backed the recommendations of the first Civil Service Commission but abandoned the effort in view of congressional intransigence. He was more persistent but equally unsuccessful when the Senate rejected a treaty of annexation with Santo Domingo. His negotiation of the Treaty of Washington provided for the settlement by international tribunal of American claims against England arising from the wartime activities of the British-built Confederate raider "Alabama."

Grant won re-election easily in 1872, with a large margin over Horace Greeley. During the campaign, newspapers discovered that prominent Republican politicians were involved in the Crédit Mobilier of America, a shady corporation designed to siphon profits of the Union Pacific Railroad. More scandal followed in 1875, when Secretary of the Treasury Benjamin Helm Bristow exposed the operation of a whiskey ring that had the aid of high government officials in defrauding the government of tax revenues. When the evidence touched the President's private secretary, Orville E. Babcock, Grant regretted his earlier statement, "Let no guilty man escape." Grant blundered in accepting the resignation of Secretary of War William W. Belknap, who was impeached on charges of accepting bribes; Belknap escaped conviction since he was no longer a government official. Discouraged and sickened, Grant closed his second term by assuring Congress that "Failures have been errors of judgment, not of intent."

Scandals have become the best remembered feature of the Grant administration, obscuring more positive aspects. Grant supported amnesty for Confederate leaders and protection for Negro civil rights. His veto of a bill to increase the amount of legal tender currency (1874) diminished the currency crisis during the next quarter century. He dealt gracefully with the controversy caused when both Republican Rutherford B. Hayes and Democrat Samuel Jones Tilden claimed election to the presidency in 1876.

Later life

In 1879 Grant found a faction of the Republican Party anxious to nominate him for a third term. Although he did nothing to encourage support, he received more than 300 votes in each of the 36 ballots of the 1880 convention, which finally nominated James A. Garfield. In 1881 Grant bought a house in New York City and began to take an interest in the investment firm of Grant and Ward, in which his son Ulysses Jr. was a partner. Grant put his capital at the disposal of the firm and encouraged others to follow. In 1884 the firm collapsed, swindled by Ferdinand Ward. This impoverished the entire Grant family and clouded the General's reputation.

In 1884 Grant began to write reminiscences of his campaigns for the *Century Magazine* and found this so congenial that he began to prepare his memoirs. Despite ex-

cruciating throat pain later diagnosed as cancer, he signed a contract with his friend Mark Twain to publish the memoirs and resolved grimly to complete them before he died. In June 1885 the Grant family moved to a cottage at Mount McGregor in the Adirondacks, and there Grant died on July 23. He was buried in Riverside Park, New York City, where an elaborate tomb was dedicated in 1897.

Grant completed his memoirs shortly before his death. Written with modesty and restraint, exhibiting equanimity, candour, and a surprisingly good sense of humour, they retain high rank among military autobiographies.

More detailed biography is available in LLOYD LEWIS, *Captain Sam Grant* (1950); BRUCE CATTON, *Grant Moves South* (1960), *Grant Takes Command* (1969); and WILLIAM B. HESSELTINE, *Ulysses S. Grant, Politician* (1935). Analyses of Grant as a soldier include J.F.C. FULLER, *The Generalship of Ulysses S. Grant* (1929); T. HARRY WILLIAMS, *Lincoln and His Generals* (1952); and KENNETH P. WILLIAMS, *Lincoln Finds a General*, vol. 3–5 (1952–59). *The Personal Memoirs of U.S. Grant*, 2 vol. (1885–86), are also available in a one-volume edition (1952). Grant's correspondence is in JOHN Y. SIMON (ed.), *The Papers of Ulysses S. Grant*, 4 vol. (1967–72).

(J.Y.S.)

Grasslands

The natural vegetation of the earth can be conveniently zoned on a combined physical and environmental basis into grassland, woodland, tundra, and desert. Each region contains distinctive plants, animals, climate, and soil. The proportion of land surface originally occupied by each region is difficult to assess because of gradual transitions from one to another and because of the modifying influence of man in altering the biotic and environmental characteristics of the landscape. Evidence suggests that, before man began the present rapid modification of environments by extensive agricultural and industrial operations, between 40 and 45 percent of the land surface of the earth was occupied by grasslands, in which grasses and grasslike plants dominated in the absence of trees or with widely spaced trees. Although tracts of grasslands and savannas still survive in a modified state as rangelands for domesticated livestock and game animals, much has also been exposed to such intensive agriculture that the original plants and animals have been virtually eliminated.

Original extent of grassland

This article is concerned with natural grasslands other than those occurring at high latitudes north of the circumpolar coniferous forest in the Northern Hemisphere and above forests on mountains. Likewise, seminatural grasslands of forest areas denuded by man are not considered, since they relate more properly to special situations within the woodland biome—*i.e.*, the worldwide complex of woodlands characterized by prevailing climate and soil conditions. Seeded grasslands are agricultural systems on arable land and will be treated here only in relation to ecological problems that arise when natural grassland flora is replaced by other species.

THE ENVIRONMENTAL SETTING

Regions of natural grassland occur where the environment is too arid for the development of closed forest but not so adverse as to prevent smaller, nonwoody but long-lived plants from forming a dense layer. Climate controls the biotic components of a region directly, through temperature and moisture extremes, as well as indirectly, through its influence on soil development by such long-term physical and chemical processes as freezing and leaching. Within the grassland zone, however, local variations in topography and soils result in microclimatic conditions so different from the typical regional norms that nongrassland ecosystems dominated by plants and animals not characteristic of the remainder of the region may develop locally. In certain warm regions, for example, the woody habit is exhibited by many plant species even under arid conditions, so that specially adapted trees are scattered throughout the grassland to form a characteristic parklike vegetation type known as a savanna.

Climate. The subhumid to semi-arid climates of natural grassland areas are characterized by marked periodicity of precipitation, both from season to season within the year and between years. Consequently, annual drought periods of several weeks to several months are typical. The severity of drought increases with the distance from the forest margin. It is also accentuated by a cyclical climatic pattern that often results in several consecutive dry years. Droughts are particularly difficult for plants and animals in regions where the dry season is lengthy—as in the Mediterranean-type climate of some temperate grasslands and in most tropical and subtropical grasslands and savannas—or where a series of moister than average years is followed by several years of below-average moisture (see SCRUBLANDS).

Annual precipitation in grasslands

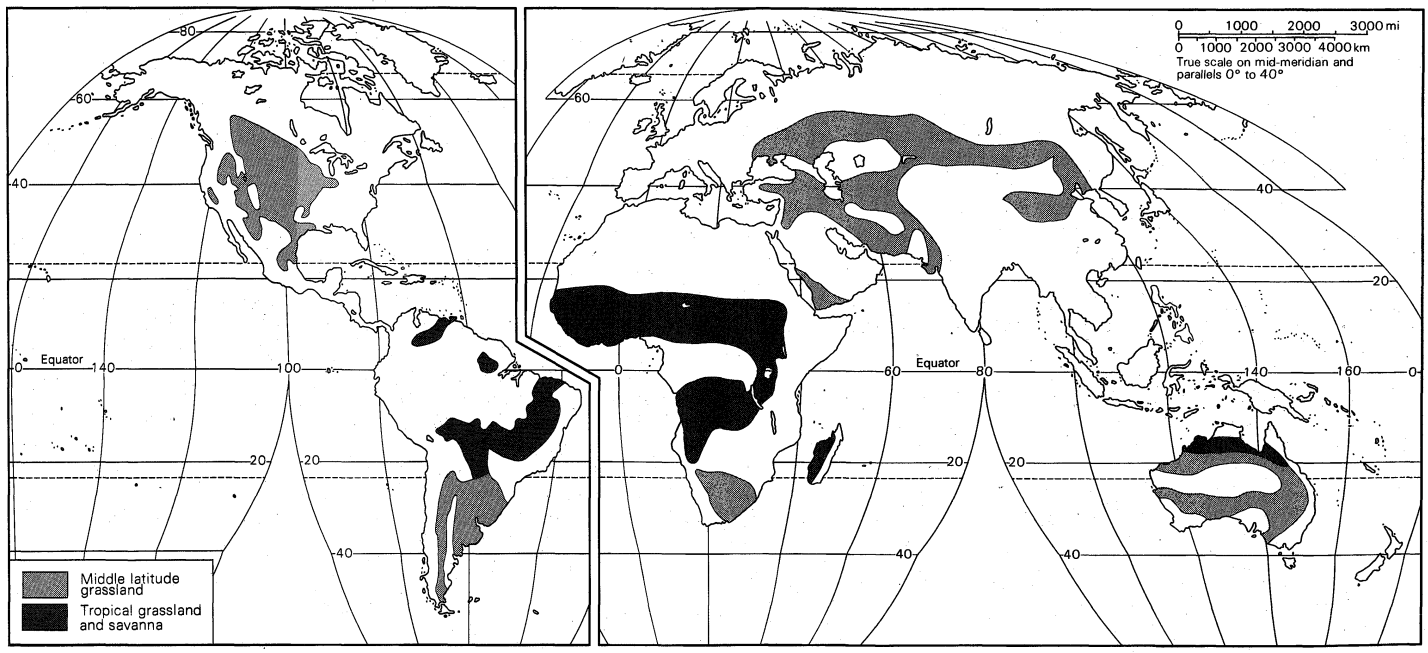
Mean yearly precipitation in most temperate grasslands ranges from ten to 30 inches (250 to 750 millimetres) and in tropical and subtropical grasslands and savannas from 25 to 60 inches (600 to 1,500 millimetres). Precipitation determines the nature and extent of natural grasslands through its effect on soil-moisture supply, since trees have difficulty competing with grasses in areas where upper soil layers are moist during part of the year but where deeper layers are continuously dry.

The adverse effect of drought on organisms is made more severe when accompanied by high temperatures. Increased duration and intensity of sunlight associated with decreasing cloudiness during periods of low rainfall tend to raise air and soil temperatures. In regions where the dry season is warm, the combined effects of drought and high temperatures make living conditions particularly adverse. Many organisms adapt to the hot dry season in grasslands of tropical, subtropical, and Mediterranean climates and to the cold season (also a time of low precipitation) of many temperate regions by becoming dormant.

In the grasslands of tropics and subtropics, the length of the growing season is determined by the length of the rainy season, ranging from 120 to 190 days. In cold, temperate regions, however, temperature is a controlling factor. Growth begins in such regions when the mean daily temperatures reach 40° to 50° F (5° to 10° C). Although the frost-free season in cold, temperate grasslands may be as short as 100 continuous days, the vegetative season usually exceeds 165 days. Less temperature difference occurs among various grasslands during the growing season than during the dormant season. The temperatures during the warmest month in temperate grasslands are usually not lower than 60° to 70° F (15° to 20° C); in tropical and subtropical regions, the mean during the rainy season is commonly no more than 20° F (10° C) higher.

Grassland regions tend to have higher than average wind speeds, in part because of low wind resistance due to the relatively smooth vegetative layer.

Fire. Fire is an important feature of the grassland environment. Lightning-induced fires are common and, before their control by man, periodically burned over extensive areas. The causes of fire are so closely related to the more or less arid nature of the grassland climate that it is not reasonable to separate fire from the more traditional climatic factors. Some geographers, however, have not been prepared to accept fires as a climatic factor and consequently have considered the natural vegetation to be that which would exist in the absence of fire. It seems more practical, in regions where aridity, continuity of combustible plant cover, and frequent thunderstorms lead to the frequent occurrence of natural fires, to consider the vegetation as it has been modified by fire to be the stable one. Fire maintains the boundaries of grasslands in climatic regions (usually the wetter portions of the grassland zone) capable of supporting forest growth. The effect of fire here, therefore, has been principally to prevent the extension of the forest into the grassland. The nature of the soil in such transition zones between grassland and forest is such, moreover, that the long-term existence of grassland is indicated.



World distribution of grassland biomes.
Adapted from *Biological Sciences Curriculum Study Green Version High School Biology*, 2nd ed.; Chicago: Rand McNally & Co., 1968

In the temperate grasslands, a climate adverse to tree growth exists except near the forest edge, but, in the tropics and subtropics, trees and shrubs are often scattered throughout the grassland to form a savanna. The luxuriant growth of herbaceous (nonwoody) plants during the rainy season provides fuel, which, in the dry season, supports fires almost annually in many regions. Whether or not a forest would develop in the absence of fires in these tropical areas is speculative. It is most satisfactory to consider them as savannas in which the herbaceous layer predominates.

Fire effects

Fire is more destructive to trees and shrubs than to grasses and other herbs, because the buds, from which new growth will begin the next season, are located well up on the stems in a position quite vulnerable to fire. In herbaceous species, the growth zones are at or below the soil surface.

Topography. Many grassland regions are characterized by level to gently undulating topography. Often, however, the land surface is sufficiently irregular to provide variations in microclimate that result in a mosaic of vegetation types, as, for example, in the glacial moraines and loessial (loess is a soil material carried to its present location by winds) hills in parts of the Central Lowland and Great Plains of North America and in sandhills everywhere. Near the forest–grassland margin, grassland is favoured, even within the forest zone, on dry slopes that are subjected to greater radiation and wind than is level terrain. Conversely, patches of trees occur within the grassland zone on protected slopes.

Contrasts in vegetation on slopes with different characteristics are particularly noticeable in the higher latitudes, where the slopes facing the equator regularly receive more radiation than do poleward-facing ones. Various habitats also are found in sheltered basins and on exposed hilltops. Forest occurs within the grassland zone in protected basins, and patches of grassland occur within the forest zone on exposed hilltops.

Within the grassland zone, the herbaceous vegetation of depressions and poleward-facing slopes often consists of species that dominate on level ground in poleward areas. In the same regions, the species in exposed habitats are those that dominate communities that range toward the Equator. Similarly, where grassland gives way to desert, desert species appear in exposed locations.

Soil. In regions where natural grasslands have developed, physical and biotic components have combined to produce soil quite different in its character from that of forest regions. In the temperate grassland, soil leaching (downward movement of water-soluble soil constituents) is restricted both by the scarcity of percolating water and by the low solubility of soil materials. The soil of natural grasslands, consequently, contains an abundance of organic matter at all depths; and chemical substances that are leached precipitate at the bottom of the soil profile (*i.e.*, the layering of soil as seen in a trench). Consequently, temperate grassland soils have the capacity to release nutrient elements to plants slowly and over a long period of time, thus permitting the production of annual crops, even after destruction of the natural plant cover. The abundance of organic matter (humus) in grassland soils is reflected in the colour of the soil profile; in temperate grassland, the colour varies from black near the forest margin, where the organic content approaches 10 percent in some areas, to chestnut and brown in areas where the organic content is below 3 percent.

Colour of grassland soils

In the tropical and subtropical grasslands, soil development is influenced by high temperatures and high precipitation in a process called laterization. By this process, soils become highly leached, and there is rapid decay of organic matter with low levels of humus accumulation. These soils are often reddish or yellowish in colour, reflecting the high content of iron left in the profile by the leaching of other minerals under conditions of high temperature. They are also very much more subject to nutrient depletion under agricultural practice than are temperate grassland soils.

Differences in soil texture and soil structure throughout the grassland zones modify the vegetative cover because of influence on water regimes. Although sandy soils hold less moisture per unit volume, they permit more rapid percolation of surface moisture than do soils of finer texture, with a lower resultant loss by runoff and evaporation. Because of their greater moisture supply and the availability of moisture to greater depths, sands support stands of tall grasses or even trees in regions where grasses of smaller stature and less depth of rooting occur on soils of finer texture.

THE BIOTIC COMPONENTS

The living members of an ecosystem are most conveniently considered as the floral (plants), faunal (animals), and micro-organism elements, which, respectively, function in a general way as producers of organic matter, consumers, and decomposers.

Flora. The vegetation of natural grasslands is primarily composed of seed-bearing herbaceous plant species, which are classified, on the basis of gross morphology, in-

to two groups: (1) grasses and grasslike plants (particularly sedges), which are collectively referred to as graminoids; and (2) nongrasslike herbs, mostly broad-leaved species, known as forbs. Woody components also occur, which, unlike the herbs, maintain perennial stems above the soil surface—*i.e.*, they live through several growing seasons. Frequently, there are dwarf shrubs that do not exceed the stature of the grasses; taller shrubs occur in some areas as isolated individuals or in patches. Scattered trees characterize the savannas, and, in some grassland areas, groves of trees are found in locally modified habitats such as along stream courses. Occasionally, colonies of non-seed-bearing plants, particularly lichens, club mosses, mosses, and algae, are found on the soil surface.

A considerable number of species comprise the vegetation of grasslands in areas of favourable moisture and temperature conditions, but the number decreases with increasing environmental adversity. In a square mile (about 2½ square kilometres) of rolling grassland in the black-soil region of eastern Nebraska, for example, over 200 different prairie species are found; in a similar area of level brown soil 1,000 miles (1,600 kilometres) to the northwest in southern Saskatchewan, the flora of seed-bearing plants is about 50 species. Similarly, the number of species in tropical savannas is limited to those that can resist the combined effects of fire and drought.

Success of grasses in occupying habitats

The graminoids (grasses and grasslike plants) are particularly well adapted to dominate in herbaceous communities, so that, although they typically make up less than 20 percent of the number of species present in grassland, they often furnish 90 percent or more of the plant biomass (dry weight) present. Similarly, though only a small percentage of the seed-bearing plant species belong to the grass family, their contribution to plant communities is great everywhere.

Grasses evolved from tropical woody ancestors, of which the bamboos are a present-day example. This origin is reflected in the relatively primitive nature of grasses composing the grasslands adjacent to forests in both tropical and temperate regions. Their adoption of the herbaceous habit, however, has permitted survival through such adversities as periodic burning and seasonal drought. Other adaptations that increase the chances of seed production in arid, windy, and cold environments include wind pollination, increased protection of flowers, and a reduced stature.

The graminoid life-form seems particularly well adapted to dominate in competition with forbs. Success of grasses seems to be associated with their ability to provide a dense plant cover in which seedlings of less aggressive species have difficulty in becoming established. Graminoids are well adapted to exist in conditions of frequent fire and in areas of animal grazing by their manner of growth. New growth is from a zone of cell division located at the bases of leaves and stems rather than at the tips, as in forbs and woody plants. This permits continued growth when the upper ends of shoots or the leaves are cut, eaten, or burned. The growth zones in the stem also assist shoots that have been bent by trampling to regain a vertical position.

Classification of grasses by height

Grasses and the grasslands they dominate are sometimes classified as high, tall, mid, and short. High grasses, frequently reaching heights of ten feet (three metres) or more, are limited to tropical grasslands with high precipitation. Tall grasses are found in the tropical and subtropical savannas and also in the most favoured parts of the temperate grasslands, moist habitats being particularly suited to them. Midgrasses, the flowering stems of which usually reach heights ranging from one to three feet (30 to 90 centimetres), dominate portions of the grassland closer to the woodlands of temperate regions. The short grasses, with leafy shoots often only three to six inches (eight to 15 centimetres) high, are dominant in the most arid grasslands. Between these extremes, the short and mixed grasses intermingle to form mixed-grass prairie, as in most of the Great Plains of North America.

The adaptation of each species of grass is also dependent on whether it is a turf former or a bunch grass. Turf-forming grasses spread by means of buds on lateral stems below the soil surface (rhizomes) or, much more rarely, above it (stolons). Bunch grasses are able to spread horizontally only far enough to extend the size of the dense bunch, which eventually declines with age. Occasional development of seeds is necessary for the perpetuation of a bunch-grass cover but not of turf grasses. Bunch grasses tend to dominate in arid habitats and turf formers in moist ones.

Grass species also differ physiologically in ways that adapt them to withstand adversity. Some species can continue growth during drought by extracting a greater amount of moisture from the soil. Others endure drought by achieving a dormant state before desiccation becomes excessive. Under extreme conditions, drought or overwinter survival is achieved only by means of seeds, in which case, the plants are known as annuals. Annuals are common in disturbed habitats in grassland, but they are more characteristic of the temporary herbaceous cover of deserts.

Root systems of grasses

The root systems of grasses are typically finely branched and rebranched to form a dense network extending through the soil. Depth of rooting of tall and midgrasses is characteristically not greater than six feet (about two metres) and those of short grasses only one to three feet. These distances are also the maximum depths of moisture penetration in the soils of the habitats in which they dominate.

In some grasslands of both temperate and tropical regions, sedges (*Carex*) are associated with the grasses and have similar ecological relationships. The composites (*e.g.*, asters, sunflowers) commonly rank next to grasses and sedges in abundance. Under the favourable growing conditions near the forest boundary, forbs are abundant; the adverse conditions in the drier grassland regions, however, reduce their abundance, relative to grasses, in number of both species and individuals. Many forbs are adapted to arid conditions by rooting to depths much greater than the grasses, by surviving as dormant underground organs for periods as long as many years and by storing water in their tissues. The root systems of some forbs are similar in structure to those of grasses, but a variety of other types exist, including taproots, bulbs, corms (rootlike or bulblike stem structures), and roots capable of forming shoot-producing buds. Species with the last type are particularly vigorous competitors with grasses and are especially abundant in the grasslands of the U.S.S.R., where in some areas forbs are considered to dominate over grasses. Eurasian forbs with such root systems have become the most persistent introduced weeds of arable land in many parts of the world. Among them are perennial species of *Euphorbia* (spurge), *Cardaria* (white top), *Centaurea* (thistle), and *Convolvulus* (morning glory).

The complexity of the vegetative cover of natural grassland is much greater than it appears to the casual observer. The many plants occupying grasslands may exhibit as much variety within a square yard as is present in an acre of forest.

The dominant and associated species are arranged horizontally into colonies and societies and vertically into layers, both above and below the ground. The number of layers discernible depends on the nature of the grassland. The uppermost one is composed of the tallest grasses and forbs. Some forbs have vegetative growth confined to lower layers but thrust their flowering parts, often on leafless stems, upward above the grass layer to insure pollination and seed dispersal. Others grow vegetatively at a rate similar to that of the taller grasses and bear their flowers on leafy stems. A lower layer is made up of species of shorter stature, some of which are secondary species that grow early in the season, before the dominants cover them.

The lowest layer above the ground is the crust of lichens, mosses, club mosses, and algae that often occurs on the soil surface among the fallen stems and leaves (litter) of the upper layers. Various groups of plants tend to root to different depths, so that short grasses and small sedges form a shallow layer underground and taller grasses a deeper layer. The roots of some forb species often branch

only below the deepest layer of grass roots; they sometimes penetrate to depths twice that of the dominants.

Seasonal aspects of grasslands

The appearance of temperate grasslands changes from season to season as a result of the successive flowering of different species. A few species thrust their flowering stems upward shortly after the disappearance of snow and before they are shaded by the spring growth of the cool-season grasses. These are followed by the spring flowers, which, in the temperate grasslands, are composed of a great variety of forbs including early legumes (members of the pea family). Early grasses and some sedges begin to flower near the end of this period. Most of the dominant grasses, of both warm and cool seasons, blossom during the summer, as do most of the legumes, all of which give a predominantly bluish and whitish tinge to the landscape at this time. The predominant colour of autumn flowers is yellow, and the floral display is made up principally of an abundance of composites. During these shifts in the seasons, the grasses also change in the early spring from the grayish colour of the preceding year's old growth through rich greens as the new leaves emerge to a straw-coloured hue of pale yellow in the late summer and early fall. Curing of shoots to a yellowish colour is characteristic of the more arid grasslands; those in more humid areas turn gray more rapidly. The growing season varies in character from year to year as differences in weather differentially stimulate or retard flowering of the various species. The grassland tends to be very drab and relatively lifeless during the winter. The changes in the season have not been as well documented in the tropical grasslands, in which the main changes apparently take place with the shift of the season from dry to rainy, with the resultant prompt resumption of luxuriant green growth that ends only with the renewed onset of drought. Some tree and forb species in tropical savannas anticipate the change in the season by leafing out before the arrival of the rainy season.

Animal life. The natural animal populations in grasslands are much more diverse than is generally realized, as many surface species are small and inconspicuous, and many other species live underground for at least part of their lives. The best known are the large grazing mammals, or game animals. Other well-known groups in grasslands include grazing marsupials (pouched animals, such as the kangaroo), predators belonging to the cat and dog families, rodents of various sizes, birds, lizards and snakes, and the larger insects, particularly grasshoppers and locusts. A large proportion of surface species are either running or burrowing types. The characteristic aggregation into colonies or herds provides some measure of protection in the open type of habitat. Invertebrates of various kinds are abundant in the soil.

Vertebrates. The large grazing mammals, subject to the influence of man have been severely reduced, and some species survive only in protected areas. The former ranges of these animals have become densely populated and are being grazed by cattle, sheep, horses, and goats. In some of the managed reserves in Africa, the natural and domesticated populations intermingle, but for the most part, the native grazing species are considered intruders, and their predators also are excluded by poisons, hunting, or fences.

Large animals of grasslands

The African grasslands were once abundantly supplied with a large number of species, of which perhaps the wildebeest, gazelles, and zebra were the most numerous over large areas. Other species included buffalo, giraffe, eland, antelope, hartebeest, hippopotamus, waterbuck, and impala. Some species, which are browsers as well as grazers, have had a great influence in restricting the growth of trees. These herbivores (plant-eating animals) are accompanied by a variety of omnivores (animals, such as the warthog, that feed on both animal and vegetable substances) and carnivores (meat eaters), particularly the lion, leopard, hunting dog, and fox. The hyena is perhaps more truly a scavenger, but it also fills the role of a predator while travelling in packs. The characteristic grazing species of the Asian grasslands include wild cattle, saiga antelope, wild horse, marmot, stag, and boar; predators are represented by the wolf and the fox. Wild horses and cattle, formerly abundant, have been exterminated by man, and antelope and marmot have largely been forced out of the grassland region.

The number of species of large grazing mammals in the Western Hemisphere, while it was larger during the early geological stages of development of grasslands, has been low in recent geological time. In North America, the principal species once were the bison and the pronghorn antelope. Their most important predators were the coyote and bobcat. In South America, the large grazing mammals have been less influential; rather, the llama and its relatives and the ostrich are the most important. The isolated fauna of Australia includes several kangaroo species as the major large grazing animals, with the dingo as their prime predator.

In some grasslands, the large grazing mammals are as important as climate and soil conditions in determining the nature of the vegetative community, since some plant species are more sensitive to grazing pressure than others.

Smaller herbivorous mammals, common in natural grasslands, include many species of rodents (*e.g.*, mice, voles, shrews, ground squirrels, gophers, prairie dogs, hares, and rabbits). Some species have increased their populations in regions where man has reduced the numbers of their predators, others (*e.g.*, the prairie dog in the Great Plains of North America) have suffered from a direct effort by man to exterminate them. Rodents, now reported to be the most frequently found mammals in some grasslands, are credited with causing widespread range deterioration, because they modify the speciation of the plant cover and expose the soil surface to erosion.

A wide variety of birds, including herbivorous, carnivorous, and omnivorous species, inhabit grasslands. The herbivores are the least numerous in terms of different species, and the omnivores are most abundant. The passerines (perching birds) are particularly common and include larks, longspurs, meadowlarks, starlings, grouse, cranes, partridges, and doves. Hawks, owls, and eagles are important predators.

The amphibians and reptiles are important organisms in many grasslands. Lizards, toads, and box turtles are mainly functional as predators of insects; snakes are predators of rodents and some other small vertebrates. These organisms, probably the least conspicuous components of grasslands, are often, however, among the most abundant vertebrates.

Invertebrates. Great numbers of species of insects and other invertebrates inhabit grasslands, forming large populations of individuals. Most conspicuous are the grasshoppers and their relatives. The numbers of surface insects present in grasslands have been estimated to be as many as 1,000 per square metre (about 100 per square foot), and the number of species present in one type of grassland may exceed 200. Insect bulk, or biomass, has been reported to be greater in some areas than that of large grazing mammals. Next to the grasshoppers (Orthoptera), the insects with the most pronounced effect on herbage are probably those of the orders Heteroptera (bugs) and Homoptera (aphids and leafhoppers). Ants (Hymenoptera) and termites (Isoptera) are found particularly in tropical and subtropical grasslands and savannas. The larvae of beetles (Coleoptera) feed on roots of plants and on feces, especially those of large grazing animals. Larvae of flies (Diptera) often affect seed production and are active in decomposing carrion. Larvae of moths and butterflies (Lepidoptera) feed on the crowns of grasses; and thrips (Thysanoptera) also affect seed production. The most abundant predatory invertebrates above the soil surface are spiders.

Insect numbers and bulk

Small soil animals are important to the grassland ecosystem. Chief among them are nematodes (roundworms), collembolans (springtails), mites, and enchytraeids (small segmented worms), as well as insects. Earthworms, although common in semipermanent and seeded grasslands, are rare in natural grassland conditions.

Micro-organisms. Microflora (bacteria, actinomycetes, fungi, and algae) probably are found in greater numbers in grasslands than are microfauna (protozoans). The great majority of micro-organisms present in the soil are

Bacteria and fungi

apparently dormant or inactive at any one time, although the bacterial biomass to a depth of 15 centimetres (six inches) in agricultural soil has been estimated to range from 330 to 720 kilograms per hectare (290 to 640 pounds per acre). Grassland soils, because they have considerable root systems, which provide habitats for markedly higher numbers of bacteria, thus contain an even greater bacterial biomass. Fungi, although present in appreciably lower numbers than bacteria, have much larger cell sizes and are estimated to possess a biomass twice that of the bacteria. Algae are commonly estimated to contribute less than 10 percent of the total microfloral biomass in mature soils.

COMMUNITY DEVELOPMENT

Stages. Grassland ecosystems have developed through an orderly series of changes in plant cover and soil, as one has affected the other through climatic influences. These progressive changes in plant cover are known as primary plant succession. As plant succession progresses toward a stabilized plant community, a soil gradually develops a profile that reflects the nature of the plants occupying it. The end of this process, a climax situation in which the organisms and soil are in equilibrium with the climate, is a stable system with many buffers to protect it from climatic changes and animal populations.

Primary succession of grasslands begins on bare, dry land surfaces or in water. In each situation, development is toward a more moderate water regime. This is accomplished in the dry habitat by the development of an insulating plant cover that protects the surface from the desiccating effects of sun and wind and by the incorporation of organic matter into the soil, which increases its water-holding capacity. In wet habitats, the process involves gradual elevation of the substrate (bottom of the water body in question) by deposition of both organic and mineral particles.

The series of changes in plant cover resulting in grassland begins with a layer of crustose lichens, followed by foliose (leafy growth form) lichens. Eventually, annual herbs and a series of perennial species—first forbs and short-lived grasses, finally a stable community of long-lived grasses and forbs—becomes established.

Gradual succession of water bodies to grassland

The succession beginning in a body of water starts with submerged aquatic species and progresses through floating-leaf, reed-swamp, and sedge-meadow stages as the water level decreases. This moist habitat may survive for thousands of years and permit the development of various vegetative stages (even of shrubs and trees) before the depression containing the water gradually fills from the edges and the vegetation becomes dependent, for the first time, on climatic factors (chiefly, precipitation) that permit the establishment of a climax grassland cover.

The uniformity of the climax vegetative cover depends on the degree of irregularity of the landscape, for the final stages of the dry-habitat succession will not be reached while exposed locations survive on sunny and windy slopes and on hilltops, and protected situations are preserved on sheltered slopes and in depressions. The regional characteristics of the vegetative cover, however, are expressed in topographic locations between these extremes. It is on this portion of the landscape, which in most grassland areas constitutes the major area, that the following brief survey of the grasslands of the earth is based. While this survey considers the temperate regions separately from the tropical and subtropical grasslands, the distinction is very arbitrary. Subtropical grasslands give way imperceptibly to temperate communities through the arid areas where contact usually takes place.

Temperate grasslands. The most extensive grassland areas of the temperate zone are the steppes of Eurasia, the prairies and plains of central and western North America, and the pampa and adjacent areas of Argentina. Less extensive areas are found in the velds of South Africa, in the mountain grasslands of South America, and in Australia and New Zealand.

North America. The North American grassland is composed of seven regional types. The largest, the mixed prairie, extending from southern Alberta and Saskatchewan southward to western Texas, lies between the 100th meridian (west longitude) and the foothills of the Rocky Mountains to the west. It is dominated in the north by bunch-forming spear grasses (*Stipa*) and turf-forming wheat grasses (*Agropyron*), which are midgrasses that gradually give way to short grasses southward, particularly blue grama (*Bouteloua*) and buffalo grass (*Buchloë*). The next largest area of grassland east of the Rocky Mountains occurs in a higher precipitation belt extending from the mixed prairie to the eastern deciduous forest. Although it is now the "corn belt," this area was formerly dominated by spear grass and dropseed (*Sporobolus*) in the drier habitats and by bluestems (*Andropogon*) in more favourable locations. Both types occur in areas east of the Rocky Mountains, where there is an early-summer peak in precipitation, followed by late-summer drought. West of the Rockies the most northerly grassland area is the palouse prairie, which occurs in eastern Washington and adjacent parts of Idaho and Oregon, and in the valleys of British Columbia. The dominant grass species is a large, bunch-forming wheat grass. The upper slopes in the northern part of this region are occupied successively by remnants of mixed prairie to the east and then by fescue prairie. The latter also occurs as a belt around the mixed prairie's northern edge in the eastern foothills of the Rocky Mountains and in parklands of Canada's "prairie provinces." Southward, in the Mediterranean climate of the valleys of California, the native, perennial grass cover has been replaced—through overgrazing—by annual weedy grasses, but spear grasses formerly dominated. Southwestern United States and north central Mexico contain the most arid prairies, the desert plains grasslands, which surround the warm desert at elevations between 1,000 and 5,000 feet (300 and 1,500 metres). Short grama (*Bouteloua*) and wire grasses (*Aristida*) abound here in an environment similar to that of the dry subtropics. The region of Texas adjacent to the Gulf of Mexico also has subtropical vegetation characteristics.

South America. The best known temperate grassland in South America is the pampa of east central Argentina, which occupies a region of level, black soil. The annual precipitation of 40 to 50 inches (100 to 125 centimetres) is the highest of the temperate grasslands, and frequent drought periods do not occur. Similar grassland extends on more rolling topography to the north through Uruguay into the semi-arid campos region of southern Brazil and northwestward in Argentina. Westward, the pampa becomes drier and the soils gradually change to chestnut and brown and then to gray in colour near the Andes mountains. In the driest areas, shrubs and small trees (*Prosopis, Cassia*) form a dwarf savanna. Southward, the pampa gives way to the semi-arid regions of Patagonia. Only part of these areas have grassland character. The extremely dry regions contain shrubby, cold desert vegetation. The pampa and the adjacent less humid grasslands have been exposed to grazing by domesticated livestock for about 400 years. Heavy grazing, particularly in the last century, has modified the vegetation to the extent that the identity of the natural dominant species is not known, although spear-grass species are thought to have been included among them. The vegetation is now composed principally of introduced species. Cool mountain grasslands are extensive at various altitudes in the Andes, occurring at high elevations even in the tropics. These areas are dominated by species of spear grass, fescue, bluegrass (*Poa*), and reed grass (*Calamagrostis*).

Eurasia. The body of natural grasslands in Eurasia lies within the U.S.S.R., extending from north of the Black Sea in the southern Ukraine eastward through northern Kazakhstan and southern Siberia. These steppes are bordered on the north by forest steppe where the elements of the boreal forest intermingle with the grassland, as is the case in the similar climate at the northern edge of the Great Plains grassland of North America. Southward, the climate becomes warmer and drier, particularly in the Asiatic portion, and the soils gradually lighten in colour from black to dark brown, brown, and gray at the edge of the cold-shrub desert region. The most important dominants are species of spear grass, feather grass (also

Stipa), and fescue. Here, the species of fescue that dominates over large areas is more drought-resistant than the dominant spear grasses and feather grasses, a situation the reverse of that in the northern American grasslands.

Africa and Australia. The South African veld, the tussock grasslands of New Zealand, and the grasslands of Australia are much less extensive. They are similar mainly in that oat grasses (*Danthonia*) are dominants in each. In Australia, however, the *Danthonia*-dominated grasslands are restricted to the southeast, with more extensive grasslands dominated by Mitchell grasses (*Astrebla*), which occur in arid situations blending into subtropics. Grassland of temperate character also occupies the highlands of East Africa.

Tropical and subtropical grasslands and savannas. Tropical and subtropical grasslands and savannas are located in central Africa, central South America, and northern Australia.

Africa. In Africa, they occur northward and southward from the tropical rain forest. The tropical high-grass savanna forms a belt up to 400 miles (650 kilometres) wide adjacent to the forest. This savanna is dominated by many grasses of the tribes Andropogoneae and Paniceae, of which elephant grass (*Pennisetum*) and cogon grass (*Imperata*) are probably the most abundant. The dominants reach five to 15 feet (1.5 to 4.5 metres) in height. Even though there is a pronounced dry season, the stability of this vegetation is considered to be more dependent on fire than on climate. The high-grass savannas give way, northward and southward, to tropical and subtropical tall-bunchgrass savannas and then to short-bunchgrass savannas, with decreasing precipitation and increasing length of dry season. All of the widespread dominants of this region are of the tribe Andropogoneae, the most abundant species being themeda grass (*Themeda*). The tall-grass areas stand three to five feet (one to 1.5 metres) high, while, in the short-grass savannas, dominants grow to about one foot (30 centimetres). The trees in these savannas are scattered or in clumps and reach heights of ten to 50 feet (three to 15 metres). In the drier areas they are shorter and more thorny than elsewhere. As the degree of aridity increases further, in areas where the annual rainfall averages less than 20 inches (50 centimetres), the savanna is replaced by semidesert and desert grassland in which important species include spear grasses and wire grasses and in which the woody element is limited to low, thorny shrubs.

Fire-maintained high-grass savanna

South America. The most extensive tropical grassland area in South America is the llanos of Venezuela, which lies between the Andes Mountains and the Orinoco River. This region is composed of a complex of plant communities including grassland and savanna, with high grasses dominating in some parts and tall grasses in others. Over large areas there are no trees, apparently because of waterlogging of soil. Less extensive savannas are found, interspersed with forest, in many other parts of tropical America, especially the Orinoco plains and lowland along the Gulf of Mexico in Colombia, parts of the Amazon River Basin, parts of Bolivia, the Pacific coast of Costa Rica, and parts of the West Indies. The best known dominants in many of these areas are Para grass and guinea grass (both of the genus *Panicum*). The semi-arid region of northeastern Brazil is similar to those on the equator side of the deserts in Africa, with wire grasses among the dominants and also with scattered shrubs.

Australia. The "savanna woodlands" of tropical Australia include many areas in which the tree cover (mostly *Eucalyptus*) is sufficiently thin to permit grasses to dominate. Here, many high and tall grasses develop during the rainy season, but (as elsewhere in the subhumid tropics) the nutrient quality of herbage in the dry season is very low. Similar types of grassland cover occur in Java, Sumatra, Ceylon, and the Philippines in places where the forest has been destroyed or thinned by various means.

Lands surrounding the Mediterranean Sea, those in Asia Minor, and parts of southwestern Asia (Iran, Pakistan, Afghanistan, Tadzhikistan, and India) have been exposed so long to the effects of man's occupation that it is no longer possible to determine their original character. It is probable that many areas that are presently desert-like were previously grassland. Elsewhere, the change from grassland to desert, because of man's occupancy, has been observed during the last century.

FUNCTIONING AND PRODUCTIVITY OF GRASSLAND ECOSYSTEMS

The organic component of a grassland ecosystem is a complex of producers, consumers, and decomposers that are highly organized into a food web. The system is driven by energy fixed from sunlight during the process of photosynthesis in the green tissues of plants (the producers). This energy is passed on in the form of organic matter—used as food—from one to the other of various groups of organisms, each of which liberates some of the energy in its own body functions. Finally, the photosynthetically produced organic matter is transformed back into mineral elements, which may again be used by plants in photosynthesis.

Biological productivity

The biological productivity of such a system is expressed in terms of the rate of fixation of solar energy by the producers and is known as primary productivity. The rate at which the consumer biomass increases, by transformation of plant materials into animal tissue, is referred to as secondary productivity. Primary productivity for natural, temperate grasslands ranges mostly between 200 and 1,000 grams per square metre of dry matter per year; that in the most favourable tropical areas is much greater. Secondary productivity is considerably less than primary productivity in all regions. In the central Great Plains of North America, for example, yearling cattle consume only a portion of the vegetation present in their grazing area, and of this it is estimated that only 9 percent is used in meat production, 48 percent being lost as heat to the atmosphere and 43 percent to other food chains in the form of feces and urine.

Plant species in natural grasslands are sensitive to the removal of more than a moderate proportion of their shoots. Unconsumed shoots die and remain standing, in some communities for periods as long as two or three years, during which time they protect the soil against erosion and contribute toward increasing the rate of its water intake. In some grasslands, there is more of this "old growth" present than the current season's crop of green shoots. The old shoots gradually decay or fall to the ground to produce a litter layer. The depth of litter depends on amount of growth, amount of consumption, and rate of transformation (by microorganisms and soil animals) to soil humus.

The plant biomass (including underground parts) of natural temperate grasslands is usually in the range of 1,000 to 3,000 grams per square metre of dry matter. As much as 85 percent of this biomass occurs underground. Dead material comprises only a fraction of the aboveground parts (both standing and as litter) but up to 75 percent of the underground parts. About half of the energy fixed in a given year is deposited in underground tissues. The rate of decomposition of dead, unconsumed plant parts is such that, on the average, the amount of biomass present disappears in about two years aboveground and about four years underground. The amount of plant litter present usually reaches an equilibrium state (*i.e.*, the condition that exists when the rate of disappearance equals the rate of new litter added), which varies from less than 100 grams per square metre in dry, temperate grasslands to about 1,000 grams per square metre in black-soil areas. Lower values than these prevail in areas where a higher than usual proportion of the shoots enter the consumer food web or where recurrent fires occur.

In grassland stands in the subhumid tropics and subtropics, biomass of herbage sometimes exceeds 5,000 grams per square metre; but the rate of decomposition of organic matter is very high in such areas, leading to low quantities of litter and soil organic matter.

It has been estimated that about two-thirds of the energy of the grassland ecosystem is released through the activity of reducers and decomposer organisms that feed on detritus and animal wastes. This activity is almost all in the soil or in the litter at the soil surface. Only general

Importance of decomposer organisms

conclusions can be given concerning the proportion of this activity caused by invertebrates and other decomposing reducers, since it has not yet been quantitatively evaluated. Under some conditions such organisms are very numerous. The liveweight of termites in the tropical savanna of the Ivory Coast, for example, has been found to be 40 grams per square metre in an area where aboveground herbivores measure only one gram per square metre. It is generally agreed, however, that the soil microflora (microscopic plants, including fungi and bacteria) is the single most important group of organisms affecting the turnover of energy. The biomass of soil microflora has been estimated to be 400 to 600 grams per square metre of soil surface on a dry-weight basis; however, probably less than 1 percent of this is active at any one time.

It is not yet possible to identify to what extent various groups of soil microflora contribute to the total of decomposer activity in any given system. The rate of decomposition in standing dead vegetation is usually slower, however, than in litter and in vegetation in contact with the ground. The bulk of the microbial decomposition does not occur until the litter has either made contact with the soil or has become densely compressed just above the soil surface. The smaller macrofauna (animals bigger than microbes), such as litter-feeding insects and worms, are active in bringing litter into more intimate contact with the soil.

UTILIZATION OF GRASSLANDS

Many early human civilizations developed in grassland regions, so man should be familiar with the ecology of grasslands. Greater interest, however, has been shown in converting grasslands to the growth of annual crops than has been devoted to considering whether they would have been a more valuable resource in an untilled state.

Domesticated grazing animals occupy the most important role in man's conversion of natural-grassland plant growth to a form of food that satisfied him. While conservationists in the past may have looked upon the domesticated grazing animal as an intruder in natural grassland, this does not necessarily mean that the grassland environment will deteriorate through the replacement of natural by introduced animals. The philosophy of range management that has developed in North America is based on the concept of obtaining the highest sustained level of animal production on natural grassland that is compatible with maintenance of the resource. Range ecologists have been much more conscious of the need to conserve land resources than have agriculturalists. In the management of arable lands, for example, the guiding principle has been almost exclusively determined by the need to produce the maximum harvestable yield, a practice hardly compatible with conservation. The advantage that the ecologist sees in the use of domesticated livestock in the rational management of rangelands is that the distribution and density of these animals is under his control to a far greater extent than would be possible with native animals. The domestication of the range is thus seen as a stabilizing situation.

The success achieved in increasing the harvestable yield of intensively managed arable land and improving semipermanent grasslands of woodland climate has led to the suggestion that the plant cover of nonarable grasslands should be changed as much as possible by the introduction of domesticated forage crops that have been selected and bred for high yield and for optimum response to fertilization and management. A high degree of environmental control is needed, however, to utilize the higher potential of these species, and the indication is that the native grass cover cannot be excelled by introduced species for range production on nonarable land.

Effects of herbicides and fertilizers

Attempts have been made to increase the productivity of natural grassland by the use of herbicides and fertilizers. Weed control of rangeland is economically practical only in cases where the weedy situation has been induced by mismanagement and when this situation is corrected. The effect of fertilizers is variable, yielding better returns where moisture conditions are most favourable. Some native species do not respond to increased levels of nutrient supply and may be replaced after fertilization by species that are more productive but dependent for survival on a continued supply of fertilizer nutrients.

After the initiation of tillage, highly fertile, temperate grasslands gradually (over a period of 50 to 100 years) attain a new level of equilibrium, which is associated with a lower content of soil organic matter. The full impact on organic-matter content will not occur until the original organic material is replaced by that formed from the annual agricultural plant cover. The concept that corrective measures can be taken by future human generations by addition of chemical fertilizer does not account for changes in soil structure that may be associated with declining organic content.

The maintenance of both arable and nonarable ecosystems in grassland zones is vital to the continued provision of food for the world. The temperate grassland zones include a very important portion of the cropland of the earth (for example, 90 percent of the grain for commerce originates here); the tropical and subtropical grasslands and savannas provide a possible means for expanding agriculture when technology is developed to manage these lands on a long-term basis.

Gravitation

Gravitation is a universal force of attraction acting between all matter. The trajectories of bodies in the solar system are determined, except for relatively tiny effects, by the laws of gravity, while on Earth all bodies have a weight or downward force of gravity proportional to their mass, which the Earth's mass exerts on them. Gravity is by far the weakest known force in nature and therefore plays no role in determining the internal properties of everyday matter. But because of the long reach and universality of the gravitational attraction, gravity plays a central role in shaping the structure and evolution of stars, galaxies, and the entire universe.

The works of Isaac Newton and Albert Einstein dominate the development of gravitational theory. Newton's classical theory of gravitational force held sway from its presentation in his *Principia*, published in 1687, until Einstein's work in the early 20th century. Even today, Newton's theory is of sufficient accuracy for all but the most precise applications. Einstein's modern field theory of general relativity predicts only minute quantitative differences from the Newtonian theory except in a few special cases. The major significance of Einstein's theory is its radical conceptual departure from classical theory and its implications for further growth in physical thought (see RELATIVITY).

DEVELOPMENT OF GRAVITATIONAL THEORY

Early concepts. The classical Greek philosophers considered the motions of the celestial bodies and of objects on Earth as basically unrelated. The former was not considered as gravitationally determined, as the celestial bodies were seen to follow perpetually repeating, nonde-

scending trajectories in the sky. Aristotle envisioned such bodies as possessing "natural" motions that did not require external causes or agents. In this view, celestial bodies underwent their own particular "natural" motion, while massive earthly objects possessed a natural tendency to move toward the Earth's centre. Two other Aristotelian viewpoints were: that a body moving at constant speed required a continuous force acting on it and that force must be applied by contact rather than interaction or force at a distance. These views impeded understanding of the principles of motion and hence retarded the development of a theory of universal gravitation. During the 16th and early 17th century, however, several scientific contributions to the problem of earthly and celestial motion set the stage for Newton's gravitational theory.

Kepler's laws of planetary motion

Johannes Kepler, accepting the Copernican perspective —in which the planets orbited the Sun rather than the Earth—and using Tyco Brahe's improved measurements of planetary movements, succeeded in describing the planetary orbits by simple geometrical and arithmetical relations. Kepler's three quantitative laws of planetary motion were: (1) the planets describe elliptic orbits, of which the Sun occupies one focus; (2) the line joining a planet to the Sun sweeps out equal areas in equal time; and (3) the square of the period of revolution of a planet is proportional to the cube of its average distance from the Sun. During this same period, Galileo made major progress in understanding the properties of "natural" motion and simple accelerated motion for earthly objects. He realized that bodies uninfluenced by forces would continue indefinitely to move and that force was necessary to change motion, not to maintain constant motion. Galileo performed experiments to show that the Earth's gravity produced constant downward acceleration and that the downward gravitational acceleration was independent of the bulk or composition of bodies.

Newton's law of gravity. The modern quantitative science of gravitation began with the work of Newton. He assumed the presence of an attractive force between all massive bodies; this force does not require bodily contact but acts at a distance. By invoking his law of inertia (bodies not acted upon by a force move at constant speed in a straight line), Newton concluded that a gravitational force exerted by the Earth on the Moon was needed to keep it in a circular motion about the Earth rather than in a straight line and that this force could be, at long-range, of the same kind as the force with which the Earth pulled objects on its surface downward. Galileo had previously measured the downward acceleration of bodies on Earth to be approximately 980 centimetres (32 feet) per second per second, while Newton calculated that circular orbital motion of radius R and period T required a constant inward acceleration A equal to the product of $4\pi^2$ and the ratio of the radius to the square of the time:

$$A = \frac{4\pi^2 R}{T^2}. \qquad (1)$$

Applying this formula to the Moon's orbit, which has a radius of about 384,000 kilometres (about 60 Earth radii) and a period of 27.3 days, the inward acceleration is approximately 2.7×10^{-3} metres per second per second; this is the same as 1/3,600 ($1/60^2$) times the Earth's surface acceleration. Newton deduced that the gravitational force between bodies diminishes as the inverse square of the distance between the bodies, as he could thus relate the two accelerations to a common interaction. A further assumption, that the mass of the Earth acts gravitationally on the outside world as if the mass were concentrated at the Earth's centre, was needed to obtain his relationship. Newton proved mathematically that this assumption was true for all spherically symmetric bodies.

Newton saw that the gravitational force between bodies must depend on masses of the bodies. Since a body of mass M experiencing a force F accelerates at a rate F/M, a force of gravity proportional to M would be consistent with Galileo's observation that all bodies accelerate under gravity toward Earth at the same rate. Newton's law of gravity can therefore be expressed mathematically by a relation expressing the law. If F_{12} is the magnitude of the gravitational force acting between masses M_1 and M_2 separated by distance D_{12}, then the force equals the product of these masses and of G, a universal constant divided by the square of the distance, D_{12}^2:

The universal constant G

$$F_{12} = \frac{GM_1M_2}{D_{12}^2}. \qquad (2)$$

The constant G is a quantity having the physical dimensions (length)^3/(mass)(time)^2, its numerical value depending on the physical units of mass, length, and time used. (G is discussed more fully in a later section.) To obtain the total gravitational force on a body produced by many masses represented as M_i, where the subscript i stands for the positions 1, 2, . . . n, the individual forces must be vectorially added together, as force has direction as well as magnitude. Letting $\boldsymbol{D}_i$ be the spatial vector from the mass M to the mass M_i in the same way, the force on M due to several masses becomes the sum of the forces due to each mass separately. In the following expression, in addition to the quantities already explained, the symbol Σ represents the sum, and the factor $\boldsymbol{D}_i/D_i^3$ is needed to give the direction and numerically is equivalent to division by D_i^2:

$$F = GM \sum_{i=1}^{n} \frac{M_i \boldsymbol{D}_i}{D_i^3}. \qquad (3)$$

This is Newton's gravitational law in its vector form. The simpler expression gives the surface acceleration on Earth; setting a mass equal to the Earth's mass M_E and the distance equal to the Earth's radius r_E, the downward acceleration of a body at the surface g is equal to the product of the universal gravitational constant and the mass of the Earth divided by the square of the radius:

$$g = \frac{GM_E}{r_E^2}. \qquad (4)$$

Weight and mass

The weight W of the body can be measured by the equal and opposite force necessary to prevent the downward acceleration; this is M_g. The same body placed on the Moon's surface has the same mass, but as the Moon has a mass of about 1/81 times that of the Earth and a radius of only 0.27 of that of the Earth, the body on the Moon's surface acquires a weight of only 1/6 its Earth weight, as demonstrated by the U.S. Apollo astronauts. In orbiting satellites, where no force prevents the free fall of the satellites in the gravitational field, the cargo of humans and instruments experiences weightless conditions although the masses remain the same as on Earth.

The two equations above can be used to derive Kepler's third law, for the case of circular planetary orbits. By putting the expression for the acceleration A in equation (1) equal to the force of gravity for the planet, GM_pM_S/R^2, divided by the planet's mass M_p, M_S being the mass of the Sun, and R, T being the radius and period of the orbit, respectively, the following equation is obtained:

$$\frac{GM_S}{R^2} = \frac{4\pi^2 R}{T^2}$$

or

$$R^3 = \left(\frac{GM_S}{4\pi^2}\right) T^2. \qquad (5)$$

Newton was able to show that all three of Kepler's observationally derived laws followed mathematically from the assumption of his own laws of motion and the law of gravity stated above. In all observations of the motion of a celestial body, only the product of G and the mass can be found. Newton first estimated the magnitude of G by assuming the Earth's average mass density to be about 5.5 that of water, somewhat greater than the Earth's surface rock density, and calculating the Earth's mass from this. Then, taking M_E and r_E as the Earth's mass and radius, respectively, the value of G was

$$G = \frac{gr_E^2}{M_E}, \qquad (6)$$

which numerically comes close to the accepted value of

6.7×10^{-8} (cm)^3/(gm)(sec)^2, first directly measured by a Cavendish balance experiment (see below).

Comparing equation (4) above for the Earth's surface acceleration g with the R^3/T^2 ratio for the planets, a formula for the ratio of the Sun's mass, M_S, to Earth's mass, M_E, was obtained in terms of known quantities, R_E being the radius of the Earth's orbit:

$$\frac{M_S}{M_E} = \frac{4\pi^2 R_E^3}{g T_E^2 r_E^2} \cong 325{,}000\ . \qquad (7)$$

By using observations of the motion of the moons of Jupiter discovered by Galileo, Newton determined that Jupiter was 318 times more massive than Earth but only ¼ as dense, having a radius 11 times larger than Earth.

Interaction among celestial bodies

When two celestial bodies of comparable mass interact gravitationally, the bodies each orbit about a fixed point (the centre of mass of the two bodies), which lies between the bodies on the line joining them at a position such that the distances to each body multiplied by each body's mass are equal. Observing that the Sun's apparent position in the ecliptic (the plane in which the Sun seems to be moving around the Earth) oscillates every month by about 12 arc-seconds (superimposed upon its annual motion) and accounting for this by means of a motion of the Earth around the Earth–Moon centre of mass, it was concluded that this centre of mass is placed about 4,800 kilometres (3,000 miles) toward the Moon from the Earth centre. From this, the Moon was found to be about 1/81 (4,800/384,000) as massive as the Earth. With slight modifications Kepler's laws remain valid for systems of two comparable masses; the foci of the elliptical orbits are the two-body centre-of-mass positions, and putting $M_1 + M_2$ instead of M_S in the expression of Kepler's third law, equation (5) above, the third law reads:

$$R^3 = \frac{G(M_1 + M_2)}{4\pi^2} T^2. \qquad (8)$$

This agrees with equation (5) when one body is so small that its mass can be neglected. The rescaled formula can be used to determine the separate masses of binary stars (pairs of stars orbiting around each other; see STAR) that are of a known distance from the solar system. Equation (8) determines the sum of the stars' masses; and, if R_1, R_2 are the distances of the individual stars from the centre of mass, the ratio of the distances must balance the inverse ratio of the masses, and the sum of the distances is the total distance R. In symbols,

$$\frac{R_1}{R_2} = \frac{M_2}{M_1}\ ; R_1 + R_2 = R. \qquad (9)$$

These relations are sufficient to determine the individual masses. Observations of the orbital motion of double stars, of the dynamical motion of stars collectively moving within their galaxies, and of the motion of the galaxies themselves verify that Newton's law of gravity is valid to a high degree of accuracy throughout the visible universe.

Ocean tides, phenomena that mystified thinkers for centuries, were also shown by Newton to be a consequence of the universal law of gravitation, although the details of the complicated phenomena were not understood until comparatively recently. They are caused specifically by the gravitational pull of the Moon and, to a lesser extent, of the Sun (see TIDES).

In the period following Kepler and Newton, improved accuracy in the measurements of planetary motion led to small discrepancies from the simple predictions of Kepler's laws. All but a few were later shown in accord with the universal aspect of Newton's law of gravity. Small corrections due to the fact that all the planets must perturb each other explained almost all variations in the planets' motions. The exceptions proved to be of large importance. Uranus, the seventh planet from the Sun, was observed to undergo variations in its motion that could not be explained by perturbations due to Saturn, Jupiter, and the other planets. The English mathematician John Couch Adams and the French mathematician Urbain-Jean-Joseph Le Verrier independently assumed the presence of an unseen eighth planet that could produce the observed discrepancies in the motion of Uranus.

The discovery of Neptune

They calculated its position within a degree of which the planet Neptune was discovered in 1846. Measurements of the motion of the innermost planet, Mercury, over an extended period led astronomers to conclude that the major axis of this planet's elliptical orbit precessed (precession is the gyration or wobble of the axis of a rotating body affected by a gravitational field) in space at a rate 43 arc-seconds per century faster than could be accounted for from perturbations of the other planets. In this case, however, no other bodies could be found that could produce this discrepancy, and very slight modification of Newton's law of gravitation seemed to be needed. Einstein's theory of relativity precisely predicts this observed behaviour of Mercury's orbit (see RELATIVITY).

INTERPRETATION OF GRAVITY MEASUREMENTS

Potential theory. For irregular, nonspherical mass distributions in three dimensions, the vector equation (3) above, which expresses Newton's law of gravity essentially in its original form, is inefficient, though theoretically it could be used for finding the resulting gravitational field. The main progress, after Newton, in classical gravitation theory was the introduction of potential theory, which allows practical as well as theoretical investigation of the gravitational variations in space and anomalies due to the irregularities and shape deformations of the Earth.

Potential theory led to the following elegant formulation: The gravitational acceleration, g, a function of position R, $g(R)$, at any point in space is given from a function, Φ, called the gravitational potential, by means of a generalization of the operation of differentiation:

$$g(R) = \frac{\partial \Phi}{\partial x}\, i + \frac{\partial \Phi}{\partial y}\, j + \frac{\partial \Phi}{\partial z}\, k,$$

in which i, j, k stand for unit basis vectors in a three-dimensional Cartesian coordinate system. Whatever restriction on g is introduced by the mass density ρ, that restriction is then transferred to the potential function Φ and is expressed in an equation that was discovered by the French mathematician Siméon-Denis Poisson:

Poisson's equation

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right) \Phi(R) = -4\pi G \rho(R),$$

in which the equation is to hold for well specified values of R. The significance of this approach is seen by observing that Poisson's equation can be solved under rather general conditions, which is not the case with Newton's equation. When ρ is non-zero, the solution is expressed as a definite integral:

$$\Phi(R) = G \int \frac{\rho(R')dR'}{|R - R'|}\ .$$

When $\rho = 0$ (that is, outside the Earth), Poisson's equation reduces to the simpler equation of Laplace and has a general solution expressed as a series of powers of the trigonometric cosine function of θ, the latitude angle measure from the north pole:

$$\Phi(R) = \frac{GM_E}{R}\left[1 - J_2\left(\frac{R_E}{R}\right)^2 \frac{3\cos^2\theta - 1}{2} - J_3\left(\frac{R_E}{R}\right)^3 \frac{5\cos^3\theta - 3\cos\theta}{2} + \ldots\right],$$

in which, if R is the distance from the Earth's centre, R_E is the average Earth radius, θ is the latitude angle measured from the north pole, and J_2, J_3, etc., are constants. The constants J_2, J_3, etc., are determined by the detailed mass distribution of the Earth; and, since Newton showed that for a spherical body all the J_n are absent, the J_n must be measurements of the deformation of the Earth from a spherical shape; J_2 measures the magnitude of the Earth's rotational equatorial bulge, J_3 measures a slight pear-shaped deformation of the Earth, and so on. By comparison of gravimeter measurements (see below) from many parts of the Earth's surface and by observations of perturbations on satellite orbits and the Moon's orbit, the parameters J_2 and J_3 have been found to be 1,082.7 $\times 10^{-6}$ and -2.4×10^{-6}, respectively. Higher terms in

the potential series are being detected and measured by continuous observation of near-Earth satellite orbits.

Effects of local mass differences. The method used to describe global features of the Earth's mass distribution is inadequate to represent gravitational variations due to local mass differences such as mountain ranges, mineral deposits of unusual density, ocean basins, etc.; so other methods have been developed for these purposes. Several geological features of the Earth were first discovered from gravity measurements. Using gravimeters and horizontal pendulums, observers expected the additional bulk of mountain ranges compared with surrounding plains to produce slight attractive gravitational forces; instead, in many cases, slight repulsion was found. Such repulsion supports the view that mountain ranges float, possessing deep roots, much as an iceberg does, of underlying lightweight material that displaces the denser material of the Earth's interior. Portable gravimeters, which can detect variations of a part in 10^9 in the gravitational force, are today in wide use for mineral and oil prospecting, unusual underground deposits revealing their presence by creating local gravitational variations (see below).

Mascons

Man-made satellites tracked during orbital motion around the Moon and around the planet Mars have followed trajectories that are best understood by assuming that these bodies possess large regions of anomalous mass densities (called mascons) that produce gravitational field variations. The lunar mascons are of sufficient size to have perturbed the Apollo manned lunar landings, and the paths of the approaching capsules were found to need adjustment to account for the perturbations and to reach their desired landing sites.

GRAVITATIONAL THEORY AND OTHER ASPECTS OF PHYSICAL THEORY

Special relativity and electromagnetic field theory

The Newtonian theory of gravity is based on an assumed force acting between all pairs of bodies; that is, an action at a distance. When a mass moves, the force acting on other masses has been considered to adjust instantaneously to the new location of the displaced mass. Special relativity theory states that all physical signals travel no faster than the speed of light. This theory, with the field theory of electrical and magnetic phenomena, have met such empirical success, however, that most modern gravitational theories are constructed as field theories consistent with the principles of special relativity. In a field theory the gravitational force between bodies is formed by a two-step process: (1) One body produces a gravitational field that permeates all surrounding space but has weaker strength farther from its source. A second body in that space is then acted upon by this field, experiencing a force. (2) The Newtonian force of reaction is then viewed as the response of the first body to the gravitational field produced by the second body, there being at all points in space a superposition of gravitational fields due to all the bodies in it.

Field theories of gravitation. If the gravitational field has a theoretical and conceptual existence of its own, various new predictions of gravitational phenomena can be made. The equations governing the time evolution of the field predict a finite speed of propagation of disturbances through the field, replacing the direct instantaneous action at a distance by a delayed interaction transmitted by the field. The gravitational field in most modern theories is, in fact, free to change dynamically in certain modes independent of sources and to transmit energy and momentum in these modes, in a manner similar to electromagnetic wave radiation. These gravitational waves, which have been extensively studied mathematically since Einstein first showed their existence in theory, may have recently been demonstrated experimentally in the form of pulsed radiation received from the centre of the Galaxy. The possible detection of these extra-terrestrial gravitational waves was performed by monitoring cotemporaneous mechanical vibrations present in a pair of isolated, several-ton aluminum cylinders located about 1,500 kilometres (900 miles) apart. Field theories of gravity predict that gravity waves will excite such mechanical oscillations in these rigid bodies.

Corrections of Newtonian force law

Field theories of gravity, Einstein's general relativity being an important example, also predict specific corrections to the Newtonian force law, the corrections being of two basic forms: (1) When matter is in motion, additional gravitational fields (analogous to the magnetic fields produced by moving electric charges) are produced; also, moving bodies interact with gravitational fields in a motion-dependent way. (2) Unlike electromagnetic field theory, in which two or more electric or magnetic fields superimpose by simple addition to give the total fields, in gravitational field theory nonlinear fields proportional to the second and higher power of the source masses are generated, and gravitational fields proportional to the product of different masses are created. Gravitational fields themselves become sources for additional gravitational fields. Examples of some of these effects are shown below. The acceleration, $\boldsymbol{A}$, of a moving particle of negligible mass that interacts with a mass, m, which is at rest, is given, in the following formula, derived from Einstein's gravitational theory. The expression for $\boldsymbol{A}$ now has, as well as the Newtonian expression as given in equation (1), further terms in higher powers of Gm/R^2—that is, in G^2m^2/R^4— and V is the particle's velocity vector, $\boldsymbol{A}$ its acceleration vector, $\boldsymbol{R}$ the vector from the mass m, and c is the speed of light. When written out, the sum is

$$\boldsymbol{A} = -\frac{GmR}{R^3} + 2\frac{G^2m^2R}{c^2R^4} - \frac{3}{2}\frac{GmR}{R^3}\left(\frac{V^2}{c^2}\right) - \frac{V \cdot AV}{c^2} - \tfrac{1}{2}\frac{V^2}{c^2}\mathbf{A} + \ldots.$$

This expression gives only the first post-Newtonian corrections; terms of higher power in $1/C$ are neglected. For planetary motion in the solar system the $1/C^2$ terms are smaller than Newton's acceleration term by at least the factor 10^{-8}, but some of the consequences of these correction terms are measureable and important tests of Einstein's theory. It should be pointed out that prediction of new observable gravitational effects requires particular care; Einstein's pioneer work in gravity has shown that gravitational fields affect the basic measuring instruments of experimental physics—clocks, rulers, light rays—with which any experimental result in physics is established. Some of these effects are listed below:

1. The rate that clocks run is reduced by proximity of massive bodies; *i.e.*, clocks near the Sun will run slowly compared with identical clocks farther away from it.
2. In the presence of gravitational fields the spatial structure of physical objects is no longer describable precisely by Euclidean geometry; for example, in the arrangement of three rigid rulers to form a triangle, the sum of the subtended angle's will not equal 180°. A more general type of geometry, Riemannian geometry, seems required to describe the spatial structure of matter in the presence of gravitational fields (see PHYSICAL THEORIES, MATHEMATICAL ASPECTS OF).
3. Light rays do not travel in straight lines, the rays being deflected by gravitational fields. To distant observers the light-propagation speed is observed to be reduced near massive bodies.

Gravitational fields and general theory of relativity. In Einstein's general theory of relativity the physical consequences of gravitational fields are stated in the following way. Space-time is a four-dimensional non-Euclidean continuum, the curvature of space-time's Riemannian geometry being produced by or related to the world's matter distribution. Particles and light rays travel along the geodesics (shortest paths) of this four-dimensional geometrical world.

Null experiments and post-Newtonian effects

The experimental foundations for modern theories of gravity can be classified into two categories—null experiments and the detection of extremely small (post-Newtonian) effects. Null experiments establish the absence of conceptually possible gravitational effects, usually thereby greatly restricting the class of acceptable laws of gravity. The small differences from Newtonian gravitation, and their interpretation, are discussed below.

At the turn of the century the Hungarian physicist Baron Lóránt (Roland) Eötvös found that different materials accelerated in the Earth's field at identical rates to an ac-

curacy of one part in 10^9. Recent experiments have increased the observed equality of accelerations to one part in 10^{11}. Newtonian theory is in accord with these results because of his postulate that gravitational force is proportional to a body's mass.

Inertial mass is a mass parameter giving the inertial resistance to acceleration of the body when responding to all types of force. Gravitational mass is determined by the strength of the gravitational force experienced by the body when in the gravitational field g. The Eötvös experiments, therefore, show the equality of gravitational and inertial mass for different substances.

Einstein's special theory of relativity views inertial mass as a manifestation of all the forms of energy in a body according to his fundamental relationship $E = mc^2$, E being the total energy content of a body, m the inertial mass of the body, and c the speed of light. Viewing gravitation, then, as a field phenomenon, the null result of the Eötvös experiments indicates that all forms of nongravitational energy must identically couple to or interact with the gravitational field, because the various materials in nature possess different fractional amounts of nuclear, electrical, magnetic, and kinetic energies, yet they accelerate at identical rates.

In the general theory of relativity the gravitational field also interacts with gravitational energy in the same manner as with other forms of energy, an example of that theory's universality not possessed by most other theories of gravitation. Eötvös' experiments using celestial bodies that contain a detectable fraction of internal gravitational energy were testing this feature of the general theory of relativity in the 1970s; these experiments are intended to determine whether the various solar-system bodies accelerate at identical rates in the Sun's field. Measurements of great precision, using radar and laser ranging, of the time-dependent interbody distances between the Earth and Moon, the Earth and Jupiter, and other such relationships are now possible (see below).

Gravitational consequences of the equivalence principle. A decade before he completed his full mathematical theory of gravity, Einstein predicted new gravitational effects using the equivalence principle. Observing that the equality of gravitational and inertial mass made impossible a distinction between uniform gravitational fields and accelerated coordinate systems, he proposed the null principle: no experiment can distinguish between local gravitational fields and accelerated coordinate systems. He then was able to show that clocks would run slower when near massive bodies and that light would be deflected toward massive bodies by their gravitational field.

Einstein's null principle

Newton's third dynamical law states that every force implies an equal and opposite reaction force. Modern field theories of force contain this principle by requiring every entity that is acted upon by a field to be also a source of the field. A recent null experiment established to a one-part-in-20,000 accuracy that different materials produce gravitational fields with a strength the same as they are acted upon by gravitational fields. In this experiment a sphere of solid material was moved through a liquid of identical weight density. The absence of a gravitational effect on a nearby Cavendish balance instrument during the sphere's motion is interpreted as showing that the two materials had equal potency in producing a local gravitational-field anomaly.

Other experiments have brought confirmation of Einstein's predictions to an accuracy of a few percent. Using the Mössbauer effect to monitor the nuclear reabsorption of resonant gamma radiation (hard X-rays), a shift of wavelength of the radiation which travelled vertically tens of metres in the Earth's gravitational field was measured, the slowing of clocks (in this case the nuclear vibrations are clocks) as predicted by Einstein has been confirmed to 1 percent precision. If ν and $\Delta\nu$ are clock frequency and change of frequency, respectively, h is the height difference between clocks in the gravitational field g. This is

$$\frac{\Delta\nu}{\nu} = -\frac{gh}{c^2}.$$

For a height of ten metres (about 30 feet) this effect produces only a one-part-in-10^{15} change in clock rates. The predicted deflection of light in gravitational fields was first detected during a 1919 solar-eclipse experiment. Recently progress has been made in measuring a related effect, the slowing of light's speed of propagation when near massive bodies. Timing the round-trip travel time for radar pulses between Earth and other inner planets or artificial satellites passing behind the Sun, experiments have confirmed to about 4 percent the prediction of an additional time delay, Δt, given by a formula in which M_S is the Sun's mass, R_1 and R_2 are the distances from the Sun to Earth and to the other reflecting body, D is the distance of closest approach to the Sun of the radar pulses. The additional time delay Δt is expressed as $4G$ times the Sun's mass over the cube of the velocity of light, c, times the logarithm of the quantity: four times the product of R_1 and R_2 divided by the square of D. In symbols,

$$\Delta t = \frac{4GM_S}{c^3} \ln\frac{4R_1R_2}{D^2}.$$

These radar ranging experiments to bodies in the solar system naturally complement the classical astronomical optical measurements of bodies' angular positions as seen from Earth. Radar tracking of the inner planets confirms to a few percent the precessional motion of the planets' elliptical orbits predicted by the general theory of relativity.

SOME ASTRONOMICAL ASPECTS OF GRAVITATION

Recent astrophysical discoveries such as quasi-stellar objects, pulsars, and the apparent gravitational radiation pulses being received from our galactic centre indicate that unusual astrophysical objects containing intense gravitational fields may exist in the universe. Modern physical theory predicts that a sufficiently massive object must, upon exhausting its nuclear fuel, inevitably collapse under its gravitational self-attraction, in most cases expelling part of its material in a supernovae explosion. Making only very general assumptions about the interaction properties of matter, it is concluded that the core of these collapsed stars will end either in a new superdense state of matter—the neutron star of typical density 10^{17} kilograms per cubic metre—or it is believed the core will collapse indefinitely toward a singularity, altering the properties of the surrounding space because of the enormously strong gravitational fields produced, so that physical communication with the outside world is quickly cut off, even light rays being trapped within this gravitational or black hole.

Pulsars

It is presently thought that the pulsars discovered in 1968 are neutron stars, having masses comparable to the Sun but diameters of only ten to 100 kilometres (six to 60 miles). The highly periodic electromagnetic radiation pulses coming from known pulsars with periods of from 1/30 of a second up to about a second require something like very small, but massive, rotating neutron stars as their sources.

The search for black holes

A black hole is the name given to the volume surrounding a collapsed star (an enormous mass in a tiny space), in which the gravitational field is so large that no radiation can get out; as a result it cannot be observed from outside. The astronomical search for a black hole is made difficult because of the very short time required for their formation (fractions of a second) and the relative infrequency of their creation. After being formed they emit no radiation or signals for the astronomer to detect. Present efforts are concentrated on the possibility of detecting a gravitational hole with a visible companion binary star. The gravitational wave pulses believed to be detected by the hundreds per year may be the gravitational radiation that would result from massive bodies being strongly accelerated into a large black hole (of thousands of solar masses) located near the centre of the Galaxy.

This field is experiencing such rapid theoretical and experimental development that these present viewpoints must certainly be considered as somewhat tentative and temporary. (K.L.N.)

THE ACCELERATION OF GRAVITY ON THE EARTH'S SURFACE

More than 300 years ago Galileo, in studying how things fall toward the Earth, discovered that the motion is one of constant acceleration. He was able to show that the distance a falling body travels from rest in this way varies as the square of the time. The acceleration due to gravity at the surface of the Earth is about 980 centimetres (about 32 feet) per second per second; that is, following its release, an object will gain in speed 980 centimetres per second for each second it falls.

Perhaps Galileo's most noted conjecture was that in a perfect vacuum all bodies would fall at the same rate; if they are released together, they will strike the ground together. This conjecture, in combination with his observation that the motion of free fall is one of constant acceleration, leads to the result that all bodies fall with the same acceleration. This assumption of a common acceleration has proved to be one of the cornerstones of gravitational physics; it has been tested many times—most notably in Eötvös experiments and in the recent extraordinarily precise experiments of the U.S. physicist Robert H. Dicke and his colleagues. Common acceleration indicates that a body's weight (the Earth's gravitational pull on the body) is proportional to its inertial mass —that is, to the resistance it offers to an accelerating force. The constant of proportionality is simply the acceleration of gravity. Thus, g plays a dual role: the value of the acceleration observed in free fall (the acceleration of gravity) is also the constant of proportionality between mass and weight (the force of gravity per unit mass).

Importance of g in many fields

Knowledge of the acceleration due to gravity is of importance to several different disciplines of the physical sciences. Its absolute value provides a base that, together with the standard of mass, establishes the derived standard of force. The standard of force, in turn, is a necessary quantity in the assignment of values to the electrical units of current and voltage. The acceleration due to gravity is also an important factor in the accurate pressure determinations needed for the thermodynamic temperature scale and the establishment of the International Practical Temperature Scale. Absolute measurements of the acceleration due to gravity are also of interest to the science of geodesy. Rapid advances have recently been made in setting up a world gravity network to establish reliable gravity values at a large number of base points located strategically over the Earth.

Variations in g. *Changes due to location.* Though often thought of as a constant over the surface of the whole Earth, the acceleration g varies by about ½ of 1 percent with position on the Earth's surface, from about 978 cm/sec^2 at the Equator to approximately 983 cm/sec^2 at the Earth's poles. This variation stems chiefly from the rotation of the Earth, as part of the Earth's pull is balanced by keeping objects rotating with the Earth instead of flying tangentially off into space (as mud does off a spinning wheel). This effect is also responsible for the bulge of the Earth at the Equator and the slight flattening at the poles. The distance to the centre of the Earth, therefore, increases with the bulge from the poles to the Equator, and consequently g, which for a spherical Earth of radius r_E and mass M_E is given simply by GM_E/r_E^2, is less toward the Equator.

In addition to this broad-scale variation, local variations of a few parts in 10^6 or smaller are caused by variations in the density of the Earth's crust as well as height above sea level. Further, at any one particular place, g, considered to be the resultant force, varies with time as a result of the changing gravitational attraction of the Sun and the Moon.

Changes with time. For most purposes, only knowledge of the variation of gravity with time at a fixed place (tidal variation; see TIDES) or of the gravity differences from place to place is required. Accordingly, the great bulk of gravity measurements that have been made are relative; that is, they measure only the differences between gravity values at various places. In tribute to Galileo the unit gal (equivalent to 1 cm/sec^2) has been adopted as the unit of acceleration of gravity, and this has been subdivided to milligal, essentially one part in 10^6 of g, for convenience; thus, one milligal (mgal) = 0.001 gal = 0.001 cm/sec^2.

Great progress was made during the 1960s in the development of new standards of accuracy for the measurement of g on land, on ships, and in the air, as well as in space. Recent progress in gravimetry has been influenced by improvement in the accuracy and reliability of absolute gravity determinations. As a result, a worldwide network of gravity base stations and calibration lines has been established. The methods used for the measurement of the acceleration due to gravity in terms of the fundamental units of length and time are described below.

Only two basic methods have been used to measure the absolute acceleration of gravity: by timing (1) freely falling bodies and (2) those that move under gravity but whose motion is constrained in some way, as in the case of a pendulum.

Pendulum measurements of g. Pendulum measurements of g are familiar to almost everyone who has taken an introductory course in physics. A pendulum is called simple if it consists of a heavy bob at the end of a nearly weightless arm or compound if the weight is distributed also through the arm. In the case of a simple pendulum, the time of swing is proportional to the square root of the length divided by the acceleration of gravity. This relative ease of timing of a pendulum swing offers a distinct timing advantage over free-fall measurements. The constraint on the body's free fall permits a large number of "drops" to be made very conveniently during a measured interval of time. The price one pays for this gain is that, having introduced a constraint, the effects of the constraint on the performance of the pendulum must be taken precisely into account. The English physicist Henry Kater showed (1817) that if the period of swing was the same about each of the points of support for a pendulum that could be hung from either of two fixed points, the distance separating these points of suspension was equal to the length of a simple pendulum having the same period. Once the equality of periods has been established (by adjusting the position of attached weights), the problem is then reduced to that of measurement of the common period and of the distance separating the two supports. Reversible pendulums, which can reach an ultimate accuracy in the range of a few parts in 10^6 (1 mgal), provided the only practical basis for absolute measurements of g from Kater's time until the middle of the 20th century.

The work of Henry Kater

The most accurate and most straightforward way of measuring the acceleration due to gravity is now to measure directly the acceleration of a freely moving body. Only relatively recently has it been possible by electronic control to realize the necessary accuracy in the measurement of short time intervals to permit effective measurement of g by direct free fall.

Accuracy attained in the known value of g. The early free-fall experiments (dating from 1952) used geometrical optics to define the position of an object as it fell. From 1963, direct interferometric methods using corner cube mirrors, one of which was dropped, have led to more accurate distance measurements during the free fall. More recently still, lasers have been used as light sources in free-fall interferometric devices. By the 1970s the best absolute-gravity experiments had demonstrated accuracies in the 0.01–0.05 mgal range. Furthermore, measurements with a semi-portable laser interferometer apparatus have now been made at a number of stations covering a gravity range of 4,800 mgal with an absolute accuracy of five parts in 10^8 (0.05 mgal).

For most purposes only a knowledge of the variation in gravity from place to place is required. Accordingly the great bulk of gravity measurements are relative and give gravity differences between places on the Earth. These can then be referred to an absolute system to produce gravitational values for the sites.

Accuracy of pendulum measurements. Since the time of Newton, measurements of gravity differences (strictly of the ratio of one value to another) have been made by timing the same pendulum at two sites where gravity is to be compared. Already in 1818, such relative measure-

ments reached an accuracy of a few parts in 10^6. The most accurate work is now done with two pendulums swinging in opposite phase; in this way the sway of the support due to the reaction of the pendulums is eliminated, and also any movements of the support will produce equal and opposite changes in the periods of the two pendulums, which can be made to cancel out if the mean period of the two pendulums is used.

The accuracy of relative measurements with a pendulum depends on timing accuracy and the constancy of the conditions. Further, the difference in gravity is obtained in absolute units and therefore does not require any instrumental calibration. Accuracy of modern pendulum observations is limited by the scatter of the results when a pendulum is swung repeatedly in one place and, mainly, by changes in the pendulums that occur during transportation from place to place. The best claimed accuracy is a few tenths of a milligal.

Use of gravity meters. Up to about 1930 the pendulum was the only instrument available for relative gravity measurements, even for small scale geophysical prospecting. The development of static gravimeters restricted pendulum measurements to providing the calibration for these gravimeters. The growing number of truly absolute determinations can be expected to make even this use obsolete.

Spring gravity meters

Spring gravity meters balance the force of gravity mg on a mass m in the gravity field to be measured, against the elastic force of the spring, using either electronic or mechanical means to achieve high sensitivity. Vibrating string gravity meters in which the string's vibration frequency is determined by g have also been developed. A device of this type was employed by the Apollo 17 astronauts on the Moon to conduct a gravity survey of their lunar landing site. One of the most recent developments has been the superconducting gravimeter, an instrument in which the position of a magnetically levitated superconducting sphere is sensed to provide a measure of g.

Modern gravity meters may have sensitivities greater than 0.005 mgal, the standard deviation of observations in exploration surveys being, in the best performance, of the order of 0.01–0.02 mgal.

Differences in gravity measured with gravimeters are obtained in quite arbitrary units—divisions on a graduated dial, for example. The relation between these units and milligals can only be determined by reading the instrument at a number of points where g is known as a result of absolute or relative pendulum measurements. Further, because an instrument will not have a completely linear response, known points must cover the entire range of gravity over which the gravimeter is to be used.

Gravimetric surveys. Recently, by combining all available absolute and relative measurements, it has been possible to obtain the most probable gravity values at a large number of sites to a high degree of accuracy. The culmination of gravimetric work begun in the 1960s has been a worldwide gravity reference system having an accuracy of one part in 10^7 (0.1 mgal) or better.

Since g is an acceleration, the problem of its measurement from a vehicle that is moving and therefore unavoidably accelerating relative to the Earth raises a number of fundamental problems. Pendulum, vibrating string, and spring-gravimeter observations have been made from submarines; using gyrostabilized platforms, relative gravity measurements with accuracies approaching a few mgal have been and are being made from surface ships. Experimental measurements with various gravity sensors on fixed-wing aircraft as well as on helicopters have been carried out. Additional information about the Earth's gravitational field has been made possible through the use of artificial satellites. Tidal gravity variations are observed through the use of sensitive recording gravimeters. One of the most remarkable recent measurements was the mapping of variations in the gravitational field on the visible side of the Moon by observed perturbations in the orbits of Lunar Orbiter satellites.

The value of gravity measured at the surface of the Earth is the resultant of such component factors as (1) the gravitational attraction of the Earth as a whole, (2) centrifugal force caused by the Earth's rotation, (3) elevation, (4) unbalanced attractions caused by surface topography, (5) tidal variations, and (6) unbalanced attractions caused by irregularities in underground density distributions. Most geophysical surveys are aimed at separating out the last of these in order to interpret the geological structure. It is therefore necessary to make proper allowance for the other factors.

The free-air and Bouguer corrections factors. The first two factors imply a variation of gravity with latitude that can be calculated for an assumed shape for the Earth. The third factor, the decrease in gravity with elevation, due to increased distance from the centre of the Earth, amounts to -0.3086 mgal/m (-0.09406 mgal/ft). This value, however, assumes that material of zero density occupies the whole space between the point of observation and sea level, and it is therefore termed the free-air correction factor. In practice, the mass of rock material that occupies part or all of this space must be considered. Where the topography is reasonably flat this is usually calculated by assuming the presence of an infinite slab of thickness equal to the height of the station, h, and having an appropriate density σ; its value is $+0.04185\ \sigma h$ mgal/m or $+0.01276\ \sigma h$ mgal/ft. This is commonly called the Bouguer correction factor.

Terrain or topographic corrections can also be applied to allow for the attractions due to surface relief if the densities of surface rocks are known. Tidal effects the amplitudes of which are lower than 0.3 mgal can be calculated and allowed for.

In defining anomalies, the observed gravity g_0 is compared with the theoretical value $g\gamma$ for the latitude of the station. The difference is then corrected for the elevation, h, of the station, using the free-air correction factor, F, with or without the Bouguer correction factor, B. The topographic correction, T, is also applied, giving in symbols: free-air anomaly $= g_0 - g_\gamma + Fh + T$ and Bouguer anomaly $= g_0 - g_\gamma + (F - B)h + T$. In exploration surveys Bouguer anomalies are most commonly used. Free-air anomalies or isostatic anomalies, in which a further correction for crustal material based on the compensation of mass above a certain depth has been applied, are those generally adopted in geodetic work.

(Ja.F.)

THE GRAVITATIONAL CONSTANT, G

The gravitational constant, G, has been introduced in the first part of this article. Although G is one of the most fundamental constants in nature, it probably is the least accurately known because of the extreme weakness and universality of the gravitational interaction. The weakness is such that the force of attraction between two spheres each weighing one kilogram spaced 0.1 metre apart is only about 1.3×10^{-13} of the pull of gravity on one of the spheres. The universality of the gravitational force, already assumed by Newton, is supported by the failure of experiment to show any variation of G that depends on the kind or size of the attracting masses, their temperature, or the amount of other matter placed between them. Consequently, in order to determine G, it is not only necessary to measure very tiny forces or torques but also to do so in the presence of the much larger perturbing forces due to all of the other matter in the universe, as it is impossible to shield the masses under investigation from the rest of the universe. The classical theory of celestial mechanics is based upon Newton's law and is used to predict with great accuracy the paths of the Moon, the Sun, the planets, and other bodies through space; but solution of the mathematical equations obtained from astronomical observations does not give G uniquely, but rather—if M is the mass of one of the interacting bodies—the highly precise product MG.

Difficulties in measuring G

Principal methods of measuring G. There are three principal methods of measuring G: (1) in which the pull of the Earth is compared with that of a large natural mass, such as a mountain or other topographical mass, on that of a known mass called a test mass; (2) in which a comparison is made between the Earth's attraction and that of a known mass on a test mass, as in the common

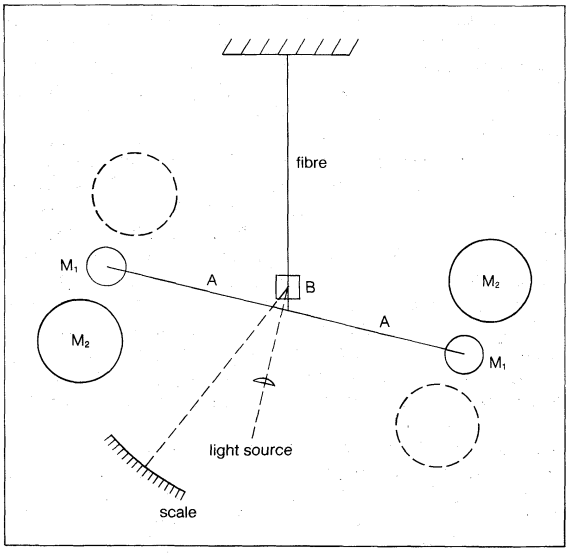

Figure 1: Modified Cavendish deflection experiment. The masses M_1 are deflected horizontally by the masses M_2, first in position shown by full circles, then at dotted circles. The twist is measured on the scale from reflection of light from a small mirror at B (see text).

chemical balance experiments; and (3) in which direct determination of the force between known masses is made in the laboratory. At the present time, experiments in the first category are of historical interest only and have not yielded a reliable value of G. As more accurate values of G become available by other methods, however, such experiments in connection with modern geophysical investigations can give valuable information concerning the densities and density gradients, especially in the Earth and Moon.

The various experimental methods of determining G in the laboratory have in the past employed some form of torsion balance or the common balance. According to the 18th-century English physicist Lord Henry Cavendish, the torsion balance was invented by the British geologist and astronomer, the reverend John Michell, for the purpose of measuring G, though Michell died before the apparatus was completed. The first reliable measurement of G was carried out by Cavendish in 1798 with a torsion balance of the Michell type. Figure 1 shows schematically the method used by Cavendish, though many details of the actual apparatus differed from those of the Figure. Two small spherical masses, M_1, are mounted on a stiff rod, A, and suspended by a torsion fibre, f. A light beam is reflected from a mirror, B, rigidly attached to A and brought to focus on a scale, S. When the large spherical masses, M_2, are placed in the fixed position shown in Figure 1, the gravitational interaction produces a torque on the small mass system, M_1, which causes A to rotate around its vertical axis. This rotation continues until the torque produced by the gravitational attraction of the small mass system, M_1, and the large mass, M_2, is balanced by the restoring torque due to the twist in the fibre. The deflection of the light beam on the scale, S, is then a measure of the twist in the fibre from which the torque, due to gravitational interaction, can be found. If the large masses, M_2, are shifted from the positions shown in the Figure into the positions indicated by the dotted circles, the small mass system is twisted in the opposite direction, and the deflection of the light beam on the scale S is reversed. The extreme smallness of the deflection of the light beam usually limits the precision of the method. This torsion-balance-deflection method was perfected by the English physicist Sir Charles Vernon Boys, who first developed the quartz-fibre suspension.

The work of Lord Henry Cavendish

The common balance method consists in supporting equal spherical masses, M_1, from the weighing pans of an equal arm chemical balance. A large spherical mass, M_2, mounted on a turntable is rotated directly under one of the masses M_1. If d is the distance between the centres of the two spheres, the downward gravitational attraction of M_2 on M_1 given by GM_1M_2/d^2 adds to the pull of gravity M_1g due to the Earth, and it tips the equal arm balance through a small angle that is measured by a pointer or optical magnification device. M_2 is then rotated until it is under the weight attached to the opposite arm of the balance, and the deflection that now takes place in the opposite direction is measured. From calibration of the balance, G can then be calculated in terms of g and d. Careful experiments were carried out with this method, principally by the English physicist John Henry Poynting, using a specially constructed balance; but M_1g was so much larger than the gravitational interaction of the two masses that the results were not as reliable as those obtained with the torsion balance, in which the pull of the Earth is not directly superposed upon the gravitational interaction.

Figure 2 shows a schematic diagram of the torsion-balance-oscillation method. The torsion balance that supports the small masses is similar to that described in Figure 1, but the large attracting masses, M_2, are placed in the same straight line that passes through the small masses, as shown in Figure 2. The torsion balance containing the small masses is then given a small displacement and the period of oscillation measured. This period can also be calculated in terms of G and the other quantities. The large masses, M_2, are then placed in the positions indicated by the dotted lines, which are in a line perpendicular to the line joining the small masses, M_1, and passing through its centre. A second determination of the period of the torsion pendulum is then measured. From these values it is possible to determine G. The advantage of this method over the torsion-balance-deflection method is that periods of oscillation can be measured with greater precision than small deflections, but it suffers from uncertainties due to the effect of gravitational gradients and neighbouring masses. This method produced what until recently was usually regarded as the most reliable value of G. In 1971 it was again used to obtain a new value of G. The new study is being carried out in the Grotta Gigante in Italy. The small masses, M_1, each weigh 10 kilograms and the large masses 500 kilograms while the torsion-wire suspension is 90 metres long. With the oscillation method, however, the torsion pendulum must be in a vacuum to prevent large damping through air resistance. The method has been modified in another study so that both the small and large mass systems are on separate torsion suspensions and are brought into resonance, but the result with this arrangement is believed to be less precise than that achieved by the U.S. physicist Paul Heyl (published in 1930; see Table).

The Table is a partial list of the measured values of G. The accuracy of the measurements made before 1930 is difficult to evaluate, but it is probable that the values re-

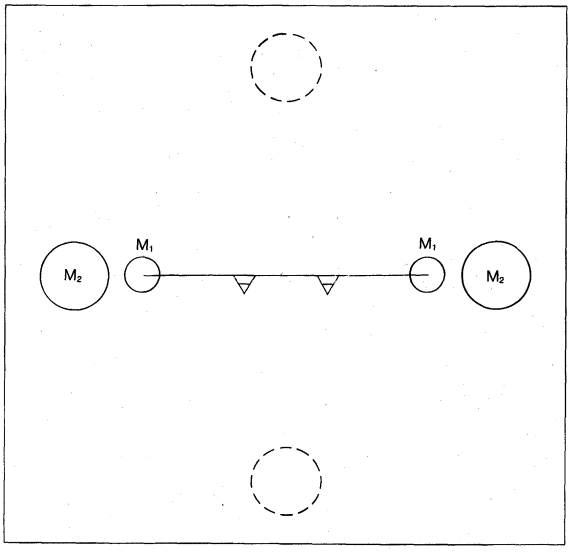

Figure 2: Elements in the torsion-balance resonance experiment (see text).

Best Values of the Gravitational Constant G
(up to 1942)

	year	method	G unit: $(10^{-11}Nm^2Kg^{-2})$
Cavendish	1798	torsion-balance (deflection)	6.754
Reich	1838	torsion-balance (deflection)	6.61
Baily	1842	torsion-balance (deflection)	6.475
Von Jolly	1881	common balance	6.465
Wilsing	1889	metronome balance	6.596
Poynting	1891	common balance	6.698
Boys	1895	torsion-balance (deflection)	6.6576
Braun	1896	torsion-balance (oscillation)	6.6579
Eötvös	1896	torsion-balance (oscillation)	6.65
Richarz	1898	common balance	6.685
Burgess	1901	torsion-balance (deflection)	6.64
Heyl	1930	torsion-balance (oscillation)	6.670
Zahradnicek	1932	torsion-balance (resonance)	6.659
Heyl and Chrzanowski	1942	torsion-balance (oscillation)	6.673

ported by Heyl and his associates—$G = (6.670 \pm 0.015) \times 10^{-11}$ Newton-square metre per square kilogram—is the most reliable among those listed.

A new method was devised in the 1960s and is illustrated in Figure 3. Two comparatively large spherical masses (ten-kilogram tungsten spheres) are mounted on a rotary table that can be turned about its vertical axis by a servo-controlled electric motor. An airtight cylindrical chamber also is rigidly mounted upon the rotary table with its vertical axis coincident with the axis of rotation. The small mass system, which consists of a small cylinder with its axis horizontal, is supported by a torsion fibre fastened to the top of the cylinder so that the fibre hangs in the axis of rotation of the table, as shown in Figure 3. The gravitational interaction between the large and small mass systems tends to rotate the small mass system in a direction that brings the axis of the small cylinder into coincidence with an imaginary line passing through the centres of mass of the large spheres. This changes the angle θ. A change in θ, however, also produces a change in the angle β between a light beam and its reflection from a mirror mounted on the small mass system. The light source and the photo-diode sensing system are rigidly mounted on the table in such a way that a change in β generates a photo-diode signal that actuates the servo-motor, which in turn rotates the table so that β and θ remain constant to less than one-half second of arc. Since the angle θ remains constant, the gravitational interaction between the small and large mass systems produces a constant torque on the small cylinder. This in turn produces a constant angular acceleration that results in an equal constant angular acceleration of the rotary table. This method possesses three novel features that should contribute to improved reliability and accuracy. First, the acceleration of the table can be measured with much greater precision than a deflection, because the change in frequency of rotation can be measured over a long period of time, and this automatically increases the precision. Second, the two mass systems rotate about their common axis many times during a measurement, and consequently the effects of gravitational fields and field gradients due to unavoidable stationary masses are essentially cancelled. Also, the effect of the masses moving with the rotary table, as well as the table itself, is eliminated by determining the acceleration of the rotary table with the large spheres removed from the table. Finally, the coordinates or positions of the interacting masses with respect to a rotating coordinate system do not change during a measurement; hence, the necessary distance can be precisely determined. A preliminary value of $G = (6.674 \pm 0.012) \times 10^{-11}$ nm²/kg² has been reported, but the method is claimed to promise much higher accuracy.

From an illustration by Marina Givotovsky in *Physics Today* (May, 1971)

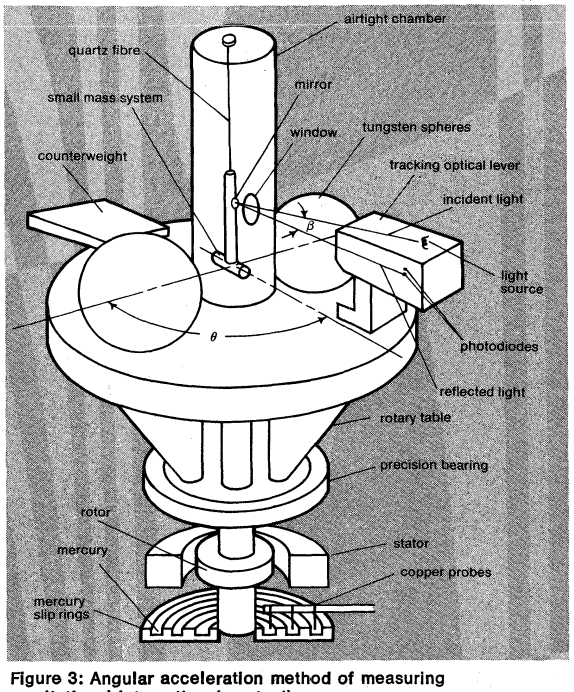

Figure 3: Angular acceleration method of measuring gravitational interaction (see text).

Weighing the Earth. If Newton's equation mentioned above is applied to the attraction of the Earth on a small mass, M_1, with g as the acceleration of gravity and M_E and r_E as the mass and effective radius of the Earth, respectively, then $g = GM_E/r_E$. Since g and r_E are known, the mass of the Earth, M_e, can be obtained if G is known. For this reason Cavendish and some of the early workers referred to their work as "weighing the Earth." Actually, no way is yet known for reliably obtaining the mass of the Earth, Moon, planets, or other heavenly bodies—say in kilograms, tons, etc.—without a knowledge of G. The mass of the Earth is approximately 5.98×10^{24} kilograms (13.18×10^{24} pounds). Since the radius of the Earth is known, its volume can be calculated so that the mean density of the Earth is obtained. This mean density of the Earth is approximately 5.52 times that of water, while the mean density of the Sun is 1.43 times that of water. These mean densities are becoming of considerable importance in geophysical research.

Important gravities dependent on G

Fundamental character of G. In addition to the above practical needs for more accurate values of G, because of its fundamental nature it necessarily must enter into all major cosmological questions. Some cosmological theories predict a minute decrease in G of about one part in 10^{10} per year. Very precise measurements made in the early 1970s of radar-echo time delays between the Earth and Mercury indicate that G does not vary by more than four parts in 10^{10} per year, unless there are unknown compensating factors in the experiments. Speculation that G may be influenced by the position in space led to proposals for the measurement of G in space vehicles. Other suggestions postulate effective changes in G at very small and at very large distances and with time. The absolute measurements of G are not yet accurate enough nor is the time base long enough to resolve these or many other important questions. On the other hand, G seems, to the limit of present accuracy, to be a truly fundamental constant, both in magnitude and sign, and independent of perturbing effects not only in the case of the gravitational interaction of matter but also that of antimatter as well.

Graywackes

Graywacke is the name applied to generally dark-coloured, very strongly bonded sandstones that consist of a heterogeneous mixture of rock fragments, feldspar, and quartz of sand size ($\frac{1}{16}$–2 millimetres [0.002–0.078 inches]), together with appreciable amounts of mud matrix (less than $\frac{1}{16}$ millimetres [0.002 inches]). Almost all graywackes originated in the sea, and many were deposited in deep water by density (turbidity) currents.

The name graywacke (from the German *Grauwacke*) was first used by the German mineralogist Abraham Werner in 1787. It describes the colour and texture of the rock, "wacke" being a term used for the heterogeneous weathering products derived from igneous and metamorphic rocks. The classic German locality for graywacke is the Devonian and Carboniferous sequence of the Harz Mountains.

In 1818 John Mawe wrote, "Geologists differ much as to what is, and what is not, Grey Wacce." This is still true. Recent definitions by various geologists characterize graywackes as sandstones that (1) contain more than 10, 15, or 20 percent mud matrix; (2) contain less than 75 percent quartz and more than 25 percent nongranitic feldspars and rock fragments; (3) have similar mineralogy and chemistry to those from the Harz Mountains; or (4) display associations of sedimentary structures that are characteristic of "turbidites"—*i.e.*, rocks deposited by turbidity currents. Many geologists now use the name only in a general sense, in reference to the dark, usually quartz-poor, often well-indurated sandstones that occur in turbidite (or flysch) sequences.

There are great differences between the Harz and Bunter sandstones in Germany, the Aberystwyth and Millstone grits in Great Britain, and the Franciscan and Navajo formations of the United States. The differences in structure and mineralogy reflect fundamental differences in both mode of deposition and relationship to phases of earth history. The persistence of the term graywacke, despite the confusion surrounding it, is testimony to the need to express these differences succinctly, for this term has been applied to the first of each pair cited above. The plethora of definitions indicates the difficulties experienced in finding generally applicable criteria that adequately express the differences.

This article treats the composition, properties, occurrence, and origin of graywacke. See SANDSTONES; SEDIMENTARY ROCKS; MARINE SEDIMENTS; and SHALES for information on related rock types; see DENSITY CURRENTS for additional discussions of origin; and see MOUNTAIN-BUILDING PROCESSES and EARTH, GEOLOGICAL HISTORY OF for the geological significance of graywackes.

PHYSICAL AND CHEMICAL PROPERTIES

Texture and structure. Graywackes typically are poorly sorted, and the grain sizes present range over three orders of magnitude—*e.g.*, from 2 to 2,000 microns (8×10^{-5} to 8×10^{-2} inch). Commonly, the coarsest part of a graywacke bed is its base, where pebbles may be abundant. Shale fragments, which represent lumps of mud eroded from bottom sediments by the depositing current, may be concentrated elsewhere in the bed.

Size, shape, and orientation of particles

Many graywackes contain much mud, typically 15–40 percent, and this increases as the mean grain size of the rock decreases. The particles forming the rock are typically angular. This, and the presence of the interstitial mud matrix, has led to these rocks being called "microbreccias." The fabric and texture indicate that the sediments were carried only a short distance and were subject to very little reworking by currents after deposition.

Although many geologists believe that the mud matrix accumulated simultaneously with the coarser material, some believe it was derived from alteration of rock fragments subsequent to burial. This question remains unresolved. Some graywackes are notably deficient in matrix (less than 10 percent, or even less than 5 percent). This deficiency can occur at the base of beds or be characteristic of beds as a whole. No detailed explanation has yet been suggested.

Sections of graywackes cut parallel to the bedding display alignment of the long axes of the grains. This usually is best developed in the lower-middle part of a bed. The alignment direction varies from level to level in the bed and commonly deviates from the direction of current markings on the underside of the bed, although some workers report parallelism between grain orientation and current markings. Imbrication (overlapping) of grains is observed in sections cut normal to the bedding. The origin of this variability in grain orientation and its deviation from current markings are not understood.

Graded bedding and interbedding

Graywacke sequences are noted for having a characteristic, and usually well-developed, association of sedimentary structures. Typically the beds are sheetlike and are interbedded in a regular fashion with shales, each bed paralleling its predecessor with almost mathematical precision (Figure 1).

The thicknesses of beds in a graywacke sequence are log-normally distributed (that is, the logarithms of bed thickness are distributed about some mean value), or nearly so, and typically there is a strong positive correlation between maximum grain size and bed thickness. Some graywacke sequences that are called "proximal turbidites," meaning that they accumulate near the source area, largely lack this parallelism and regular interstratification.

The most widespread internal structure of graywackes is graded bedding (Figure 1), although some sequences display it poorly. Sets of cross strata more than three centimetres (1.28 inches) thick are very rare, but thinner sets are very common. Parallel lamination is very common, and convolute bedding is usually present. These internal structures are arranged within graywacke beds in a regular sequence. They appear to result from the action of a single current flow and are related to changes in the hydraulics of the depositing current. In some beds, the upper part of the sequence of structures is missing, presumably because of erosion or nondeposition. In others, the lower part is missing. This has been attributed to change in the hydraulic properties of the depositing current as it moves away from its source and its velocity decreases to the point at which the first sediment deposited is laminated, rather than massive and graded as is the case closer to the source.

The most typical external structures of graywacke beds

Sole marks, casts, and fossil remains

are sole markings, which occur on their undersurfaces. Flute and groove molds (Figure 1) are the most characteristic, but many other structures have been recorded. Sole markings are not readily visible in all graywacke sequences, particularly where the beds are flat lying or the shale interbeds are well indurated (hardened). Most sole markings originate as infillings of sculptures on the surface of the underlying mud bed. Many of the sculptures are produced by the scouring action of the current before it commences to deposit and are infilled by sand during later stages of the same current. Many molds are elongated in the direction of movement of the current. They are therefore widely used as indicators of the initial direction of current flow and, by inference, the direction of the local paleoslope and location of source areas.

Usually the sculptures become somewhat distorted during their infilling because of the effects of compaction of the soft mud. In vertical sections this is expressed by characteristic "overhangs" of shale, termed load casts, along the irregular sand–shale contact.

The upper surfaces of graywacke beds are less well characterized by sedimentary structures. The most typical are current lineation and various worm tracks, particularly the highly sinuous form *Nereites*. Apart from these trace fossils, graywackes are usually sparsely fossiliferous. Where fossils occur they are generally free-floating organisms (graptolites, forams) that have settled to the bottom, or bottom-living (benthic), shallow-water organisms displaced into deeper water as part of sediment mass.

Colour. Fresh graywackes are, as their name suggests, coloured various shades of gray, ranging from neutral gray through greenish- to bluish-gray. The intensity of the colour varies from dark to light throughout.

Within this range, volcanic lithic graywackes are predominantly greenish-gray; graywackes with intermediate amounts of quartz are greenish- or bluish-gray; and quartzose graywackes are neutral gray. Plagioclase graywackes, and some more quartz-rich varieties of predominantly granitic derivation, are generally light greenish-gray to light gray.

Mineralogy. The mineralogical composition of graywackes varies widely (Table 1). Three groups can be recognized in terms of the content of free quartz grains of sand size (Figure 2). The first contains less than 15 percent free quartz and is derived from igneous rocks. It comprises two types of volcanic derivation, plagioclase graywacke (Figure 3), volcanic lithic graywacke, and serpentine graywacke, which is derived from serpentinite, a subcrustal rock. Of these, volcanic lithic graywacke is by far the most abundant. Sequences in which it occurs usually contain some beds of plagioclase graywacke. Serpentine graywacke is rare but is important because it reflects a deep rupture of the earth's crust.

Role of quartz in composition of graywackes

Quartz-poor graywackes are widespread in eastern Australia and around the margins of the Pacific and Caribbean but also occur within continents—for example, in the Urals. Serpentine graywacke is recorded from Colombia and the Solomon Islands.

Graywackes with from 15 to 65 percent free quartz form the second group. They are of varied composition and origin. Some are almost devoid of feldspar and are derived from sedimentary and low-grade metamorphic rocks. Others, richer in feldspar, are from heterogenous source areas containing volcanic, plutonic, metamorphic, and sedimentary rocks. Still others come from sources in which granite is widespread. The typical graywackes of North America and Europe are representatives of this group. Representatives also occur in New Zealand and eastern Australia.

The third group of graywackes (the subgraywackes of some authors) contains from 65 to 95 percent free quartz. Many of these would not be termed graywacke by those workers who adopt a mineralogical definition of the term, for such definitions commonly permit not more than 75 percent free quartz in the rock. These quartz-rich varieties exhibit the same dark colour and sedimentary structures as those poorer in quartz. They occur in thick geosynclinal sequences (deposits in great subsiding troughs), either as the dominant rock type or as a minor component with more common graywackes of the second group. Their high quartz content reflects source areas dominated by quartz-rich igneous, sedimentary, and metamorphic rocks or more heterogenous source areas in

which intense chemical weathering eliminates the less stable minerals before the sediment is finally deposited.

Chemistry. The bulk chemistry of graywackes reflects their variable mineralogy. Four major groups can be recognized, which differ most notably in their silica (SiO_2) content. Volcanic lithic graywackes average 54 percent SiO_2 (Table 2A). Analyses of plagioclase graywackes are not available; they probably have a similar silica content. Analyses of serpentine graywackes are likewise unavailable. From their mineralogy they can be expected to form a second group, averaging about 40 percent SiO_2. The third group (Table 2B, C), with 65–70 percent SiO_2, essentially represents the graywackes of mixed origin, with from 15 to 65 percent free quartz. The fourth group, equivalent to graywackes with more than 65 percent free quartz, is poorly represented by analyses. Available data suggest an average content of approximately 85 percent SiO_2 (Table 2D).

Because graywackes contain unweathered detritus (disintegrated material), including appreciable mud, that accumulates as thick sequences in elongate troughs, the average composition of the graywackes in any sequence represents an average sample of the bulk mineralogy and chemistry of the source area. When data from several chemically similar sequences are averaged, such averages should represent typical average compositions for significant portions of the Earth's crust.

This is evident from comparison of the three chemical types of graywackes listed in Table 2 with other average rocks. The volcanic lithic graywackes strongly resemble andesites (Table 2E) but are richer in sodium. They are a sample of the crust in the vicinity of the boundary between continents and oceans. Graywackes with 65–70 percent silica, as might be expected from their location, approximate continental crust and granodiorite in composition (Table 2G, F). The high-silica graywackes have no evident analogue in standard geochemical average compositions but probably represent a fair average for the sandstone cover of continental platforms, excepting the readily soluble components such as carbonate and evaporite minerals.

Evidence of diagenesis. The almost universal strong induration of graywackes testifies to diagenetic processes; that is, to modification after burial. Their mineral content is not in equilibrium with near-surface conditions, and they accumulate in sequences of sufficient thickness to promote significant increases in pressure and temperature. Their initial permeability to fluids is low, owing to the presence of a mud matrix between the sand grains. Diagenetic reactions therefore proceed by internal chemical rearrangements rather than by the addition of material from outside.

The volcanic lithic graywackes display the most notable diagenetic (or burial metamorphic) effects. These involve the formation of hydrated calcium aluminosilicates and iron-magnesium silicates in the course of reactions that both utilize the water trapped within the sediments on burial and generate heat, thus promoting widespread and relatively uniform modification of mineral assemblages. Commonly, these reactions are not accompanied by strong deformation, so that the original fabric of the graywackes is preserved.

Mineral assemblages and mineral replacement

The newly formed mineral assemblages are in equilibrium with the temperature and pressure in the rocks. Many of the minerals are stable over only limited ranges of temperature and pressure. Thus a zonation of secondary minerals, approximately according to depth of burial, is commonly observed.

At shallowest depths, various zeolites (*q.v.*) are the char-

acteristic secondary calcium aluminosilicates, and montmorillonite is characteristic of the clay minerals (*q.v.*). With increasing temperature and pressure, prehnite, pumpellyite, epidote, and finally lawsonite take the place of the zeolites, and chlorite replaces montmorillonite. These minerals replace glass in rock fragments; typically, the calcium aluminosilicates also occur as replacements of feldspar and in the interstices between the sand grains. Pseudomorphic replacement of calcic plagioclase by sodic plagioclase (albite) is ubiquitous in rocks in which zeolites are no longer stable.

Graywackes rich in quartz commonly lack the highly unstable detritus present in volcanic lithic graywackes. Diagenetic modification is therefore less dramatic and probably occurs at somewhat lower temperature for a given depth of burial because exothermic chemical reactions are more limited. The principal modifications affect the sheet silicates, particularly biotite, which undergoes progressive bleaching and chloritization. The clay minerals of the matrix are also commonly reconstituted; this is largely responsible for the strong induration of these rocks.

The diagenetic mineral assemblages of graywackes provide information on the grade of metamorphism (temperature and pressure conditions) to which the rocks were subjected. Indeed, the two lowest grade facies (kinds) of metamorphism, the zeolite facies and prehnite-pumpellyite metagraywacke facies, are most typically developed in graywackes.

OCCURRENCE OF GRAYWACKES

Rock associations in geosynclinal sequences

The sedimentary rock most commonly associated with graywacke is mudstone, or shale, which in many cases is indurated to argillite or slate. Conglomerate and pebbly mudstone occur in addition in some proximal graywacke sequences. Other sequences have pelagic limestones between the graded-bedded units. In still other sequences, thick units of radiolarian chert and argillite are present that may contain occasional graywacke interbeds.

Radiolarian chert, spilite, and serpentinite form the geosynclinal rock association known as the "Steinmann Trinity." This association in fact has a fourth member, volcanic graywacke. All four rock types occur in the early formed parts of geosynclinal sequences, although the serpentinites are late intrusive bodies. The association indicates that the geosynclinal trough probably formed at depth, on a basement of oceanic-type crust.

Graywacke, together with shale, is an important component of the flysch sequence (primarily "turbides") that normally constitutes the major part of the "fill" of a geosynclinal trough. The flysch predates the deformation of the trough. In some geosynclines, sediments that are mineralogically and chemically similar to the flysch graywackes accumulate after the deformation of the trough. These are termed molasse sequences. They differ from the flysch in their sedimentary structures as a consequence of their accumulation in shallow marine or subaerial depositional environments.

Data presently available are insufficient to permit the presentation of the global distribution of the major types of graywackes. Graywacke sequences occur in almost all fold mountain belts except those dominated by limestones, such as the Canadian Rockies. Classic Paleozoic graywacke localities include the Harz Mountains, Germany; the Welsh Geosyncline; the Appalachians; and the Tasman Geosyncline of eastern Australia. Mesozoic and Cenozoic localities include the Coast Ranges of western U.S. and the New Zealand Geosyncline.

Graywacke sequences as old as Archean and as young as Pleistocene are known. Graywackes probably accumulated somewhere on earth during every geological period, but they seem to be less well represented in Proterozoic strata than in older and younger sequences.

ORIGIN AND GEOLOGICAL SIGNIFICANCE

Graywackes are commonly regarded as deep-sea sediments deposited by turbidity currents. This opinion stems from the classic investigations by P.H. Kuenen and C.I. Migliorini, who were the first marine geologists to demonstrate convincingly by experimental and field studies that dense sediment-charged currents hugging the sea floor could deposit sequences of muddy graded-bedded sands in deep water. The explanation has been given further impetus by observations on breaks in submarine cables following earthquakes. One such sequence of cable breaks to the south of the Grand Banks of Newfoundland in 1929 has been interpreted as due to a large turbidity current that reached velocities of 55 knots. Bottom samples taken over the abyssal plain to the south of the Grand Banks reveal the presence of a graded sand bed from 40 to 100 centimetres (12.7 to 39.4 inches) in thickness that is believed to occupy an area of 100,000 square kilometres (39,000 square miles). Relatively little is known about the hydrodynamics of turbidity currents. This accounts for the inadequacies of interpretation of the structures encountered within graywacke beds.

Turbidity-current and normal-current hypotheses

An alternative view of graywackes is that normal ocean currents may be responsible for their laminated and rippled portions and even for graded-bedded units. Observations in the deep sea reveal the existence of contour currents that flow parallel to the base of the continental slope and have sufficient velocity to produce ripples in sand. Several sequences are known where the paleoslope, as indicated by slump structures (slumping of bedding planes) that have scarcely moved laterally, is perpendicular to the current direction indicated by sole markings. Some of these can be explained by assuming a basin shape like that of the modern Adriatic Sea. There, much of the material introduced enters at one end and moves axially along the basin. Lesser amounts are introduced laterally, producing deposits that reflect the paleoslope of the basin sides. Such assumptions cannot, however, explain occurrences where slump structures are oriented normal to paleocurrent indicators in adjoining beds.

Many graywackes with graded beds are interstratified with and pass laterally into laminated graywacke–shale sequences. The latter deposits may require a different emplacement mechanism than the graded beds, but they may be deposits from the dilute distal parts of turbidity currents.

Some investigators consider that the high velocities claimed for turbidity currents on the basis of studies of submarine cable breaks are excessive, but no satisfactory alternative explanation for cable breaks upslope from graded sand deposits has yet been advanced.

Evidence from submarine canyons and fans

Investigations off the coast of southern California suggest that turbidity currents and submarine canyons are intimately related. Sediment is known to accumulate in the heads of the canyons by longshore drift and to be periodically flushed out. Although most people believe that the sediment moves down the canyon as a turbidity current, attempts to generate such currents artificially in the canyon heads have so far been unsuccessful. The observation of sand moving down modern canyons as grain flows and cascades with little displacement of water suggests an alternative mode of flushing. Sediment movement by this means, however, does not appear to be rapid enough to explain observed sudden losses of material from canyon heads. The role of grain flows in sedimentation has not yet been evaluated.

The canyons debouch at bathyal (deep-sea) to abyssal (sea-floor) depths and are fronted by submarine fans of sandy or coarser sediment. These fans are transected by channels with levee banks. Turbidity currents are believed to move down these channels, spreading laterally and eventually reaching the distal parts of the fans where they merge into the abyssal plain. These fans and their lateral equivalents make up the continental rise, which is believed to consist of turbidites.

The existence of submarine fans suggests that the typical geometry of a graywacke bed will be a tongue-shaped sheet. Numerous sheets of this kind may be stacked one upon the other with interbeds of finer sediment partly deposited from suspension. Ancient graywackes with this geometry are known in California, Wales, and eastern Australia.

The change in geomorphic character and current velocities across submarine fans betokens changes in sediment characteristics. Variability in the sedimentary features of graywackes has given rise to the concept of "proximality," a measure of the closeness of a graywacke bed to its source—*e.g.*, the distal end of a submarine canyon.

Deep-sea versus shallow-marine graywackes

Some rare exceptions to the general rule of deep-sea origin for graywackes are known, although one of these apparent exceptions was re-interpreted in the early 1970s: an occurrence of graywacke with limestone in the Middle Devonian of the Hill End Trough, New South Wales, once thought to have accumulated in protected water some tens of metres deep, is now thought to have formed in deeper water. The Upper Ordovician of Girvan, Scotland, comprises a flysch sequence with abundant graywackes, the sedimentary features of which indicate a neritic or shallow marine origin. From the Tertiary flysch of the Pyrenees, bird footprints and other features suggestive of very shallow-water origin have been described. Lacustrine graywackes are known in the Tertiary of the Ridge Basin, California. Apparently the lake in which the sediments accumulated was sufficiently deep to prevent disturbance of the bottom, and bounded by two major transcurrent faults, the relief at its margins was sufficient to promote formation of turbidity currents.

Although the concept of turbidity currents has proved a powerful tool for the interpretation of graywacke sequences since about 1950, the emergence of data not well explained by this concept is leading to the development of new concepts, of which grain flow and contour currents are the most significant. The wish to extend or supplant the turbidity current concept reflects both inadequate knowledge of submarine processes, including the behaviour of turbidity currents, and a facile, if preliminary, assumption that marine sedimentation below wave base is dominated by a single process. There is little doubt that the term flysch, which is used by many geologists as a synonym for graywacke sequences, embraces a range of sedimentary sequences as varied in their internal characteristics as are the subaerial and shallow-marine sequences dominated by cross stratification. Only when flysch sequences can be grouped into classes that reflect variations in deep-water environments will the relative importance of the various concepts be properly assessed. Nevertheless, it seems likely that the turbidity current concept will continue to play an important part in the interpretation of such sequences.

Depositional sites, geosynclines, and earth history

Three major depositional sites for contemporary graywackes have been recognized. The first sites, recognized early in the history of geology, are the deep-sea troughs adjoining fold mountain ranges, as, for example, those off the west coast of North and South America. These troughs have been the traditional site for ancient graywackes, especially those containing intermediate amounts of quartz. The second depositional sites, recognized rather more recently, are the troughs adjoining volcanic island arcs (*q.v.*)—for example, in Indonesia and Melanesia. These are the traditional sites of accumulation of volcanic graywackes. The third sites, recently recognized, are the continental rises along the margins of continents that lack adjacent high relief, as, for example, the east coast of North America. This latter has not been cited so far to explain any particular type of graywacke, but analyses of modern North Atlantic sediments (Table 1H) and considerations of the composition of ancient graywackes suggest that it is the typical site of accumulation of quartz-rich graywackes.

There is an intimate relationship between these depositional sites and geosynclines. The first and second sites have long been recognized as the modern analogues of ancient geosynclines. More recently the continental rise has been suggested by R.S. Dietz, an American marine geologist, as the precursor of many fold mountain belts that have been regarded as sited on old geosynclines.

Because of their association with geosynclines and their occurrence in thick sequences that have subsequently been folded, graywackes are taken to indicate zones of tectonic activity (folding and faulting) in the Earth's crust. They are generally regarded as pre-tectonic deposits, with respect to the basin in which they occur. They can also be contemporaneous with deformation of an adjoining earlier-filled basin that becomes the source of the graywacke sequence. Insofar as the Atlantic continental rise of North America is a modern graywacke accumulation, graywackes may also reflect tectonic quiescence with respect to both source and the basin of deposition.

The feature common to all modern depositional sites is that they adjoin land masses in areas of high submarine relief. The land mass may be the seismic or aseismic margins of a continent, or the margins and interstices of juvenile continental crust, the island arcs. Thus, all occurrences are related to major discontinuities in the Earth's crust. The quartz-poor graywackes include such types as serpentine graywacke; these reflect the emergence of subcrustal material at the Earth's surface, an intimate part of mountain building processes.

Great Barrier Reef

The largest structure ever built up by living creatures, the Great Barrier Reef is one of the most fascinating, as well as one of the most beautiful, of the natural wonders of the world. The dazzling, surf-fringed reef extends for some 1,250 miles (2,000 kilometres) off the northeastern coast of Australia, at a distance varying from ten to 100 miles offshore. Its length is thus comparable to the entire west coast of the continental United States south of the Canadian border, and, if placed off western Europe, it would extend from Portugal to Norway. It covers some 80,000 square miles, or an area larger than Syria. The reef actually consists of many thousands of separate reefs, many dry or barely awash at low tide, some with islands of coral sand, or cays, others fringing high islands or the mainland coast. In spite of this variety, the reefs share a common origin: each has been formed, over millions of years, from the skeletons and skeletal waste of a mass of living marine organisms. The "bricks" in the reef framework are formed by the calcareous remains of the tiny creatures known as coral polyps and hydrocorals, while the "cement" that binds these remains together is formed in large part by the remains of the organisms known as coralline algae and polyzoas. The interstices of this framework have been filled in by vast quantities of skeletal waste produced by the pounding of the waves and the depredations of other boring organisms. The reef as a whole has a remarkably large number of coral species (at least 350), and some regions are justly famous for

their riotous profusion of colour and form. The reef has risen on the shallow shelf fringing the Australian continent, in warm waters that have enabled the coral to flourish (it cannot exist where average temperatures fall below 70° F [21° C]). This sustaining continental shelf experiences a change of gradient at about 50 fathoms (300 feet) depth. In addition to its scientific interest, the reef has become increasingly important as a tourist attraction, while growing concern over the preservation of its magnificent natural heritage had led, by the early 1970s, to increased controls on such potentially threatening activities as drilling for petroleum resources.

Exploration and scientific study. The first physical encounter between Europeans and the Great Barrier Reef may be said to date from 1770, when the British explorer Capt. James Cook ran his ship, the "Endeavour," aground upon it. Earlier references in his journal to the various component reefs sighted in his run up the coast of what became Queensland refer to them as "banks" or "shoals," and the reef's coralline structure was only discovered when dawn broke after the grounding. The work of charting channels and passages through the maze of reefs, begun by Cook, continued during the 19th century, when many scientists, including the American marine zoologist Alexander Agassiz, made expeditions to this newfound wonder of the world. The contribution of the Great Barrier Reef Expedition of 1928–29 remains unsurpassed in the fields of coral physiology and the ecology of coral reefs, while a modern laboratory was set up on Heron Island, at latitude 23° S, in 1951. This is jointly administered by the University of Queensland and the Great Barrier Reef Committee, the latter body representing a number of individuals and institutions interested in the reef.

Discovery of the reef

Structure and hydrology. Borings have established that reefs were growing on the continental shelf as early as Miocene time, more than 25,000,000 years ago, but underlying nonmarine sediments of the Lower Tertiary, more than twice as old, indicate that the region was then above sea level. Subsidence of the continental shelf has proceeded, with some reversals, since the early Miocene: platform-like surfaces on the seabed and changes of gradient on the sides of the reefs are distinguishable at ten, 16, 20–22, and 32 fathoms and, less certainly, at 36, 56, and 80 fathoms and may well be related to periods of standstill in the sea-level fluctuations associated with the melting of Ice Age glaciers. A bench lying six to ten feet above the present sea level was probably formed during the latest postglacial maximum rise in sea level. The submarine topography of the reef area is complicated by the valleys, products of ancient periods of land erosion, that cross the continental shelf linking present river mouths with some of the deeper gaps in the outer reef barrier.

The water environment of the Great Barrier Reef is formed by the surface water layer of the southwest Pacific Ocean. The reef waters show little seasonal variations: surface-water temperature is high, ranging from 70 to 100° F (21° to 38° C), and vertical gradient, or change in temperature with depth, is small, due to the perpetual stirring action of the southeast trade winds, which pound the outer edge of the reef for nine months of the year. Average salinity is about 35 parts per 1,000; the oxygen content is high, with a 90 percent saturation most of the time. The origins of the reef waters are complex. Probable surface sources include those of the Trade Wind Drift, Southern Equatorial, and East Australian current systems, with a seasonal influx from the Arafura Sea to the north. Upwellings at the fringe of the continental slope bring in subsurface water masses from the adjacent Coral Sea, while monsoonal rains and land runoff add a further contribution. Reef tides have a daily cycle; the range is nowhere less than eight feet, and the draining waters often form foaming white falls at the reef edges. At the entrance to Torres Strait, at Australia's northern tip, and in Broad Sound on the central eastern Australian coast, tidal range reaches a massive 13 feet and 30 feet, respectively. The waters are generally crystal-clear, with submarine features clearly visible at depths of 100 feet.

Water composition

Life and resources of the reef. The marine life of the Great Barrier Reef is very rich, with some reduction in the number of species southward. The forms of life include, in addition to the corals, anemones, worms, gastropods, lobsters, crayfish, prawns, and crabs, and a great variety of fishes and birds. Many of the small fishes of the reef are strikingly colour banded and of bizarre shapes, darting or gliding in and out of complex coral structures that are muted in every colour of the rainbow. The giant clams are famous; they reach four feet in width and weigh up to 200 pounds, display a remarkable variety of colours when open, and can send spouts of water shooting upward when they close. The deadly sea wasps (the jellyfish *Chironex fleckeri*) have a more infamous reputation, but the most notorious reef animal is the crown-of-thorns starfish (*Acanthaster planci*), which has reduced the colour and attraction of many of the central reefs by eating much of the living coral. Among the reef organisms, marine algae are second only to the corals; the encrusting red algae *Lithothamnion* and *Porolithon* form the fortifying purplish-red algal rim that is one of the Great Barrier Reef's most characteristic features, while the green alga *Halimeda* flourishes almost everywhere. Above the surface, the plant life of the cays is very restricted, consisting only of some 30 to 40 species, practically all of them widely characteristic of the Indo-West Pacific biological province. Some varieties of mangrove occur only in the northern cays, although they are common on mainland mud flats along the full length of the Queensland coast.

The reef has contributed little to the fishing industry, as net fishing is precluded by the irregularities in the sea floor, although a small amount of trawling for mackerel and coral trout does take place, and tuna is taken in the adjoining Coral Sea waters. Turtles are now protected from commercial exploitation, but the pearl-shell industry is still important to the Torres Strait islanders in the north. Though world demand for mother-of-pearl has been reduced by the increased use of plastics, shells are still gathered in considerable numbers, being taken to culture farms for the making of artificial pearl. Large beds of prawns have been found on the sea floor at nine to 18 fathoms in the central section; the deadly sea wasps appear in the waters above the prawns and apparently feed on them. Saucer scallop beds have also been exploited.

The influence of man

The Great Barrier Reef also attracts an increasing number of tourists. Green Island, off Cairns in northern Queensland, has a complex underwater observatory and is but one of the high islands and cays that have been developed. Cruises set out from the coastal cities, with landings on the remoter reefs, and big-game fishing for 1,000-pound and larger black marlin, as well as swordfish and barracuda, is also popular. Other potential resources of the Great Barrier Reef include the large quantities of lime and quartz sands. Although petroleum companies have made surveys and preliminary drillings in the reef area, operations were in the doldrums in the early 1970s while a royal commission enquired into possible effects of further oil development on the complex ecology of the reef.

The controversy over oil drillings was but one facet of a growing concern for the future of the Great Barrier Reef. The advent of modern communications had opened up the region for the pursuit of both pleasure and profit, and it was becoming increasingly apparent by the 1970s that some form of regulation of man's activity would become necessary if the reef's fine natural endowment was to be preserved for future generations.

Great Lakes

The Great Lakes—Superior, Michigan, Huron, Erie, and Ontario—form part of the St. Lawrence River system of east central North America and are one of the great natural features of that continent and the globe. Although Lake Baikal in the Soviet Union has a greater volume of water, the combined area of the Great Lakes—94,560 square miles (245,000 square kilometres)—represents the largest surface of fresh water in the world, covering an area larger than the United Kingdom, Uganda, or Romania. Their drainage basin of 291,100 square miles (753,950 square kilometres) extends approximately 690 miles from north to south and about 860 miles from Lake Superior in the west to Lake Ontario in the east; it covers an area larger than France or Afghanistan. Except for Lake Michigan, the lakes provide a natural border between Canada and the United States, a frontier that was stabilized by a boundary-waters treaty of 1909. It is a source of pride for both countries that there are no fortifications or warships along the boundary.

Individually, the lakes rank among the 15 largest in the world (see Table). They played a central role in the European colonization and development of North America, have continued to attract people and industry, and are now ringed with large urban concentrations. The lakes have not benefitted from this development, however, and by the 1960s they were suffering greatly from pollution. Lake Erie was pronounced "dead" in 1960, and it has been projected that Lake Michigan might well share the same fate. Concern over the fate of the lakes reached a high pitch in the 1970s, with both governments and individuals investigating plans for reversing the tragic consequences of years of misuse of the lakes' waters. (For related articles, see SAINT LAWRENCE RIVER; SAINT LAWRENCE SEAWAY; NIAGARA RIVER AND FALLS.)

Areas and Volumes of the Great Lakes

	surface area		world rank	volume		world rank
	sq mi	sq km		cu mi	cu km	
Superior	31,700	82,100	2nd	2,935	12,230	4th
Michigan	22,300	57,750	6th	1,180	4,920	6th
Huron	23,100	59,830	5th	849	3,540	7th
Erie	9,910	25,670	11th	116	483	15th
Ontario	7,550	19,550	14th	393	1,640	11th

HISTORY OF EXPLORATION AND RESEARCH

The Great Lakes have been an integral part of the exploration and development of the North American continent. A broken sword, an axe, and a shield boss found near Lake Nipigon, Ontario, and the rune stone at Kensington, Minnesota, have been cited as evidence of early Viking exploration of the region, although the authenticity of these artifacts has not been established. French exploration of the region commenced in 1535, when the explorer Jacques Cartier travelled up the St. Lawrence River to the site of modern Montreal in his search for a route to the Orient. The Huron Indians told him of the great seas lying beyond, but the upper St. Lawrence and Lake Ontario were controlled by the Iroquois, who were not friendly to the Europeans. Consequently, further exploration by another leading French explorer of North America, Samuel de Champlain, followed the course of the Ottawa River, Lake Nipissing, and the French River to Georgian Bay. He reached Lake Huron in 1615 and is credited with being the first European to see the Great Lakes. In 1634 Jean Nicolet—dispatched by Champlain to seek a route to China—led an expedition into Lake Michigan and down the length of Green Bay to the Fox River, where he encountered the Winnebago Indians. Other French explorers, including Robert Cavelier, sieur de La Salle, explored the lakes, made peace with the Indians, and established early settlements.

French exploration

Three major conflicts affected the history and development of the Great Lakes. The French and Indian War (1754–63)—a struggle between the French and British to gain control of rich fur-producing lands—concluded with the cession of Canada to England. The main consequences of the American Revolution (1775–83) to the Great Lakes region were the migration of thousands of Loyalists to New Brunswick, Nova Scotia, and Ontario and the establishment of the international boundary between the United States and Canada. During the War of 1812, Lake Erie was the site of a major naval battle.

Although several of the early explorers recorded observations of short-term fluctuations in water levels in early geographical writings, the first purely scientific expedition on the Great Lakes was not carried out until 1848. It was led by the Swiss naturalist Louis Agassiz and concentrated on studies of the north shore of Lake Superior. Water-level gauges were established in all the lakes by 1860, and all waters were charted by 1882. Studies of plant and animal life began in the 1870s, and the first study of lake currents was conducted in the early 1890s. Interest in lake fisheries was strong throughout the early 20th century, and, since the 1960s, research on the changes in plant and animal life wrought by pollution has increased considerably.

GEOLOGY

The age of the Great Lakes is still not definitely determined. Estimates range from 7,000 to 32,000 years of age. It is generally accepted that Lake Erie reached its present level about 10,000 years ago, Lake Ontario about 7,000 years ago, and Lakes Huron, Michigan, and Superior around 3,000 years ago.

The present configuration of the Great Lakes Basin is the result of the movement of massive glaciers through the midcontinent, a process that began during the Pleistocene Epoch, about 1,000,000 years ago. Studies of Lake Superior indicate that a river system and valleys formed by water erosion existed before the Ice Age. The glaciers undoubtedly scoured these valleys, widening and deepening them and changing the drainage of the area.

The last glacial stage in North America is called the Wisconsin Glaciation because it advanced southward to what is now the southern border of the state of Wisconsin. As the ice sheet melted and receded about 18,000 years ago, the first segments of the Great Lakes were created. Lake Chicago, in the southern Lake Michigan Basin, and Lake Maumee, in western Lake Erie and its adjacent lowlands, originally drained southward into the Mississippi River. As the ice retreat continued, Lake Maumee was drained into Lake Chicago through a valley that now contains the Grand River in Michigan. Eventually, drainage to the east and into the Atlantic Ocean was established, first down the Mohawk Valley and then along the course of the upper St. Lawrence River. At one high-water stage, the waters of the Superior, Huron, and Michigan Basin formed the large Lake Algonquin. At the same time, Lake Duluth, in the western Lake Superior Basin, also drained to the Mississippi.

The weight of the ice sheet exerted great pressures on the land mass. As the ice sheet retreated, low-lying areas, such as the region to the east of Georgian Bay, were exposed. About 10,000 years ago, the upper lakes evidently discharged through this area via the Ottawa River Valley, and their levels were substantially reduced. After the weight of the ice was removed, the land began to rise, closing off some outlets and changing the water levels of the lakes. The largest postglacial lake, Nipissing, occupied the basins of Huron, Michigan, and Superior. Drainage through the Ottawa River Valley ceased, and outflow from the upper lakes was established by way of the St. Clair and Detroit rivers into Lake Erie. Uplift continues at about one foot in 100 years; this is evidenced by the drowned river mouths of western Lake Erie.

Retreat of the ice

A wide range of rock types and deposits are found in the Great Lakes because of their great area and glacial origin. The ancient rocks of the Canadian Shield are part of the Superior and Huron basins, while younger sedimentary rocks make up the remainder of the basins. There are limestone outcrops and large deposits of sand and gravel, usually near shore. Glacial clays and organic sediments occur in the deep areas.

THE LACUSTRINE SYSTEM

The lakes drain roughly from west to east, emptying into the Atlantic Ocean. Except for Lakes Michigan and Huron, their altitudes drop with each lake, usually causing a progressively increasing rate of flow.

Lake Superior, bordered by Ontario, Minnesota, Wisconsin, and upper Michigan, is the northernmost and westernmost lake and can be considered the headwater of the system. It is the deepest lake (mean depth 487 feet), lies at an altitude of 600 feet above sea level, and discharges into Lake Huron through the St. Marys River at an average rate of 74,200 feet per second.

Lake Michigan lies directly south of Lake Superior and is bordered by upper and lower Michigan, Wisconsin, Illinois, and Indiana. It has a mean depth of 276 feet. The average water level is 579 feet above sea level, and its waters flow northward into Lake Huron through the Straits of Mackinac at 56,000 cubic feet per second.

Lake Huron lies at the same altitude as and is slightly larger than Lake Michigan. Its mean depth, however, is only 195 feet. It is bounded by Ontario and Michigan. The average outflow is 177,500 cubic feet per second through the St. Clair River, the shallow basin of Lake St. Clair, and the Detroit River to Lake Erie.

Lake Erie is bordered by Ontario, lower Michigan, Ohio, Pennsylvania, and New York. It is the shallowest of the Great Lakes, with a mean depth of 58 feet. The basin slopes from west to east with depths of 24 feet and 210 feet, respectively. It lies at an altitude of 570 feet, and its waters discharge at an average flow of 194,300 cubic feet per second. The course of the outflow is along the Niagara River and includes a rapid plunge over Niagara Falls before the waters reach Lake Ontario.

Lake Ontario is the smallest of the system. It has, however, the second greatest mean depth, 283 feet. It lies between Ontario and New York, at an altitude of 245 feet, and discharges into the St. Lawrence River at a rate of 233,000 cubic feet per second. It flows for about 750 miles until it empties through the Strait of Gaspé (Détroit de Gaspé) into the Gulf of St. Lawrence.

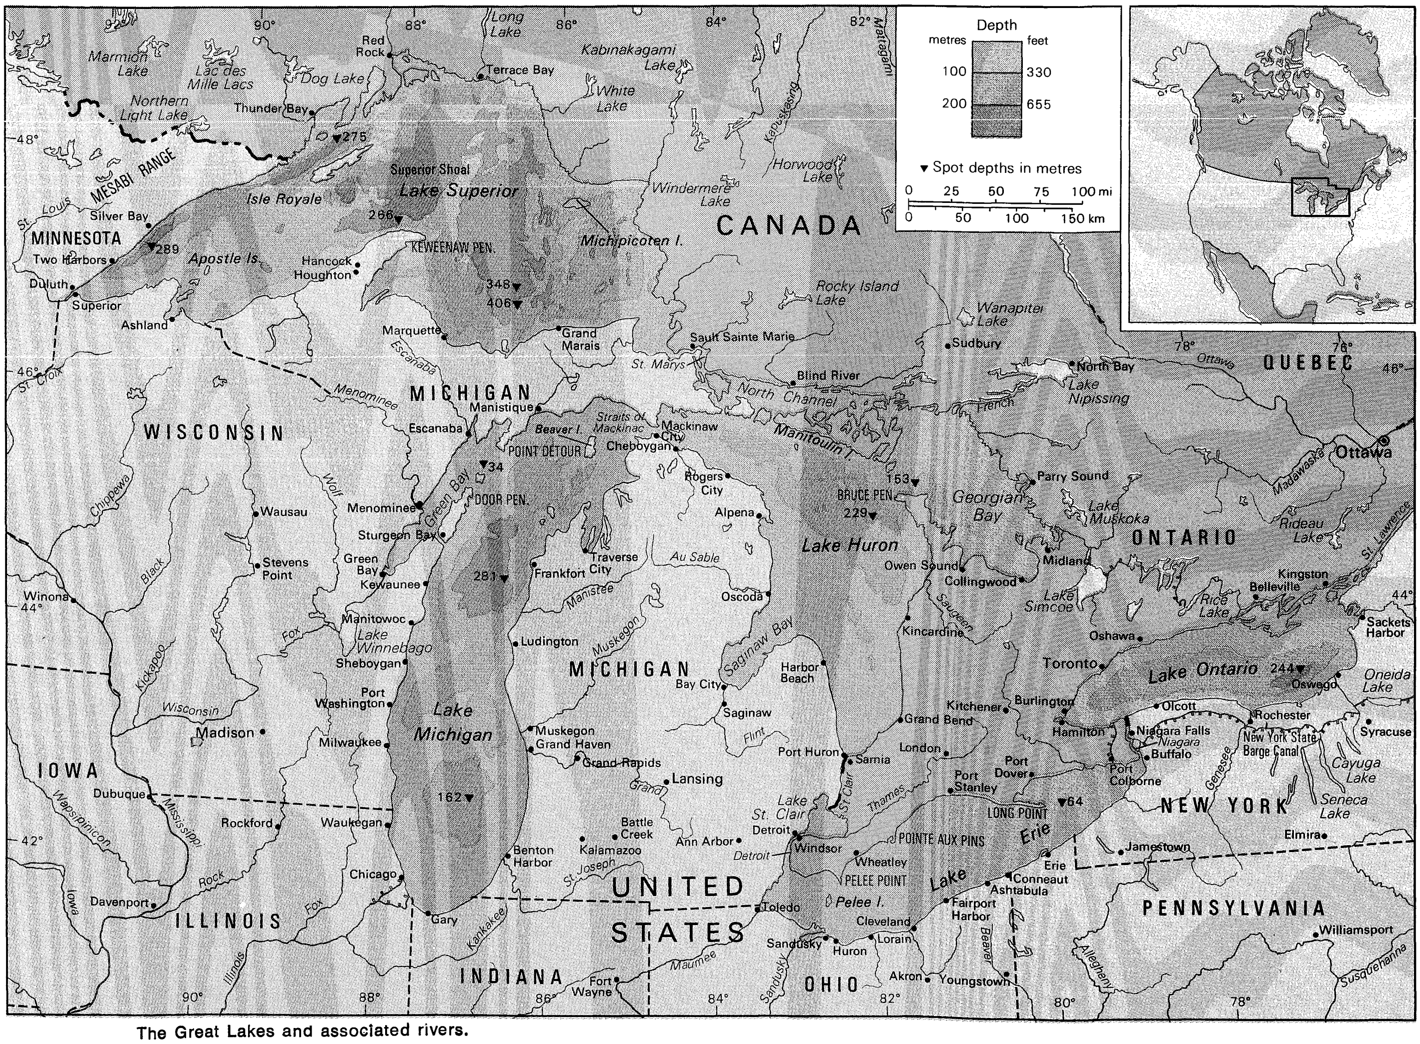
PHYSICAL AND CHEMICAL CHARACTERISTICS

The lakes ultimately receive their water supply from precipitation, which increases from west to east. The average annual precipitation in the Lake Superior Basin is 29 inches, in Lakes Huron and Michigan it is 31 inches, and in Lakes Erie and Ontario it is 34 inches. About two-thirds of the annual precipitation is lost by evaporation: 22 inches on Lake Superior; 35 inches on Lake Erie (Erie receives most of its water from Lake Huron); and 26 inches on Lakes Huron, Michigan, and Ontario. Some water enters Lake Superior from the Hudson Bay drainage system via the Long Lake–Ogoki River diversion, while water is taken out of Lake Michigan by the Chicago Sanitary and Ship Canal.

Effects on climate

The lakes greatly modify the climate of the surrounding region. They absorb large quantities of heat in the warmer months, which are lost to the atmosphere during the colder months. This causes cooler summers and warmer winters. Precipitation is substantially higher along the eastern shores of the lakes, creating the snow belt that afflicts Erie, Pennsylvania; Buffalo, New York; and similarly situated cities.

Lake levels vary about one to two feet throughout the year, the highest levels occurring in summer and the lowest in late winter and early spring. There are small tides of around two inches, but they are relatively unimportant. Seiches—harmonic oscillations of the lakes—



The Great Lakes and associated rivers.

are caused by such atmospheric disturbances as winds or differences in barometric pressure. They have resulted in a piling up of water on one side, or end, of the lakes and have caused differences in the water level between Buffalo and Toledo, Ohio, on Lake Erie, as high as 13.5 feet. Currents are highly variable; they respond quickly to wind changes; their direction is determined by the rotation of the earth and the shape of the lake basins.

The Great Lakes have bicarbonate waters, the alkalinity of which ranges from 46 parts per million of carbonates in Lake Superior to 110 parts per million in Lake Michigan. Because Lake Huron is fed by both Superior and Michigan, its chemical content lies in the middle of the range. Alkalinity then increases as the waters flow into and through Lake Erie (95 parts per million) and into Lake Ontario (102 parts per million).

The overall chemical composition of the lakes does not differ greatly from that of other large bodies of fresh water. Limestone in the Lake Michigan Basin supplies large amounts of calcium and magnesium to the system, while sodium concentrations are greater than those of magnesium in Erie and Ontario. Although chemical distribution is relatively uniform in any one lake, concentrations of phosphorus and nitrogen are greatest along the shores, in bays and harbours, and especially near urban centres.

During the 20th century, concentrations of most chemicals have increased significantly in all the lakes except Superior. Chloride, sodium, and sulfate have increased significantly in Lakes Erie, Michigan, and Ontario. Chloride concentrations have increased almost four times over levels reported in 1900, and limited data for Lake Erie indicate that nitrogen concentrations increased five times and phosphorus threefold in 30 years. Especial importance is attached to these nutrients because they stimulate growth of algae.

PLANT AND ANIMAL LIFE

Algae and crustaceans. Diatoms—microscopic algae with glasslike shells of silica—are the major forms of algae, although green and blue-green algae are abundant during the summer in Lakes Erie, Ontario, and Michigan.

Microscopic life

Copepods and cladocerans, microscopic crustaceans, are important in the animal forms of plankton. Most abundant during the spring months in the upper lakes, plankton reaches two peaks of abundance—spring and fall—in the lower lakes and in the more productive waters of the upper lakes.

The organisms living on the bottom in shallow waters are the same kinds of snails, clams, worms, mayflies, and caddis flies found in most small lakes. The deep waters, however, are the realm of some organisms that are found only in the deep, cold lakes of the northern latitudes. These include the delicate opossum shrimp, the deepwater scud (a crustacean), two types of copepods, and the deepwater sculpin (a spiny, large-headed fish).

Fish. The fish community of the lakes and tributaries includes representatives of most families of North American fishes. Lake trout, whitefish, and lake herring have always been important in the lakes, while perch, pike perch, bass, and catfish are abundant in the shallow, warmer waters. The fish populations have changed drastically over the past century. By 1880, the damming and pollution of tributaries had caused the elimination of the Atlantic salmon and the restriction of the whitefish. At the same time, the lake sturgeon was purposely overfished, and the carp was introduced. Smelt entered Lake Michigan in 1927 and in a short time had spread throughout the lakes. The predatory sea lamprey (an eel) migrated into the upper lakes and established spawning populations in the 1930s, causing the collapse of the lake trout populations in Lakes Huron and Michigan by the early 1950s. Other large predators were also drastically reduced by the sea lamprey. Consequently, when the alewife migrated into the upper lakes between 1931 and 1954, it met little competition and predation and soon became the most abundant species. Alewives are of little commercial value, however, and cause costly sanitary operations when, periodically, millions of them die and are washed up to rot on the beaches. During the 1960s, lake trout were reintroduced when it appeared that the sea lamprey was under control. Coho and chinook salmon were also introduced, both to provide a sports fishery and to control the alewife.

The changing fish population

Bird life. Herring and ring-billed gulls and terns are the most common birds; small islands are important nesting grounds for them. The lakes are important as wintering areas for ducks such as the scaups and the old-squaw duck, and a diversity of shorebirds and songbirds migrate through the region during the spring and fall. Various places along the shoreline, such as Pelee Point in Lake Erie, are favoured locations for birdwatching.

RESOURCES AND THEIR DEVELOPMENT

Early interest in the lakes was stimulated by the easy transportation route that they offered into the heartland of the continent. The value of the extensive forests and fertile land in the region was soon realized, and lumbering and agriculture became important. Large coalfields and deposits of iron, copper, limestone, and other minerals were found along or near the extensive shorelines. The combination of these vast resources with a plentiful water supply naturally favoured the development of huge industries and large metropolitan areas around the Great Lakes. The population of these increased from around 300,000 at the start of the 19th century to around 37,000,000 by 1970. Present population growth supports the speculation that a large megalopolis ultimately will extend from Milwaukee and Chicago around southern Lake Michigan, across the state of Michigan to Detroit, and along the southern shore of Lake Erie and will include the Toronto–Hamilton area on Lake Ontario.

Transportation. About 246,000,000 net tons of shipping were moved annually by Great Lakes vessels in the late 1960s. Most of the total included iron ore, coal, and grain for lake ports, but about 14,000,000 net tons were shipped overseas through the St. Lawrence Seaway. The Welland Canal allows passage around Niagara Falls from Lake Ontario into Lake Erie, and the channels and locks in the St. Marys River have made Lake Superior accessible to ships up to 730 feet in length.

Forestry and agriculture. Although the virgin pine forests were felled by 1910, the growing of timber is important and is supported by both federal and state governments. The counties bordering the lakes in the United States have about half of their lands in farms, and over 5 percent of the value of U.S. agriculture is produced in the lakes region. Bordering Canadian counties have roughly 30 percent of their lands under agriculture, producing about 10 percent of the total agricultural value.

Minerals. The iron ranges around Lake Superior—such as the Mesabi in Minnesota—were once a major source of iron for the United States. Peak production occurred in 1953, when almost 100,000,000 net tons were produced. The large deposits of rich ores have since been depleted, but low-grade taconite ores can now be efficiently processed. Lake Superior's Keweenaw Peninsula is a major source of copper, although sources outside of the lakes are relatively more important.

Industry and power. The industry of the lakes region is highly diversified. Perhaps the more important are the large steel mills in Illinois, Indiana, Ohio, and Ontario and the automobile industry centred in the Detroit area.

Commercial fishing was once a major industry on the lakes, but the decline of the more desirable species led to its collapse. Emphasis has switched to developing major sports fisheries based on coho and chinook salmon, lake trout, and rainbow trout.

Fisheries

The value of the lakes for a broad spectrum of recreational activities is inestimable. Powerboating and sailing have become major activities. Many miles of sandy beaches stretch along the lake shores. State, federal, and county lands offer many camping, picnicking, and park areas for a thriving tourist industry.

Of major importance is the water supply that the lakes provide for industries and for about 240 municipalities, which use almost 16,000,000,000 gallons per day. Hydroelectric generating stations on the St. Marys, Niagara,

and St. Lawrence rivers have a total capacity of about 8,000,000 kilowatts. Over 30 large thermal-power plants around the lakes use their waters for cooling. The total capacity of these plants is about 20,000,000 kilowatts.

THE FUTURE

The multiple uses of the lakes are often conflicting. The shipping and hydroelectric-power industries favour higher water levels, but shoreline-property owners find that high levels increase erosion of the shoreline. Conservationists believe that diversion of treated sewage away from the lakes, such as is now done at Chicago, is the best solution for maintaining the quality of the lake waters. Regardless of the approach that is taken, it is obvious that changes have occurred in the plant and animal life of the lakes and that these changes are related to increases in the chemical content, depletion of dissolved oxygen in some areas, and the accumulation of sewage sludge. Significant changes started around 1900 and paralleled the buildup in human population. Misuse of the lakes can be seen at a number of beaches closed due to pollution, but the less obvious deterioration in water quality is more dangerous. It affects either directly or indirectly all uses—raising the cost of water treatment, killing valuable fish species, and adversely affecting the tourist industry and the value of shoreline property. Unless every effort is made to control pollution, more areas will follow the deterioration of Lake Erie, and a major resource of North America will be spoiled.

HOUGH, *Geology of the Great Lakes* (1958), detailed information on the origin of the lakes.

(A.M.B.)

Great Plains

A major physiographic province of North America, the Great Plains lie between the Rio Grande on the south and the delta where the Mackenzie River empties into the Arctic Ocean on the north, between the Central Lowland of the United States and the Canadian Shield on the east and the Rocky Mountains on the west. Their length is some 3,000 miles, their width from 300 to 700 miles, and their area approximately 1,125,000 square miles (2,900,000 square kilometres), roughly equivalent to one-third of the United States. Parts of ten states of the United States (Montana, North Dakota, South Dakota, Wyoming, Nebraska, Kansas, Colorado, Oklahoma, Texas, and New Mexico) and the three Prairie Provinces of Canada (Manitoba, Saskatchewan, and Alberta), and portions of the Northwest Territories are within the Great Plains proper. Some writers have used the 100th meridian as the eastern boundary, but a more precise one is an eastward-facing escarpment that runs from Texas to North Dakota, generally somewhat east of the 100th meridian. In the Canadian portion the line dividing the Great Plains from the Canadian Shield runs east of the Red River of the North; cuts through Lake Winnipeg; then curves northwestward, crossing Lake Athabasca, Great Slave Lake, and Great Bear Lake to reach the Arctic Ocean east of the Mackenzie Delta.

Landscape. Once known as the Great American Desert, the Great Plains are a vast high plateau of semi-arid grassland. Their altitude at the base of the Rockies in the United States is between 5,000 and 6,000 feet above sea level; this decreases to 1,500 feet at their eastern boundary. The altitudes of the Canadian portion are lower, and near the Arctic Ocean the surface is a little above sea level. Some sections, such as the Staked Plains in the Texas Panhandle, are extremely flat; elsewhere, tree-covered mountains—the Black Hills of South Dakota and the Bearpaw, Big Snowy, and Judith mountains of Montana—rise 1,500 to 2,000 feet above the general level of the Plains. In the United States the Great Plains are drained by the Missouri River and its great tributaries (the Yellowstone, Platte, and Kansas) and the Arkansas, which flow eastward from the Rockies in broad, steep-sided, shallow valleys.

Surface features, soils, and climates

The soil groups of the Great Plains are correlated with rainfall and grass cover. In the more humid region with heavier grass cover, deep, black soils with much organic matter developed. Sections with less moisture have lighter, shallower soils with less organic matter, while in the most arid regions the soils are even thinner, lighter in colour, and less organic in composition.

The Great Plains have a continental climate. Over much of their expanse, cold winters and warm summers prevail, with low precipitation and humidity, much wind, and sudden variations of temperature. The major source of moisture is the Gulf of Mexico, and the amount falls off both to the north and west. Thus, the southern Plains have 15 to 25 inches of rain annually, the northern Plains 12 to 15 inches, the eastern margin in Nebraska 25 inches, and the western margin in Montana less than 15 inches. The southern parts of the Canadian Plains receive 10 to 20 inches and have a growing season of 70 to 110 days. The growing season averages 240 days in Texas, 120 days at the United States–Canadian boundary, and from 70 to 110 days in the Prairie Provinces. Grasses are the dominant natural plant life, with trees generally confined to river valleys.

Before settlement, the Plains were the home of the great grazing herd mammals—the buffalo and the pronghorn antelope. North of the 54th parallel the grasslands give way to forest, where the moose, woodland caribou, Canada lynx, and timber wolf make their homes.

Human settlement. European immigrants played an important role in settling the Plains. By 1910 foreign white stock (foreign-born and their children) made up 43 percent of the population of the six northern Plains states (Montana, North Dakota, South Dakota, Wyoming, Nebraska, and Kansas), with the British, Germans (many of them from Russia), and Scandinavians the leading ethnic groups. On the southern Plains, peoples of a pre-Columbian stock with Spanish surnames are also important. The Prairie Provinces were settled by British, German Russians (many of them Mennonites), Ukrainians, and Scandinavians.

Many of the immigrants were religious, thrifty, hard-working people with an attachment to the land. Kinship and nationality ties drew the plainsmen together, and they would travel long distances to visit and exchange work. Class differentiation was less and the status ladder shorter than in older parts of North America or Europe.

By 1970 the population of the Plains proper was about 5,000,000 in the United States and about 3,300,0000 in Canada. Although there were few large cities, some 60 percent of the population was urban. The largest cities were Edmonton (440,000 in 1971) and Calgary (400,000) in Alberta; Denver, Colorado (515,000 in 1970); and Lubbock, Texas (150,000). The rural population was also sparse, about 4 per square mile in the United States and in the settled portion of the Canadian section.

Life-styles of the Plains

Ranchers enjoyed their remoteness and looked upon their rangeland as the last remaining trace of the Old West, with its vast expanse of plains and untamed wilderness. Not generally a gregarious kind of people, they were highly individualistic in politics. Farmers, more inclined to social interaction, made economic cooperatives strong on the Plains. In recent years, ranchers and farmers alike have valued horsemanship and rodeos as symbols of a tradition and style of life that evolved from the natural habitat.

The need for larger farms and ranches to produce viable economic units has led to a heavy migration from the rural areas. This exodus has been demoralizing for the farmers, ranchers, and businessmen who remained, and it has made survival more difficult for churches, schools, and the rural trading centres. The low density of population has concentrated services more and more in a few centres, necessitating long trips to attend school and church, to do business, and to find recreation. To meet

these difficulties, some farmers have moved into town to live and commuted back to their land to work, a revival of a centuries-old pattern.

Economic development. Indians on horseback had long exploited the buffalo herds, but in the 1870s cattle replaced the buffalo, and cowboys replaced the Indians. In the 1880s and 1890s farmers began to crowd the ranchers, and wheat began to replace cattle. Settlement came in years of good rains, so the Plains were overpopulated in the first rush; and a heavy emigration followed. Many grain farmers left because their farms were too small and more vulnerable to drought than the cattle ranches. Those who stayed built up the size of their holdings, saved against hard times, and added livestock to grain farming. From 1930 to 1970 the outmigration brought a decline of 31 percent in the rural population of the United States portion of the Great Plains proper, but urban population grew by 166 percent.

Agricultural and mineral bases of the economy

The Great Plains remain basically an agricultural area producing wheat, cotton, sorghum, and hay and raising cattle and sheep. In 1971 seven of the ten leading U.S. wheat states (Kansas, North Dakota, Montana, Nebraska, Colorado, Oklahoma, and South Dakota) lay within the Great Plains; and the Prairie Provinces were leading wheat producers in Canada. Livestock brought the largest cash farm receipts in nine of the ten Plains states. Only in North Dakota did crop income exceed that from livestock.

The Great Plains states also produce much mineral wealth, with Texas leading the nation and three other Plains states (Oklahoma, New Mexico, and Wyoming) ranking in the top twelve. Four of the Great Plains states have the largest coal reserves in the nation (Wyoming, North Dakota, Montana, and Colorado) but rank low in actual production. Texas leads the United States in production of petroleum and natural gas, and eight other Plains states are substantial producers. Alberta leads Canada in petroleum and natural gas.

Prospects. In the 1960s, the urban population gains in the United States portion of the Great Plains proper barely equalled rural losses, and the total Plains population grew only minutely. Population growth in the Prairie Provinces, although far greater in terms of percentage, was also slowing down. In both Canadian and United States portions of the Plains such other trends as urbanization, emphasis on soil and water conservation, larger and fewer farms, town residence for farmers, and expansion of Plains communities will probably continue. Planners for county reorganization, for example, believe that North Dakota could best be served by 8 counties, each with a principal trade centre, instead of the present 53; Nebraska and Saskatchewan each need only 15. By expanding the communities and integrating rural and urban areas, such reorganization, the planners argue, would reduce costs and improve the services of government, provide more specialized business and professional services, and increase cultural opportunities for the widely scattered population.

Great Salt Lake

Its waters so dense that swimmers are buoyed above the surface, the Great Salt Lake, in northern Utah, is the largest body of saline water in the Western Hemisphere and among the most saline inland bodies of water in the world. Like the Dead Sea, it exists within an arid environment and has chemical characteristics similar to that of the oceans. It has a much greater salinity than the oceans, however, since natural evaporation exceeds the supply of water from the rivers feeding it. This evaporation and changes in the flow of the rivers feeding it have varied its area drastically—from 2,400 square miles (6,200 square kilometres) in 1873 to 950 square miles in 1963 and some 1,600 square miles in the early 1970s. It is generally less than 15 feet (4.5 metres) deep, with a maximum depth of 35 feet.

Character and location

Surrounded by great stretches of sand, salt land, and marsh, the Great Salt Lake remains strangely isolated from the nearby cities, towns, and other human habitations, though in recent years means have been found to turn its apparent sterility to a profit in both economic and recreational terms. It has become important not only as a source of minerals but also as a beach and watersports attraction and a wildlife preserve.

Geological and human history. The Great Salt Lake is the largest of the saline-lake remnants of prehistoric freshwater Lake Bonneville, the others being Bear Lake, on the Utah–Idaho border, and Utah Lake, west of Provo, Utah. Originating some 1,000,000 years ago in the Pleistocene Epoch, Lake Bonneville covered almost 20,000 square miles of western Utah, extending also into present-day Nevada and Idaho. During succeeding glacial periods, large quantities of freshwater entered this intermontane basin and drained out through the Snake River—ultimately into the Columbia River and the Pacific Ocean. During the interglacial and postglacial periods, however, water levels decreased and outflows were cut off. Water, thus, could escape only through evaporation, and the mineral salts from the inflowing rivers remained trapped in the lake.

Exploration and settlement

The lake appeared on 18th-century maps of the continent through reports of explorer-trappers and Indian tales, a semilegendary body alternately named Timpanogos or Buenaventura, depending on the source. The first Westerners whose accounts are fully credited were the trappers Étienne Prevost and Jim Bridger, who came upon the lake independently in 1824–25. More detailed investigations were made by Capt. John C. Frémont in 1843 and 1845. The Mormons' settlement in 1847 of their "promised land," on the nearby site of Salt Lake City, brought the region more fully into national awareness. The lake was surveyed in 1850, and in 1869 the last spike of America's first transcontinental railroad was driven near the lake's northeastern shore. The study of the Great Basin region by the U.S. Geological Survey in 1890 was an important source of information about the lake, and later studies have been led by that agency.

Surface features and chemistry. The lake's basin is defined by the foothills of the Wasatch Range to the north, east, and south and by the Great Salt Lake Desert, a remnant of the bed of Lake Bonneville, to the west. The part of this desert known as the Bonneville Salt Flats has become an automobile raceway, the site of many trials for world land-speed records. The varying shoreline comprises beaches, marshes, and mudflats. The 30-mile-long Lucin Cutoff, a causeway laid down for a rail line in 1959, connects the cities of Ogden and Lucin, splits the lake, and affects the water level. Because the main tributaries enter from the south, the water level of the southern section is several inches higher than that of the northern part. Several islands, the largest of which are Antelope and Fremont (36 and 14 square miles, respectively), lie south of the cutoff.

Saline components

Freshwater enters the lake from the Bear, Weber, and Jordan rivers, which carry in over 1,100,000 tons of salts annually. The total accumulation in the lake basin is 6,000,000,000 tons, mainly sodium chloride, though sulfate, magnesium, and potassium are abundant. Table salt and potash production dates from the 19th century, while magnesium production from brines was begun on a large scale only in 1971. Extraction of other minerals is anticipated.

Natural life. The high salt content makes the lake unviable for all but a few forms of life. A small crustacean, the brine shrimp *Artemia*, which lives in saline lakes throughout the world, is abundant. The larvae of two kinds of salt flies and a few species of protozoans, bacteria, and algae are found. The marshes, mudflats, and islands, however, attract much waterfowl, including peli-

cans, herons, cormorants, terns, and gulls, while Antelope Island has been made a refuge for the bison.

Greco, El

El Greco was a unique genius whose true greatness as a religious painter and portraitist came first to be recognized in the early part of the 20th century.

Early life and works. El Greco was born in 1541 at Candia, on the island of Crete. He never forgot he was of Greek descent and usually signed his paintings in Greek letters with his full name, Doménikos Theotokópoulos. He is, nevertheless, generally known as El Greco (the Greek), a name he acquired when he lived in Italy, where the custom of identifying a man by designating country or city of origin was a common practice. The curious form of the article (El), however, may be the Venetian dialect or more likely from the Spanish.

Whether El Greco first learned his trade as an icon painter in the Byzantine tradition is disputed. The icon of "St. Luke Painting the Portrait of the Madonna" in the Benaki Museum at Athens is signed in Greek "By the Hand of Domenikos" (Cheìr Doménikou). Greek writers believe that this painter was Theotokópoulos, known as El Greco, but it cannot be assumed that only he among Greek artists of the 16th century had the name Doménikos.

"Burial of the Conde de Orgaz," canvas by El Greco, 1586–88. In the church of Santo Tomé, Toledo, Spain. 4.8 m × 3.6 m.

Study in Venice

Since Crete was then a Venetian possession and the young artist a Venetian citizen, he decided to go to Venice to study. The exact year in which this took place is not known; but speculation has placed the date anywhere from 1560, when he was 19, to 1566. In Venice El Greco entered the studio of Titian, who was the greatest painter of the day.

Knowledge of El Greco's years in Italy is limited. A letter of November 16, 1570, written by Giulio Clovio, an illuminator in the service of Cardinal Alessandro Farnese, requested lodging in the Palazzo Farnese for "a young man from Candia, a pupil of Titian." On July 8, 1572, "the Greek painter" is mentioned in a letter sent from Rome by a Farnese official to the Cardinal. Shortly thereafter, on September 18, 1572, "Dominico Greco" paid his dues to the guild of St. Luke in Rome. Just how long the young artist remained in Rome is unknown, since he may have returned to Venice, *c.* 1575–76, before he set forth for Spain. An anecdote told by Guilio Mancini, author of a treatise on artists in Rome, relates that El Greco suggested that if Michelangelo's "Last Judgment" in the Sistine Chapel were destroyed he (El Greco) "would have made it with honesty and decorum." Mancini reported that El Greco was forced to leave Rome because of this criticism. Such picturesque gossip is characteristic of writings of the period, however, and there is no reason to accept it literally. Besides, Michelangelo's fresco was under general attack at this time because of the nudity of the figures.

Another anecdote, first published in 1923, proved to be a literary forgery. It holds that Giulio Clovio recorded in his diary a visit to El Greco's studio in Rome, where he found the artist on a sunny day with the curtains drawn. The young Greek is quoted as saying that the light of day destroyed his inner light. No diary of Giulio Clovio exists in the library at Split, in Yugoslavia, where is was falsely claimed to have been found.

To the artist's first years in Italy has been attributed a small, portable altar of three panels in the museum at Modena, Italy, usually referred to as the "Modena Triptych." Signed "Hand of," in the manner widely used by all Greek artists of the 16th century, it also has only a first name, Doménikos. Finally, El Greco's authorship is dubious because the altar is clearly a Veneto-Cretan work that combines Greek and Venetian elements in a way frequently practiced by many artists who had been exposed to both artistic traditions.

The certain works painted by El Greco in Italy are completely in the Venetian Renaissance style of the 16th century. They show no effect of his Byzantine heritage except possibly in the faces of old men; for example, in the "Christ Healing the Blind." The placing of figures in deep space and the emphasis on an architectural setting in High Renaissance style are particularly significant in his early pictures, such as "Christ Cleansing the Temple"; a slightly later version is in the Minneapolis (Minnesota) Institute of Arts. In his use of rich colour he reflects the traditions of Titian, but he had also clearly studied the works of Paolo Veronese, Jacopo Bassano, and Tintoretto. During his sojourn in Rome, El Greco indubitably admired the painting and sculpture of Michelangelo, as demonstrated by his "Pietà," in which the composition is based upon Michelangelo's sculpture of the same subject, now in the cathedral at Florence.

The first evidence of El Greco's extraordinary gifts as a portraitist appears in Italy in a portrait of a friend, "Giulio Clovio." The arrangement of a half-length figure silhouetted against a plain background that has an open window revealing a distant landscape is known in the works of Titian and other Venetians. In the portrait of Vincentio Anastagi, El Greco employed the full-length

figure, with brilliantly painted armour against a red curtain. Again, this type of composition has ample precedent in the work of Titian and north Italian masters.

Move to Spain

Middle years. El Greco first appeared in Spain in the spring of 1577, initially at Madrid, later in Toledo. One of his main reasons for seeking a new career in Spain must have been knowledge of Philip II's great project, the building of the monastery of San Lorenzo at El Escorial, some 40 miles northwest of Madrid. Moreover, the Greek must have met important Spanish churchmen in Rome through Fulvio Orsini, a humanist and librarian of the Palazzo Farnese. It is known that at least one Spanish ecclesiastic who spent some time in Rome at this period—Luis de Castilla—became El Greco's intimate friend and was eventually named one of the two executors of his last testament. Luis' brother, Diego de Castilla, gave El Greco his first commission in Spain, which possibly had been promised before the artist left Italy.

In 1578 Jorge Manuel, the painter's only son, was born at Toledo, the offspring of Doña Jerónima de Las Cuevas. She appears to have outlived El Greco, and, although he acknowledged both her and his son, he never married her. That fact has puzzled all writers, since he mentioned her in various documents, including his last testament. It may be that El Greco had married unhappily in his youth in Crete or Italy and therefore could not legalize another attachment.

For the rest of his life El Greco continued to live in Toledo, busily engaged on commissions for the churches and monasteries there and in the province. He became a close friend of the leading Humanists, scholars, and churchmen. Antonio de Covarrubias, a classical scholar and son of the architect Alonso de Covarrubias, was a friend whose portrait he painted. Fray Hortensio Paravicino, the head of the Trinitarian order in Spain and a favourite preacher of Philip II of Spain, dedicated four sonnets to El Greco, one of them recording his own portrait by the artist. Luis de Góngora y Argote one of the major literary figures of the late 16th century, composed a sonnet to the tomb of the painter. Another writer, Don Pedro de Salazar de Mendoza, figured among the most intimate circle of El Greco's entourage.

The inventories compiled after his death confirm the fact that he was a man of extraordinary culture—a true Renaissance Humanist. His library, which gives some idea of the breadth and range of his interests, included works of the major Greek authors in Greek, numerous books in Latin, and others in Italian and in Spanish: Plutarch's *Lives*, Petrarch's poetry, Ariosto's *Orlando Furioso*, the Bible in Greek, the proceedings of the Council of Trent, and architectural treatises by Vitruvius, Vignola, Alberti, Palladio, and Serlio. El Greco himself prepared an edition of Vitruvius, accompanied by drawings, but the manuscript is lost.

In 1585 and thereafter El Greco lived in the large, late-medieval palace of the Marqués de Villena. Although it is near the site of the now-destroyed Villena Palace, the museum in Toledo called the Casa y Museo del Greco was never his residence. It can be assumed that he needed space for his atelier more than for luxurious living. In 1605 the palace was listed by the historian Francisco de Pisa as one of the handsomest in the city; it was not a miserable ruined structure, as some romantic writers have presumed. El Greco surely lived in considerable comfort, even though he did not leave a large estate at his death.

First commission in Spain

El Greco's first commission in Spain (given to him by Diego de Castilla) was for the high altar and the two lateral altars in the conventual church of Santo Domingo el Antiguo at Toledo (1577–79). Never before had the artist had a commission of such importance and scope. Even the architectural design of the altar frames, reminiscent of the style of the Venetian architect Andrea Palladio, was prepared by El Greco. The painting for the high altar, "Assumption of the Virgin," also marked a new period in the artist's life, revealing the full extent of his genius. Though in a general way inspired by Titian's "Assumption" (1516–18; Sta. Maria dei Frari, Venice), it is majestic and solemn rather than triumphant. The figures are brought close into the foreground, and in the Apostles a new brilliance of colour is achieved. The technique remains Venetian in the laying on of the paint and in the liberal use of white highlights; yet the intensity of the colours and the manipulation of contrasts, verging on dissonance, is distinctly El Greco. For the first time the importance of his assimilation of the art of Michelangelo comes to the fore, particularly in the painting of the "Trinity," in the upper part of the high altar (now in the Prado, Madrid), where the powerful sculpturesque body of the nude Christ leaves no doubt of the ultimate source of inspiration. In the lateral altar painting of the "Resurrection," the poses of the standing soldiers and the contrapposto (a position in which the upper and lower parts of the body are contrasted in direction) of those asleep are also clearly Michelangelesque in inspiration.

At the same time, El Greco created another masterpiece of extraordinary originality—the "Espolio" ("Disrobing of Christ"). In designing the composition vertically and compactly in the foreground he seems to have been motivated by the desire to show the oppression of Christ by his cruel tormentors. He chose a method of space elimination that is common to middle- and late-16th-century Italian painters known as Mannerists, and at the same time he probably recalled late Byzantine paintings in which the superposition of heads row upon row is employed to suggest a crowd. The original altar of gilded wood that El Greco designed for the painting has been destroyed, but his small sculptured group of the "Miracle of St. Ildefonso" still survives on the lower centre of the frame.

Elongation of the human figure

El Greco's tendency to elongate the human figure becomes more notable at this time; for example, in the handsome and unrestored "St. Sebastian," which was inspired in the pose by Michelangelo's statue of "Victory" (1532–34; Palazzo Vecchio, Florence). The same extreme elongation of body is also present in Michelangelo's work, in the painting of the Venetians Tintoretto and Paolo Veronese, and in the art of the leading Mannerist painters. Writers unfamiliar with Italian art of the 16th century have proposed erroneously that El Greco elongated the human figure because he had astigmatism. The increased slenderness of Christ's long body against the dramatic clouds in "Crucifixion with Donors" foreshadows the artist's late style.

El Greco's connection with the court of Philip II was brief and unsuccessful, consisting first of the "Allegory of the Holy League" ("Dream of Philip II") in the Escorial (1578–79) and second of the "Martyrdom of St. Maurice" (1580–82). The latter painting did not please the King, who promptly (1584) ordered another work of the same subject to replace it. Thus ended the great artist's connection with the Spanish court.

The "Martyrdom of St. Maurice" is one of the artist's most notable paintings, despite the fact that Philip II rejected it. The King may have been troubled by the almost shocking brilliance of the yellows as contrasted to the ultramarine in the costumes of the main group, which includes St. Maurice in the centre. On the other hand, to the modern eye El Greco's daring use of colour is particularly appealing. The brushwork remains Venetian in the way the colour suggests form and in the free illusionistic and atmospheric creation of space. This essentially optical method of painting, preferably called illusionism rather than impression, was a creation of Titian in his mature years, and thereafter it was adopted by the Venetian school in general.

The "Burial of Conde de Orgaz"

The "Burial of the Conde de Orgaz" (1586–88) is universally regarded as El Greco's masterpiece. The supernatural vision of Gloria (Heaven) above and the impressive array of portraits represent all aspects of this extraordinary genius' art. El Greco clearly distinguished between heaven and earth: above, heaven is evoked by swirling icy clouds, semi-abstract in their shape, and the saints are tall and phantomlike; below, all is normal in the scale and proportions of the figures. According to the legend, SS. Augustine and Stephen appeared miraculously to lay the Conde de Orgaz in his tomb as a reward for his generosity to their church. In golden and red vestments

they bend reverently over the body of the Count, who is clad in magnificent armour that reflects the yellow and reds of the other figures. The young boy at the left is El Greco's son, Jorge Manuel; on a handkerchief in his pocket is inscribed the artist's signature and the date 1578, the year of the boy's birth. The men in contemporary 16th-century dress who attend the funeral are unmistakably prominent members of Toledan society.

El Greco's Mannerist method of composition is nowhere more clearly expressed than here, where all of the action takes place in the frontal plane. In contrast, Raphael, a classical High Renaissance master, disposed his figures throughout a series of parallel planes in deep space, as, for example, in the "Disputa" and the "School of Athens" (1508–11; Vatican, Rome).

Later life and works. *Religious paintings.* From 1590 until his death in 1614 El Greco's output was prodigious. His pictures for the churches and convents of the Toledan region include the "Holy Family with the Magdalen" and the "Holy Family with St. Anne." He repeated several times the "Agony in the Garden," in which a supernatural world is evoked through strange shapes and brilliant, cold, clashing colours. The devotional theme of "Christ Carrying the Cross" is known in 11 originals, many copies, and some modern forgeries. El Greco depicted most of the major saints, often repeating the same composition: St. Dominic, Mary Magdalen, St. Jerome as cardinal, St. Jerome in penitence, and St. Peter in tears. St. Francis, however, was by far the saint most favoured by the artist; it is no wonder that Francisco Pacheco, the Spanish painter and art theorist who visited El Greco in 1611, declared him the best interpreter of the founder of the Franciscan order. About 25 originals representing St. Francis survive and in addition more than 100 pieces by followers and as many modern forgeries. The most popular of several types was "St. Francis and Brother Leo Meditating on Death," of which there is a fine example in the National Gallery of Canada at Ottawa.

Two major series ("Apostolados") survive representing Christ and the Twelve Apostles in 13 canvases: one in the sacristy of Toledo Cathedral (1605–10) and another, unfinished set (1612–14) in the Casa y Museo del Greco at Toledo. The frontal pose of the Christ blessing in this series suggests a medieval Byzantine figure, although the colour and brushwork are El Greco's personal handling of Venetian technique.

El Greco's artistic individuality

In these works the devotional intensity of mood reflects the religious spirit of Catholic Spain in the period of the Counter-Reformation. Although Greek by descent and Italian by artistic preparation, the artist became so immersed in the religious environment of Spain that he became the most vital visual representative of Spanish mysticism. Yet, because of the combination of these three cultures, he developed into an artist so individual that he belongs to no conventional school but is a lonely genius of unprecedented emotional power and imagination.

Several major commissions came El Greco's way in the last 15 years of his life: three altars for the Chapel of San José, Toledo (1597–99); three paintings (1596–1600) for the Colegio de Doña María de Aragon, an Augustinian monastery in Madrid; the high altar, four lateral altars, and the painting "St. Ildefonso" for the Hospital de la Caridad at Illescas (1603–05). A litigation over payment showed the hospital authorities to be malicious and deceptive, but the documents provide valuable data about the artist's life.

Extreme distortion of body characterizes El Greco's last works; for example, the "Adoration of the Shepherds," painted in 1612–14 for his own burial chapel. The brilliant, dissonant colours and the strange shapes and poses create a sense of wonder and ecstasy, as the shepherd and angels celebrate the miracle of the newly born child. In the unfinished "Fifth Seal of the Apocolypse," El Greco's imagination led him to disregard the laws of nature even more. The gigantic swaying figure of St. John the Evangelist, in abstractly painted icy-blue garments, reveals the souls of the martyrs who cry out for deliverance. In like manner, the figure of the Madonna in the "Immaculate Conception," originally in the church of San Vicente, floats heavenward in a paroxism of ectasy supported by long, distorted angels. The fantastic view of Toledo below, abstractly rendered, is dazzling in its ghostly moonlit brilliance; and the clusters of roses and lilies, symbols of the Virgin's purity, are unalloyed in their sheer beauty.

Landscapes. In his three surviving landscapes El Greco demonstrated his characteristic tendency to dramatize rather than to describe. The "View of Toledo" (*c.* 1595) renders a city stormy, sinister, and impassioned with the same dark, foreboding clouds that appear in the background of his earlier "Crucifixion with Donors." Painting in his studio, he rearranged the buildings depicted in the picture to suit his compositional purpose. "View and Plan of Toledo" (1610–14) is almost like a vision, all of the buildings painted glistening white. An inscription by the artist on the canvas explains quite fancifully that he had placed the Hospital of San Juan Bautista on a cloud in the foreground so that it could better be seen and that the map in the picture shows the streets of the city. At the left, a river god represents the Tagus, which flows around Toledo, a city built on rocky heights. Although El Greco had lived in Italy and in Rome itself, he rarely used such classical Roman motives.

Views of Toledo

The one picture with a mythological subject, so dear to most Renaissance artists, is the "Laocoön." For ancient Troy he substituted a view of Toledo, similar to the one just discussed, and he displayed little regard for classical tradition in painting the highly expressive but great, sprawling body of the priest.

Portraits. Although El Greco was primarily a painter of religious subjects, his portraits, though less numerous, are equally high in quality. Two of his finest late works are the portraits of "Fray Felix Hortensio Paravicino" (1609) and "Cardinal Don Fernando Niño de Guevara" (*c.* 1600). Both are seated, as was customary after the time of Raphael in portraits presenting important ecclesiastics. Paravicino, a Trinitarian monk and a famous orator and poet, is depicted as a sensitive, intelligent man. The pose is essentially frontal; and the white habit and black cloak provide highly effective pictorial contrasts. The Cardinal, in crimson robes, is almost electrical in his inherent energy, a man accustomed to command. El Greco was able to project the domineering personality of this powerful politician, archbishop, and grand inquisitor.

His portrait of "Jeronimo de Cevallos" (1605–1610), on the other hand, is most sympathetic. The work is half-length, painted very thinly and limited to black and white. The huge ruff collar, then in fashion, enframes the kindly face. By such simple means, the artist created a memorable characterization that places him in the highest rank as a portraitist, along with Titian and Rembrandt.

El Greco died on April 7, 1614, and was buried at Toledo in the chapel in Santo Domingo el Antiguo. Because of a dispute with the nuns, his son, Jorge Manuel, transferred the family vault to San Torcuato. Since the destruction of that church a century ago, no sign of the artist's burial place survives.

No followers of any consequence remained in Toledo after El Greco's death. Only his son and a few unknown painters produced weak copies of the master's work. His art was so personally and so highly individual that it could not survive his passing. Moreover, the new Baroque style of Caravaggio and of the Carracci soon supplanted the last surviving traits of 16th-century Mannerism.

MAJOR WORKS

ITALIAN PERIOD: "Christ Cleansing the Temple" (signed, 1560–65; National Gallery of Art, Washington, D.C.); same subject (signed, 1570–75; Minneapolis Institute of Arts, Minnesota); "Boy Lighting a Candle" (1570–75; Museo e Gallerie Nazionali di Capodimonte, Naples); "Christ Healing the Blind" (*c.* 1570; Galleria Nazionale, Parma, Italy); "Giulio Clovio" (signed, *c.* 1570; Museo e Gallerie Nazionali di Capodimonte, Naples); "Pietà" (1574–76; Hispanic Society of America, New York); "Vincentio Anastagi" (signed, *c.* 1575; Frick Collection, New York); "Annunciation" (1575–76; Contini Bonacossi Collection, Florence).

SPANISH PERIOD (RELIGIOUS PAINTINGS, 1577–1644): "Assumption of the Virgin" (signed and dated 1577; Art Institute

of Chicago); "Trinity" (1577–79; Prado, Madrid); "Espolio" (1577–79; Cathedral, Toledo, Spain); "St. Sebastian" (signed, 1577–78; Cathedral, Palencia, Spain); "Crucifixion with Donors" (signed, *c.* 1580; Louvre, Paris); "Martyrdom of St. Maurice" (signed, 1580–82; Museos Nuevos, Escorial); "Christ Carrying the Cross" (1585–90; Metropolitan Museum of Art, New York); "St. Louis of France" (1585–90; Louvre, Paris); "Burial of the Conde de Orgaz" (signed, 1586–88; Santo Tomé, Toledo, Spain); "Holy Family with the Magdalen" (1590–95; Cleveland Museum of Art); "Holy Family with St. Anne" (1590–95; Hospital of San Juan Bautista, Toledo, Spain); "Christ at Gethsemane (1590–95; Toledo Museum of Art, Ohio); "St. Francis Kneeling in Meditation" (1595–1600; M.H. de Young Memorial Museum, San Francisco); "St. Jerome as Cardinal" (1595–1600, Frick Collection, New York); Chapel of San José, Toledo, Spain (1597–99), all signed: High altar, "St. Joseph and the Infant Christ," lateral altars, "St. Martin and the Beggar" and "The Virgin with St. Agnes and St. Tecla" (these two now in the National Gallery of Art, Washington, D.C.). High altar, Colegio de Doña María de Aragon, Madrid (all signed, 1596–1600): "Annunciation" (Museo Balaguer, Villanueva y Geltrú, Spain); "Adoration of the Shepherds" (Art Museum of the Socialist Republic of Romania, Bucharest); "Baptism" (Prado, Madrid). "St. Ildefonso" (1600–03; Hospital de la Caridad, Illescas); "St. Dominic" (1600–05; Cathedral, Toledo, Spain); "St. Francis and Brother Leo Meditating on Death" (1600–05; National Gallery of Canada, Ottawa); Illescas, Hospital de la Caridad (1603–05), altars, sculpture, and paintings; "Agony in the Garden" (1605–10; Santa María, Andújar); "Immaculate Conception" (from San Vicente; 1607–14; Museo de Santa Cruz, Toledo, Spain); "The Fifth Seal of the Apocolypse" (1608–14; Metropolitan Museum of Art, New York), original intended in altar in San Juan Bautista, Toledo, Spain; "Adoration of the Shepherds" (1612–14; Prado, Madrid). (LANDSCAPES): "View of Toledo" (*c.* 1595; Metropolitan Museum of Art, New York); "View and Plan of Toledo" (1610–14); Casa y Museò del Greco, Toledo, Spain); "Laocoön" (1610–14; National Gallery of Art, Washington, D.C.). (PORTRAITS): "Knight Taking an Oath" (1578–80; Prado, Madrid); "Cardinal Don Fernando Niño de Guevara" (*c.* 1600; Metropolitan Museum of Art, New York); "Jerónimo de Cevallos" (1605–10; Prado, Madrid); "Fray Feliz Hortensio Paravicino" (1609; Museum of Fine Arts, Boston).

Greco-Persian Wars

The Greco-Persian Wars, fought intermittently for a hundred years (*c.* 546–*c.* 448 BC), reached a climax in the period 490–479, when the Persians twice invaded mainland Greece. At that time the empire ruled by the Achaemenian house of Persia (Iran) was at the height of its power. The Greek states beyond its western borders seemed insignificant by comparison; yet a number of them combined so well and fought so skillfully that they not only drove the Persians out of Europe but also liberated the Greek states in Anatolia from Persian rule. Finally they extracted from Persia a treaty of nonaggression, known as the Peace of Callias, about 448. Greek success was of cardinal importance. Independent states survived in Europe and created the cultural forms and the political systems of Greece and Rome, which continued to flourish long after the fall of the Persian Empire was complete.

Expansion of the Persian Empire (559-500 BC). Within 30 years the Persian kings Cyrus and Cambyses created an empire that extended from the Indus Valley to the Aegean Sea and from the Caucasus to Arabia. After the Persians defeated Croesus of Lydia about 546, the small Greek states situated on the Asiatic coast were reduced piecemeal.

In the meantime, Sparta, the strongest state on the Greek mainland, did nothing more than lodge diplomatic protests. Darius, who reigned from 522 to 486, consolidated and extended the Persian Empire. From his capital, far inland at Susa, the royal roads led to about 20 provinces, called satrapies, which were governed by satraps possessing full military and civil powers. The conquered peoples owed tribute and military service to the king. So long as they fulfilled their obligations they were generously treated, being permitted to practice their own religion and manage their internal affairs; but disobedience was harshly punished by massacre or deportation. The imperial army consisted of the Median and Persian cavalry, archers and spearmen, and of the best troops of the subject peoples; the navy was drawn from the Greek states of Anatolia and from the lands of Phoenicia, Cyprus, and Egypt.

Supreme authority in war and peace was vested in the Persian monarch, whose absolute powers were tempered only by the custom of consulting his Persian officials. Darius was described as "the great king, king of kings, king of the countries possessing all kinds of peoples, king of this great earth far and wide." As the vicegerent of the Persian god, Ahura Mazdā, Darius laid claim to world rule.

Darius' first European expedition

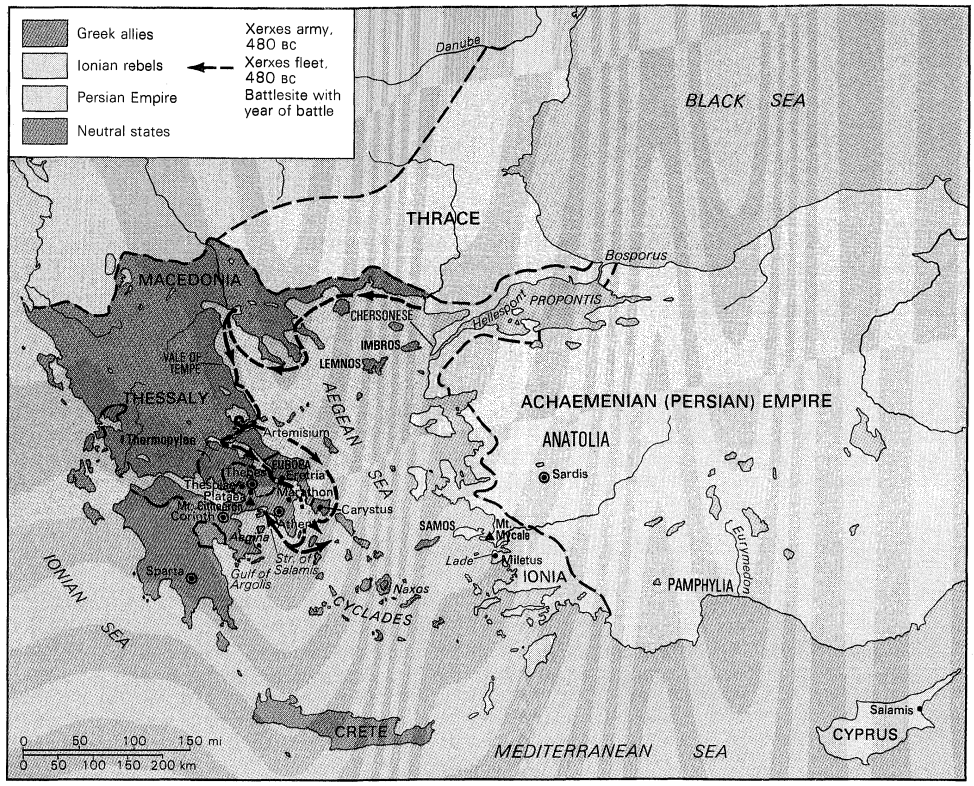
In 514 Darius prepared to conquer Europe. Having made a reconnaissance of Greece and Scythia, he decided to attack Scythia first and instructed a Samian engineer to build a pontoon bridge across the Bosporus. The imperial army overran eastern Thrace, crossed the Danube (where the navy of Greek contingents had made a pontoon bridge), and advanced far into what is now the Ukraine, probably in 513. The Scythians retreated until Darius outran his lines of supply and then harassed his forces when he turned back. The Greek commanders in the Persian navy, although asked by the Scythians to cut the bridge over the Danube, remained loyal to Darius, but some Greek states bordering the Bosporus and the Hellespont rose in rebellion at the news of his discomfiture.

These operations convinced Darius that a strong bridgehead in Europe was necessary. His generals punished the Greek rebels, established in southern Thrace a satrapy that cut off the Scythians from their Spartan allies, and received the submission of the king of Macedonia. Meanwhile, the Persian navy reduced Lemnos and Imbros (Imroz), and a Persian force was ready in 500 to attack Naxos, the strongest island in the Cyclades. This expedition was probably intended to pave the way for an invasion of Greece.

Ionian revolt (499–493 BC). When the Naxos expedition failed in 499, its promoter, Aristagoras of Miletus, instigated the Ionian states on the coast of Anatolia to rebel and obtained help from Athens and Eretria. In 498 their forces took and burned Sardis, capital of the satrapy; they were then joined by the Greek states of Cyprus, the Bosporus, and the Hellespont and by the Carians, while Athens withdrew its support. The Persians subdued Cyprus in 496, and the Bosporus and Hellespont by 495. Their naval victory over the Ionians at Lade in the same year, and the capture of Miletus in 493, virtually ended the revolt.

The Ionian revolt was of great value to the Greek cause. It postponed the Persian attack on Greece for a decade and showed the need of close cooperation and strong leadership. The Ionians had indeed created a council of deputies drawn from the individual states and had entrusted to it the direction of strategy, but they had failed to include in the council the Greeks of the Bosporus, Hellespont, and Cyprus, and they had not appointed a commander in chief of the allied forces until the eve of the battle of Lade, when it was already too late.

Persian attack on Eretria and Athens (490 BC). Darius punished the ringleaders in Asia by execution or deportation, but he made a liberal settlement with the states. Democratic governments were permitted, a moderate rate of tribute was imposed, and the states were required to submit their disputes to arbitration. This was politic,



Greece during the Greco-Persian Wars.

since Darius hoped to use the Ionian fleet against Greece. In Europe, his son-in-law Mardonius reestablished Persian rule in Thrace and reduced Macedonia, while his envoys visited the free Greek states to ask for "earth and water," the tokens of submission to Persia. In 491 Eretria and Athens were well informed that an attack by sea was impending.

Before the Ionian revolt Sparta and Athens had been at war, but the Persian threat brought them closer together. In 491 the Spartans tried to prevent their ally Aegina from joining Persia, and in 490 Athens attacked Aegina (the chronology is disputed). Athenian policy toward Persia had vacillated before and during the Ionian revolt, but the will to resist was now strengthened by the Persian support of the exiled tyrant Hippias and by the advice of Miltiades (*q.v.*), previously a ruler in the Chersonese, who had returned home with knowledge of Persian tactics. Even so, Sparta and Athens had no plans for united action when the Persian force, perhaps comprising about 25,000 fighting men, sailed across the Aegean Sea, landed on Euboea, and captured Carystus and Eretria. In September 490 the Persian army landed unopposed on the Plain of Marathon in northeast Attica, whence the lines of supply with Euboea and the east were easy and secure. The speed and the initiative of the Persians found Athens still isolated.

Battle of Marathon

The Athenian army was at Athens, prepared to repel any landing in its vicinity, and the small fleet was ready to attack any Persian convoy heading for Aegina. When news came from Marathon, a runner was dispatched to inform Sparta and the assembly decided on the proposal of Miltiades to send the heavy-armed hoplite army (infantry) to the foothills above Marathon. The decision was wise; for the alternative, to stay and defend Athens, would have cut Athens off from Sparta by land and sea, exposing the city to blockade. At Marathon, however, the ten generals (of whom each held operational command for one day, according to Herodotus) and Callimachus, the "polemarch" or nominal commander in chief, had to choose between attack and delay. Miltiades' advice prevailed: to attack as soon as opportunity offered. First the Athenians advanced their position to within a mile of the enemy by felling trees and making obstacles against the dreaded Persian cavalry. Then the opportunity came. Before dawn some Ionian deserters reported "The cavalry are away." Miltiades, who chanced to hold the operational command, attacked at dawn. With a thin centre and strengthened wings the line of about 10,000 Athenians and 1,000 Plataeans charged the enemy infantry before the cavalry could return. The Greek wings defeated the Persians and wheeled inward to attack the Persian centre, which had driven the Greek centre back. The longer spear and heavier armour of the bronze-clad Greek infantryman prevailed over the Persian with his short spear, wicker shield, and padded clothing. The rout was complete. According to Herodotus, the Greeks lost 192 men, the Persians 6,400. The majority escaped to the fleet, which sailed at once, hoping to surpise Athens, but the Athenians—by a forced march—arrived that evening to defend the city. The Persians then departed. A Spartan force, which had been delayed by religious observances at Sparta, arrived at Marathon too late to take part in the battle.

Expedition of Xerxes (480–479 BC). The Persian failure was followed by a full-scale invasion. It was delayed by a revolt in Egypt and the death of Darius until 480, when Xerxes crossed the Hellespont in late spring with a vast army and a large fleet. The advance was slow and the fleet had to provision the army. The Greeks therefore had ample time to make preparations. The problem of uniting the 30 states that had the will to resist Persia was solved by Sparta, which held a congress of delegates and formed a general alliance. The states agreed to stop all wars among themselves and conferred the command by land and sea on Sparta. The congress met regularly, each state having one vote, and decisions by the majority were binding on all members. It possessed recruiting, diplomatic, and judicial powers. In the field the commander in chief, who was nominated by Sparta, consulted the commanders of the national contingents but made his own decisions.

Thus the Greek congress was a highly centralized and efficient organization for allied action. Its chief strength on land lay in the Spartans and their allies; at sea it lay in the Athenians, ably led by Themistocles, who had increased the fleet to 200 ships. A coordinated defense on

both elements was now possible. It lay with Sparta to choose the time and place for applying the relatively small but excellent forces of the Greek congress.

The first decision, to hold the narrow Vale of Tempe between Macedonia and Thessaly, was abandoned when it was realized that the position could easily be turned. On news of this the Athenians voted, on the proposal of Themistocles, to entrust themselves to "the wooden wall" of their ships in accordance with an utterance of the Delphic oracle, and plans were made for evacuating the noncombatants. Next the Greeks occupied the still narrower pass of Thermopylae with 6,000 or 7,000 hoplites and stationed 271 ships at Artemisium in northern Euboea. The positions were linked by communication between the Spartan commanders, King Leonidas at Thermopylae and Eurybiades at Artemisium, who intended to halt and damage the Persian forces. Meanwhile, Xerxes was advancing slowly. He made no use of separate columns, and his fleet suffered heavy losses in a storm when it was convoying supply ships along the coast. It was already August when Xerxes began the operations, which extended over three days.

Thermopylae

On the first day he sent a detachment of 200 ships, unseen by the Greeks, to sail round Euboea and close the narrows of the Euboean Channel; and he also attacked with his best infantry at Thermopylae, where the Greeks inflicted heavy casualties. During the afternoon the Greek fleet, having learned about the Persian detachment from a deserter, engaged the main Persian fleet with some success. The Greeks intended to sail south that night and destroy the detachment next day, but a tremendous storm kept the Greeks at Artemisium and wrecked the 200 Persian ships off south Euboea. On the second day news of the Persian disaster was brought up by a reinforcing squadron of 53 Athenian ships. Xerxes attacked again with no success at Thermopylae, and the Greeks sank some Cilician vessels off Artemisium. That evening a Greek traitor, Ephialtes, offered to guide the Persians along a mountain path and turn the position at Thermopylae. The Persians' best infantry, called the "Immortals," were entrusted to him. At dawn on the third day they began to descend toward the plain behind the Greek position. Leonidas retained the troops of Sparta, Thespiae, and Thebes and sent the remainder south. He then advanced. Except for the Thebans, who surrendered, he and his men fought to the death. Meanwhile the Persian fleet attacked at noon. Both sides suffered heavy losses and the Greeks realized that they could only succeed in narrower waters. That evening, when the fall of Thermopylae was known, the Greek fleet withdrew down the Euboean Channel and took station in the narrow Strait of Salamis.

In September, Xerxes, joined by many Greeks north of Attica, burned Athens. The city was almost deserted, for the evacuation had been completed. The Greek congress decided to fortify the isthmus and keep the fleet forward at Salamis. This decision caused dissension among the ship captains. Many wished to retire to the Argolic Gulf. As a stratagem, Themistocles informed Xerxes of their desire; Xerxes, who saw the end of the campaigning season close at hand, sent 200 ships that night to cut the Greek line of retreat and posted the main fleet, numbering probably 1,207 ships, off the eastern exit of the Straits of Salamis. During the night the Greeks learned of his dispositions and intentions. Putting to sea at dawn they feigned a retreat, actually sending a detachment northward to look out for the 200 Persian ships, and their manoeuvres led the enemy to advance incautiously into the narrow waters where superior numbers were of little effect. Within the narrows the Greek ships, stoutly built for ramming, had room to manoeuvre against the congested stream of Persian ships, which, designed for boarding tactics, proved less handy under oar and fell foul of one another. The result was a complete triumph for Greek seamanship. The Persians fled in confusion. Soon afterward their fleet, still superior in numbers but not in morale, set sail for Asia.

That winter, while Xerxes departed to Asia, a large army wintered in Thessaly under the command of Mardonius. By skillful diplomacy he drew the Greeks forward in the summer of 479 to the northern foothills of Mt. Cithaeron near Plataea, where difficulties of supply forced the Greek army of 110,000 men to withdraw during the night. The withdrawal was disorderly and dawn found the army scattered. Mardonius at once attacked a group of 11,500 Spartan and Tegean hoplites who had halted on hilly ground. Their commander, Pausanias, undismayed by the swarms of Persian infantry, led his men downhill in close formation, charged at the double, and overwhelmed the enemy. When the Athenians came up after defeating the Thebans, the Greeks stormed the camp and the survivors of the Persian army fled. Meanwhile, the Greek fleet had passed to the offensive at Mycale on the Asiatic coast opposite Samos. The Persians refused battle, beached their ships, and joined a large supporting army, but the Spartan king Leotychidas landed his men farther north and attacked with complete success. The victories of Plataea and Mycale ended the Persian invasion.

Plataea and Mycale

Greek offensive (478–448 BC). The Greek triumph was due to Spartan leadership, Athenian loyalty, and Greek fighting power. The Spartans, however, had no desire to campaign in Asia, whereas the Athenians were ready to deploy their fleet in support of the Ionians. Hence arose the Delian League, formed by Athens as executive leader and by many Greek states on the islands and Asiatic coast, to defend Greek liberty and exact retribution from Persia. A series of successful operations culminated *c.* 466 in victory at the Eurymedon River in Pamphylia, where an allied force of 300 ships defeated a Persian army and navy. In 460 the Athenians and their allies supported Egypt in a successful revolt. But the Persian army returned to the attack; Egypt made a separate peace, and the Greeks, overconfident in their sea power, were trapped on the Nile and annihilated in 454. By this time the Athenians were at war with Sparta, but a truce on the Greek mainland enabled them to launch successful attacks on Cyprus in 450–449. A treaty of peace was concluded, probably in 448, by the Athenians, their allies, and Artaxerxes I of Persia that recognized the liberty of the Greek states in Europe and Asia and kept the Persian fleet out of the Aegean Sea.

Greece

A constitutional monarchy until 1974—though the reigning monarch fled the country in 1967 as part of a series of events that continues to mold the nation—Greece is a European republic stretching across the tip of the Balkan Peninsula from the Ionian Sea to the Aegean and including islands in both seas. Its area—50,960 square miles (131,986 square kilometres)—is about that of Czechoslovakia or North Korea, and its neighbours (clockwise from the northwest) are Albania, Yugoslavia, Bulgaria, and Turkey; its insular possessions stretch as far south as the major Mediterranean island of Crete (Kríti). Its capital is Athens (Athínai).

There is about Greece a vitality, all too often undisciplined, that makes many another European country seem tame, even dull, by comparison. This is evident immediately on sailing into a Greek port or crossing a Greek border: sounds, smells, movements, colours—the very tempo of things—conspire to heighten sensibilities and intensify expectations. But alongside all this is the serene coolness, even aloofness, of what remains in Greece from classical antiquity, the visible monuments of which constantly stand as a challenge to (if not even a rebuke of) contemporary endeavours.

The vitality of Greece and Greeks can be said to stem from the heady mixture over centuries of many peoples and ways of life. That land, now the home of about 9,000,000 persons, has long been "at the crossroads"—at that place in the Balkans where "three roads meet," where Europe, Africa, and the East converge, and at that point in time where the ancient, the medieval, and the modern coexist and conflict. The Greek is familiar with the Middle East: his language and food, to say nothing of his religion and history, are marked by exotic and even oppressive elements from Turkey, the Holy Land, Egypt, and beyond. But he is familiar as well with the more sober West, with the Europe to which the young go for training and for work, with the Americas and Australia to which so many have gone for a new home. Greeks, like the Jews whom they resemble in so many ways, have long been able to adjust themselves as merchants in many climes and to many ways of life. But, also like the Jews, they have preserved in their heart of hearts a vital memory of the homeland to which they yearn to return.

The crossroads

This homeland is as much a state of mind as it is a place to be found on maps. The yearning to "return," then, is almost as strong among those who have never left Greek soil as among those who find themselves abroad. Perhaps it is a yearning to attain that which has never been but which has always been aspired to. It is a yearning evident in the melancholy of Greek music, the nostalgia that can be heard even in the lively tunes and ballads sung on festive occasions. It is a yearning that can be heard as well in interminable conversations, especially those with which Greeks refresh themselves through the long cool nights that follow blistering summer days. And it is a yearning that can be seen in the faces and deeds of the Greeks, a yearning that makes it impossible for them "to leave well enough alone." A perpetual restlessness, much like that which was said to characterize the political life of ancient Athens, is evident, a restlessness that can continue subterraneanly despite surface conformity to the tyranny of the moment.

Indeed, there have been many tyrannies in Greece, tyrannies that are as much a part of the much-discussed "Greek experience" as (if not even the most frequent result of) their volatile democracies. Perhaps, it might even be said, memories of tyrannies remind Greeks of the unpredictability of human things, of the disaster that can follow upon prosperity, of the trials that even the most successful encounter from time to time. Life can be expected to be as hard, as unyielding, and as toughening as the soil and the sea from which Greeks have for centuries wrested their livelihood. But it can also be as enriching and as exciting as the landscape and the light for which Greece has always been celebrated and that can be seen, if not at this moment or place, then surely in a little while or down the road a few kilometres.

The following article surveys contemporary Greece. Additional information may be found in the articles on AEGEAN CIVILIZATIONS; AEGEAN SEA; ATHENS; BALKANS, HISTORY OF THE; BYZANTINE EMPIRE; CRETE; GREEK CIVILIZATION, ANCIENT; and the appropriate sections of VISUAL ARTS, WESTERN, and LITERATURE, WESTERN.

THE LAND

Topography. The Greek landscape is conspicuous not only for its beauty but also for its complexity and its variety. The dominant influence—as noted by Strabo, the great geographer of classical antiquity, and confirmed by a glance at the map—is the sea. An ever-present factor, the sea presses deep into the land in a host of arms and inlets, which are often separated by the rocky spines of peninsulas that thrust back into the sea and are continued in the arcs and clusters of beautiful islands across its surface. Only a small, wedge-shaped portion of the interior of modern Greece is more than 50 miles from the sea. Mountains are the second major element in Greek topography. They cover about three-quarters of the country's surface, forming a ribbed, interlaced network, trending generally from northwest to southeast, and enclosing numerous small basins. The basins—together with narrow valleys, small plains (spreading more extensively about river mouths), and a thin, broken coastal strip—form the third element in the relief, the lowland.

The three elements in the topography

In their combination and interaction, these three elements have been of immense significance in shaping national development: the rich soils of the basins nurtured agriculture and the first stirrings of civilization, but the mountains (while often serving as a barrier against invaders) constricted this social development to small, fiercely independent areas and impeded communications between them. The sea—as both history and the ancient stories attest—made for contact between the separate communities and stimulated contacts farther afield, although it also exposed the coastal regions to external attack. For the geographer these three elements, in local combination, are a convenient basis for a division of the contemporary Greek landscape into six natural regions.

The Pindus Mountains. The core region in Greek topography is unquestionably the rugged Pindus Mountains (Píndhos Óros) area of the northwest interior. Following the general northwest–southeast trend of the mountains of the Balkan Peninsula, the Pindus sweep down in a series of rugged, roughly parallel ridges from the Albanian and Yugoslavian frontier and are structurally a part of the Dinaric mountain system of those countries. This system of young fold mountains was created relatively late in geological time, and earthquakes continue to afflict the region as the mountain structures settle down. The highest point in this region is Smólikas Óros (*óros*, plural *óri*, "mountain"), 8,651 feet (2,637 metres) high. The mountain scenery, with jagged granitic peaks, wild gorges, and a succession of magnificent views glimpsed from winding roads, is justly famed.

Macedonia and Thrace. A number of topographic regions surround this mountainous core and are often penetrated by extensions of it. The northernmost division, roughly the regions of Macedonia and Thrace (Thráki), extends in a long, narrow east–west band between the north Aegean coast and the frontier with Yugoslavia and Bulgaria. It is bounded on the east by the Maritsa River (Évros Potamós; *potamós*, "river"), which marks the Turkish frontier, and consists of hills and forest-clad mountains interpenetrated by valleys, river basins, and alluvial plains. Along the Bulgarian border and beyond it rise the ancient crystalline rock structures of the Rhodope Mountains (Rodhópi Óri), against which the newer mountains of the Pindus were crushed during their formation. In the west, the three-pronged peninsula of Khalkidhikí (Chalcidice) forms a distinctive feature as it thrusts out into the Aegean. On the easternmost prong, Áyion Óros (Holy Mountain), is located Mt. Áthos, the site of the famous monastic community.

The Khalkidhikí peninsula and Mt. Áthos

The peninsula is separated from the rest of the coastal region by a fault line of structural weakness, marked by the lakes Korónia and Vólvi. Just to the west extends a large plain drained by the Vardar (Axiós) and Aliákmon rivers, whose swampy deltas are slowly pushing out into the nearby Thermaïkós Kólpos (*kólpos*, "gulf"). The forested Vérmion Óros and, beyond it, the barren inland basins around lakes Vegorrítis and Kastorías mark the boundary with the Pindus proper. Farther east is a succession of plains, often swampy; that of Sérrai, around the lower Struma (Strimón), and the deltaic plain of the lower Néstos are most significant. Inland basins of structural origin include that of the Pedhiás Drámas.

Central Greece. Central Greece lies to the south of Macedonia and Thrace and is lent character by four spurs that thrust out from the main Pindus mass, following the northwest–southeast trend of that region. A number of

distinctive basins and plains lie amidst these upland ribs. The northernmost, a rather broken spur called the Kamvoúnia Óri, runs along the coast of the Thermaïkós Kólpos and continues south to form the peninsula bounding one side of the Órmos Vólou (*órmos*, "bay"). One of its peaks is Mt. Olympus (Óros Ólimbos)—the mythical seat of the gods, whose often cloud-topped summit rises to 9,570 feet (2,917 metres), the highest point in Greece—and also the equally fine peaks of Óssa and Pílion (Pelion). The next spur on the west is the Óros Óthris range, which continues across the narrow Dhíavlos Oreón (Oreón Channel) in the northern sector of the long, narrow island of Évvoia (Euboea). Between the two spurs lie the ancient basins (formerly the site of lakes) of Thessalía (Thessaly), Tríkkala (Tríkala), and Lárisa, drained by the Piniós. Just to their south, the basin of Almirós, of similar origin, lies around the Órmos Vólou.

To the southwest, the third spur leaving the Pindus is that of the Oíti, continued in the Ókhi Óros of southern Évvoia. Just before the Oíti reaches the sea, near the head of the Maliakós Kólpos, lies the pass of Thermopylae (Thermopílai), scene of the famous battle of antiquity. The last (and perhaps the most important) of the four spurs thrusting down into central Greece is that curving away to the southeast through the twin-peaked mass of Mt. Parnassus (Parnassós). This mountain rises to 8,061 feet (2,457 metres) and was held to be the home of the muses. The view from its summit at sunrise, with a broad expanse of the heart of Greece gradually unfolding, is regarded as one of the finest in the world. The range continues as the backbone of the peninsula lying between the Vórios Evvoïkós Kólpos and the Gulf of Corinth (Korinthiakós Kólpos), and it reaches as far as Párnis Óros, just to the north of Athens. To its north lie the plains of Fokís (Phocis) and Voiotía (Boeotia) and around its southern tip lie the depressions of Attica (Attikí), hotter and more arid but with a strategic importance that helps to explain the rise of Athens.

Mt. Parnassus and its regional context

The Pelopónnisos. The entire southern portion of mainland Greece forms a peninsula lying to the south of the Gulf of Corinth. Technically, this region, the Pelopónnisos, or Peloponnese, also known as the Morea, is now an island, for the 3.9-mile (6.3-kilometre) Dhiórix Korínthou (Corinth Canal) cuts across the narrow neck of land formerly separating the Gulf of Corinth from that of Aíyina (Aegina). The Pelopónnisos consists of an oval-shaped mass with mountains rising to 7,800 feet and four peninsular prongs pushing out southward toward Crete. The limestone mass of the plateau of Arkadhía (Arcadia), where streams disappear underground in the soluble rocks, forms the heart of this mass, with the barren land of Taïyetos Óros (rising 7,897 feet, or 2,407 metres) extending southward to form the backbone of one of the subsidiary peninsulas. This mountainous core is surrounded by a thin fringe of fertile coastal plain in the north and west and by the larger alluvial depressions of Lakonía (Laconia), Messinía (Messenia), and Árgos, which head the inlets between the peninsulas to the south. The coast is indented and offers some fine harbours, and the whole region is noted for its wild beauty.

The western uplands and islands. The western side of the Greek mainland north of the Gulf of Corinth to the Albanian frontier and the offshore islands (the Ionian Islands; Iónioi (Nísoi) possess their own distinctive topography and regional character. This effect has been enhanced by the fact that the mountainous barrier of the Pindus lying inland and the ameliorating climatic influences from the west have led to historic isolation from the rest of Greece. Fertile basins are not as well developed as in some other parts of Greece because they are constricted by the parallel ranges of coastal mountains, but the mountain regions themselves, being adequately supplied with rainfall, are not so barren as elsewhere. Kérkira (Corfu), the island lying opposite the Albanian frontier, is the northernmost of the seven major Ionian Islands. It is fertile and well watered. The other islands, Paxoí (Paxos), Levkás (Leucas), Skorpiós, Itháki (Ithaca), Kefallinía (Cephalonia), and Zákinthos (Zacynthus), lie farther south. Lack of rainfall accentuates their gaunt, broken limestone relief, although Levkás and Zákinthos have sheltered eastern plains.

The Aegean Islands (Nísoi Aiyaíou). Just as ridgelike extensions of the Pindus interpenetrate the basins and coastal plains of mainland Greece, island groups, which are often further extensions of the same mountain chains, form distinct regional clusters in the Aegean Sea. In the northeast, the island region forms the most extensive—and, visually, perhaps the most attractive—of the physiographic divisions of Greece. In the north, off Thrace (Thráki), lie Thásos (an oval block of ancient mineral rocks similar in composition to neighbouring blocks on the mainland) and harbourless Samothráki (Samothrace), an island of volcanic origin. Límnos, situated midway between Asia Minor and Áyion Óros, is almost cut in two by the northern Órmos Pourniá and the deep southern harbour afforded by the Kólpos Moúdhrou.

Regional clusters of islands

To the southeast, the rocky but sheltered islands of Lésvos (Lesbos), Khíos (Chios), and Sámos lie close to the Turkish coast and are extensions of peninsulas on the coast of Asia Minor. Across the central Aegean, near northern Évvoia (Euboea), lie the Northern Sporades (Voríai Sporádhes), or "scattered" islands; their crystalline rocks are similar to those of the Greek mainland. Farther south, in the heart of the Aegean, lie the Cyclades (Kikládhes), "islands in a circle." These roughly centre on Dhílos (Delos) and represent the tips of drowned mountain ridges continuing the structural trends of Évvoia and the region around Athens.

Between the Cyclades and the Turkish coast, the Dodecanese (Dhodhekánisos) group, with Rhodes (Ródhos) the largest of a dozen major islands, have a varied geological structure ranging from the gray limestones of Kálimnos, Símí, and Khálki to the complete ancient volcanic cone that forms Nísiros. Finally, the long, narrow shape of Crete stands at the entrance of the Aegean in the extreme southern portion of Greek territory. Its harsh, rugged landscapes mark yet another extension of the fold mountains of the Balkan Peninsula.

Climate and drainage. The basically Mediterranean climate of Greece is subject to a number of regional and even local variations occasioned by the country's physical diversity. In winter the belt of low pressure disturbances moving in from the North Atlantic shifts southward, bringing with it warm, moist, westerly winds. Squalls and spells of rain ruffle the Aegean, but sunshine often breaks through the clouds. As the low pressure areas enter the Aegean region, they may draw in cold air from those eastern regions of the Balkans that, sheltered by the Dinaric mountain system from western influences, are open to climatic extremes emanating from the heart of Eurasia. This icy wind is known as the boreas. Partly as a result, Thessaloníki (Salonika) has an average January temperature of 43° F (6° C), while Athens has 50° F (10° C). *Shilok*, or warm winds, are similarly drawn in from the south. The western influences bring plentiful rain to the Ionian coast and the mountains behind it; winter rain also starts early, and snow lingers into spring. At Kérkira (Corfu), January temperatures average 50° F (10° C), and the island's average annual rainfall is 52 inches (1,300 millimetres), compared with the Athens total of 16 inches (400 millimetres).

In summer, when the low pressure belt swings away again, the climate is hot and dry almost everywhere, with the average July sea-level temperature approaching 80° F (27° C), although heat waves can push the temperature up over the 100° F mark for a day or so. Topography is again a modifying factor: the interior northern mountains continue to experience some rainfall, while all along the winding coast the afternoon heat is eased slightly by sea breezes. In other regions the hot, dry summers are accentuated by the parching etesian winds, which become drier and drier as they are drawn southward.

The quality of Greek light

In all seasons—perhaps especially in summer—the quality of the light is one of Greece's greatest treasures. Although the larger cities have not escaped the pernicious effects of industrial and vehicular pollution, the Greek atmosphere is generally pure and clear. The interplay of light and varied landscape is remarkable. The harsh white

limestone crags of the islands, contrasting with the deep blue of the Aegean waters and an equally powerful sky; the dusty green olive groves, the burnt-orange tiled roofs, and dazzling whitewashed walls of coastal communities; and the ever-present weathered stones of the country's great number of ancient monuments all add their own tones.

The drainage pattern of Greece is significantly influenced by the porosity and solubility of the rocks of the limestone regions; hence, seasonal downpours are often immediately lost through seepage and runoff. Much rainfall is also lost in rugged terrain of the geologically young northern mountains, where there is a tortured network of rushing mountain streams, often falling into narrow, spectacular gorges. Finally, the irregular, deeply penetrating coastline makes for short river courses. The overall effect is to produce short rivers with an erratic seasonal flow, virtually useless for navigation and limited for irrigation purposes. The Vardar, Struma, and the Néstos, which crosses Macedonia and Thráki to enter the northern Aegean, are the major rivers—but only because they drain large regions beyond the Greek frontier. A host of small and medium-sized rivers drain the rest of the country: the Aliákmon, the Piniós (running east across the main peninsula), and the Evrótas of the Pelopónnisos are noteworthy.

Plant and animal life. Like other Balkan countries, Greece is open to influences from several major biogeographic zones, with the major Mediterranean influences supplemented by plants and animals stemming from the central European interior. Hence, local topographic and climatic conditions also occasion great variety. On the mountain flanks, and in the north generally, the central European types of vegetation prevail. In central and southern regions and in narrow belts along the valleys of the mountains, about half the land is under scrub of various kinds; and maquis, the classic Mediterranean scrub complex—with oleander, bay, evergreen oak, olive, and juniper—is particularly well developed in the Pelopónnisos. Evergreen trees and shrubs and herbaceous plants are found in the lowlands, with the flowers offering brilliant patterns in springtime. Pines, planes, and poplars line the rivers, the higher slopes, and the coastal plains. Oak, chestnut, and other deciduous trees are found in the north, giving way at higher altitudes to coniferous forests dominated by the Grecian fir, in which clearings are carpeted in spring and summer with irises, crocuses, and tulips. Forests and scrub are found at the highest levels: the black-pine forests coating Mt. Olympus are particularly noteworthy.

The forested zones, especially in the north, harbour such European animals as wildcat, martin, brown bear, roe deer, and, more rarely, wolf, wild boar, and lynx. Animals of the Mediterranean regions include jackals, wild goats, and porcupines, all adapted to lack of moisture and to the heat. Birds include pelicans, storks, and herons, while many varieties winter in Greece from farther north. Reptile and fish life is rich and varied.

The human imprint. The large number of monuments dotted across Greece are testimony of the antiquity of man's attempts to wrest a living from this sometimes harsh environment. Contemporary patterns of settlement, especially in the rural areas, bear the marks of long centuries of development.

Village life remains a powerful influence. It nevertheless has a cosmopolitan nature—seen especially in the village-square discussions—and the modern cities have something of the village in their character. The rural communities themselves range from the little communities of the northern mountain interior, reminiscent of central Europe, to the sun-beaten villages of Crete, which are almost African in appearance. Although rural settlement patterns reflect the vagaries of physical geography and the changing currents of history in a particular region, the tiled roofs, low, whitewashed walls, long, narrow windows, the central church, and the traces of fortifications are frequent features of village communities. Between villages, the ancient stone walls and winding roads add their own character to the landscape.

Yet town and city life is becoming increasingly important, and more than half of the people were classified as urban in the early 1970s. The metropolitan sprawl centred on Athens (home of over 2,500,000 people) is one of the great urban complexes of the Mediterranean, complete with industrial and port facilities. The port of Thessaloníki, with a metropolitan population close to 550,000, is the second major urban centre. There is then something of a gap, for the next half dozen or so major centres—often ports—have populations generally falling between 50,000 and 100,000. Urbanization and the modernization of the economy—especially improvements aimed at the influx of tourists—are also leaving their mark on the traditional Greek landscape.

THE PEOPLE

Linguistic, ethnic, and religious background. Despite the great variety of influences that have shaped modern Greece, and the marked differences among the many isolated regions, a sense of community binds the Greeks together, especially in a national emergency, such as World War II. A common religion, a great heritage, and a common popular tongue (variations in regional dialects notwithstanding) tend to make all Greeks feel that they are somehow one people equal to each other in important respects. Combined with this sense of equality is the interest in, and appetite for, political discussion.

The sense of community

All but about 5 percent of the populace adheres to the Greek Orthodox Church (see EASTERN ORTHODOXY). This body appoints its own ecclesiastical hierarchy and is headed by a synod of 12 metropolitans under the presidency of the archbishop of Athens. The Greek Church has links in dogma with the other Orthodox churches. The Muslim minority, just over 1 percent of the populace, is mainly Turkish and is concentrated in western Thráki and the Dodecanese. Roman and Greek Catholics (concentrated in Athens and the western islands formerly under Italian sway) account for less than 0.5 percent, and there are a few thousand adherents of Protestant churches, the Gregorian Rite of the Eastern Church (mostly Armenians), and Judaism, the last named being much reduced in numbers by the German genocide of World War II.

In terms of ethnic composition, Greeks again make up all but 5 percent of the total, the remainder being composed of Macedonians, Turks, Albanians, and Romanians. Except in Cyprus, southern Albania, and Turkey, there are no major enclaves of Greeks in nearby foreign countries, although Greek communities play a distinctive role in Europe, the Western Hemisphere, and Australia.

Demographic trends. The Greek population has never displayed the high rates of growth attributed to it by some analysts, although—despite grievous losses in a succession of wars and constant emigration as a result of poor economic conditions—it has usually shown a regular increase since the first census, in 1828. Most of its growth in the years since it gained its independence from the Turks resulted from two factors—annexations of surrounding areas (the Ionian Islands; Thessalía [Thessaly] and Árta; Ípiros [Epirus], Macedonia, and Crete; Thráki [Thrace]; and the Dodecanese) and the influx of more than 1,000,000 Greek refugees from Asia Minor in the 1920s. Emigration continues to be a limiting factor, the most active periods having been 1911–15 when nearly 130,000 persons left, 1956–60 (160,000), and the decade of the 1960s (830,000). The commonest destinations of the emigrants are the United States, Canada, Australia, and, most recently, West Germany, which has also attracted the largest number of the 300,000 Greeks working temporarily in western Europe. Vital statistics are comparable to those of the developed countries of Europe —deaths are 8.5 and births 16.1 per 1,000 annually, giving a natural increase of 7.6 per 1,000. Higher birth rates after World War II, however, have produced a youthful population: about 25 percent are less than 15 years of age and 45 percent less than 30. Along with population growth, urbanization has been a most important factor, especially since World War II. The rural component has shrunk to about one-third of the total. All these factors have had important social and political implications. The average density of population is about 175 per square mile (68 per square kilometre), although the variation in natural conditions makes the average rather meaningless. It is perhaps more significant to note that more than eight out of every 10 Greeks live on the main peninsula, and in 1971 more than one Greek in four lived in the Greater Athens area. (G.An.)

THE NATIONAL ECONOMY

Although Greece is a Balkan country, its principal economic links are with the United States, the European Economic Community (EEC; Common Market), of which it is an associate member, and the Organization for Economic Cooperation and Development (OECD), of which it is a member. Trade with the Socialist bloc and with Yu-

goslavia has increased, however, and by 1974 about 16 percent of Greece's annual exports were going to those countries; they account, however, for only 5 percent of imports into Greece. With a population of only about 9,000,000 and a relatively low annual income per capita, Greece is not an important country industrially or in international trade. In the world of international shipping, however, Greek owners occupy an important place. If tonnage actually controlled by Greek nationals (as opposed to tonnage flying the Greek flag) is considered, the Greek fleet of about 4,380 ships, aggregating about 43,630,000 tons gross by 1976, was the second largest in the world (after Liberia). The fleet flying the Greek flag ranks fifth in the world, with more than 2,740 vessels aggregating 22,530,000 tons.

The extent and distribution of resources. *Mineral resources.* Greece's total mineral and quarry deposits are estimated at between 5,000,000 and 10,000,000 tons. There are important reserves of bauxite, lignite, and chromiferous iron, while the main quarry products are ceramic clays, gypsum, asbestos, and the famous Greek marble. Oil has been drilled for in several parts of the country, but commercially exploitable fields have not been found except in the northern Aegean Sea, and these have led to disputes with Turkey.

Greece is one of the main bauxite-producing countries in Europe. Proved reserves in mainland Greece amount to 40,000,000 tons, and probable deposits are estimated at more than twice as much. Output (mainly for export) doubled in the 1960s to approach 2,000,000 tons a year. A substantial and increasingly larger portion is used in the local production of alumina and aluminum metal. Total lignite (brown coal) reserves are estimated at 1,000,000,000 tons. About three-quarters of the lignite mined is used by power stations, the remainder for the manufacture of chemical fertilizers and domestic fuels. Ordinary iron ores and ores with a chrome and nickel content are present, but only the latter are exploited.

Biological resources. About 30 percent of the total area of Greece is arable land, about 40 percent is rough pasture land, 20 percent is forest, and the remainder is either unsuitable for cultivation or is unexploited.

In spite of the natural poverty of the soil and a system that leads to excessive fragmentation of the land (the average parcel is only about 1.4 acres, or 0.56 hectare), Greece is still essentially an agricultural country, about half the working population being directly engaged in farming and related activities. Agricultural products account for more than half the total exports, though Greece also imports substantial amounts of food.

Principal crops

The chief crops are wheat, cotton, tobacco, currants and seedless raisins, grapes, olives, and citrus fruit, production of which grew rapidly in the 1960s, partly owing to United States aid. Attempts are being made to improve dairy and meat production. Forestry is not important, though progress has been made in restoring the forests that were severely depleted during World War II. The very long coastline and numerous islands help nourish an important fishing industry. With the modernization of the fishing fleet and the extension of refrigeration and processing facilities, output has increased; the once-important sponge-diving industry, on the other hand, has declined in the face of competition from synthetic products.

Power resources. Waterpower and lignite are the most important power resources in Greece, about 70 percent of the electric power being derived from them. A power station at Megalópolis in the Pelopónnisos successfully utilizes lignite of remarkably low calorific value and high moisture content. This plant has interested specialists in other countries dependent upon low-grade lignite deposits. Surveys are still being carried out (with United Nations aid) with the aim of developing more hydroelectric stations, and the establishment of a nuclear generating plant has been under consideration.

Sources of national income. *Agriculture, forestry, and fishing.* The agriculture, forestry, and fishing sector accounted for 31 percent of the gross domestic product (GDP) in 1958, but thereafter it declined steadily. The decline was caused by the drift of workers from the land, either to other employment in Greece or to work abroad. In the period from 1961 to 1971 employment in agriculture declined at an average annual rate of 1.4 percent. Productivity, nevertheless, has been growing faster in this sector than in industry and in the services sector. As a result, agricultural production actually increased on average by nearly 3 percent a year in the period from 1965 to 1970, notwithstanding its decline as a proportion of total national output. Despite the comparatively more rapid growth of productivity in agriculture, however, its level of productivity is still a good deal lower than that of the average in other sectors—a factor experienced by the agricultural workers themselves as poverty. In an attempt to alleviate this, the government has tried to shift the emphasis away from excess production of wheat and tobacco to more profitable crops, notably cotton. Wheat subsidies were abolished in favour of a system of intervention price that sets a minimum selling price guaranteed by the government, which will buy wheat if prices fall below it and sell such purchases at free market prices. Farmers have also been compensated for loss of income by the waiving of debts and by grants to help pay for seeds, fertilizers, and agricultural machinery.

Government intervention in agriculture

Mining and quarrying. The mining and quarrying sector employs about 0.6 percent of the total labour force and accounts for just over 1 percent of the GDP. According to the industrial census of 1969, the number of mines and quarries (including quarries of building materials) and of solar-evaporation salt plants was 1,604, and average annual employment was 22,600 workers. In 1973 the value of the mining output was equivalent to 5.6 percent of total industrial output. In volume terms, more than one-half of the total output is accounted for by lignite production. The mining of bauxite is playing an increasingly important part in the economy, though if production of aluminum reaches the level planned for the mid-1970s, bauxite may have to be imported.

Manufacturing. Manufacturing output has tended to expand at a rate of about 10 percent per annum, but, largely because of the rapid growth of the services sector, manufacturing output as a proportion of the GDP remained around the level of 16 percent during the early 1960s; by the mid-1970s, however, it had risen to more than 25 percent of the GDP. Employment in the industrial sector as a whole (including building, mining, power production, and manufacturing) grew in the 1960s at an average annual rate of just over 4 percent, and over the latter half of this period productivity grew at the rate of 4.3 percent a year.

The main branches of industry are food processing, textiles, chemicals, steel, aluminum, and handicrafts. Athens and Thessaloníki are the main industrial centres, but government policy is to encourage industry to develop in other areas as well. The main change in the pattern of industry, however, has been the establishment of large industrial complexes, notably the huge Esso–Pappas complex at Dhiavatá, near Thessaloníki, which started production in 1966. Steel production is about 600,000 tons a year. The French-owned Pechiney complex at Dhírfis (Delphi) produces large quantities of aluminum for export. Another important industry, located at Elevsís (Eleusis), near Athens, is shipbuilding and ship refitting.

Products of industry

Energy. Electricity and gas production accounts for 2 percent of the GDP. In 1950, when 665,000,000 kilowatt-hours of electricity were produced, only 823 towns and villages in Greece were supplied with electricity; the Athens area accounted for 84 percent of the country's total consumption. In that year was founded the Public Power Corporation, on the initiative and with the aid of the United States; its first plant started operating in 1953. By 1970 a further 6,657 remote villages were receiving electricity, and the output was 9,000,000,000 kilowatt-hours; Athens then accounted for only 40 percent of consumption. Greece is still heavily dependent on imports for fuel supplies.

Financial services. The central bank is the Bank of Greece, founded in 1928. The bank is privately owned, but the governor is appointed by the government, and the state has a share in the profits. The Bank of Greece

is also the sole bank of issue, and it supervises all banking operations in the country, implementing the decisions made by the Currency Committee. Consisting of the governor of the bank and the ministers of coordination, finance, agriculture, and industry and commerce, this body formulates all monetary, credit, and foreign-exchange policy.

There are eight commercial banks, which are private competitive institutions. In addition to undertaking short-term financing, they extend long-term loans to industry and trade and sometimes take up shares in the equity capital of industrial firms. Two of the commercial banks have also set up special investment banks. There are also an agricultural and a mortgage bank. The latter, besides granting housing loans, arranges for loans to public corporations and to the tourist sector of the economy. Long-term industrial development is also promoted by the Hellenic Industrial Development Bank, which is wholly state owned and endowed with government funds. The capital market is still relatively underdeveloped, though a number of measures have been introduced to improve matters. There is one stock exchange, located in Athens, in which there is active trading in about 30 banking and commercial shares.

Foreign trade. Over the 1960s exports more than doubled, as did imports. Exports also increased at a somewhat faster rate than imports; however, because imports were generally about three times as large as exports, the trade gap grew steadily throughout the decade, until it was equivalent to more than 18 percent of national income. An encouraging feature of trade trends in the second half of the 1960s was the growth in exports of industrial and handicraft products; exports of aluminum were particularly important. Exports of tobacco, once Greece's largest export earner, declined, and the market appears to be saturated. Items of capital equipment and fuel accounted for an increasing share of imports, but imports of manufactured consumer goods (and also food) also expanded, in spite of government attempts at restriction. The resulting inflation contributed to the fall of the military junta in 1974.

The widening trade gap

Although the Greeks have expressed dissatisfaction from time to time at the effects of their association (as associate member) with the EEC, trade with this area has grown steadily since 1964, when EEC countries absorbed 38 percent of Greek exports and supplied 42 percent of imports. West Germany is Greece's main trading partner, taking about 19 percent of the country's exports and supplying 20 percent of its imports.

Although Greece has a persistent and increasing trade deficit, the balance of payments is helped by a steady surplus on invisible services, notably shipping, foreign tourism, and funds sent back home by workers who have emigrated to other countries.

Management of the economy. *Private enterprise and the role of the government.* The Greek economy remains predominantly one of private enterprise, with the state limiting its intervention to the field of tax incentives, cheap finance, and its own or bank guarantees to overseas suppliers (and then only for large projects). With the exceptions of electric power, railways, telecommunications, and broadcasting, the state produces neither goods nor services, and its policy is to refrain from activities that can be undertaken effectively by private firms.

It has been official policy to aim at a surplus on the ordinary budget and to use this surplus to finance part of the deficit on the public investment budget, the rest of this deficit being met by domestic issues of bonds and interest-bearing treasury bills and by borrowing abroad. Direct taxes contribute about 20 percent of the total revenues of the Greek fiscal system; between 1957 and 1966 direct taxes on households rose by more than 8 percent annually. Over the same period net indirect taxes rose on average by more than 13 percent, and their share in the total gross national product at market prices rose from 9.7 percent in 1957 to nearly 14 percent 10 years later. In the 1970s policy appeared to aim at more efficient collection of existing direct taxes instead of alteration of the fiscal structure as such.

Taxation

Trade unions and employer associations. The military government dissolved most trade unions and deported many union leaders soon after it came to power in 1967. After the fall of that government, trade union activity revived. The interests of employers are promoted by the Federation of Greek Industries, founded in 1907, and by the Federation of Shipowners and Industrialists. There are chambers of commerce in Athens, Piraiévs (Piraeus), and Thessaloníki.

Economic policies. The broad aim of economic policy is to secure growth through augmenting the share of industry in national output, while keeping prices as stable as possible. Since 1967 great emphasis has been put on the latter objective, and prices were held down by administrative measures for three years. Beginning in 1970, however, prices began to edge upward. In agriculture, the aim is to raise productivity through switching to more profitable crops, and the government no longer subsidizes the growing of wheat and tobacco at uneconomic prices. Under the first Five-Year Plan of the military regime of 1967–74, investment in infrastructure, in tourist facilities, and in industry was meant to be considerably increased, and the primary source of finance for the projected investments was intended to be found in domestic budgetary savings.

At the same time, however, great efforts were made to encourage private foreign investment. This was done not only in order to supply much-needed investment capital and technical and managerial expertise but also to balance the external-payments account by meeting the current deficit with a large inflow of capital. The government also did all it could to promote tourism and shipping, which are major sources of earnings.

In October 1975 a flexible Five-Year Plan (1976–80) was outlined, aiming at a 6 to 7 percent annual growth rate during the plan period and providing for fuller use of domestic energy resources, exploitation of mineral resources, and more active solicitation of foreign investment involving export industries.

The chief economic problem for Greece is the age-old one of lack of natural resources. The structure of employment and of the national income shows Greece's great dependence on secondary economic activities: only about 25 percent of the working population is engaged in manufacturing and construction, and very nearly half of the GDP is generated in the services sector. This leads to a persistent balance-of-payments problem, and foreign indebtedness has grown steadily.

Resource scarcity

(E.I.U./Ed.)

Transportation. Not unexpectedly, the Greek landscape and seascape have had immense effects on the development of transportation patterns in the country and perhaps help to account for the pre-eminence of Greek names in the world of international shipping. The needs of tourism, military and political considerations, and the general economy have helped stimulate the development of a modern national transport system.

Sea transport. The importance of Greek (and Greek-owned) shipping fleets in national and international trade was noted above. Partly as a result, there has been strong emphasis on port development. Piraíevs (Piraeus), the port of Athens, is the major centre, followed by Pátrai, Préveza, Iráklion, Kaválla, and Vólos, among others. There is a developed steamer service to the various islands, and car ferries ply across many of the straits and inlets. Cruise ships and private vessels add to the demand for service facilities at ports.

Road transport. About 50 percent of the road network remains unpaved, and many of the smaller rural roads, especially in the mountain regions, still leave much to be desired. The Athens–Pátrai, Athens–Lamía, and Athens–Thessaloníki highways are modern roads, and the total amount of paved road tripled during the 1960s. There is also an extensive network of rural bus routes.

Railway transport. Extensive modernization has been effected in the Greek railway system, the aims being to improve the existing tracks, to standardize differing metric gauges, to forge links with western Europe, and to coordinate development with that of the roads. The

Greek topography and a late start (railways date only from the 1880s, and Greece was one of the last European countries to develop them) have made this modernization costly and difficult.

Air transport. Air transport is operated by the government-owned Olympic Airways, which took over the financially troubled Greek National Airlines (founded 1951) in 1957. Increasing tourist traffic has resulted in a major expansion of facilities. Athens has a modern air terminal, regional facilities have been improved, and there are new airstrips on some of the islands. **(G.An.)**

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. *The constitution.* The military junta (1967–74) ruled under a constitution approved in 1968 by a referendum held under martial law and preceded by a vigorous campaign in its behalf in the censored press. Political activity was prohibited, and the junta ruled by decree.

The republic

On June 1, 1973, the junta decreed that the monarchy was abolished and replaced by a republic. This was confirmed by popular referendum on July 29, but the validity of this referendum was challenged. After the fall of the junta and the restoration of democratic government, another referendum was held, on December 8, 1974, and 69.2 percent of those voting chose "uncrowned democracy."

On August 1, 1974, the prime minister, Konstantinos Karamanlis, announced that the constitution of 1952 would be reintroduced as a provisional measure until, in his words, "the country acquires a charter fully approved by the people."

The powers of head of state were to be exercised by the president of the republic. The word king in the constitution was replaced by the word president. Under the constitution of 1952 the government had full control over the armed forces, and the judiciary was free.

The draft of a new constitution was published on December 23, 1974, after endorsement by the full Cabinet. It provided for Greece to be a parliamentary republic, with a president as head of state and supreme commander of the armed forces. Legislative power was to be exercised jointly by the president and Parliament, the latter a unicameral body composed of 200 to 300 deputies (the exact number to be determined by Parliament itself) elected for five-year terms. The freedom to form political parties was guaranteed.

The president was to be elected by Parliament for a five-year (later reduced to four-year) term, and he was eligible for a second term.

The president was to appoint as prime minister the leader of the party with an absolute majority in Parliament; if such did not exist, other methods were prescribed. The draft constitution would also create an advisory body, the Council of the Republic, to consist of elder statesmen and the current leaders.

Administration. The Cabinet is composed of the prime minister and ministers of foreign affairs, national defense, coordination and planning, public order, culture and science, justice, national education and religion, employment, social services, interior, finance, agriculture, industry, commerce, public works, transportation and communication, and mercantile marine. There are also a minister for northern Greece and a minister to the prime minister.

Dhiamerísmata and *nomoí*

Officially, Greece is divided administratively into 10 *dhiamerísmata* (regions), although only four (and part of a fifth) have their own governments. A further subdivision is into more than 50 *nomoí* (departments; singular *nomós*); special arrangements are provided for the Greater Athens area, and the peninsula of Áyion Óros (Mt. Áthos) is a self-governing monastic community with a civil governor, appointed by the government, who is responsible for public order outside the monasteries.

Municipal government, with elected mayors and urban and rural councils, was established in Greece in the mid-19th century. Local authorities may levy certain taxation, but, in general, provincial services are supported by the national government.

Political parties. After the downfall of the military junta in 1974 and the restoration of democratic government, two decrees, published on September 23, 1974, authorized the resumption of party political activities in Greece. Four major new parties emerged:

The Centre Union–New Forces Party, a merger of the Centre Union and the Movement of New Political Forces. The Centre Union represented the rump of the Greek liberal movement, the Centre Union Party (founded in 1961) of Georgios Papandreou. The new Movement of New Political Forces was founded to campaign for policies of "democratic socialism."

The New Democracy Party, founded by Konstantinos Karamanlis. It was pledged to work for the establishment of democracy in Greece through political, economic, and social reforms.

The Pan-Hellenic Socialist Movement (Pasok), incorporating two resistance organizations and founded by Andreas Papandreou, son of Georgios Papandreou. Its platform called for a non-aligned foreign policy (opposed to both the North Atlantic Treaty Organization and the EEC) and nationalization of private enterprises.

The United Left, a union of the United Democratic Left (EDA) and the two factions of the Communist Party of Greece (KKE). The EDA had been founded originally in 1951.

There were also a number of smaller parties representing various right-wing groups and groups that favoured the restoration of the monarchy.

New Democracy Party in power

Parliamentary elections were held on November 17, 1974, the first since 1964. The New Democracy Party of Karamanlis won 54 percent of the votes cast and a very large majority of the seats in Parliament; the next largest number of seats went to the Centre Union–New Forces Party (20 percent of the vote). On December 9, 1974, the Greek Parliament met for the first time in seven years.

The port of Palaiá Epídhavros (Epidaurus), Greece.

Justice. The Supreme Court consists of four sections, three civil and one criminal. There are 11 courts of appeal, having jurisdiction in cases of criminal and civil law of second degree; in exceptional cases they may also adjudicate in cases of first degree. Below these are the 58 courts of first instance, which function also as criminal courts. They have jurisdiction in cases of first degree and, in exceptional cases, second degree. Criminal and juvenile courts exist in towns where courts of first instance sit. Some towns also have tax courts. There are many courts of justices of the peace throughout Greece, and also magistrates' (police) courts. District attorneys function in all courts except justices of the peace and magistrates'; in magistrates' courts the duties of district attorney are carried out by a public prosecutor.

Procedure in the courts follows the French model; *i.e.*, the investigating magistrate examines the evidence and

interrogates witnesses and, if he decides that there is a prima-facie case, refers it to the public prosecutor, who decides whether or not a charge shall be brought. Judges of the higher courts are appointed for life, and others may be removed only if convicted of a criminal offense.

In addition to the regular courts, there is a State Council, having jurisdiction over administrative disputes, administrative contraventions of law, and revision of disciplinary procedure on permanent civil servants.

Police. There are two main bodies of police, the city police (in Athens, Piraiévs, Pátrai, and Kérkira) and the gendarmerie, the latter a paramilitary force with responsibility for the whole country outside the four cities. Both forces are administered by the minister of the interior. The police forces were reorganized by a British mission after World War II. The gendarmerie and city police provide personnel for the tourist police. In addition, there are small forces of farm police, customs guards, and forest police and a Harbour Corps.

Armed forces. The Greek armed forces consist of an army, navy, and air force recruited on the basis of compulsory military service for all male citizens aged 21, for a period of two years. There is also a National Guard recruited from reservists for local security duties in frontier districts.

In 1967 a clique of army officers, mainly colonels, seized power in Greece by means of a coup d'etat. After the restoration of parliamentary government in 1974, Prime Minister Karamanlis stated (December 11), in a policy announcement, that the aim of the government would be to modernize the armed forces and ensure that they "recovered their concord and discipline." A gradual review of all members of the armed forces was begun, and in March 1975 a reorganization got under way. Clearly, it would be some time before the government could be confident of the loyalty of the military services.

Social conditions. Wages in Greece are low by reason of chronic rural underemployment and because the low agricultural income leads many young peasants to seek employment in the towns and there swell the ranks of unskilled labour. Minimum wages are fixed by the Ministry of Employment.

The Workers' Housing Organization, an agency of the national government, constructs housing and also provides technical assistance and loans for home building. Its projects are largely financed by a national lottery.

Health. After World War II the government took the lead in combatting disease, establishing modern health services and facilities. Malaria, once a scourge, has been virtually eradicated, and standards of hygiene and sanitation have been greatly improved. In the larger cities and towns the water supply is generally safe, though the same claim cannot be made for rural areas. Health measures taken in conjunction with the World Health Organization have been responsible for a great decline in deaths from infectious diseases. The main causes of death are cancer, cerebrovascular disease, and senility.

The Ministry of Social Services is responsible for the maintenance of hygiene, malaria control, establishment and financing of health and medical care centres and pharmacies, and for providing drugs, maternal and child care, and mental care. The large hospitals are concentrated in Athens, Thessaloníki, and Pátrai.

Social insurance. In 1968 the government unified the complex social insurance schemes, which are now controlled and supervised by the Ministry of Social Services through the Social Insurance Institution (IKA), the Unemployment Insurance Organization, the Farm Insurance Organization, and several separate main and auxiliary semi-public funds. The IKA insures workers in government, business, and industry, some agricultural workers, nonfarm self-employed persons, and domestic workers. The main and auxiliary funds offer insurance programs by occupation—*e.g.*, a fund for seamen, a fund for newsboys in Thessaloníki.

Social Insurance Institution (IKA)

Social insurance costs are largely financed by contributions paid into IKA by employees, in the form of payroll deductions, and by matching contributions from employers. Taxes on manufactured products and income from investments made by the insuring agency also help pay for social insurance.

Education. Education is the responsibility of the state, through the Ministry of National Education and Religion, policy being formulated by a Supreme Board of Education. In 1964 a new Education Act introduced radical changes, making school attendance compulsory till the age of 15 and covering both primary school (six years) and part of secondary school (three years). It also made demotic Greek (the colloquial language) the main language of instruction throughout the school system. The military junta in 1967 practically abolished the act of 1964, requiring attendance at school for only six years and reinstating Katharevusa (the literary language) as the principal teaching medium.

Junior secondary schools offer a three-year program, either a general academic course or a more technically oriented course, the former intended for students who plan either to end their education with secondary school or to continue in higher education, the latter for those planning to enter higher technical or vocational schools. Beyond the junior secondary schools are the advanced secondary schools, also offering a three-year program.

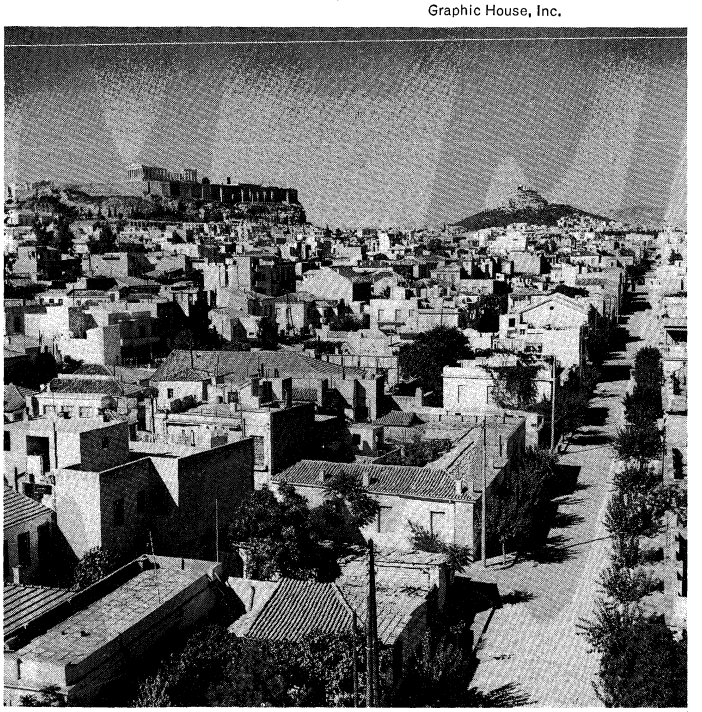
Universities

For higher studies there are universities at Athens (National Capodistrian University of Athens, founded in 1837, and National Technical University of Athens, founded in 1836) and at Thessaloníki (Aristotelian University of Thessaloníki, founded in 1925). The University of Ioánnina (1964) and the University of Pátrai (1966) are newer institutions. Athens also has a number of higher schools with university status: the Higher School of Fine Arts (1836), the Athens Graduate School of Economics and Business Science (1920), the College of Agriculture (1920), the Graduate School of Industrial Studies (1938), the American School of Classical Studies at Athens (1881), the Panteios School of Political Sciences (1930), and Pierce College (1875). The Graduate School of Industrial Studies at Thessaloníki (1958) also has university standing. (Ed.)

CULTURAL LIFE

The physical remains of the culture of ancient Greece, whether preserved *in situ*, in the fine network of museums, or (as a result of past activities) in the museums of other countries, are an ever-present reminder of the country's classical heritage. It continues as an important element in the culture of contemporary Greece and plays

Graphic House, Inc.



The Acropolis (background), in Athens.

a major role, through its attraction to tourists, in the economy. In addition, the deep religious traditions of the country—which found rich expression in the medieval icons and in the mosaics and frescoes that made the 14th century one of the triumphant eras of Byzantine art—continue to provide a fertile cultural source, generating a great variety of contemporary folk art and religious festivals. These are at their most vigorous in the rural areas generally and in the remoter regions in particular. Easter is the major event in the Orthodox calendar, and the sombre processions of Good Friday are followed by the festivities—including roasting of lambs and dancing in traditional costume—celebrating Easter Sunday. Other religious ceremonies occur throughout the year, beginning with the New Year blessing of the sea at Piraiévs (Piraeus) and elsewhere. The summer months are renowned for international music and drama festivals, particularly at Athens and Palaiá Epídhavros (Epidaurus). A revival of Byzantine iconography may be seen in the work of such artists as Fotos Contoglou and Stathis Trahanatzis as well as in the restoration of medieval frescoes and mosaics. The traditional Karankiózis puppet theatre is preserved by such masters as Panayioti Mixopoulos.

Modern Greek writers

Modern Greek poetry is considered by many to be among the best of the 20th century. Poets of international renown include Constantine Cavafy (who spent most of his life in Egypt), George Seferis (who won the Nobel Prize for Literature in 1963), Angelos Sikelianos, Odysseus Elytis, and Yannis Ritsos. Another remarkable writer was Nikos Kazantzakis, who experimented with several forms of expression. Contemporary Greek literature is fortunate in its English translators, especially the Americans Kimon Friar, Edmund Keeley, Themis Vasils, and Theodora Vasils.

The Greek character is reflected in the opening verses of the "Hymn to Liberty" written by the 19th-century poet Dhionísios Solomós. These lines, set to the stirring music of N. Manzaros as the national anthem of Greece, read (in a prose translation by Theodora Vasils),

> I know you by the sword's dread cutting edge, I know you by the look that with vigour measures the earth. Out of the sacred bones of the Hellenes you issue valiant as before, hail o hail, Liberty! You dwelt therein, sorrowful, withdrawn, waiting for a mouth to tell you, "Come again." That day was long in coming, and all were silent, cowering under the terror and the crush of slavery.

The other great "national" song of the Greeks is the fervent Resurrection hymn attributed to an 8th-century monk, St. John of Damascus,

> Christ has risen from the dead, by death trampling upon death, and has upon those in the tombs life bestowed.

The music of these two hymns, a millennium apart in composition, is both joyful and haunting. The listener is reminded of Greek nostalgia, of the deepest fears and hopes of the Greeks and indeed of all mankind.

Greek musicians with international followings include Manos Hadjidakis and Mikis Theodorakis. After the fall of the military regime in 1974 there was a revival in Athens of an irreverent political theatre as well as of the film industry. It remains to be seen what effect a decade of suppression will have on young literary talent. It also remains to be seen what effect the constantly growing tourist industry will have on the cultural integrity of the country.

THE OUTLOOK

The future of Greece remains in serious question, and in the decades ahead the fundamental alternatives facing the Greeks may be the exciting dangers of Balkan and eastern Mediterranean politics or the complacent prosperity of a closer association with the European community. Forces may already be at work among the Greeks that compel them toward further urbanization and industrialization and toward greater exposure to the homogenizing (if not demoralizing) "culture" of the international mass media.

Continuity with the past, a very long past, remains Greece's burden as well as its glory. The past and its significance are often obscure but always present. Their very language constantly reminds Greeks both of what they have been and of what they have aspired to. The ramifications of old influences go deep and are unpredictable; they seem to make permanent solutions impossible, so long as Greece retains its identity. Perhaps it is true for all peoples that there are no "permanent solutions" and that most of what can be done in the present depends intimately on what has happened in centuries past. But these limitations upon self-determination are much more evident in Greece than in most other countries. After all, the light of Greece has long been known to make many things clearer there than they are likely to be elsewhere. (G.An.)

BIBLIOGRAPHY. The most comprehensive single-volume work on Greece in all its aspects is vol. 10 of the *Megali elleniki enkyklopaideia, Ellas*, rev. ed. (1965), with bibliographies that are numerous and extensive but that often do not incorporate works more recent than the early 1930s. A comprehensive and less dated guide to sources is J.E. BAXEVANIS, *Modern Greece: A Bibliography* (1964). The two most extensive works on the geography of Greece are ALFRED PHILLIPSON, *Die griechischen Landschaften*, 4 vol. (1950–59), and the two-volume study *Synchroni geografia* (1965) by P. RHODAKIS and K. TRIANTAPHYLLOS. In English, the BRITISH ADMIRALTY NAVAL INTELLIGENCE DIVISION, *Greece*, 3 vol. (1944), is still the best summary of conditions to that time; later events and trends may be studied in JOHN CAMPBELL and PHILIP SHERRARD, *Modern Greece* (1968). For publications providing the statistical basis for analysis of Greece's population, society, and economy, see works published by the SOCIAL SCIENCES CENTRE (Athens), the CENTRE OF ECONOMIC RESEARCH (Athens), the NATIONAL BANK OF GREECE, and the NATIONAL STATISTICAL SERVICE OF GREECE (chief of which is the annual *Statistical Yearbook of Greece*) and the publications of various European organizations, especially the ORGANIZATION FOR ECONOMIC COOPERATION AND DEVELOPMENT (OECD).

The land. In addition to the general geographical works cited above, reference should be made to *Geological and Physicogeographical Bibliography of Greece* (*Géologiki kai fisikogeografiki vivliografia tis Ellados* (1961), by D. HARALAMBOUS; specific publications dealing with individual aspects of the landscape include E.G. MARIOLOPOULOS, *Klimatografia ton diaforon periochon tis Ellados* (1960), a comprehensive discussion of climate; there is, however, only a very meagre literature on Greece's animal and plant life. Soils are covered in D.S. KATAKOUSINOS, *Les Sols de Grèce* (1963).

The people. The monograph *Greece* (1974) prepared by D. TRICHOPOULOS and G. PAPAEVANGELOU for the World Population Year 1974 gives an authoritative picture of Greece's population both currently and in historical perspective; other useful studies include B. KAYSER, *Géographie humaine de la Grèce* (1964), and D. PENTZOPOULOS, *The Balkan Exchange of Minorities and Its Impact upon Greece* (1962). Publications of the censuses of 1961 and 1971 provide both basic data and analysis.

The national economy. Characteristics of Greece's people and economy are illuminated in B. KAYSER and K. THOMPSON, *Economic and Social Atlas of Greece* (1964), and in H. HOCHHOLZER, *Industrial Atlas of Greece* (1966). Greece's economy is surveyed regularly in the publications of the OECD, COMMERCIAL BANK OF GREECE, NATIONAL BANK OF GREECE, and ATHENS CHAMBER OF COMMERCE AND INDUSTRY as well as in those of the national government and various ministries. The five-year plans provide a general overview and analysis. Other useful surveys include *Problems of Greek Regional Development* (1962), by BENJAMIN WARD, and *Long-Term Prospects for the Greek Economy: A Forecast of Development in the Next 15 Years* (1968), issued by the ROYAL HELLENIC RESEARCH FOUNDATION.

Social conditions. Changing Greek social conditions as well as the relatively unchanging Greek countryside, people, and customs are described in PATRICK L. FERMOR, *Mani: Travels in the Southern Peloponnese* (1958); TIMOTHY WARE, *The Orthodox Church* (1963); ERNESTINE FRIEDL, *Vasilika: A Village in Modern Greece* (1962); JOHN K. CAMPBELL, *Honour, Family and Patronage: A Study of Institutions and Moral Values in a Greek Mountain Community* (1964); BERNARD KAYSER, PIERRE-YVES PECHOUX, and MICHEL SIVIGNON, *Rural Exodus and Urban Attraction in Greece* (1971); GEORGE ANASTAPLO, *The Constitutionalist* (1971), includes citations to 10 of the author's articles on contemporary Greek affairs republished in the *Congressional Record*, and his *Human Being and Citizen* (1975) has discussion of Greek affairs and character. (Ed.)

Greek Civilization, Ancient

The special role of Greece in the history of Western civilization is easier to demonstrate than to explain. The land itself offered no particular advantages such as far earlier had determined the importance of the great valley civilizations of the Nile, Mesopotamia, or the Indus. It plays little part in the history of early man. Its Bronze Age history has something to contribute to the history of civilization but is trivial beside the great contemporary empires of the East and Egypt. Something that may help explain why Greece emerged as a great civilization is the happy combination of geography and temperament: a geographical location that permitted it to receive the benefits of the skills and resources of older civilizations and contemporary civilizations to the north, east, and south, and yet that was not especially vulnerable to attack by them; and a spirit of inquiry, bred, perhaps, in far earlier generations of nomadic life, which was manifested by the Greeks' exploration, travel, and colonization and by a speculation about man and his world, which soon led to a sound basis for philosophical, political, and even scientific theory. Another important factor was a language that developed into the most subtle instrument for the expression of thought, science, and emotion that the West has known.

Achievements of Greek Civilization

The achievements and legacy of Greek civilization can be assessed under many different heads, and yet, the most significant contribution was probably an attitude of mind and an approach to political life rather than works of art and literature. The autocratic dynasties of the East and Egypt with their royal and priestly hierarchies could provide no model for politics in Greece. Instead, the small kingdoms progressed from systems of rule by families or dictators (in the modern sense) to rule by elected assemblies and councils and to recognition of the virtues of democracy, as well as of its practical shortcomings. The practice of government came to be systematically analyzed for the first time, and the systems of different contemporary states compared. The problems of the slaves and the poor could be recognized, if not solved. In the fine arts, the technical skills of the Greeks were mainly learned from foreigners, except perhaps for the art of mural painting. It was in terms of conception and precision that Greek artists outstripped their teachers and set standards of artistic expression and craftsmanship that seem almost superhuman. Their special contribution to narrative art lay in their genius for giving expression to subtleties of mood and feeling while seemingly confining themselves to mere reportage. Their graphic art exhibits similar qualities, expressing a perfect compromise between, on the one hand, a sense of pattern and proportion, and, on the other, shrewd observations of man and the world around him.

Ancient Greece was the most literate of all ancient cultures—witness the profusion of public and private inscriptions, from state decrees to graffiti on walls. Some of the earliest uses of the newly learned alphabetic script were for epic poetry; for law codes; and for lyric poetry, private and public, on themes of state, war, humour, and love. Eventually, there emerged choral and dramatic treatments of the traditional myths, done in a spirit of moral speculation, religious affirmation, or sheer irreverence. The great prose histories are models of disinterested inquiry and of a critical concern for recording man's motives as well as his behaviour.

The attempt of Greek philosophy to provide a theory of the universe to replace the cosmologies of myth eventually led to practical scientific discoveries. And, by exploring man's processes of thought and argument, principles of description and logic were defined that were both an expression of and an influence upon the practice of political and personal morality. The search for principles was in fact carried so far that, too often, theory was preferred to the more mundane process of observation, so that progress in the natural sciences and medicine was slow compared to achievements in other fields.

That man is the measure of all things and mankind his special study may appear today the most remarkable tenets of ancient Greece, especially in light of the obsessional religions, oppressive governments, and conventionalized arts of other early societies. This is, on the whole, a just appreciation of the Greek achievement, but in the past it has led to an unreal, not to say sentimental, idealizing of Greek standards of virtue, wisdom, and beauty. More recent studies have dwelt more objectively on the Greeks as one society out of many in antiquity, whose debts to others were at times considerable and whose success must be measured against the not inconsiderable achievements of other peoples. But it remains true that no other ancient people exhibited such a wide range of genius or left such a vigorous legacy. The heroic quality of Greek history—the stand against Persia, the exploits of Alexander, expressed so proudly by their own historians and poets—is, if anything, enhanced by this new objectivity, by the understanding that the Greeks were subject to the same fears, hopes, motives of power, self-interest, love, duty, and cruelty that have beset men throughout history.

The geography of the Greek homeland. The Greek landscape is that of the miniaturist—with rapid but never drastic transitions from valleys to hills and, for such a small country, with so many geographically distinct enclaves, including its many islands, that it is totally unlike the broader tracts of plains and mountains that are characteristic of most other Mediterranean lands. This simple geographic factor explains the separate development of the Greek city-states, which were bound by a common language and interest rather than by any sense of belonging to a distinct geographical entity—until, that is, a sense of national unity was imposed on them from outside. Greece's long coastline and the difficulties of land communication meant that seafaring always played an important part in Greek life and politics and probably contributed to the Greeks' readiness to explore the farther Mediterranean shores. Unlike Asia Minor, or even Italy, Greece is a country of sea routes, not roads.

Influence of geography on Greek life

The provinces of Greece represent geographic, racial, or dialect unities rather than political unities. In the north, Macedonia, a peripheral Greek area until the age of Philip and Alexander, marked the end of the main routes from Europe. To the south, the country is split lengthwise by the Pindus Range, with Epirus and Aetolia to the west, facing the Adriatic, and the broad Thessalian plain sloping to the Aegean. The mountain range is difficult to cross at any time and almost impossible in winter. East central Greece, east of Mt. Parnassus and Delphi, forms a separate enclave with the plain of Boeotia, the hillier country of Attica with its thinner soil, and the long and rather bare island of Euboea flanking them. The Corinthian Gulf nips the peninsula, making the isthmus to the Peloponnese a natural focus of routes and power. The isthmus was dominated by Corinth, which built a channel (*diolkos*) for dragging ships overland. From the east, the seaward approaches were controlled by Athens and Aegina, while Megara, north of the isthmus, must have owed much of its wealth to its position beside the only north–south route overland. The mountains of south Greece, the Peloponnese, were equally effective as dividers of the land. There are only two plains of any importance, serving Argos and Sparta, and the coastline is generally inhospitable. The jutting masses of Euboea, Attica, and Argolis are continued southeast in a broad scatter of islands reaching across to the southwest corner of Asia Minor. These are the Cyclades, with Dorian Rhodes and the Dodecanese at the eastern end. South lies the great island of Crete, halfway from Athens to Africa, geographically the southern border of the Aegean world.

The west coast of Asia Minor is quite unlike Greece, with broad river valleys, massive mountain ranges running inland to the east, deep gulfs, and large offshore islands. The Greeks, whose communications ran more readily by sea than by land, naturally came to regard the coastal areas and islands of the east Aegean as theirs to exploit, which they did through much of the period, coming regularly into conflict with the mainland powers

(Lydia, Persia), which could not brook foreigners on their flanks.

The Greek climate

The climate of Greece is temperate, with long dry summers favouring the cultivation of vine and olive, and wet winters, especially in the western areas, but not generally very harsh. Barely one-fifth of the land area is arable, and, in parts of the country and islands, it can be seen that bad farming and erosion have reduced the areas once cultivated. Wheat grew well enough, but, even as early as the 8th century BC, not in sufficient quantity to satisfy the demands of growing urban populations. Specialized crops producing oil or wine, which could be traded for wheat, proved a more economic use of land for some states (Athens and Chios, for example). The hillslopes provided pasture for cattle, sheep, and goats, which played an important part in the provision of food and clothing. Greece was well wooded, but the demands of housebuilding and shipbuilding, as well as the attentions of the goats, considerably diminished the forested area even in antiquity. There is good fishing in the Aegean, especially of tunny, and the Greeks ate much fish, fresh and dried.

Climatic changes since antiquity have probably been slight, but there may have been a period of drought in the Early Iron Age which contributed to the severe depopulation of the country in about the 12th and 11th centuries BC. There has been a general rise in sea level since antiquity of at least two metres (6½ feet). Some parts of the coastline, notably in Crete and parts of the Peloponnese, have suffered local disturbance through earthquake. Most of Greece, especially southern Greece, is subject to these disturbances, which have at times proved disastrous. Mineral resources exploited in antiquity were few—some gold and silver and slight deposits of copper and iron. But there were rich sources of fine-quality stone for building and statuary and plentiful deposits of sedimentary clays for potting.

Sources for the study of Greek civilization. The prime source for all except the earliest periods is the record of ancient historians, describing events recent and remote, local and national. Early accounts of the foundation of cities and of political or military conflicts were in verse, in a literary form influenced by epic and barely recognizable as history in the modern sense. They were, nevertheless, of quite a different character from the bald chronicles of the East and Egypt, which were narrow in theme and almost never explored or explained motives. In the 6th century BC, the study of geography (Anaximander) and the writing of travel books (Hecataeus) recorded much information of historical value, but of this work only scraps have been preserved in later authors. This is true also of many works by important 5th- and 4th-century-BC writers. The handling of this patchwork of information requires great care and observation of the context and of the intention of any later author who recorded a quotation or excerpt from an earlier work.

The work of Herodotus

The first major work to have survived in nearly complete form is Herodotus' *History*, composed in the third quarter of the 5th century BC and devoted to a study of the background to and course of the wars against Persia. Herodotus travelled widely, collecting written and oral evidence. He displays a spirit of critical inquiry that has earned him the title of the "Father of History." He is ready with digressions that are often informative about earlier periods of Greek history; his interest ranges over problems of religion and culture; and his account of the customs and history of the neighbouring barbarian empires presents a more vivid picture of them than do their own records. His history can be seen as a logical development of the work of the earlier geographers and ethnographers.

Thucydides, writing at the end of the 5th century BC, told the story of the Peloponnesian War and incidentally of the years of the Athenian Empire after the Persians were repulsed from the Greek homeland. He succeeds in being a dispassionate observer of the greatest internal struggle that Greece had seen. It was a struggle that tested the quality and ethics of the political life of the city-states involved. Fortunately, Thucydides, too, was interested in the motives and interests that led to decisions by states or individuals, and he discusses these in passages of personal speculation or through the more dramatic device of speeches placed in the mouths of generals and statesmen.

Of the 4th century BC, there is Xenophon's *Hellenica*, which continues Thucydides' history. Xenophon did not have the flair of his predecessors, but he was a man of action, and his account of military operations carries the authority of experience. Ephorus' universal history is lost, but it was much used by the Sicilian Greek Diodorus Siculus, a writer of the 1st century BC, on whom it is necessary to rely for a consecutive account of events in the 5th and 4th centuries BC. Other historians of the Roman period draw on various earlier sources for Greek history. Arrian is a notable example; he gives an account of the reign of Alexander. And Plutarch's *Lives* and *Moralia* are rich in quotations of earlier sources, as well as being interesting historical commentaries in themselves. No less valuable than the historians as contemporary sources are the 4th-century-BC orators Isocrates, Demosthenes, and Aeschines, whose speeches have survived more for their literary than their historical content. Works on political theory by Plato, Aristotle, and others are also of use as sources. The remoter the writer from the events he describes, the greater the likelihood that the account has been distorted by invention or systematization either for political ends or for the sake of continuity. This most affects genealogies, and to these many events of early Greek history are tied.

A different type of literary source is offered by inscriptions on stone or clay. Some are private, recording epitaphs or dedications, but even these may allude to historical events of wider significance. Many are public documents: state decrees, treaties between states, honorific decrees, and tribute lists. They are valuable contemporary records and can usually be dated either by the context in which they were found or by the letter forms used. Most of importance are later than the 6th century BC in date.

Archaeological sources

Strictly archaeological evidence is being used increasingly by historians, especially for the early period of Greek history. Study of style and scientific aids have helped to determine a fairly reliable chronology for even the commonest objects recovered from an excavation, and this often makes possible a historical account of an area or town that written sources ignored. Archaeology can provide direct evidence for trade, but only for trade in commodities or containers that have survived. More important, it may indicate, in early periods of colonization or trading, which states of homeland Greece were operating overseas. While the ancient historian was inevitably attracted to the great names and events, archaeology can complete the picture of life in parts of Greece that escaped the limelight and can explore problems of society and technology that ancient writers generally ignored. It is a major source for the history of myth and religion and the only source for the history of art.

This article is divided into the following sections:

I. The Early Archaic and Archaic periods

In this article, the story of ancient Greek civilization begins with the Early Archaic period; that is, the period from the disintegration (*c.* 1200 BC) of the Bronze Age civilization in Greece to the beginning of the literary and cultural revival of the Archaic period proper (*c.* 750–*c.* 500 BC). For the history of the earlier Bronze Age cultures of Greece see AEGEAN CIVILIZATIONS.

THE EARLY ARCHAIC PERIOD

The Dorian Invasion and Proto-Geometric period, c. 1100–900 BC. The collapse and gradual destruction of the Bronze Age civilizations in Greece are subjects for archaeological investigation only, and it is natural to look first to archaeology for any account of the period that immediately followed. During this following period, the few remaining centres of the earlier Mycenaean culture were abandoned or destroyed. These included not only settlements at the older capitals, like Mycenae, but shorter lived refugee settlements in west Greece (Achaea, Cephallenia), east Attica (Perati); settlements on eastern Aegean islands (Emporio on Chios); and settlements in the islands that had hitherto escaped the worst effects of the invasions.

The "invasions" may be thought of as having occurred in waves for over a century. It is possible that many of the effects attributed to them were in fact the result of internal dissensions. Observing the areas that seem to have been least disturbed by the earliest attacks, and the directions in which refugees moved, it may be judged that the main course of invasion passed through Greece from the northwest. The identity of the earlier invaders is not abundantly evident in the archaeological record, which probably means that the attacks were carried out by raiders who may have quickly passed on or turned back with their prizes. Some objects of new types, or of types only familiar on the borders of the Mycenaean world, are introduced: an efficient bronze sword, violin-bow fibulae (clasps), some distinctive armour, knives, and handmade pottery. Prototypes for these are readily found in northwest Greece and the Balkans beyond.

The overall effect of the invasions was a depression of all cultural standards and considerable depopulation, except in Athens, parts of Thessaly and the Argolid, and in the refugee areas. It has been suggested that a contributory or even dominant factor was a climatic change that brought about conditions of drought and famine. The evidence for or against this hypothesis is difficult to judge, but the sudden upheaval, after so many years of prosperity and heavy settlement, is hard to attribute solely to the hand of man.

It is concerning the final wave of invasions or destruc-

Ancient Greece.

tions in the early and middle 11th century that the archaeological record is somewhat more informative. It reveals some continuity of settlement with a new population or, at least, a somewhat changed way of life. This is most easily observed in Attica and the Argolid.

The new culture is distinguished from what had gone before in a number of ways. The Mycenaeans buried their dead in family graves. The new cemeteries are of individual burials in slab-lined cists. These are not altogether unknown in earlier Greece; they were normal in the Middle Bronze Age, and, toward the end of the Bronze Age, cist cemeteries were made in north Greece (Epirus and Thessaly). As an alternative burial practice, cremation was introduced and became dominant in the following period in Attica and Crete but remained rare in the Peloponnese and is only occasionally found elsewhere. Cremation was very rare in Mycenaean Greece but was practiced during the Mycenaean period in the central Balkans and was regular farther north. Straight dress pins make their appearance, and iron for weapons. These were to be characteristic of the new Proto-Geometric period, whose other characteristics are examined below. It is impossible not to associate the invasions of this period and the resettlement or continued settlement of the surviving Mycenaean sites with later Greek tradition about the Dorians. The Dorians were Greeks from northwest and north central Greece, and there is nothing in the archaeological record to upset seriously the theory that they were the last invaders and settlers of the Mycenaean Greek world. They effected a shift of emphasis rather than a revolution in the Greek way of life. Tradition told of the "Return of the Heraclidae," suggesting a number of earlier or repeated raids from the north. There were moves from Thessaly into central Greece and Boeotia and moves from Epirus and the northwest into the Peloponnese. Not all the immigrants were Dorian, but it was the Dorian invasion of the Peloponnese that overthrew the remaining Mycenaean centres and led to the strongest new settlements in Laconia, the Argolid, and Corinthia. Athens was marginally affected, perhaps mainly by refugee populations. A Mycenaean "pocket" remained in Arcadia, using a dialect related to that of the Mycenaean refugees in Cyprus. Dorians settled also in the southern Aegean islands, in Rhodes, and especially in Crete, where again there were pockets of Bronze Age survival—some even non-Greek Mycenaean (the Eteocretans). It is possible that less of Greece was totally depopulated during the invasions than has been thought. It may well be that the interaction between the new and old Greeks in what had been centres of Mycenaean power proved responsible for developments in religion and myth about which it is now only possible to speculate, since no contemporary written records survive. In Greece itself, the art of writing had been lost with the palace bureaucracies that disappeared as a consequence of the invasion. One of the prime achievements of the new Proto-Geometric period of which there is material evidence was in pottery and pottery decoration—from this the period gets its name. The notable refinement in shapes and decoration exercised by the Proto-Geometric potters represents not a break with earlier tradition but a reworking of old forms and patterns with a new precision and eye for proportion and design that the Mycenaean Greeks had failed to achieve in their adaptations of Minoan art. This is the beginning of Greek Classical art. It seems most likely that Athens saw the inception of the new style, and it was certainly in Athens that it was most successfully developed. And from Athens other areas of Greece drew inspiration. Athens was never Dorian, but it shared with the Argolid the first manifestations of the new style. Skeletal material from Athenian graves reveals a marked intrusion of northern types, and so the responsibility of the new Greeks for the changes observed in Athens may well be real, and possibly not wholly indirect.

Identification of the invaders

Cemeteries are the main source of information for the Proto-Geometric period, and it can be seen from them that as the style develops, through the 10th century, there is a growth of population accompanied by growth of prosperity. This prosperity is indicated by the increasing number of metal objects deposited in the graves. Apart from east central Greece and Argolis there was a strong unity of development in this period in Thessaly, Euboea, and into the Cyclades. In these areas the Proto-Geometric style died hard. The Euboeans and islanders, in particular, seem already at this time to have been busy seafarers; and, from the site of Xeropolis (Levkandí) on Euboea, between Eretria and Chalcis, there is evidence for a variety of imported goods from Cyprus and the Near East. By comparison, Laconia and western Greece were backward, slow to repopulate and to trade. Crete is a special case since the island suffered less than most of Greece from the disasters attending the end of the Bronze Age. Some centres in the island seem to have developed with a certain vigour and degree of independence. There are clear signs in Crete, also, of contact with Cyprus and the Near East.

Apart from archaeological sites, pottery, a restricted range of metalwork, and cemeteries, little can be assessed of Proto-Geometric culture. Virtually nothing is known about temples or even houses. Yet it was during this period that the tenets of myth-history and religion found in an already developed form in the Homeric poems at the end of the following period were being established. Much of the ordinary way of life described in those poems was probably typical of the Proto-Geometric period. And, despite an overall unity of culture in Greek-speaking lands, it is possible to detect that differentiation of customs (mainly burial) and style that came to be most fully expressed in the stout independence of the city-states.

The Ionian migration

There is one other event, rather loosely described and dated by ancient writers, which archaeology suggests may be placed in this period—the "migrations" to the east coast of the Aegean. The area had already been much visited and partly settled in the Bronze Age, and offshore islands had received refugees from the Mycenaean world. But none of these communities survived into the Proto-Geometric period, and for most of the area there is reason to believe that there was a break in Greek occupation, although not so obliterating that later Greeks were unable to find their way again to the same sites. The migration was described by ancient sources as a single event involving the marshalling in Attica of refugees from Pylos, together with other Greeks from Boeotia and elsewhere, and their passage east to found Miletus and Ephesus, and thence the other major cities of Ionia. There may be archaeological evidence for such refugees in Late Helladic Attica, and there is certainly archaeological evidence for the settlements in Ionia in the 11th and 10th centuries. The style of pottery found in them indicates some relationship with Attica. Miletus was founded by the start of the Proto-Geometric period, and this seems to support the literary tradition. Finds in most of the other major cities indicate that all were probably established before the end of the 10th century, but the diversity of the records about their composition and founders and the inadequate evidence of excavation make it difficult to decide how much was effected by fresh immigration from the homeland and how much by local expansion.

By about 900 BC Athens had emerged as the cultural centre of the Greek world; the Euboeans and islanders had begun their eastern voyages, which were to lead to new trading ventures and transform the prosperity of the Greek world; and the Aegean had become for the first time a truly Greek sea.

The world of Homer: the Geometric period, c. 900–c. 700 BC. The Geometric period is named after the style of pottery decoration that was developed in Athens out of the more austere Proto-Geometric idiom. It was wholly abstract at first but eventually admitted figure decoration. The closing phases of the period saw the introduction of elements derived from the arts of the Near East, a phenomenon that resulted from new Greek trading enterprise in the east Mediterranean. The desire and need for this trade reflect the more stable and prosperous conditions of life in Greece, which gave rise to a

notable increase in population and the need for colonizing ventures. The same period sees the introduction of writing and the possibility of written records. Greece moves into the light of history.

The material culture of the new period is best judged in Athens, where the cemeteries encircling the city have proved most productive, and in the countryside of Attica. The method of burial becomes more varied, ordinary inhumation becoming as common as the cremation that had been dominant in the preceding period. Grave offerings, with weapons and metalwork, give some indication of the new standards of life, while some burials in Athens (the so-called Dipylon graves) are marked by monumental clay vases decorated with scenes of the laying out of the body and its removal to burial, implying funeral rites and celebrations of some complexity and expense. Iron appears more often and is used for swords and spearheads; bronze is used for dress pins, ornaments, and implements. There is a considerable increase in the production of minor works in bronze and clay for dedication in sanctuaries, mainly in the form of men and animals. The most impressive bronzes are the great tripod caldrons, best known at Olympia but also in Athens and elsewhere in Greece. Precious metal was still comparatively rare, but immigrant eastern goldsmiths were at work in Attica in the early 8th century, and there was some local production of goldwork in the Geometric style. Some eastern metalwork and jewelry had arrived by the 9th century and had been deposited in graves. Another luxury craft, forgotten since the Bronze Age, was the cutting of seals in ivory and stone, indicating some sophistication in the safeguarding of property and identity of ownership.

This Geometric culture of Athens is repeated all over Greece, although nowhere else with comparable complexity and wealth, except possibly in Crete. Athens still seemed to give the lead in pottery decoration, but regional schools developed, especially in the 8th century. The new wealth and growing population of the Greek states were soon to lead them to test their strength and independence against each other in fields other than that of craftsmanship.

The Proto-Geometric unit formed by Thessaly, Euboea, and the Cyclades remained a strong entity, with Euboea the dominant partner. At Levkandí, the site between Eretria and Chalcis in the Lelantine Plain, there is clear evidence for metalworking and signs of trade with the Near East. The town was destroyed before 700 BC, while the site of classical Eretria was first settled only in the early 8th century. These events are in some way to be related to the Lelantine War, a conflict between Eretria and Chalcis, which, according to ancient authors, split Greece into two camps. The Thessalians were, not unexpectedly, directly involved. The affiliation of Levkandí and the outcome of the conflict, which may have been protracted, are not clear, but the immediate result was considerable restriction in the activity of the Euboean states at home and overseas. In the islands there were several important Geometric towns, notably on the sacred island of Delos.

The Lelantine War

In Boeotia, Thebes seems the strongest site and most active culturally, although dependent on Athenian styles. Delphi was prosperous by the 8th century and received many Corinthian goods.

In the Peloponnese, archaeological evidence indicates the rapid growth in wealth and size of Corinth and a considerable concentration of prosperous sites in Argolis —at Argos, Mycenae, Tiryns, and Nauplia especially. While there is not the volume of imports and precious metals found in Attica, it is in Argos that is found the earliest suit of all-metal armour of the type later worn by hoplite soldiers, as well as offerings of spits (*obeloi*) in sets of six. Corinth's prosperity began in the 8th century, especially after the middle years, when its pottery began to appear in quantity on a great many Greek sites at home and overseas.

Crete presents a checkered picture, with several important sites in the centre (notably Knossos) and the east. Relations with Cyprus remained strong, and by the end of the 9th century a group of eastern goldsmiths had settled in Knossos. They worked there, in gold, bronze, and stone, for some three generations. Crete, like Thera —another Dorian island that prospered at this time— generally preferred cremation for its dead. Some tombs, though used for the new rite, retain the form of the old Bronze Age *tholoi*: the Minoan heritage is imprinted in a number of ways on Archaic Cretan culture.

In east Greece (Asia Minor and the eastern Aegean islands), several towns on Dorian Rhodes were flourishing and developing a regular trade with Cyprus by the 9th century. It is not until the 8th century, however, that the major sites in Ionia show marked signs of growth, notably at Smyrna and on Samos, where the first temples of the Heraeum were built. The archaeological record from other cities and islands is sparse. Farther north, the coastline of Aeolis as far as Troy was settled. Finds on sites as far south as Chios and Samos show evidence for increasing awareness of the hinterland powers of Phrygia and Lydia, while farther south Greek fashions were penetrating Caria.

The material pattern of life in Geometric Greece is characterized by growth in population and wealth, but a special quality is also increasingly apparent, and this must be summarized and explained. Objects from Cyprus, Syria, and Phoenicia (and to a limited degree Egypt) arrived in the Greek world in increasing numbers through these two centuries. The presence of immigrant craftsmen can be detected in Attica and Crete; there may have been ivory workshops in the Peloponnese, Attica, and east Greece; and, by the second half of the 8th century, most Greek crafts were beginning to betray the imminence of the influence from the East that became more fully apparent in the 7th century. This appears most clearly in Corinth, Crete, Rhodes, and Attica. The goods and craftsmen followed routes that may not at first have carried much else by way of serious trade, but the expanding Greek states looked overseas for new resources, especially for metals—copper, tin, iron—that were in short supply at home and that were especially required for weapons. Tradition has it that the Phoenicians conducted much of the early trade with Greece, but physical evidence for this is hard to find, and the first clear sign of organized trade is a Greek enterprise. This involved the establishment of a trading post at the mouth of the River Orontes in north Syria at a site known as al-Mīnā. There is no literary record of the venture, but it, or a similar operation, provided Greece with its first opportunity to keep written records, since it was through intercourse with the Aramaic-writing peoples on this coast that the Greeks learned and adapted for their own use alphabetic writing. This must have happened by the mid-8th century, and if Olympia had accurate written records going back to 776 BC, then it may be surmised that writing reached the Peloponnese about that time.

Eastern influences on the Greeks

The physical world of the Homeric poems is dominantly that of Geometric Greece, overlaid as it is with the myth-history and geography of an earlier age and with stock epithets and descriptions perhaps out-of-date by the 8th century. The picture is a convincing one of independent kingdoms centred on single cities with dependent villages and linked only by bonds of kinship or mutual convenience. Rule is generally autocratic and fighting an affair of the nobility, the citizen mass not yet being a decisive force. Hesiod, writing around 700 BC, paints a more sombre but moralizing picture of the hardships of a farmer's life in Boeotia.

Homer and Hesiod are poor guides to religious life in Geometric Greece. Homer's gods are already acquiring set attributes and an Olympian family life, imposed in the interest of the story. The process may have been going on for some time, but this is bards' work and for long afterwards bore little relationship to the Greeks' view of the town's patron deity and that deity's functions and dues. Hesiod's cosmogony is, if anything, even more artificial and owes much to Eastern cosmic myths. His systems and tales also find little echo in later Greek religious practice, but in parts of his work natural justice and the will of the Father of the Gods correspond

Religion in the Geometric period

well enough to permit recognition of an attitude to the gods based on humane respect rather than fear. Archaeology can offer evidence of only the trappings of religious life. The earliest cult places are altars for sacrifice, which also serve as the focus for offerings. The provision of a house (*oikos*) to accommodate the symbol or cult image of the deity comes late, and the few Geometric examples of such primitive temples all resemble contemporary domestic architecture. The images themselves may well have been aniconic (symbolic rather than representational). The offerings are bronze or clay substitutes for the offerer himself, representations of the deity, or intrinsically valuable objects such as the metal caldrons that in the Homeric poems are offered as prizes. In the grave a warrior may be buried with his weapons, sometimes rendered useless (swords bent or folded), but most offerings are of pottery and seem to indicate provision for a meal, no doubt for the journey to the other world. There is no clear evidence for continued rites at the graves of the recent dead, but in the 8th century there is evidence of attention being paid to some Mycenaean tombs and of the introduction of some hero cults which may have been inspired by the Homeric poems, as at the Agamemnoneion of Mycenae.

Certain other aspects of Greece's remarkable Bronze Age past must have affected its new and rapidly developing Iron Age civilization. The walls of Mycenaean citadels were viewed as the work of giants, the Cyclopes. These physical monuments, together with the poems, were clear evidence for a golden age, long past and replaced by one of iron. Geometric and later artists were very rarely moved to imitate these works. The degree of continuity from the Bronze Age is more difficult to assess but has been enthusiastically championed. The palatial arts were lost and had to be relearned from the East. Old sites reoccupied had led scholars to believe in the continuous use of cult places and sanctuaries, but they are difficult to identify in Bronze Age terms.

Although their new literacy may have awakened an intelligent interest in their past, the strongest motivation for progress in the Geometric period came from the Greeks' own efforts to improve their lot at home and from their enterprise overseas, which brought them both valuable new resources and invigorating new ideas.

THE GREEK COLONIZING MOVEMENT, C. 750–C. 500 BC

The Mediterranean world and Greek needs. The geography of Greece determined the Greeks' interest in seafaring, and, when their homeland could no longer support their growing population, it was their seafarers who offered the solution. Early sailing was a hazardous business, generally restricted to a few months in the year and to routes which, so far as possible, never took the mariner too far from sight of land. Not until the 6th century were maps being drawn, and, even then, they were of little practical value, compared to experience and the reports of others. The need now was for land and new resources. What could the Mediterranean seaboard offer? First, a climate that was at no point so markedly unlike that of Greece that Greeks could not readily adapt themselves to the new conditions of life and agriculture, and, second, sea and river routes to remote peoples and resources. The sources of raw materials were discovered early and exploited fairly easily by trade, even if in the teeth of foreign, usually Phoenician, competition. The western Mediterranean gave access to the tin and silver of Spain, France, and even Britain; central and north Italy could offer copper and the iron of Elba. The richer mineral resources of Europe were reached only with more difficulty. On the shores of the Black Sea there was gold (in Colchis), and there was iron in north Asia Minor. The copper island, Cyprus, pointed the way to areas in which metallurgy had long flourished and from which many even more distant sources had been exploited. But food was even more important than metal, and this involved seeking new land for settlers. This, of course, depended upon finding unoccupied but cultivable land or upon the goodwill of new neighbours.

Expansion and trade

The Mediterranean world offered several such opportunities for expansion and trade. The northern shore of the Aegean flanked the territories of the minor kingdoms within Macedonia and Thrace. The Macedonians were Greek in culture; but neither they nor the Thracians were seafarers, and the coast of Macedonia, especially the peninsula of Chalcidice, proved an important colonial area for the earliest of the active colonizing cities in Euboea. Farther east, new towns were founded from the islands and east Greece, and the gold of Mt. Pangaeum was soon exploited. On the east shores of the Aegean the hinterland powers also had little interest in the coast, and the already established Aeolic and Ionian cities soon expanded along the coastal strip up to the Dardanelles. The passage up into the Black Sea, against wind and current, was difficult but not impossible. The Thracians to the west seem to have welcomed the Greeks. In the north the newly arrived nomadic Royal Scythians provided a ready market rather than competition, and again the Greeks were able to benefit from the fact that they were more interested in the sea and coastal areas than the natives were. They soon learned to exploit the riches of the south Russian cornfields and fisheries. The less hospitable eastern and southern shores of the Black Sea offered fewer but important places for foundations that could tap important mineral resources.

In Cyprus, the Near East, and Egypt the situation was very different. All the local states were well established, and all had an interest in seagoing. The Egyptians also had a deep-seated suspicion of all foreigners. Their trading routes inland were well trodden, and there was no foothold there for a colony. Libya was a different matter, with a broad green plateau and disorganized native tribes which appeared cooperative. Farther west, the Phoenicians had forestalled the Greeks, and Carthage was founded while the Greeks were still exploring Italy and Sicily.

The Greeks were slow to explore routes up the Adriatic and crossed straight to south Italy and up to the promising markets of Etruria. There, as in Egypt, the opportunities were for trade. The natives of south Italy and Sicily were landlubbers, their natural ports and coastal plains mainly empty, it seems. There the Euboeans, followed by Corinth and other Peloponnesian states, were able to establish important agricultural communities. East Greeks later prospected farther afield, to France and Spain.

There were solutions to the land problem other than the sending out of colonies; but they were rarely resorted to. Sparta annexed the land of its neighbour, Messenia, acquiring a large slave population and its attendant problems. A dissident group in Sparta threatened state unity and was dispatched to found Tarentum in south Italy. Athens had been an active seagoer earlier in the 8th century, but it did not join the first colonizing movement and later avoided the necessity by specializing its economy in export materials—oil, wine, and silver. The Euboean cities, Eretria and Chalcis, were the earliest and most energetic traders and also the earliest colonizers, since their home island offered little scope for their new wealth.

Relations between colony and mother city

The first colonizing parties were probably very small, and families from neighbouring states seem often to have been free to join. This contributed to mixed feelings of loyalty, and, given the forced circumstances under which some colonies were dispatched, it is not surprising that relations with mother cities were sometimes less than cordial. When the colonizing states were seagoers, like the Euboeans and Milesians, the routes and possible destinations were already known to their merchants. The Therans turned to a Cretan who knew it was safe to bear south for the Libyan coast. Other states may have sought information from the Delphic oracle: the latter's newfound wealth and reputation may have been in some part due to the role it played or claimed as promoter of the siting, cults, and laws of new foundations.

The immediate needs of any new city may have been quite basic, but its identity as a full Greek *polis*, or city-state, on the model of its mother city, was immediately

affirmed by the establishment of the appropriate cult places and the demarcation of an agora area for political and commercial assembly. The new cities had not the architecture of an old city to impede or limit their planning, and their political and legal institutions were perhaps less trammelled by local, family, or territorial traditions. But it did not take long, with the growth of wealth and strength, for their political and social life to acquire all the complexity of the homeland.

The trading posts. There had been refugee Mycenaean Greek settlements in the island of Cyprus, and some surviving Greek element in the culture and population of the island may account for the fact that it was only with Cyprus that some sort of trade relations, even if casual, were maintained through the "dark ages" of Proto-Geometric and Geometric Greece. Archaeology shows that this was true especially of Crete, Euboea, and eventually Athens. Cyprus itself, from its geographical position, was a cultural extension of the Levant, and, by the 10th century at least, new Phoenician cities had been founded in the island. Before the end of the 9th century it seems that Cypriots had led Euboean traders to the eastern mainland and, with them, established a trading port at the mouth of the River Orontes, at a site known as al-Mīnā, excavated before World War II but not recorded by any ancient author. Euboean and island interest was dominant there until about 700 BC, and this site and port, with immediate access to the Syrian hinterland and Mesopotamia, may have been the major source for the flow of Eastern materials into the Greek world of the 8th century. After 700 the Cypriot and Euboean interest gave place to one that was mainly east Greek but shared by a mainland Greek state, perhaps Corinth or Aegina—at least a state using Corinthian pottery. By this time there may have been Greek trader elements in other eastern cities, such as Tarsus in Cilicia and farther south on the Syro-Phoenician coast (at Tall Sūkās, for example). There would have been no serious rival to this route, which brought prosperity to another Greek staging point for Eastern objects destined for the Greek world—Rhodes. In Asia Minor, the roles of Phrygia and Lydia as purveyors of Eastern goods and ideas seem to have been strictly limited to the east Greek world, and the direction of the flow was soon turned.

In Cyprus and north Syria there was no question of establishing colonies, although in time Cyprus was to become thoroughly Hellenized and isolated from its Eastern associations. Greek trading in Egypt gave rise to a still different type of settlement. In the mid-7th century the Egyptian king Psamtik I had employed east Greek mercenary soldiers, some of whom were allowed to settle in the country, and it is evident from excavations that by about 620 BC a Greek trading town had been established at Naukratis on the western branch of the Nile Delta. Herodotus describes a reorganization of the town under King Ahmose II in the mid-6th century that confirms what the finds indicate: that it was in the hands of various east Greek states and of Aegina. This was virtually the same consortium that had been operating at al-Mīnā since about 700 BC. In Egypt their operations were limited to trade through Naukratis, carrying in wine, oil, and silver, and carrying off papyrus, manufactured goods, and, eventually, corn. The community was better established than at al-Mīnā, since the Egyptians allowed a degree of local government by overseers appointed by each trading state and a number of temples, including a joint Hellenium. The latter may have been involved in collecting the taxes that had to be paid over to Egyptian temple treasuries.

The Greek trading settlement in Egypt

Precolonial trade in other areas of the Mediterranean world was far less firmly established and was conducted, it seems, by regular visit rather than through trade settlements. Evidence for it, therefore, is in the form of Greek objects in native towns. These appear sporadically in south Russia, up the Dnepr and the Don, and more often in Etruria. Some Greek place-names in the Carthage area suggest that Euboeans may have explored this coast, too, but Phoenician settlement there by about 750 BC forestalled possible development of trade or settlement.

Greek colonies in the west. *South Italy and Sicily.* Finds in Etruria show that Euboean merchants had been visiting its shores early in the 8th century BC. Before the middle of the century, a settlement had been established on the island of Ischia, offshore of Naples, at a site called Pithecussae. It was easily defensible and offered a good harbour at a convenient point on the approach to the Etruscan cities in the north. Its early years were its most prosperous, it seems, and the Greeks on this agriculturally unpromising volcanic island must have relied heavily on trade. There are early traces of ironworking, with material no doubt acquired from Elba. By the middle of the century, a second colony was established, on the mainland at Cumae, mainly by Chalcidians from Euboea. This provided better opportunities for livelihood off the fertile coastal strip, and it naturally came to eclipse Pithecussae in importance. These, the first of the Greek colonies, were also the most remote on this coast and the nearest to Etruria. The approach to them from Greece lay through the Strait of Messina, and the Chalcidians soon took note of the Sicilian coast—both for staging points and for its resources. The Chalcidians founded Naxos in Sicily in 734 BC. It seems that the Greeks had to displace a native settlement, and the same was true of the Chalcidians' next foundation in Sicily, at Leontini, which lay to the south of Naxos and a little inland, commanding a rich plain. Lower down the valley, on the sea, they founded Catana in 729 BC. This had a good harbour and plain. Thus it can be seen that, as in Italy, the first settlements were determined as much as anything by marine or mercantile needs and were soon supported by agricultural foundations.

The passage through the Strait of Messina had also to be safeguarded. Chalcidians, with a party from Cumae, founded Zancle (later called Messana, modern Messina) on the Sicilian side, in a position that was more strategic than comfortable and that was supported in 716 BC by the foundation of Mylae, at the other side of the northeast spur of Sicily, where there was a plain. On the Italian side, Rhegium was founded at about the same date by Chalcidians and a party invited from Messenia in the Peloponnese (noble refugees from Spartan expansion). The Euboeans had sought to safeguard their approach to the west by a colony on the western Greek island of Corcyra. In 733 BC the Eretrians were expelled from the island by Corinth, whose own settlers were soon at loggerheads with their mother city. They did, however, eventually press on up the Adriatic, founding Epidamnus in Illyria in 627 BC. Corinth's eyes were not on the north, however, but on the west and the trail blazed by the Euboeans, and its further colonizing along the western coast of Greece was mainly in the interest of protecting the approaches to the Corinthian Gulf.

According to ancient sources, it was only a year after the first Euboean foundation in Sicily that Corinthian settlers occupied the best port site on the east coast, and one which was to become one of the strongest cities in the whole Greek world—Syracuse (*c.* 733 BC). This was, in fact, an island site, soon linked to the mainland by a causeway; it commanded a broad coastal plain that seems to have been virtually unoccupied. Settlers from Megara had a harder time, spending a while in Chalcidian Leontini, then moving to a bare promontory at Thapsus before being invited by the native Siculi (Sicels) to what was to prove a valuable coastal site—Megara Hyblaea—in 728 BC. All these foundations were in the east of the island, and it was another generation before some Dorians, from Rhodes and Crete, ventured a little way along the south coast, to Gela, in 688 BC. Farther west lay the Elymi (Elymians), but active Phoenician interest in the west of the island and the establishment of a Phoenician town at Motya some time before 700 BC discouraged the Greeks from pressing far in this direction, although there was at this time no direct confrontation between the two great colonizing and trading nations.

The founding of Syracuse

The Euboeans established colonies in Italy that were as much strategic as agricultural. They were soon followed by Peloponnesians who had an eye rather to the rich and unoccupied coastal plains that the Euboeans sailed past.

Most came from Achaean cities. Sybaris, whose prosperity was short-lived but became legendary, was founded in about 720 BC, followed by colonies at Metapontum, Croton, and eventually Caulonia. These enjoyed the best of the land on the southeast coast, but there were valley routes northwest to the Tyrrhenian Sea, bypassing the Strait of Messina, and there was an early flow of Greek goods through the native towns of the hinterland. The other important Achaean colony, Poseidonia (Paestum), lay at the end of one of these routes and was established by about 700 BC.

The Achaeans were not alone in south Italy. In about 706 BC the Spartans settled the fine port at Tarentum, beside a native town that had been in touch with Greeks long before. Locri was settled from central Greece in about 673 BC. The first Ionian colony was at Siris, settled by Colophonians who had been displaced from their homes by Lydians—a circumstance that was to set other Ionians on the move west in the next century. Within less than a century, and mainly in its first 50 years, Greek states had found for themselves new and prosperous homes on the coasts of south Italy and Sicily. They had established generally good relations with their neighbours, were well placed to dominate trade with Etruria, and were already courting the jealousy of the Phoenicians and Carthage.

South Italy and Sicily: expansion and consolidation. The first colonies had all been on or very close to the sea. The period of expansion and consolidation, after the mid-7th century, saw more inland foundations, bringing the Greeks into closer contact with the native peoples. New cities toward western Sicily began to challenge the Phoenician hold on that part of the island. Although some of the new cities were manned by newcomers from Greece, much was undertaken by the colonies themselves, which sought to confirm and safeguard their positions. Syracuse established its hold on southeastern Sicily by founding Acrae (663 BC); Casmenae, yet farther inland (643 BC); and Camarina (598 BC). Smaller settlements, as at Helorum on the coast south of Syracuse, confirmed its domination of the corn lands and, by enslaving the Siculi, Syracuse had, by the early 6th century, progressed from being an outpost on a foreign shore to command of an area and cities rivalling any controlled by a homeland city. Camarina alone claimed a measure of independence: it quarrelled with Syracuse and was defeated and laid waste in 552/551 BC.

Expansion of Syracuse

Megara Hyblaea, hemmed in by the Chalcidian cities and Syracuse, looked to the opposite end of the island and founded Selinus soon after the mid-7th century in territory close to the Phoenician town of Motya. This was to prove another of the most prosperous western cities, long to outlive its mother city. At about the same time (648 BC) Chalcidians, joined by a group from Syracuse, also struck westward to found Himera, lying about as close to Phoenician Panormus (Pallermo) as Selinus did to Motya.

The last of the important Sicilian foundations was made by Gela at Acragas (Roman Agrigentum) along the coast to the west, in 580 BC. Eastward expansion was contained by Syracuse, and the Geloan cities were to be a serious challenge to Syracusan supremacy in Sicily.

In south Italy, the new foundations were mainly of the 6th century and were sponsored by the existing colonies establishing routes across the peninsula or "filling in" the coastline. The only newcomers were from east Greece. They had considerable trouble establishing themselves and provoked the first serious troubles with the Phoenicians. A party from Rhodes and Cnidus tried to settle too close to the Phoenicians at Lilybaeum in west Sicily and were expelled soon after 580 BC following a dispute involving the Phoenicians, Selinus, and Segesta—a native Elymian city that was strongly Hellenized and constantly at odds with Selinus. The unlucky colonists moved on to the Lipari Islands, where they established some form of communal ownership of land and annoyed the Etruscans by attacks on their shipping.

In the face of the Persian invasion of western Asia Minor in the mid-6th century, several east Greek states considered the possibility of mass emigration to the west, one suggestion being that the Ionians should move to Sardinia. The Phocaeans lost their city to Persia and sailed west to join the colony they had founded at Alalia on Corsica in 560 BC. Their piratic behaviour produced an alliance against them between the Etruscans and the Carthaginians, and, although the Phocaeans defeated them at sea, they had to leave Alalia and seek a new home. They stayed a while at Rhegium and then founded Elea (Velia) on the coast just south of Poseidonia in about 535 BC.

Internally, the Greek colonies developed much as their mother cities at home. There were rare examples of political innovations, as at Lipara. The progress was generally from aristocracy to rule by tyrants, but the landowners of Syracuse were long influential. Disputes between the colonies did not always follow "national" lines, and the division between Dorian and Ionian had little weight in the colonial period.

Political life of the colonies

Relationships with the native population rapidly became a matter of master and slave in Sicily, where only the Elymians enjoyed some security under the protection of the Phoenicians in the west. The other native towns of Sicily became progressively more Hellenized. Many were taken over, so that by the end of the 6th century the large native population was no longer a significant force in the island. Much the same was true in the southernmost part of the mainland, but the native tribes of Apulia, Lucania, and Campania were made of stouter stuff, retaining an individuality of culture well into the Classical period.

Conservatism is perhaps a characteristic feature of colonial areas. It was certainly a feature of the culture of the western Greeks. Their new cities were rich and powerful, and they sought to demonstrate this wealth both by the splendour of their offerings and by athletic missions to the national sanctuaries and games of Greece itself, and by their building at home. At Olympia at least half the pavilion treasuries dedicated by individual states were paid for by westerners—Gela, Metapontum, Sybaris, Selinus, and Syracuse. A majority of the surviving temples of the Greek world constructed in this period stand in the west, and in Syracuse a start was made to emulate even the colossal temples of the Ionian cities. This was an isolated venture in the Ionic order: most western work is Doric, massive and conservative in proportions, but often admitting uncanonical decorative detail, "vulgar" by metropolitan standards. Lacking fine white marble, the statuary is in stuccoed limestone or clay and is decidedly provincial in appearance. Only in the minor arts of clay and bronze did some western studios make original contributions to the development of Greek art.

Spain, France, and north Italy. The Phoenicians had been trading with the south of Spain since the later 8th century, and by 700 BC they had established at least one trading post there. The Greeks also took an early interest in these western waters and for a while held their own against the Phoenicians, whose foundations in Africa, Spain, Sardinia, and western Sicily eventually led to their domination of this area. The attraction was the tin and silver obtainable in Spain and, via Spain, from more northerly sources. Greek goods continued to arrive in Spain through the 6th century, but many, like the earliest of them found in the Phoenician trading post at Almunecar, may have been carried by Phoenician ships.

An alternative route for the tin was overland, through France, down the valley of the Rhône to Marseille. Here the Phocaeans, who seem to have been the most active of the east Greek merchants in these seas, founded Massilia in about 600 BC. A vigorous trade into France and north Spain developed and was later reinforced by other colonial foundations from Massilia. By this route Greek works of art travelled deep into France and Germany, and a Celtic chieftain at Heuneburg near Munich seems to have employed a Greek to plan his fortification for him. But, by the end of the 6th century, the balance of power had shifted, and, as a result of the diminished trade along the Rhône, Massilia's days of high prosperity were over. Its fortunes are an example of how much and

how long some colonies relied on trade rather than on local resources for their riches and even livelihood.

Greek colonies in the north. *North Greece.* The Euboeans, who were the first in trade and colonizing in east and west, were also the first to exploit the northern shores of the Aegean, where their neighbours were the part-Greek Macedonians. The centres of activity were the lower valleys of the Axius and Strymon and the three-pronged peninsula between them that took its name, Chalcidice, from one of the colonizing cities. It seems that both Eretria and Chalcis had been active in these regions in the 8th century: the Chalcidians at Torone and Dicaea; the Eretrians at Mende and then at Methone. After the Lelantine War Chalcidian interest was dominant in this area, and in the mid-7th century Chalcis sponsored colonies sent out from the island of Andros to sites on the east coast of Chalcidice—Acanthus, Argilus, Stagirus, and Sane. Eretrian control seems to have been confined to the westernmost promontory, Pallene. It is likely, however, that it was by agreement with Chalcis rather than Eretria that Corinth established Potidaea at the neck of the Pallene peninsula in about 600 BC.

Colonization of Chalcidice

The important Euboean foundations had probably been made by about 700 BC. In the 7th century, when the coast to the east was being colonized, it was other Greek states in the islands and east Greece that were active. An early foundation, *c.* 680 BC, was by Paros on the island of Thasos. Thasos soon set colonies on the mainland opposite, at Neapolis (Kaválla) and Oisyme. From Ionia the Chians came to colonize Maroneia and the Clazomenians to colonize Abdera, on the coast east of Thasos. There is indication of serious trouble with the natives—Thracians in this area, belligerent and reluctant to Hellenize. They expelled the Greeks from Abdera for a while, but, after the mid-6th century, it was settled again from Teos in Ionia, by Greeks escaping from the Persian threat. These settlements had a trade interest in the minerals and timber of the mainland, but they were also strong agricultural communities where the vine was grown with considerable success.

The Black Sea. Dates as early as the 8th century BC, which have been proposed for some of the Black Sea colonies, are supported neither by finds nor by considerations of geography, which show Greek colonial interest in the approaches to the Black Sea only at the end of the 7th century. But references and names in Greek poems show knowledge of the area by about 700, as in the Argonaut story. Miletus was the leading colonizer in this area, and most of its foundations were made in the later years of the 7th century, sometimes with the collaboration of other Ionian cities. The progress was not one of gradual exploration along the shores but of settlement, within a single generation, of key sites around the whole of the inland sea, especially at river mouths and points propitious for trade with the natives. The greatest Milesian city was at Olbia, at the mouth of the River Bug, but settlement there seems to have been preceded by a post on the island of Berezan, farther out in the Bug-Dnepr estuary. Olbia was the main point of contact with the Scythians of the south Russian steppes. Herodotus tells of the Scythian prince who was so corrupted by the Greek way of life that he was murdered by his followers.

South of the Danube delta the Milesians founded Istrus, and later Tomis (modern Constanţa, Romania) to the south, on what was to be a frontier of the Roman Empire. The other important area of Milesian colonization lay around the Kerch Straits, leading into the Sea of Azov east of the Crimean Peninsula. The oldest and strongest city in this area was at Panticapeaum (Kerch).

On the east coast, the wealth of the Caucasus was known to Greeks, and there was settlement there by Milesians at Phasis and elsewhere, about which there is still much to learn. The coastal route back to the Aegean lay along the north shore of Asia Minor, which is notoriously inhospitable to shipping. Three important staging points were settled as colonies along this coast, at Sinope, Amisus, and Trapezus (Trebizond). Apart from their value to transit shipping, Amisus, in particular, also gave access to the mines of Anatolia.

The Megarians, from mainland Greece, were other notable colonizers in the Black Sea region. They placed Mesembria to the north, and Heraclea just east of the straits, and in the 5th century crossed the sea to Chersonesus in the Crimea.

Economy of the Black Sea colonies

The prosperity of the Black Sea colonies depended on various factors. They generally had no lack of land for local needs and were able to introduce Mediterranean plants without too great difficulty—the climate of the Crimea can be remarkably like that of the Aegean for much of the year. They relied, too, on their trade in the products or raw materials of the hinterland. Corn from the Black Sea was already on its way to Greece before the Greco-Persian Wars, and the local production of works of art in precious metals in some of the Greek cities is a fair indication of how much of the same material might have been sent home. The waters of the Black Sea also yielded their riches. Kerch herring were prized, and quantities of pickled fish were sent back to Greece. In the Scythians they had to deal with a people whose culture was in many respects barely inferior to their own. Although passage of goods was free between them, the Greeks never really succeeded in assimilating the Scythian, in either their arts or manner of life, in the way in which they could the Eastern or the Egyptian. The frozen north remained for the Greeks the home of ogres and gifted savages.

Greek colonies in Africa. The easy route south from Crete to the Libyan coast may well have been travelled by Greeks in the Bronze Age. When, in the mid-7th century, the island of Thera was obliged to send away part of its population, it was from its Dorian neighbour Crete that a pilot was found to lead them south. They settled for two years on an offshore island and were visited there by Colaeus the Samian on his famous voyage west. They then moved for six years onto the mainland, to Aziris, before being led by the apparently friendly natives up on to the Libyan plateau where they found a site whose climate and setting closely resembled Greece, at Cyrene (about 632 BC). The attraction was agricultural, since the plateau was fertile and well watered. It was soon to become famous as a breeding ground for horses and as a nursery of the valuable silphium plant (now extinct), and in time it became an important source of corn for the Greek and Roman world. The foundation at Cyrene was soon followed by exploration along the coast. Apollonia was founded as the port of Cyrene, and to the west, the site later called Ptolemais, Taucheira, and Euesperides (modern Banghāzī). All of these, with the possible exception of the last, were founded before the end of the 7th century. The royal family at Cyrene was not always popular, and in the mid-6th century Barce was founded by an oligarchic faction, together with brothers of the king, farther west on the plateau.

This was the one colonial area that early suffered at the hands of the Persians. The cities submitted to Persian rule once Egypt had fallen to the new empire in 525 BC and had to suffer one armed Persian raid as far as Euesperides. But, even in this period, it is clear that Cyrene prospered, as its temples and tombs matched those of some of the richer western colonies. Dorian interest in the area was maintained not only by the founder islands, Thera, Crete, and Rhodes, but also from the Peloponnese, notably by Sparta.

In Egypt itself, the fortunes of the Greek trading town at Naukratis flourished through the 6th century and were barely dimmed by the arrival of the Persians. There were other small Greek communities in Egyptian towns that may have admitted "native quarters" or mercenary garrisons, but never anything like a colony. Out in the Libyan desert, at Siwa Oasis, the cult of Amon attracted Greek attention and soon became a recognized and respected oracle for all Greeks. The god was recognized as Zeus Ammon and figures on coins of Cyrene.

To the west, any Greek exploration had been cut short or wholly forestalled by the Phoenician settlement at Carthage. The only Greek attempt in this area came soon after 515 BC, when the Spartan Dorieus was led by Therans to make a settlement at Cinyps on the bare coast of

Tripolitania. Here he was pressed by both Phoenicians and natives and had to retire.

ARCHAIC GREEK CULTURE

Religion in Archaic Greece. The Archaic period offers a first opportunity to study more closely the religious life of the Greeks without paying undue attention to the rather artificial and literary pantheon of the Olympian family and dynasties of heroes. These, however, still provided the material for song and epic and were increasingly invoked or manipulated to serve political or personal ends. In the city-state can be distinguished two elements: the agora, which served as assembly and market place, and the temple area, where its god or gods were honoured. All the monumental architecture of Greece in this period was devoted to temples, altars, and other sanctuary buildings, and only toward the end, in Athens, were public administrative buildings treated in a comparable manner. The major deity of a city may have been determined by its Bronze Age history and the identification of a warrior god or fertility goddess as one of the Olympian pantheon; or by the promotion of a local deity or hero, often associated with a natural feature, to the same rank; or, in a colony, by the precept of the mother city or the Delphic oracle. The temple was at once a statement of confidence in the guardian power and a demonstration of wealth. Loyalty to the city god could be a stronger incentive to concerted action than loyalty to a family or tyrant. And, as the national sanctuaries won greater importance, either through their oracles or the staging of games, so loyalty to their deities—the Zeus of Olympia, the Apollo of Delphi—strengthened, together with the bond of language and their attitude to the "barbarian."

Dominance of religious architecture

Festivals were of different types and could serve different purposes. The state festivals, notably the Panathenaea in Athens, were occasions for the display of citizen solidarity and were readily exploited by tyrants to reinforce their own position. The many other festivals generally had a connection to agriculture—spring or harvest festivals, or celebrations associated with particular crops or activities (Dionysus for wine, Artemis for hunting)—or to the hero of a locality. The agricultural character of these is apparent in accounts and representations of the Archaic period, but their significance gradually became overlaid by other considerations when they were performed by city dwellers, whose life and interests became more and more remote from the countryside.

The conduct of festivals and of sacrifices by private individuals for favours received or hoped for was in the hands of priests whose office went by lot or family. Burial was a private affair but was regulated by the state. The Homeric magnificence of burials of the Geometric period was restricted by legislation (as by Solon in Athens) generally directed against excessive expense and public display. In the Archaic period, the dead were better served above ground, by monuments which reflected as much credit on the living, than below, and the few offerings laid with the body were but a token of a presumed brief need for sustenance on the way to the other world. But some religions or sects provided for man's fears for his afterlife. This was achieved through ritual purity in way of life or through initiation in a "mystery" religion such as that at Eleusis. The former method involved a complicated theory of evolution and matter and a mythology of the underworld with precepts for the journey there. Such was Orphism. The philosophy of Pythagoras, who left Samos to found a school in Croton in the later 6th century, was similar, teaching the migration of the soul into another body, which might be human or animal. Pythagoreanism codified many precepts that elsewhere would be classified as magic. Orphism, together with aspects of the Dionysiac worship (which was late to win importance in Greece), was also rooted in a religion of ecstatic "possession" by the god working through a priest or in the bodies of dancing worshippers. In the Archaic period there was, thus, little in the religious practices of the Greeks to mark them from other early societies. The difference lay in their literary treatment of stories about gods, from Homer on. Only with the Classical period did their interest in man and man's behaviour begin seriously to condition their views about their gods.

Orphism and Pythagoreanism

The early philosophers. The cosmogonies of Hesiod and other early poets described the beginning of the world in terms of the supernatural, but in poems that, at the same time, showed the artists' shrewd observation and appreciation of man as an object deserving study. The sometimes ribald treatment of divine behaviour probably accelerated the process of critical inquiry and scepticism about the validity of myth and the attempt to replace it with a view of the world and man's place in it that did not depend upon the antics of anthropomorphic deities. In the 6th century the centre of this new criticism lay in Ionia, and especially in Miletus, the city of explorers. The exercise of reason and the seeking of truth through argument were the two methods of inquiry, and they owed virtually nothing to Eastern science and very little to scientific observation. This is why the systems devised by the early philosophers seem so naïve and impractical to the modern mind, but what is most interesting is why they saw the need to devise them at all. They looked for the basic principles of matter and the world around them—in water (Thales); in the "boundless" separating into opposites (Anaximander); in air (Anaximenes); and fire (Heracleitus). Yet they were practical men, too, involved in the commerce and politics of their day, and it was probably due to their understanding of some of the mathematical and geometrical discoveries of the East and Egypt that certain of the more ambitious technical achievements of late Archaic Greece were made possible.

The Archaic style in the arts. The Archaic period saw the absorption by Greek artists of the artistic styles and techniques of the Near East and Egypt and their molding into a distinctive and original idiom in which lay the seeds of everything that was to be achieved in the Classical period.

The 8th century had seen foreign craftsmen and goods in Greece, but only toward the end of the century did these new arrivals begin to exert a profound effect on the work of Greek artists. Their metallurgy was always of a high order, and they refined techniques of casting and hammering bronze long before this was practiced in the East. New materials required new techniques, as in the case of ivory, and this, together with the filigree and granulation of the goldsmith, was a craft that had to be learned afresh, although it had flourished in Bronze Age Greece. The formal changes were more important. Geometric art could be subtle, but the more realistic conventions of Eastern art, involving the rendering of detail, offered far greater possibilities in the depiction of action. This was not, however, immediately applied to the needs of narrative or myth, and the hallmark of Eastern-influenced Greek work is the appearance of animal-frieze decoration. With the animals came a selection of monster motifs like the sphinx and griffin, to which the Greeks could add their own subhuman creations like the centaur and the satyr. Another new element was floral decoration, which gradually replaced the geometric and offered the possibility of considerable compositional invention—of which the Greeks were not slow to take advantage.

In the mid-7th century the Greek feeling for the monumental was stimulated by knowledge of Egyptian art. This gave rise to the first sculpture in hard stone (white marble) at life size or more, which successfully overcame the sterile conventions of work done in more easily managed materials and at a smaller, purely decorative scale. It also led to the creation of monumental stone architecture, with "orders" of moldings and columns based on timber prototypes (Doric) or on Oriental patterns (Ionic). This successful expression of the monumental probably helped the vase painter shake off the more restrictive conventions of decoration and indulge wholeheartedly in scenes of everyday life or myth, as on Athenian black-figure vases of the 6th century. A set iconography of scenes and figures was soon established, but never so rigidly as not to allow for the invention of a gifted artist or for originality in the execution of detail.

Developments in sculpture

Progress in the physical appearance of figures in Greek

art through this period was not rapid, despite the ease with which technical problems had been overcome. The figures were rendered with greater detail, and this was inevitably more realistic. Overriding considerations were proportion and pattern—the pattern of anatomical detail or the pattern of drapery pulled tight across limbs or hanging free from the body in a cascade of folds. In representing poses, the artist only very slowly broke with the uncompromising frontal or profile views and the abrupt juxtaposition of these views. But the change was not toward greater realism for its own sake. It was rather a refinement of the expression, by means of symbols for heroes, men, or monsters, of more and more complicated action and compositions. It was only just before the Greco-Persian Wars that the Greek artists began to see the merit of observing life and living forms and of adding a whole new dimension of expression to their storytelling.

Commerce. In Homeric Greece commerce was not an honorable profession, but, by the end of the Archaic period, the survival and wealth of most Greek city-states depended on trade, and commercial advantage could be a cause of war. The demand for raw materials, manufactured goods, and food in the expanding Greek economy was generally in this period met by private enterprise. A merchant embarked with his goods, paid his passage, and sold where he would; or, like Colaeus the Samian, it might be the captain of a ship who took what opportunities and profits were presented. Although it was to the state's advantage that there should be enough food or bronze for a hoplite army, it was some time before the state, as such, took a leading part in fostering or directing trade, although some tyrants did, it seems, as at Corinth. And, in early 6th-century Athens, Solon's reforms were in part directed at the Attic economy by encouraging an export market in oil. There was also an indirect interest in trade wherever taxes were levied on goods entering or leaving ports or passing through controlled territory. Slowly an ethic of commerce was evolved as trade became of more pressing importance to states. Piracy probably became less menacing, which is remarkable since there was no central government, let alone any policing force; it speaks well for the common sense of the Greeks and their readiness to submit dispute to the arbitration of fellow Greeks. It seems to have been remarkably easy for goods to pass between Greece and non-Greek enemy territories. There was a naïve simplicity about Archaic trade, but the days of tariff barriers and economic warfare were not far off.

Local or retail trade was, for most of the period, conducted by barter, the countryman exchanging his foodstuffs for manufactured goods or recognized precious objects, such as iron spits, which served as a form of primitive currency. But there was no question of the weighing of precious metals for retail payment, and for a long time Greeks were incapable of precision weighing. When dumps of precious metal were first stamped with a state or personal blazon (by about 600 BC, in Lydia, it seems) this guarantee was of the issuing authority rather than of weight. The use of coinage spread quickly through Greece. It was for local exchange, however, perhaps for payment of mercenaries by the state, and certainly for payment of fines or taxes. But there was seldom any provision of small change to serve a retail market and no passage of money from state to state to indicate its use for general trade. Only toward the end of the Archaic period and in places in which the precious metal was in good supply, as in Athens, was the production of coinage by the state apparently intended to serve "internationally" as recognized bullion. This is the beginning of a money economy, but coinage was not invented to serve this end, nor did it serve it for a century or more.

(Jo.Bo.)

II. The Greek city-state

THE GROWTH OF THE POLIS

The period of nearly three centuries in Greece after the great migrations of *c.* 1100–*c.*1000 BC is often called the Greek "dark ages" because little is known about it. Habitation was in villages and towns, which have left few traces except for pottery of Proto-Geometric and Geometric types. Rather before 700 BC a revival began, largely because of Oriental influence, and the term Archaic is given to the age *c.* 750–*c.* 500 BC to distinguish it from the Classical period that followed. Among the outstanding developments of the Archaic age was the growth of urban life and political institutions.

Character and early condition. The type of settlement emerging in many parts of Archaic Greece was the *polis* (plural *poleis*), or city-state. The *polis* was a sovereign political unit. Usually it had a fortified centre on a hill, where the inhabitants took refuge from attack; a residential and commercial town arose at the foot of the hill, and the town was surrounded by a dependent territory, which served for agriculture and pasture and, in the case of large *poleis*, included villages subordinate to the main city. Thus at Corinth the fortification was on the steep hill called Acrocorinth; the town of Corinth arose at the foot of the hill and commanded an extensive territory, which included subsidiary settlements such as Lechaeum, Sidus, and Crommyon. (It should be noted that this was not the only characteristic type of settlement; in much of European Greece, especially in the northwest, the unit was not the *polis* but the *ethnos* [plural *ethnē*], or nation. An *ethnos*, such as Phocis or Aetolia, held extensive land, which was divided among unfortified villages; the villages were linked in a loose federation, and no single centre predominated. But until the 3rd century BC, the political development of the *ethnē* was slow.)

In the early Archaic *polis*, public authority was weak. Society was agrarian, and each community had people of quite varied status—wealthy landowners, small farmers, landless labourers, artisans, and in some places serfs. The strong unit was the family; a large and powerful family attracted numerous dependents, giving them protection and economic help in return for their labour.

The divisions in society, consequently, were not horizontal but vertical: conflicts were not between classes but between groups. Each group was led by one or a few strong households, which had many dependents. (These groups have been aptly compared to pyramids because each had a broad base of humble men.) Eventually these relationships became formalized and hereditary; the consequent terms are known in the case of Athens. There *genos* (plural *genē*), or clan, was the word for a group of powerful families that led a body of dependents; each *genos* claimed descent from a common ancestor, who was usually mythical. The *genos*, together with the body of dependents attached to it, constituted a phratry, or *phratria*.

The citizens of each *polis* were also divided into hereditary units called *phylai* (singular *phylē*), a word often translated by the Roman term tribes. In Dorian *poleis* there were usually three tribes—the Hylleis, the Pamphyli, and the Dymanatae; among the Ionians the number of tribes was less uniform, but some of the same tribal names occur in several Ionian *poleis*. Evidently the tribes date back to the age of migration, before their members had settled in cities.

Political institutions

Three political institutions were commonly found in each early *polis*—a king, a council, and an assembly of adult male citizens. These institutions arose understandably from the migrations. Each migrating host required a war leader, whose office developed into hereditary kingship when the host found land and settled down. The war leader consulted the leaders of distinct contingents (his council) among his followers before taking action; and he announced his decisions to a gathering of all his able-bodied men, assembled to receive marching orders. (Such practices are reflected in the *Iliad* and the *Odyssey*.) But in sedentary conditions changes came about. The kingship was more vulnerable than the council: the king might be a minor, or there might be a disputed succession. In many cities additional offices, often elective and annual, were created alongside the kingship; even the kingship became annual and elective in some places, including Athens.

The council, though at first merely advisory, gained in

power from the decline of the kingship and became the primary scene of political rivalries. The assembly changed from a gathering that heard decisions to a gathering that reached decisions. This does not necessarily mean, as has often been supposed, that the common people, working through an assembly, asserted themselves against an aristocracy, working through a council. More likely, it means that when leaders of prominent families could not get their way in council, they took the issue to the assembly, calling out their followers to fight for and later to vote for them; and as this practice became habitual, the assembly became a second place for settling political rivalries.

Oriental influence. During the 8th century BC, Oriental influences began to reach the previously static societies of the Greek communities. A Semitic and probably Phoenician alphabet was borrowed and adapted for writing Greek. Perhaps in the same period Greeks learned the Oriental stories that appear in the *Theogony*, an account of the beginning of creation and the birth of the gods by the poet Hesiod (fl. *c.* 800 BC). Changes in pottery provide the clearest indication of foreign influences in Greek societies. Geometric pottery was superseded by new naturalistic styles in different cities at different times during the 8th and 7th centuries. Collectively the new styles are called "Orientalizing" styles, but they varied according to place of manufacture. The pottery made at Corinth was more widely exported than any other during the 7th century; the subdivisions of the proto-Corinthian and Corinthian styles span the period *c.* 725–*c.* 550. The adoption of the Orientalizing styles and the fact that these new styles travelled farther than had Geometric pottery indicate a growth of overseas trade, and this was likely to dislocate the traditional societies of the rudimentary Greek *poleis*. The colonization movement (*c.* 750–*c.* 500 BC) is evidence of profound social changes.

Hoplites. A change in military practice—the introduction of hoplite equipment and hoplite tactics—had effects that are difficult to estimate. In the "dark ages," fighting was mainly conducted by comparatively few warriors: each had a shield, a sword, and spears, usually for throwing, but lacked armour for the head and body; warriors fought as individual champions, not as an organized group. In the 6th and 5th centuries the characteristic force of the developed *poleis* was the phalanx of hoplites, or heavily armed infantrymen. The hoplite had a sword and a thrusting spear; and above all, he had plentiful protective armour, including a closed helmet, a bronze plate corslet, greaves, and a large round shield with armband and handgrip. In traditional practice the front row of hoplites tried to push the enemy off the field, and the succeeding rows of the phalanx added weight to the impact.

Until recently it was believed that many Greek states had adopted the hoplite phalanx within a few years of 700. But fresh study of vases that depict armed men has revealed a more complex development of the hoplite phalanx. The various items of hoplite equipment were adopted separately in the period 750–700, but at first the old manner of fighting by uncoordinated champions was not changed. The complete hoplite panoply is first attested on a vase *c.* 675, and the massed hoplite phalanx first appears *c.* 650. Moreover, the social effect of the change in tactics is disputable. A widely accepted theory says that in consequence of the change, the burden of fighting passed from relatively few aristocrats to a wider class of substantial peasant farmers; that the latter accordingly demanded a share in political power; and that revolutionary rulers, the tyrants of the 7th century, arose as their leaders. Against this view it has been argued that peasant farmers were more likely to be conservative than revolutionary, and they would dislike war and disturbance as threatening their land and taking them away from tillage; in Etruria and Rome hoplite tactics were adopted during a period of aristocratic ascendancy. Perhaps the social significance of the hoplite phalanx was something different: the new type of fighting was much more highly organized than was the old, and so hoplite discipline contributed to the growth in the authority of state.

Tyrannies in Archaic Greece. Some increase in public authority was brought about by the tyrants, who arose in many cities—especially of the Peloponnese—during the 7th and 6th centuries BC. The words tyrant and tyranny do not necessarily imply oppressive rule. Essentially a tyranny began when a man without any hereditary or

Greek expansion *c.* 550 BC.

official claim to rule seized control of his city. Usually a tyrant held no office and did not alter the city's laws or institutions. He exercised an informal and extralegal preeminence; the nearest modern equivalent is the "boss" of a small town.

The rise of tyrannies

Because several tyrannies began in the Peloponnese within a limited period, scholars have often sought a common cause for them all. Some scholars have suggested commercial factors; others have argued that tyrants arose as champions of the pre-Dorian element in the population against Dorian aristocracies; others have attributed their rise to class conflicts consequent upon the introduction of hoplite tactics. But no one factor can be adequately attested for all the tyrannies of the Archaic Peloponnese. Local conditions varied, and the only note common to all tyrants was one of magnificence; they made a display of their power and wealth.

The word tyrant was not Greek in origin; it may have been a Lydian word for "king," and the Lydian kings of the Mermnad dynasty (*c.* 680–*c.* 544 BC) impressed the Greek imagination with their power and display. In Greek the word tyranny first occurs (7th century) in a quatrain of the poet Archilochus, who there associates it with his contemporary, Gyges, the founder of the Mermnad dynasty, and with ostentatious wealth.

Pheidon. Pheidon, a hereditary king of Argos, was a forerunner of the tyrants. Aristotle says, enigmatically, that he began as king but became a tyrant. He brought the whole of the Argolid (the area of Argolis) under the control of Argos; this was the basis for further expansion. Pheidon proceeded southward into the plain of Thyrea, which the Spartans too wished to seize; the Argives defeated them at the Battle of Hysiae in 669, and this ensured control of Thyrea to Argos for more than a century.

A tradition known to Herodotus said that Argos once ruled the whole southeastern coast of the Peloponnese as far as Cape Malea and even the island of Cythera. This tradition, if sound, must refer to the time of Pheidon, but it may be exaggerated. Probably in 668, although the date is disputed, Pheidon intervened at the Olympic festival; he excluded the regular Elean presidents of the competition and took the presidency himself. In this action he took advantage of tension within the territory of Elis. There the Eleans, who had arrived during the migrations, had ascendancy; but there was a rural and underprivileged class, the Pisatans, who were descended from those who had inhabited the land before the migrations. Pheidon promoted the aspirations of the Pisatans, and from his time intermittently until 580 they succeeded in seizing the presidency at the Olympic competition. Pheidon evidently achieved military ascendancy in much of the Peloponnese. He struck standard weights and measures, dedicating the models at the Argive Temple of Hera, and these standards were accepted permanently by many Peloponnesian states.

Cleisthenes of Sicyon. The fullest information on early tyranny concerns Corinth and its western neighbour Sicyon. Under Cleisthenes (reigned *c.* 600–*c.* 570 BC), Sicyon achieved greater power than at any other time. Herodotus, the best source, tells two stories about Cleisthenes of Sicyon. In one he relates how Cleisthenes, being at war with Argos, took several anti-Argive steps in domestic affairs; for example, he tried to suppress the cult of the Argive hero Adrastus. Further, according to the story, Cleisthenes altered the names of the tribes at Sicyon. Previously there were the three Dorian tribes of Hylleis, Pamphyli, and Dymanatae, and a fourth tribe called Aegialeis; Cleisthenes gave his own tribe the name Archelai (Rulers of the People), but he renamed the Dorian tribes, calling them Hyatae (Pig-ites), Oneatae (Ass-ites), and Choereatae (Swine-ites). Thus Herodotus represents the tribal change as merely a change of names carried out because of the war against Argos; Cleisthenes did not want the Sicyonians to have the Dorian tribes in common with the Argives. But something more serious must have been intended. By Herodotus' time the tradition was already becoming anecdotal; the story of the change in names conceals a real reform. Previously, the non-Dorian element in the population—that is, the descendants of those inhabitants who held Sicyon before the Dorian settlers arrived—were underprivileged, at least to the extent of constituting only one tribe in contrast to the Dorian three. Cleisthenes altered this condition drastically; the change was in the nature of a social revolution. Doubtless it was carried out not because of the war with Argos but for internal reasons. Moreover, the conjecture can hardly be avoided that this social reform was the source of Cleisthenes' power: he ruled as the champion of the pre-Dorian element in the population.

Reforms of Cleisthenes

The other Herodotean story tells of how Cleisthenes sought a bridegroom for his daughter, Agariste. On winning a chariot victory at Olympia, he invited prospective suitors to come to Sicyon within 60 days. Men came not only from the Peloponnese but from places as far away as Crannon in Thessaly and Sybaris and Siris in southern Italy. Cleisthenes inquired into their descent and kept them at his court for a year, testing them in all manner of gentlemanly exercises. He was inclined to prefer the two Athenian suitors, Hippocleides and Megacles, and especially Hippocleides. But on the last evening, after dinner, Hippocleides climbed on a table, stood on his head, and danced with his legs in the air. When Cleisthenes told him that he had danced away his marriage, Hippocleides retorted that he did not care. So Cleisthenes chose Megacles, but he announced his choice to the suitors in a banal speech; he said that he honoured them all and would gladly gratify them all, but with only one daughter to give away he could not please everyone.

This story may have gained in the telling, but it reveals much. Hippocleides of the Philaid clan traced his descent to the legendary hero Ajax. Later writers said that Cleisthenes was the great-grandson of a butcher or cook; Herodotus made the point more effectively by putting a banal speech into his mouth. By inviting suitors to compete for his daughter, Cleisthenes made a display of magnificence. He had to; he was a self-made man.

Writers later than Herodotus made Cleisthenes a member of a dynasty, which took its name from its founder, Orthagoras, and which allegedly ruled Sicyon for 100 years; the dynasty may have lasted from *c.* 656 to *c.* 556, but modern research has not fully determined the chronology. Even if Cleisthenes had predecessors in the tyranny, he transformed its basis by the tribal reform. Perhaps the only fact of value provided by the later sources is that Cleisthenes joined in the First Sacred War against Crisa (see below *Relations among the Greek poleis to the end of the 6th century BC: The early Archaic period*), which stood on the north shore of the Corinthian Gulf. Sicyon on the south shore could regard Crisa as a commercial rival, and trade was the ultimate source of Sicyonian prosperity under the tyranny.

The Cypselids. The prosperity of Corinth, too, depended on overseas trade. In the 8th and early 7th centuries the city was ruled by a group called the Bacchiads, whose members traced descent from a legendary common ancestor and were so exclusive as to practice intermarriage within the group. But one of their daughters, Labda, was lame and thus was given in marriage to Aetion, who was not one of the Bacchiads; he claimed descent from the pre-Hellenic inhabitants of Greece and came from Petra, a village in Corinthian territory at some distance from the city. Their son was Cypselus; and when he came of age, he overthrew the Bacchiads and started the Cypselid tyranny of Corinth. He killed some of his opponents and exiled others. After ruling for 30 years he was succeeded by his son Periander, who continued and intensified his father's severities; Periander kept a bodyguard of spearmen, whereas none is attested for Cypselus. Periander was succeeded by his nephew Psammetichus, who was overthrown after a short reign. The Cypselid tyranny is commonly dated *c.* 657–*c.* 584 BC, although somewhat later dates (*c.* 610–*c.* 540 BC) can be defended.

The tradition recorded by Herodotus and Aristotle has not been kind to Cypselus or his dynasty; it stresses their overthrow of the Bacchiads and their alleged cruelties.

Yet a comparison of Cypselid policy with Bacchiad policy reveals not contrast but continuity. The export of Corinthian pottery flourished increasingly until *c.* 575; then the ware began to decline in quality, and after *c.* 550 it yielded to Attic competition, which may have had to do with the fall of the tyranny.

Corinthian colonies

Corinthian trade was helped by colonization. Under the Bacchiads, Corinthian colonies were established at Syracuse and Corcyra *c.* 733. Cypselus founded colonies at Leukas, Anactorium, and Ambracia; these commanded the Gulf of Ambracia and the approach to southern Epirus. Early in the time of Periander, the Corcyreans sent a colony northward to settle at Epidamnus on the coast of the Adriatic; they invited Corinth to send a leader of the colony, and the man sent was a Bacchiad. (This apparently indicates a reconciliation between the Cypselids and at least some of the Bacchiads.) Indeed, Periander controlled Corcyra and eventually sent one of his sons to rule it. A Corinthian colony was founded at Apollonia, somewhat south of Epidamnus, probably in the time of Periander; Epidamnus and Apollonia were situated at the two western termini of one of the few natural routes leading into the Balkan highlands and even into Macedonia. A son of Periander led a colony to Potidaea on the Isthmus of Pallene in the northeast; this, too, was well placed for opening up Macedonia.

Besides colonization, other items of Cypselid policy assisted trade. The tyrants, for example, built a stone causeway, or *diolkos*, across the Isthmus of Corinth. Commerce may have been among the considerations inducing Periander to maintain good relations with Lydia and Egypt.

Other tyrants. Little is recorded of other contemporary tyrants in or near the Peloponnese. Theagenes ruled Megara *c.* 632. According to Aristotle, he caught the flocks of the wealthy at pasture and slaughtered them; this may mark the overthrow of a wool-growing aristocracy. Procles, the tyrant of Epidaurus, is known only from his relations with Periander. The latter married Procles' daughter, but after her death he quarrelled with his father-in-law and overthrew him.

Conditions producing the tyrannies

The conditions producing the several tyrannies varied; no one common cause can be specified. Tension between the Dorian and pre-Dorian elements in the population, for example, was important in Sicyon and in Elis, but it has not been proved for Corinth. Admittedly, in virtue of his paternal descent Cypselus appears to have begun as a man on the fringe of the ruling group, and he may consequently have been motivated by jealous ambition; but his policy, so far as known, did not attempt any drastic change in the social structure of his city. Yet the note of magnificence, common to the different tyrants, may have had political significance. They set a new standard of wealth and power; the first stone buildings in Greece since the Bronze Age were the work of the tyrants. (For example, the Corinthian treasury at Delphi was built by Cypselus.) Such achievements marked a greater concentration of resources and authority than had been known before. It is often said that the tyrants overthrew traditional aristocracies; and this is not incorrect, but it can be misleading since "aristocracy" may suggest a regime within a fully organized city. In fact, under the traditional aristocracies the organization of the *polis* was still rudimentary; the Archaic tyrannies marked a stage in the growth of public power.

SPARTA

Early period. The territory south of the Arcadian highlands, which form the centre of the Peloponnese, consists of two plains bounded by mountain ranges. In ancient times, the eastern plain was Laconia and the western plain was Messenia. The plain of Laconia was bounded by Mt. Taygetus on the west and Mt. Parnon on the east, and it was drained by the Eurotas River. Dorian invaders reached Laconia in the age of migrations; they came as conquerors but mingled to some extent with the previous inhabitants. The earliest Laconian pottery of Proto-Geometric type belongs to the period *c.* 1000–*c.* 950 BC; it may mark the beginning of settled conditions, as a number of townships arose in the plain. One of these, Sparta, situated well up the valley of the Eurotas, consisted of four villages—Pitane, Mesoa, Limnae, and Conoura. The account given by Pausanias of the early expansion of Sparta is credible, although one cannot be sure whether it rests on genuine tradition or on plausible reconstruction. According to this account, the Spartans first moved northward, conquering Aegys at the approach to Arcadia. In the next generation they advanced southward against the strong town of Amyclae—a long war that led to the absorption of that town into the city of Sparta, which thenceforth consisted of five units instead of the original four—and against the towns of Pharis and Geronthrae, whose inhabitants were expelled. Pausanias' account continues by saying that, in the generation following these conquests, the Spartans overcame Helus on the coast; other coastal towns, such as Las and Gythium, probably fell about the same time. These gains should belong to the 9th and 8th centuries; they built up a large state, embracing the plain of Laconia.

Early expansion of Sparta

The Messenian Wars. The population of Greece was growing, and many states sought relief in colonization. Sparta founded only one colony, namely Tarentum in southern Italy; its earliest pottery belongs to the period *c.* 700–*c.* 650 BC. For the most part, Sparta sought land for its surplus population by expanding against its neighbours. Expansion was attempted in two directions. Northeast of Mt. Parnon lay the coastal plain of Thyrea; there Spartan ambitions came into conflict with those of Argos. In 669 the Argives defeated the Spartans at the Battle of Hysiae; this had the effect of excluding Spartan interests from the plain of Thyrea for more than a century.

The other direction of expansion led westward into Messenia. This plain had been settled by Dorians, and numerous townships had arisen there, probably in much the same way as in Laconia. A Spartan attack on Messenia led to protracted warfare. The poet Tyrtaeus, exhorting the Spartans at a late stage in the struggle, said that under King Theopompus "the fathers of our fathers" conquered Messenia; he added that they fought there for 19 years but in the 20th year the defenders fled from the mountains.

Conquest of Messenia

The chronology of the fighting is obscure. After 370–369 BC, when the Theban commander Epaminondas led a successful campaign against the Spartans and restored Messenian independence, a previously sparse tradition on early Messenian history became contaminated with romantic inventions. Many modern historians believe that there were two early Messenian Wars: the first (*c.* 735–*c.* 715), was the first Spartan conquest of Messenia; but a Messenian revolt (*c.* 660) precipitated a second war, in which the Spartans were ultimately successful. The date suggested for the first war rests largely on an argument from the list of Olympic victors: until 736 the victors are from the western Peloponnese and chiefly from Messenia; but after 736 there is no Messenian, and the first Spartan victor is recorded in 716. But the reliability of the early entries in the Olympic list is an unsolved problem. Moreover, it must be admitted that although writers after 369 distinguish between two early Messenian Wars, earlier writers such as Thucydides (writing in the late 5th century) merely mention fighting without specifying any number of wars. Perhaps the most valuable indication of date is a remark of the Theban general Epaminondas; in 369 he said that he had restored Messenia after 230 years. Evidently something concerning Messenia came to an end about 600.

The conquest of Messenia, completed by the end of the 7th century BC, gave the Spartans extensive land. Much of it was divided into allotments for Spartans. The whole state, consisting territorially of Laconia and Messenia, was properly called Lacedaemon; it was a federal state of somewhat authoritarian type. The institutions of the city of Sparta had sole direction of foreign policy and exercised supervision of all Lacedaemon.

Among the inhabitants of Lacedaemon, three main sta-

tuses should be distinguished. First there were Spartan citizens—the most privileged group. Each family of Spartan citizens had an allotment (*klēros*) of land in Laconia or Messenia; the allotments were deemed to be equal. Secondly there were the *perioikoi*, or free inhabitants of the other towns of Laconia and of those Messenian towns that were allowed to survive after the conquest; each perioecid town had some local autonomy. Finally there were the helots, whose name may be derived from the town of Helus. They were serfs bound permanently to the soil; a group of them was assigned to each Spartan allotment of land, and they tilled it for the Spartan masters as well as for their own subsistence.

The new political system. Aristotle, referring to Tyrtaeus as his source, says that during the Messenian War some people in Lacedaemon demanded a redistribution of land. The protracted warfare against the Messenians and the eventual conquest of their land probably caused extensive political changes within Sparta, but the nature of the change is obscure. Here it will be convenient to consider first the institutions of the city of Sparta as they were in the 6th century BC, and then to try to discern the changes that produced them.

Political institutions in the 6th century. The Spartans attributed their institutions to an early lawgiver called Lycurgus; scholars, however, have not determined whether he was real or, if real, what institutions should be attached to his name.

The dual kingship

Sparta had two hereditary kings, drawn from two royal families. It is often conjectured that the dual kingship arose from the early amalgamation of different communities, perhaps from some combination of the original four villages. The powers of each king included command in warfare, and during the Archaic period this carried with it a large share in determining foreign policy. But by the later decades of the 5th century, decisions on foreign policy were taken in the public assembly; and in their military capacities the kings became merely the executors of the assembly's will, although they retained discretionary control of strategy in the field. In home affairs the kings enjoyed some priesthoods and perquisites, they were members of the council, and they exercised judicial powers of three kinds: they judged cases concerning public roads, they arranged the marriages of unbetrothed heiresses, and they presided over all adoptions of sons within the community. These functions may at first seem slight, but in Archaic societies, where public authority was weak and the family was the strong unit of society, matters concerning heiresses and adoptions were important. Later the domestic powers of the kings did not decline, but the state undertook additional functions through other organs.

The council, or *gerousia* (*gerōn*, "elder"), consisted of 30 members including the kings. The other 28 councillors had to be at least 60 years old; they were chosen by acclamation in the public assembly and remained in office for the rest of their lives. The council could advise the kings, served as a court to try capital cases, and probably had the task of preparing business for the public assembly. The extent of its real influence in politics is a delicate question and requires careful attention.

Any adult male citizen of Sparta could attend the public assembly. In addition to electing councillors, this body elected officers called ephors and had the ultimate decision on questions of legislation and policy. Voting was usually by acclamation, a procedure that allowed some discretion to the presiding officer, but occasionally a division was taken.

The ephorate

A king, a council, and an assembly were the usual pattern in any Greek state; but Sparta developed a further major organ—the ephorate. The ephors were five in number and were chosen by acclamation in the public assembly; each group of five held office for only one year. In the 5th and 4th centuries the ephors transacted a good deal of day-to-day business. They presided at meetings of the assembly, and, because they formulated an issue for voting, they could sometimes influence the outcome. Probably they could preside at meetings of the council. They carried out the instructions issued by the assembly for beginning military campaigns, and they transmitted orders to commanders in the field. They received foreign envoys and provided for bringing their business before the assembly. They exercised supervision over the helots.

The ephorate may have existed in some form from very early times. Each month the ephors exchanged oaths with the kings; the kings swore to rule according to the laws; and the ephors, on behalf of the city, swore to preserve the kingship provided that the kings kept their oaths. Since the oath was monthly, not annual, it may have come from a time when the moon, but not the sun, was observed for calendric purposes. But the functions of the ephors were probably small at first and grew later. Spartan tradition held that the powers of the ephorate were much increased by Chilon, who was ephor for a year within the period 556–553, but nothing specific can be said about his work in internal affairs. Scholars once supposed that for periods of many years the ephors pursued a single corporate policy in opposition to the kings, but this is not plausible; because there were five ephors in office together and because they changed each year, it is more likely that rival political groups used every opportunity to get their own sympathizers elected to the ephorate. Indeed, instances are known where one or two ephors pursued a policy distinct from that of their colleagues and their immediate predecessors. To explain the growth in the significance of the ephorate, perhaps the most likely hypothesis is that public authority, as it grew stronger, increasingly assigned new functions to the ephors.

A special question concerns the relationship between the ephors and the kings. By the time of Thucydides, the ephors could imprison the kings; but this was merely a power of arrest with a view to trial, not a power to judge and condemn. An incident occurring about the mid-6th century is suggestive. King Anaxandrides had a wife but no children, so the ephors urged him to divorce her and take another wife in her place. He refused. As a next step the ephors and the councillors together urged Anaxandrides to take a second wife in addition to the first, and they suggested that the Spartan citizens might take action against him if he did not comply. Although he did comply, it is not clear whether he yielded to the authority of the councillors or to the suggested threat from Spartan citizens. But it is evident from the incident that the ephors alone could not coerce the king.

The genesis of Spartan institutions. Such were the main institutions of Sparta in and after the 6th century. Discussion of the way they developed in the previous century has concerned itself mainly with the relationship between the council and the assembly. Plutarch in his *Life of Lycurgus* preserves a document that may have a bearing on this. Although its text is uncertain at some points, probable readings give the following sense:

> After the people has set up a sanctuary of Zeus Syllanios and Athena Syllania, after the people has arranged itself by tribes and obes, after the people has set up a council of thirty together with the kings, let them gather from season to season for the festival of Apellae between Babyka and Knakion; let the elders introduce proposals and decline to introduce proposals; but let the people have the final decision.

Commenting on the text, Plutarch says that two later kings, Polydorus and Theopompus, added a further clause; this addition, now often called "the rider," says: "But if the people make a crooked utterance, let the elders and the kings decline it."

The Spartan *rhētra*

Plutarch says that the document was an oracle, which Lycurgus brought from Delphi, and that the Spartans called it a *rhētra*. The word *rhētra* means here "an enactment"; and the name suggests that the document was an enactment of the Spartan assembly, even if it was based on an oracular response. Its authenticity can be disputed on linguistic grounds. Even if it is authentic, it mentions a good many institutions that required further definition; so it can only have been part of a body of legislation or perhaps a summary of measures, which required further and more specific enactments.

The main clauses of the *rhētra* deal with the decision-

making functions of the council and the assembly, the festival of Apellai being the occasion for meetings of the assembly. The *rhētra* provides that measures are to be introduced by the council but that the final decision shall be taken by the assembly, which thus has at least a yea or nay competence. A two-stage procedure of this kind is attested later in Athens and in other Greek states.

According to a theory accepted by many present-day historians, the two-stage procedure was introduced by the *rhētra* and was a Spartan invention of the 7th century; it appeased strife between the aristocracy, whose organ was the council, and the wider class attending the assembly; and it achieved this by defining their respective shares in determining policy. The theory has also a social aspect. The hoplite phalanx is first attested *c.* 650, and adoption of hoplite tactics may have enabled the Spartans finally to overcome the Messenians; if their adoption spread the burden of fighting to a wider class than before, this may explain why that class demanded a share in making policy.

This theory is impressive. It is less than explicit, however, about the change made by the *rhētra* and about what the previous condition was. A public assembly of some kind must have existed since the age of the migrations, when it began as a parade of the army to receive marching orders; analogies with other Greek states suggest that in settled conditions such an assembly is never likely to have had less than a yea or nay competence. Moreover, a two-stage procedure for determining policy was not necessarily a deliberate Spartan invention adopted subsequently by other Greek states. Comparable procedures are attested in the Roman Republic—where it was customary to bring measures to the Senate before presenting them to the assembly—and among the ancient Germans. Indeed, in the *Iliad*, Agamemnon, having conceived a plan for withdrawal, first discusses it with a "council of elders" and then summons the army to hear it. From these parallels it appears that in Sparta and in other Greek states the two-stage procedure may have arisen from custom and convenience, without any specific enactment designed to appease a conflict.

The problem is complicated by a fragment of a poem of Tyrtaeus. It reads thus:

> After listening to Phoebus they brought home from Pytho the oracles of the god and perfect words: "Let the lead in deliberation be taken by the god-honored kings, who have care of the lovely city of Sparta, and by the elderly councillors, and then let the men of the people, answering with straight enactments. . . .

The fragment breaks off. It can be read as a paraphrase of Plutarch's *rhētra*, but even so it is much more monarchical in spirit. Alternatively, Tyrtaeus' remarks can be adequately understood even if the *rhētra* is inauthentic; in that case he would seek to commend the two-stage procedure in a monarchical spirit by alleging that it was sanctioned by an oracle. Indeed the fragment is good evidence for only one assertion, namely that the Spartans followed the two-stage procedure.

Plutarch introduces the *rhētra* to indicate the importance that Lycurgus attached to the council. If the rider is combined with the *rhētra*, the result gives the council unusual authority, for the rider grants the council some power of veto over the assembly. Obscure passages of Aristotle and Diodorus have been used to explain and illustrate the provision embodied in the rider, but their proper interpretation is not wholly clear. Until recently it was commonly believed that in Sparta the real policy decisions were usually taken in the council; the assembly, it was supposed, failed to assert itself and merely ratified decisions of the council. New research has led to a different conclusion. The best evidence on Spartan procedure concerns the 5th and 4th centuries and is provided by Thucydides and Xenophon; these two authors hardly ever mention the council, but they indicate regularly that real decisions on policy were taken in the assembly.

Discussion of 7th-century changes in Sparta must be largely inconclusive, but some probabilities can be indicated. It is likely that the struggle with Messenia caused internal tension. It is also likely that hoplite tactics were adopted by the Spartans during the 7th century and had political effects. Those effects need not have been an exacerbation of tension; on the contrary, hoplite discipline may have accustomed the citizens to accepting a higher degree of organization. By the early 6th century, Spartan institutions were relatively articulate and defined; a hundred years earlier they had probably been much more amorphous and fluid.

Social organization. Sparta developed for its citizens an elaborate system of public education and discipline, often called the *agōgē*. At the age of seven, children were taken from their mothers and began to pass through a series of annual stages. The content of education included music and poetry as well as physical exercises and games. Girls were freed from public control when they reached maturity, but for boys, education culminated in two years of intensive military training. Then at the age of 20 each man sought admission to one of the living and eating groups, called *phiditia*. Each *phidition* had 15 members and served as a unit on military campaigns; each member contributed to the common stock a fixed monthly amount of food drawn from his *klēros*, or land allotment. The members of each *phidition* lived together until they reached the age of 30, when they could live at home with their wives. For military purposes men were summoned according to year classes, and the first incidence of fighting fell on those between the ages of 20 and 30; but they could be required for service until they were 60 years old.

The *agōgē*

The *agōgē* probably takes its origin from changes carried out in the 7th or early 6th century BC. It included initiation ceremonies that may go back to an earlier date; what calls for explanation, however, is not the details of the *agōgē* but its incorporation into a well-designed system. As that system trained men for fighting as hoplites, it is not likely to have originated before the adoption of hoplite tactics. The success of the system is reflected in Sparta's military victories from the mid-6th century onward.

The adoption of the *agōgē* may be connected with the introduction of a new way of organizing the citizen body. Originally the Spartans were divided into the three Dorian tribes, membership being hereditary. Tyrtaeus mentions the three tribes in a passage that seems to be an exhortation to Spartans of his own 7th century. But eventually a different method of division, on a territorial basis, was adopted. Spartan inscriptions of Roman date attest citizen units called obes; and the names of these coincide for the most part with those of the five divisions of classical Sparta—with Amyclae and the four original villages. Further, Aristotle says that Sparta had five ancestral regiments; he names them, and one of the names—Mesoa—is that of one of the villages.

Territorial division of citizens

These facts led to the hypothesis that the division into three tribes was replaced by a division into five territorial units called obes. Because membership of the tribes was hereditary, they would have become unequal in size; parallels in other states suggest that the aim in adopting the new division was to distribute evenly the burdens of citizenship, including military service. The problem became complicated by recognition of an Archaic Spartan inscription that names a sixth obe, called Arkaloi. Theories have been propounded that combine the division into three hereditary tribes with a division into numerous territorial obes, but such schemes would leave the ultimate units unequal and thus frustrate the purpose of introducing the territorial division of citizens. The figure five was significant in Spartan institutions; both the ephorate and a board of public messengers called *agathoergoi* consisted of five men each year. This fact and Aristotle's reference to five ancestral regiments suggest that the territorial division of the citizens was fivefold; whether "obe" was the word for the five chief divisions or for subdivisions of them is another question.

The social structure of Sparta produced a strong military force that served both to maintain the city's ascendancy in Lacedaemon and to expand its power in the Peloponnese. It does not follow, as has sometimes been as-

Life in Lacedaemon

serted, that life in Lacedaemon became narrow, militaristic, and inartistic as early as the 6th century. Pindar praised Sparta as the place "Where the counsels of the old men and the spears of the young excel, as do dances and the Muse and splendor." The crafts and trade were conducted mainly by the *perioikoi* because Spartans were excluded from trade. Although the use of coinage was not adopted in Lacedaemon, archaeological finds show that the export of Laconian vases and bronzes continued through the 6th century. Laconian vase painting, though not among the best in Greece, was respectable and reached its highest level *c.* 560–550; its subsequent decline was not as acute as in the case of Corinthian pottery and can best be explained by the competition of Attic ware. Laconian craftsmen continued producing bronze figurines of good quality into the first half of the 5th century.

The condition of the helots was severe, but their misfortunes and discontent in the early period should not be exaggerated. Tyrtaeus indeed compares them to asses worn down by heavy burdens and says that they surrendered half of the produce of the soil. But he wrote during warfare, and "half" may be approximate; Plutarch says that each *klēros* had to supply its master with a fixed and uniform amount of produce, and this suggests that the helots could keep the surplus. For the Battle of Plataea in 479, Sparta supplied 5,000 citizen hoplites and 35,000 helots; the helots were servicing troops, not fighting troops, but it would have been foolish to surround every armed man with seven thoroughly disaffected men, even if the latter were unarmed. Probably relations between Spartans and helots grew much more tense after the helot revolt of the 460s.

The Peloponnesian League. After the reduction of Messenia, and perhaps in consequence of it, Sparta came into conflict with some cities of Arcadia. The fighting culminated in a long war (*c.* 580–*c.* 550 BC) against Tegea. Although the Spartans may have gained some superiority, they were not able to overwhelm the Tegeans, and instead they concluded the war by making an alliance with their enemy. Shortly afterward (*c.* 544) the Spartans resumed their former struggle against Argos; the immediate issue was control of the plain of Thyrea, and this time the Spartans won a decisive victory.

Spartan alliances in the Peloponnese

The alliance with Tegea began a new development. In the 7th century the Spartan policy toward Messenia had been one of conquest and absorption; in the second half of the 6th century, Sparta tried to bring more and more cities of the Peloponnese into an alliance. Moreover, on allying with Tegea, Sparta brought from there the cult of the pre-Dorian hero Orestes; although Sparta remained a Dorian state, by this and subsequent actions it posed as the champion of the pre-Dorian element in the population, thus exploiting an issue that some of the tyrants had used. After defeating Argos, Sparta was evidently the strongest state in the Peloponnese, and during the next decades it succeeded in winning most of the Peloponnesian cities as allies. The resulting organization is called the Peloponnesian League. The stages of its growth are obscure; in 510 the Spartan king Cleomenes I led a force by land against Athens, and this shows that he had the goodwill of Corinth and Megara.

The name Peloponnesian League is modern; the ancient name was "the Lacedaemonians and their allies." The league began from bilateral treaties between Sparta and the several allies. Eventually a congress of the allies met and contracted a multilateral agreement; this may have occurred in the closing years of the 6th century, when Spartan attempts to intervene in Athens precipitated a crisis among the allies (see below *Relations among the Greek poleis to the end of the 6th century BC: Spartan policy under Cleomenes*). The main provision of the multilateral agreement was that all members would be bound by a majority vote of the allies. The league lasted till 366, although its extent varied from time to time. It was a new experiment in interstate organization. Regional leagues elsewhere (*e.g.*, in Aetolia and Boeotia) relied on a fiction of common descent; the Peloponnesian League was an artificial creation of political power.

ATHENS

Early period. The city of Athens, with its Acropolis, was one of the few Greek sites where habitation was not interrupted at the end of the Bronze Age. Indeed, Athens was comparatively prosperous in the Proto-Geometric and Geometric periods. But it is not proven that any political institutions survived from the Bronze Age. Moreover, it is most unlikely that Athens retained in the "dark ages" any ascendancy over other parts of Attica that it may have previously exercised. Attica, Athens' territory in the Classical period, was large, but its unification was only completed at a late date.

Geographically, Attica consisted of several plains divided by hills. The central plain held the city of Athens and a strip of coast, including the bay of Phaleron. Farther west was the plain of Thria, on which the largest settlement was Eleusis. Eastern Attica consisted partly of low-lying territory and partly of hills; and it held several settlements, the most important being at Brauron and Marathon.

Unification of Attica

A lengthy process of Attic unification was probably composed of two stages. In the first, the strongest settlement in each plain acquired control over the other towns of its plain; thus three or four powerful states emerged. In the second stage, Athens, which already controlled the central plain, absorbed the communities of the outlying districts. This second stage was completed not later than the first half of the 7th century BC, but perhaps not much before.

The result was a unitary state; the political organs of the city of Athens were the sole focus of Attic political activity. But in the 7th century, public authority was still weak; real power belonged to locally influential families, each commanding numerous dependents. Recollections survived of conditions that prevailed before the final steps of unification; late in the 5th century, people remembered that there had once been warfare between Eleusis and Athens. Accordingly, at least some of the political conflicts of the 7th and 6th centuries were struggles of "regionalist" type—that is, struggles of leading families in the outer districts against the ascendancy of those in the central plain.

Athenian political institutions

The chief political institutions of the unitary state were an executive board called the "nine archons," a council, and a public assembly. Tradition held, credibly enough, that Athens had once been ruled by kings who retained office for life but whose powers had been diminished in two ways: other offices were created to take over some of their functions, and the term of all the officers was reduced to one year. Hence, the word king survived as the title of one of the nine archons; the others were the archon (or eponymous archon, since his name was used to designate the year), the *polemarchos* ("war commander") and the six *thesmothetai* ("setters of verdicts"). The evidence conflicts on the exact mode of selecting the nine archons, but it is safe to say that until 487 they were always elected by the assembly.

The council came to be called the "council of the Areopagus" because it held some of its meetings on that hill west of the Acropolis. The council consisted of all who had held any of the nine archonships. Doubtless it had begun as a council advising the kings. (The public assembly, too, probably existed in some form from time immemorial, and questions were brought before it for ultimate decision; but probably its meetings were infrequent in the Archaic period.) Athenian writers of the 5th and 4th centuries BC knew that the council had once been powerful, but their attempts to define its former functions produced little more than vague generalities. Probably its ascendancy in the Archaic period rested not on specific powers but on a personal factor. The minimum age for the nine archons was 30 years. As one of the archons, a man had only one year in office, but thereafter he could expect some 30 years of active life as a councillor. The archons were likely to respect the opinion of their seniors, to whose august company they would soon be admitted.

Cylon's uprising

Probably in 632 an uprising led by Cylon tested the stability of the unified state. Cylon had married the

daughter of Theagenes, tyrant of Megara. Encouraged by an oracle, Cylon gathered his friends and a force from his father-in-law and seized the Acropolis during the Olympic festival. But the Athenians came en masse from the fields, beseiged the Acropolis, and entrusted operations to the nine archons. Cylon escaped but his followers ran short of food and made terms with the archons, who agreed to spare their lives; then, as the Cylonians came down from the Acropolis, the archons killed them. Later those responsible for the breach of faith were exiled as being accursed, but later still they were allowed to return. The scandal of the curse was revived more than once against their descendants.

The nature of the rising is obscure. Evidently Cylon hoped to make himself tyrant, but attempts to regard him as a champion of popular discontent have no evidential support. A clue may perhaps be found in the identity of his opponents. Whenever the scandal of the curse was revived, it was used against the powerful family of the Alcmaeonids and their associates; apparently the Alcmaeonids predominated among the archons of 632. As will be seen later (see below *Peisistratus and his sons*), the Alcmaeonids belonged to the central plain or possibly to southeastern Attica. Cylon could get forces without impediment from Megara; and this suggests, though by no means proves, that he belonged to western Attica. Possibly his rising reflects a conflict between families powerful in different regions.

Still greater mystery surrounds the activities attributed to Draco (Dracon) in 621. Later Athenian tradition said that he wrote down all the laws but that subsequently Solon repealed the laws of Draco except those on homicide. This story sounds artificial, and it is more likely that Draco concerned himself only with homicide laws. In 409 the homicide laws of Draco were reinscribed on stone, and the part of the inscribed text dealing with unintentional homicide has been recovered. The law provided that if a man killed another man unintentionally his case should be judged by a "Court of Fifty-One," called the *ephetai;* if they upheld his plea, the relatives of the victim could grant him pardon by a unanimous vote, but if the relatives declined to do so, the state provided the killer with a safe-conduct to the border.

Laws of Draco

Supplemented by evidence from the 4th-century orators, the inscribed text throws a good deal of light on early Attic procedure. The blood feud is implied, and the complementary institution of wergild (payment to relatives of a slain person, according to a determined value for the deceased) is attested. By recognizing the killer's intention as distinct from his act, the law moved toward greater sophistication; by setting up a court to judge intention and by providing a safe-conduct to the border for the unintentional but unpardoned killer, the state asserted its authority to a modest but real degree. Unfortunately the inscribed text of Draco's laws is incomplete.

By the 4th century, Athens had no less than five homicide courts, including the Areopagite council, which dealt with intentional homicide. This system of courts observed other distinctions besides those based on intention; for example, it recognized a category of lawful homicide, and it treated the killer of a slave or foreigner differently from the killer of a citizen. So complex a system must have taken a long time to develop, even though all the provisions may have had an early origin. It is not clear whether all parts of the system were attributed to Draco, and it is not clear which items were innovations of 621. But at least it can be said that by 621 the state had asserted itself in the originally private sphere of killing and the blood feud.

The reforms of Solon. Athens in the Geometric period was prosperous, but in the 7th century BC its economy was comparatively backward. Its failure to found any colonies in that century indicates political weakness at a time when population was doubtless growing in Attica as in the rest of Greece.

Early in the 6th century, Solon—in political poems of which parts are preserved—spoke of acute antagonism between rich and poor. This economic crisis has often been regarded as the result of impoverishment, but the archaeological record suggests a more complex explanation. The export of Attic pottery decorated with black figures on a red background began in the period 620–600, and the ware reached farther afield until *c.* 520; thereafter Attic ware retained the predominance it had achieved, but pottery decorated with red figures on a black background eventually became more popular than the black-figure ware. This export trade was not only in vases but also in their contents, perhaps wine and olive oil. Thus the Athenian economy was already expanding in the early 6th century. The expansion may have brought complex dislocation; in particular, amid growing prosperity, many people may have come to resent conditions they had previously tolerated.

Solon was eponymous archon in 594; then or later he received a special commission to appease the strife and write down the law. Nothing is known about the political steps leading to his appointment; perhaps the normal rivalry between powerful families grew more acute, with the risk that one group of families might exploit the grievances of the poor. The nature of the economic predicament and of Solon's solution appears in part in one of his poems. He says that he removed the "marking stones" (*horoi*), which had held the land in slavery; he adds that he freed men who had formerly trembled at the whims of their masters. These freed men should be identified with the *hektēmoroi*, or "sixth-parters," who according to Athenian tradition tilled the soil for wealthy landowners before Solon's reforms and paid a sixth of the produce to the landowners.

Solon's solution to economic problems

Thus a tolerably clear picture emerges, but the origin of the dependent status of the *hektēmoroi* is another question. Athenian scholars of the 4th century BC held that this status arose from debt, and many modern theorists have made the same assumption. One of the more sophisticated of these theories says that, as population grew, the land was cultivated more and more intensively. Eventually the peasant found that his crop would not suffice for his family until the next harvest; he therefore borrowed from a wealthy neighbour and expected to reap a surplus in the coming year. But because the need to fertilize the soil or to let it lie fallow was not understood, the next year's crop was inadequate; soon the peasant contracted a permanent tie with his wealthy neighbour, paying him a sixth of the crop, and a marking stone was placed on the land to show that it was now under an obligation.

Solon, however, does not mention debt in the extant poems, and perhaps an alternative explanation should be preferred. This says that the position of the *hektēmoroi* was not a recent development due to economic pressures and debt but a traditional status of inferiority, which arose in the "dark ages," when humble men offered their services to powerful men in return for protection in unstable conditions. A dependent status of this kind is attested in several Greek states, including Argos, Sicyon, and Thessaly. Solon in any case abolished the status of the *hektēmoroi*, making them fully free citizens and probably granting them full ownership of the land from which they had previously paid part of the crop. The wealthy landowners thus lost their claim on the *hektēmoroi* and gained little beyond freedom from the threat of violent revolution. The reform was called the *seisachtheia*, or "throwing off of burdens."

Solon tried to draw up a comprehensive statement of the law, and his laws were written on wooden *axones* and *kyrbeis*, objects of disputed character. Some of his provisions are quoted by the Attic orators and by later writers. Athenians in Classical times, however, tended to attribute all their laws to Solon, and thus the question of authenticity is sometimes difficult.

The recent study of indisputably genuine provisions has shown that the penalties known to Solonian law were negative. The state could withdraw legal protection from a culprit, thereby making him an outlaw (*atimos*), or it could utter a curse against him; correspondingly, fines could be imposed only in an indirect way—that is, the culprit could buy himself free from the basic penalties of outlawry or the curse. Positive penalties such as death,

Penalties in Solonian law

imprisonment, and confiscation of property arose only later in Attica, when the state learned to intervene actively. Few things illustrate more clearly the weakness of public authority in the early 6th century.

Some of the laws may have been intended to improve the economy. One of them offered citizenship to those aliens who settled in Attica with their families in order to practice a craft. Another, cited from the first of Solon's *axones*, allowed export of olive oil but forbade export of any other agricultural produce. The effect of such measures should not be exaggerated. They may have been traditional rules, which Solon reduced to writing. Even if they were innovations, it would be naïve to attribute the growth of Athenian prosperity primarily to them; the *seisachtheia* may have increased freedom of movement, but the forces determining the growth of the 6th-century economy were more complex than contemporary legislation. The tradition that Solon changed the standard of Athenian coinage—from that current in much of the Peloponnese to that of Corinth and Euboea—should be rejected; Athenian coinage did not begin so early.

Modern writers have often attached large significance to those Solonian measures that affected the constitution. The most important of these was the division of the Athenians into four property classes. The first class, the *pentakosiomedimnoi*, consisted of those whose estates produced at least 500 measures of grain, wine, and olive oil annually. Membership in the next two classes, the *hippeis* and the *zeugitai*, depended on annual production of 300 and 200 measures respectively. Those who lacked sufficient land to produce 200 measures annually constituted the fourth class, the *thētes*. Political privilege was graded according to the classes. Only *pentakosiomedimnoi* qualified for the office of treasurer of Athena; the nine archons were drawn probably from the first two classes; the *thētes* enjoyed no privilege beyond membership in the assembly.

Division into property classes

A widely held theory maintains that the property classes were a major innovation. It is supposed that after the unification of Attica was completed, political privilege was restricted to a hereditary ruling class, or caste, the eupatrids; they alone, it is said, were admissible to the nine archonships and hence to membership on the council. By the early 6th century some families outside this caste had achieved comparable or even greater wealth and demanded a share in political power. Solon conceded this demand, replacing heredity with wealth as the qualification for office. By so doing he transformed Athens from a closed to an open society.

Several criticisms may be made of this theory. Some of the evidence for the existence of a eupatrid class is poor, and the better evidence does not show when that class monopolized political office; it is conceivable that the eupatrids ruled Athens only at a very early stage, when the long process of unification had scarcely begun. Moreover, as Athens gradually absorbed the rest of Attica, it must have made compromises with the groups ruling at least some of the other communities; the political institutions of Athens and the other towns must have been adjusted mutually to some extent. This process would be likely to break down the exclusiveness of a hereditary ruling class in Athens; and compromises between the leading families of different towns may have even led to the adoption of wealth as the criterion for political privilege. Indeed, study of the names of the property classes suggests a pre-Solonian origin. The name of the first class, *pentakosiomedimnoi*, refers etymologically to qualification by 500 measures, but the names of the other classes are not derived from words for numbers of measures: *hippeis* refers to cavalry service; *zeugitai*, to a yoke of animals. Because the names are thus disparate, Athenian law probably accepted them at different times; in other words, at least the three lower classes were probably recognized as the basis for graduated political privilege before the work of Solon.

The poem of Solon that mentions marking stones appears complete and provides a summary of his work. It devotes 17 lines to the *seisachtheia* but only two lines and a word to his other legislative work; in those two lines he says merely that he "wrote laws alike for the bad man and the good, fitting straight justice into each." If he had carried out a major innovation by introducing the property classes, surely he would have had something to say about it.

The same argument may be used against the attribution to Solon of another major innovation—the Council of Four Hundred. Aristotle says that Solon created such a council, drawing 100 members from each of the four tribes into which the Athenians were traditionally divided. Plutarch adds that the task of this council was to prepare business for the assembly. But neither Aristotle nor Plutarch explains how the members of the council were selected or how long they stayed in office; thus neither has any clear conception of the council. There is no certain reference to the activity of this council in the 6th century; and that is strange if Solon really created such a council, for so serious a step ought to have had some perceptible effect. The question of the authenticity of the Council of Four Hundred attributed to Solon has not been finally resolved; perhaps the easiest hypothesis is that the story of that council is a later fiction, designed perhaps in the 4th century to provide justificatory precedent for the Council of Five Hundred, which Cleisthenes introduced.

Authenticity of the Council of Four Hundred

As comparisons with other ancient states at a similar stage suggest, Solon may have conceived his task for the most part as one of writing the laws down, not of making new laws. Even in the *seisachtheia* he may have believed that he was restoring a pristine condition. Reducing customary law to writing is a major improvement because it diminishes the liberty of judges to favour their friends. It also brings new precision into the law. For example, lawsuits, in the time of Solon, except for cases of homicide, were heard by the nine archons separately (each of the nine archons decided one group of cases), but serious cases could then be referred to the assembly, which was called the *hēliaia* when it sat as a court. In writing down the laws, Solon had to specify how serious an issue had to be before it could be referred to the *hēliaia*. A written statement of the law was a more valuable contribution to the growth of the Athenian state than were the deliberate innovations sometimes attributed to Solon.

Peisistratus and his sons. Thanks to Herodotus, Athenian political conflicts become clear toward 560 BC. The main rivalry was between a group called "the men of the plain," led by Lycurgus, and one called "the men of the shore," led by Megacles. But Peisistratus, who had won popularity by commanding a successful campaign against Megara, organized a third group—"the men from beyond the hills." Pretending to have been wounded by his enemies, Peisistratus persuaded the assembly to grant him a bodyguard of club bearers; with these he seized the Acropolis in 560. But within a few months, Megacles and Lycurgus joined forces and drove out Peisistratus, who withdrew, probably not from Attica but to his private estates at Brauron.

The rise of Peisistratus

A few years later Megacles quarrelled with Lycurgus and allied himself with Peisistratus, who agreed to marry Megacles' daughter. The confederates dressed up a woman as Athena, and she conducted Peisistratus back to Athens. But in 556 Peisistratus quarrelled with Megacles, who withdrew his support; and so this second tyranny collapsed. This time Peisistratus left Attica and stayed away for ten years; he spent much of the time at Mt. Pangaeum in Thrace, where he exploited the silver mines. Several powers worked for his restoration. Thebes, among other cities, gave him money, Argos sent a force of troops, and Eretria let him use its territory as a base. In 546 he sailed from Eretria and landed above Athens, at Marathon, unopposed. When he began marching toward Athens his enemies brought their forces from the city against him; but he defeated them at Pallene and met no further resistance. The tyranny that Peisistratus thus won was passed on to his sons after his death.

Attempts have often been made to explain the conflict

The conflict between Peisistratus and his rivals

between Peisistratus and his rivals in terms of constitutional programs, class interests, and even differences of foreign policy; but such theories are not convincing. The readiness with which Megacles, Lycurgus, and Peisistratus could make and break alliances suggests that the followers of each were bound firmly to the person or family of their leaders rather than to any abstract principle, program, or interest. Moreover, any explanation of the rise of Peisistratus must do justice to the regional names that Herodotus records for the three parties. In Attic usage, the word plain meant the plain of the city of Athens; evidently Lycurgus' men belonged there. The "shore" was a long coastal strip, beginning perhaps within the city plain and extending southeast toward Sunium. Megacles came of the Alcmaeonid family, which belonged in the city during the 5th century; his party of the shore probably had its centre in or near the plain of the city. The party of Peisistratus is called by Herodotus "the men from beyond the hills." (Aristotle calls it "the men of the hills," but this term is less likely to be accurate because by Aristotle's time the tradition had become contaminated by speculation.) Brauron, the home of Peisistratus, was indeed separated by hills from the city of Athens, as was Marathon, where Peisistratus landed unopposed in 546.

The rise of Peisistratus is a clear instance of "regionalist" conflict. Previously there had been moderate rivalry between the parties of Lycurgus and Megacles, both based in or near the city, for the unification had brought ascendancy to men of that district. Bringing his local following to Athens, Peisistratus injected a new acerbity into the political struggle; he expressed the resentment toward leading families of the city felt by leading families of eastern Attica. To say this is not to deny that he won popularity outside his native district; that is proved by the grant of a bodyguard in 560, and after the Battle of Pallene he was accepted by the great majority of Athenians.

Rule of the Peisistratids

Peisistratus ruled until his death in 528 and was succeeded by his eldest son Hippias, who allowed some influence to his brothers. Later Athenian tradition was to speak favourably of the tyrants; Herodotus, Thucydides, and Aristotle said that they ruled well and observed the laws. The tyrants ensured, however, that each year some of their supporters should be among the men elected to office; hence, through the nine archonships there arose within the council of the Areopagus a group of men fully committed to the tyrants, and this may have been the key to their continued rule. Peisistratus and his sons tried to conciliate as many Athenians as possible. Herodotus says that the Alcmaeonids and some others withdrew into exile in 546, and this is credible. But the Alcmaeonids were persuaded to return before 525, when their leader, Cleisthenes, was archon.

It is often asserted that on winning his third tyranny, Peisistratus seized land from his leading opponents and distributed it to peasants. This is a modern conjecture unsupported by ancient evidence, although it is not unlikely; a possible redistribution of land was much discussed in 6th-century Athens. Peisistratus introduced the first direct taxation in Attica; he exacted a proportion of produce, recorded variously as one-twentieth (by Thucydides) and one-tenth (by Aristotle). Aristotle says that Peisistratus created judges to tour the countryside (*dikastai kata dēmous*), so that the state provided jurisdiction even in distant parts of its territory. The same office was certainly created in 453, and it is difficult to see how it could have lapsed before then. Thus the attribution to Peisistratus may be apocryphal; but if it is genuine, the establishment of this office in the 6th century was an important step toward increasing the unity and internal power of the state.

An ambitious foreign policy gave the Athenians an increased chance to take pride in their city (see below *Relations among the Greek poleis to the end of the 6th century BC: Athenian foreign policy*). The same can be said of the building policy of the tyrants; although little can be asserted about this with confidence, at least a temple was built on the north side of the Acropolis to house the ancient wooden image of Athena. Magnificence, a common note of tyranny, is apparent among the Peisistratids; such poets as Anacreon of Teos, Lasus of Hermione, and Simonides of Ceos were invited to sojourn at their court.

Fall of the tyranny

An incident occurred in 514 that began a series of events that brought about the fall of the tyranny. Two men—Harmodius and Aristogeiton—felt they had been slighted by Hipparchus, a younger brother of Hippias, and they plotted to overthrow the family. But their plans were ill conceived; they succeeded only in killing Hipparchus, and in the consequent investigation Hippias came to believe that discontent was widespread. He therefore made his rule more severe, killing many Athenians. The Alcmaeonids withdrew into exile again. A year or so later they led a party of exiles into Attica and fortified a position at Leipsydrium, but they were driven away by the forces of Hippias; evidently the bulk of the Athenians was not willing to turn against the tyranny.

The Alcmaeonids resorted to diplomacy. They won the favour of the Delphic oracle, which accordingly urged the Spartans repeatedly to overthrow Hippias. A first Lacedaemonian expedition was sent by sea under Anchimolius, but it was unsuccessful; Hippias had gained cavalry from his allies, the Thessalians, and when Anchimolius landed his force in the bay of Phaleron, the cavalry overcame him. In 510 the Spartans sent a land expedition under King Cleomenes I. He defeated the Thessalian cavalry and besieged the Peisistratids on the Acropolis until they yielded and agreed to leave Attica; they withdrew to Sigeum.

The above narrative of the overthrow of Hippias is the Athenian account, the only one to survive. It emphasizes the role of the Alcmaeonids, but it does not conceal the fact that the fall of the Peisistratids was due to foreign intervention; the step fatal to Peisistratid rule was a decision taken in Sparta, although the Delphic oracle was useful in providing religious justification.

The reforms of Cleisthenes. Some time after the fall of Hippias, rivalry developed between Cleisthenes and Isagoras, who was archon in 508. Cleisthenes was worsted, but he instituted reforms that gave him ascendancy. So Isagoras appealed to Cleomenes, with whom he had contracted friendship during the campaign that overthrew Hippias. Cleomenes sent a herald and then came himself to Athens; he demanded the expulsion of Cleisthenes and of 700 families descended from those who had become accursed by slaying the followers of Cylon (see above *Athens: Early period*). Further, he tried to dissolve the council and replace it with 300 supporters of Isagoras; but the Athenians rallied to the support of the council and expelled the Spartan king. Cleomenes tried once more to make Isagoras master of Athens: he brought the army of the Peloponnesian League to Eleusis and persuaded the Boeotians and Chalcidians to attack Attica from the north and the northeast, respectively. But at Eleusis the Corinthian contingent in the Peloponnesian force mutinied, and the force disbanded; then the Athenians defeated the Boeotians and Chalcidians successively.

Rivalry between Cleisthenes and Isagoras

It is difficult to ascertain with clarity the nature of the rivalry between Cleisthenes and Isagoras. Inferences from the measures of Cleisthenes are not easy to draw, because the program of Isagoras is not known. But Isagoras' local origin may provide a clue. Herodotus observed that the relatives of Isagoras worshipped Zeus Karios. In Attica the cult of Zeus Karios is attested only at the village of Icaria just north of Mt. Pentelicus. It is therefore likely that Isagoras came from an easterly district separated by hills from the city of Athens. The possibility must be considered that his conflict with Cleisthenes was "regionalist" in character. Perhaps Isagoras attracted the support of those Areopagites who had become councillors through their loyalty to the Peisistratids; not many men had been expelled with Hippias in 510.

New tribal system

The reforms of Cleisthenes introduced a new tribal system. Previously Athenian citizens had formed four hereditary tribes, but thenceforth these were retained only for some religious purposes. Cleisthenes introduced a divi-

sion of the citizens into ten new tribes, constructed in a complex way. The basic unit was the deme—a village or parish; all Attica, including Athens itself, was now divided into more than a hundred demes, which varied in size. To form tribes from the demes, Cleisthenes divided Attica into three large districts, called "the city," "the coast," and "the interior." Each of these districts was subdivided into ten *trittyes*, or "thirdings"; their boundaries were drawn so that each *trittys* held one or more complete demes. Then to form each tribe Cleisthenes put together three *trittyes*, drawing one from each of the three districts.

Each deme had its own assembly and its annual headman, or *dēmarchos*. It kept a list of its adult male members, and membership in a deme constituted proof of citizenship. In the first instance men were assigned to demes because of local residence; but for the future, membership was hereditary. The *trittyes* failed to develop any extensive functions and served essentially as a means of distributing demes among tribes. Each tribe had its own officers and assembly. Moreover, the tribes were used for distributing the burden of military service; thenceforth the main Athenian land force was ten regiments of hoplites.

Other ancient states underwent a change from hereditary tribes to territorial tribes when the former became seriously unequal in size and could not absorb new immigrants; the introduction of territorial tribes served to equalize burdens. Considerations of this kind may have influenced Cleisthenes, but they do not explain the peculiar tripartite nature of the new Attic tribes. Some historians, unable to discover any precise purpose, have followed Aristotle in saying that Cleisthenes sought merely to mingle together citizens of different districts and thus break down local barriers. But this explanation is inadequate; the reforms gave Cleisthenes ascendancy over Isagoras, and so they must have had a partisan character. Some recent historians have observed that in outlying parts of Attica the boundaries of some *trittyes* were drawn in such a way as to break down powerful units. For example, in the northeast a unit of four townships—called the "Tetrapolis" and including Marathon—continued to exercise religious functions, but it was split between two *trittyes* and hence between two tribes. Such steps were doubtless deliberate, but they could have been achieved through unitary tribes; they do not explain why each tribe had demes from different districts.

Explanations for tribal systems

No fully satisfactory explanation for the Cleisthenic tribal system has been offered. Yet it must be admitted that the tripartite composition of the tribes looks like a measure taken in a "regionalist" struggle; it may have promoted the ascendancy of the leading families residing in or near the city. How it might serve this end can only be discerned in part. With one exception the assemblies of the several tribes met in the city; thus influential families of the city could bring their dependents to vote more easily and in greater numbers than could influential families of outlying districts. Again the rule of candidature for office may be significant. In 501 the office of general (*stratēgos*) was introduced or reformed; thenceforth each year ten generals were elected by the assembly of all citizens, but one had to be chosen from each tribe. Likewise the number of archons was increased from nine to ten through the addition of the secretary of the *thesmothetai*, although they continued to be called the nine archons. If one member of the board of ten generals was to be chosen from each tribe, then, because each tribe held some city territory, all members of the board might be city men; and this was likely to happen because the electoral assembly met in the city.

Council of Five Hundred

The other major reform of Cleisthenes was the introduction of the Council of Five Hundred. The members of this were chosen by lot and held office for one year; in the 4th century one second term was permitted, but at first even this may not have been allowed. Each tribe supplied 50 members to the council, and within the tribes each deme supplied a number of councillors roughly proportionate to its size. The task of the council was called *probouleusis* and consisted of preparing business for the assembly; the rule was that no item could come before the assembly unless it had been considered previously by the council.

The reason for establishing the new council is not difficult to discern. As Aristotle observed, there had to be a smaller council to prepare items for a public assembly. A mass meeting of several thousand could not deal with business in the raw. But the preparatory council, if it had the will, was in a position to influence the outcome of the assembly's vote by its formulation of the issues. The members of the Council of Five Hundred, however, were not men of particular talent or ambition because they were chosen by lot; and they did not acquire expertise because they served only for one year or, at most, two. Thus by virtue of its personnel the council was not likely to assert itself. In practice it prepared business efficiently but left the real decision to the assembly; its existence ensured that no other body would encroach on the assembly's authority.

The practice of ostracism

Aristotle, perhaps correctly, attributed to Cleisthenes a further measure—the introduction of ostracism. By this practice, in late winter of each year the assembly was asked whether or not it would hold an ostracism; if it answered affirmatively, at the next possible meeting each citizen deposited a potsherd on which he had written the name of the man who he would most wish to have leave Attica. A valid ostracism required 6,000 votes. The man against whom the most votes were cast had to leave Attica for ten years but retained possession of his property. Attempts to link the presumed reasons for this custom with the other measures of Cleisthenes are not persuasive. The origin and purposes of ostracism remain opaque.

In the second half of the 5th century, Cleisthenes was regarded as the founder of the democracy. The introduction of the new council may have been even more effective than the tribal reform, both for the outcome of the struggle with Isagoras and for the further development of Athens. The council ensured that real decisions were taken in the assembly, and in a sense this was democratic. But the word *dēmokratia* had not yet been coined in the time of Cleisthenes, and there was no synonym; his purposes should not be sought in democratic ideas. The assembly met in the city, and so it could most readily be influenced by families of the city and its immediate neighbourhood. Cleisthenes brought "regionalist" struggles to an end by winning victory for the city.

Society and the economy. In antiquity the Athenian economy depended upon the natural resources of Attica. Noteworthy mineral resources included silver in the southeast and clay for pottery. Attica's pronouncedly Mediterranean-type climate—mild temperatures and less rainfall than in many parts of Greece (the annual average is 16 inches, but there is considerable variation from year to year, and virtually all the rain comes in winter)—suited the territory to fruits such as the vine, the olive, and the fig, which can send roots deep down into the soil and in summer draw on moisture stored up from the previous winter.

Economy in the late 7th century

In the late 7th century BC, Attica was predominantly a land of subsistence farming. The main crop was grain—especially barley, which is hardier than wheat—but vines were also grown. There was some fishing. Relatively few animals were kept. Marginal land was brought under cultivation to support the growing population. But as the record of black-figure ware shows, exports were beginning to expand even before 600. Furthermore, there was contact with the flourishing commercial cities of Corinth, Megara, and Aegina. The crisis facing Solon was due not only to the poverty that arose when population grew beyond the local means of subsistence but also to the desire to achieve better conditions.

The measures taken by Solon are now obscure, but something can be said about their effects. Thenceforth rural Attica was a land of free peasants; there is no later trace of any quasi-servile status, such as that of the *hektēmoroi*. On the other hand, wealthy men could still command a large following of humble dependents. (As late as 480, at the Battle of Artemisium, Cleinias supplied his own trireme, which he equipped and manned at his

own expense; this means that he could command about 200 able-bodied men.) By abolishing the status of the *hektēmoroi*, Solon increased the mobility of rural manpower; thenceforth a subsistence farmer who failed might drift to the city. A tradition about Peisistratus may indicate some growth of an urban proletariate; Aristotle says that the tyrant lent money to poor men so that they could settle as farmers. Such a scheme probably concerned newly cleared land on the hills, where vines and olives could be grown but required capital.

Growth of trade

The distribution of black-figure ware is the clearest indication of the growth of the Athenian economy. In the period 560–520, Attic vases reached Chios, Lesbos, Cyprus, Asia Minor, the coasts of the Black Sea, Egypt, south Italy, Etruria, and southern France. (Many of the vases were of high artistic quality and prove the existence of skilled potters in Athens.)

Some political developments helped the trade. Sometime between 600 and 560 the Athenians captured the island of Salamis from Megara. Thus, the bay of Phaleron became safe from attack, and trade with Corinth was facilitated. Athenian goods reaching the west may have travelled in Corinthian ships. After Peisistratus had finally made himself tyrant, an Athenian expedition under Miltiades settled the Thracian Chersonese on the European shore of the Hellespont, and the tyrants kept up the connection with the settlement into the next generation. Peisistratus captured Sigeum in the Troad from the Mytilenaeans and sent one of his sons to rule there as tyrant. The expeditions to Sigeum and the Chersonese suggest that Peisistratus was interested in the trade route through the straits to the shores of the Black Sea.

The effect of coinage on the Athenian economy is difficult to determine. Studies conducted since World War II have shown that the earliest coins were struck in Lydia *c.* 640–*c.* 630, not *c.* 700 as previously supposed. The invention was adopted gradually by many Greek cities. The earliest Attic coins, called by numismatists "Wappenmünzen," bore a variety of heraldic designs, which may stem from different families; these were struck not before *c.* 575. They were superseded by coins bearing the design of the owl, the emblem characteristic of Athens, and these began not before *c.* 527. Some scholars indeed would put the earliest "Wappenmünzen" soon after 550 and the earliest "owls" *c.* 510.

While in exile, Peisistratus drew silver and perhaps gold from the mines of Mt. Pangaeum; this enabled him to raise forces for his restoration and to maintain a bodyguard thereafter. He may have begun working the silver mines at Laurium in southeast Attica. The Peisistratids were not the only family to interest themselves in foreign sources of wealth. A legend of the Alcmaeonids told how one of their ancestors, Alcmaeon, visited the Lydian king Croesus and came away laden with gold. Part of a grave monument honouring an Athenian named Croesus and erected *c.* 530 has been found to the southeast of Mt. Hymettus and has been claimed as indicating the home of the Alcmaeonids. This inference is not necessary; there is no reason to suppose that the Alcmaeonids were the only Athenian family to develop relations with the Lydian kingdom.

Foreign sources of wealth

Although the stages of economic growth are obscure, by 500 Attica was a very different place than it was a century before. It had become the leading exporter of vases among the Greek cities; its other exports included oil, wine, and silver. It imported grain, fish, and ship timber. The population was growing, and economic expansion had attracted immigrants. According to Herodotus, toward 500 the number of adult male citizens was 30,000; the reorganization by Cleisthenes had entailed some survey of the citizen body, and this figure may be approximately correct.

OTHER IMPORTANT POLEIS

The Greek *polis* was usually small, and therefore special interest attaches to those *poleis* that achieved rule over a comparatively large territory. Chief among these were Sparta, Athens, and Thebes. Lacedaemon was, strictly speaking, a federal state, although most power belonged to the dominant city, Sparta. Athens organized Attica as a unitary state. Boeotia, however, in which Thebes was located, was a federation of about a dozen cities that varied greatly in size and power.

Thebes. Geographically, most of Boeotia consisted of two river basins—those of the Asopus in the south, where Thebes predominated, and of the Cephissus in the north, where Orchomenus was the strongest city. There was rivalry between Thebes and Orchomenus, and usually Thebes had the superiority. Starting in or before the 6th century BC, the Thebans built up a federation of Boeotia, which was dissolved in 479. Nothing is recorded about its constitution, but it is fair to infer from the structure of a restored confederacy (447–386) that it was organized on relatively liberal principles. (The constitution of the restored Boeotian confederacy is known and has remarkable features: each city managed local affairs, and the supreme federal organ was a representative council of 660 members; in 395 Thebes supplied 240 of these—more than any other city but less than a majority.) Apparently by 519 the early federation embraced much of Boeotia. Orchomenus, however, did not belong, and on the southern border Plataea refused to join; attacked by the Thebans in 519 (or possibly *c.* 509), the Plataeans gained the alliance of Athens and hence preserved their independence.

Boeotian confederacy

Phocis and Thessaly. Northwest of Boeotia, Phocis lay as a broad wedge separating Locris into two parts. As late as the early 5th century, the men of East and West Locris were still aware of their mutual bond and cooperated to found Naupactus on the north shore of the Corinthian Gulf. For a long time in the 6th century, Phocis was on the defensive in an intermittent conflict with Thessaly; finally about 500 the Thessalians invaded Phocis, but the Phocians inflicted heavy defeats on the Thessalian infantry and cavalry in two successive battles.

Thessaly itself, a large plain surrounded by four ranges of mountains, stood apart from the political development of the rest of Greece. It was dominated by a landowning aristocracy; indeed its several cities may have been brought into existence by their local dynasties, such as the Aleuads of Larissa and the Scopads of Crannon. These cities were strongholds or market towns rather than centres of any lively political development. Intermittently, the leader of a local dynasty gained recognition of his ascendancy in all Thessaly and took the title of *tagos;* but at other times federal organization was dormant.

Overseas settlements. The Aegean islands and the cities of western Asia Minor were the scene of a particularly brilliant development in the Archaic period. The affairs of Mytilene, the chief town of Lesbos, are known in part from the fragmentary poems of Alcaeus (*c.* 620–*c.* 580). His lifetime saw the final overthrow of the Penthilids, a clan that had once controlled the city. A complex series of factional struggles within the aristocracy followed; there is no sufficient warrant for the common assumption that Pittacus, one of the contenders, led a popular movement. Alcaeus was at first an ally but later an enemy of Pittacus and was driven into exile, probably more than once. Eventually the Mytilenaeans chose Pittacus as *aisymnētēs*, a position which Aristotle described as an elective tyranny. Pittacus' primary task was to preserve the city from the threat posed by the exiles. He seems to have succeeded in bringing civil strife to an end, and he then laid down his office. Hellenistic scholars said that Pittacus ruled for ten years (590–580), but the chronology of Mytilene is difficult. Alcaeus in exile said that he longed for the assembly (*agora*) and the council (*bolla*).

Developments in the Aegean islands

Farther south, on the island of Chios, an inscription of *c.* 575–*c.* 550 attests a *bole demosie*, a term often taken to mean a "popular council" as distinct from an "aristocratic council," although other interpretations are possible; for example, the term may mean a "state council" as distinct from "local councils." At least the occurrence of the epithet suggests that there was more than one council in Chios, and this indicates some sophistication of political development.

On the west coast of the Asiatic mainland, the Ionian

settlements were among the most prosperous Greek cities of the Archaic period. They held the alluvial plains at the mouths of major rivers, which flow westward into the sea; so they could expand considerably before feeling the pressure of population on local means of subsistence. Moreover, the rise of the Mermnad dynasty in Lydia meant that the Ionian settlements had a strong, stable, and wealthy power as their neighbour; excavations at Sardis show that Lydian trade with Greek cities increased steadily during the Mermnad period. It is not surprising that the 6th-century Ionians were ahead of other Greeks in some spheres; for example, Thales of Miletus, who predicted the year of the solar eclipse of 585, began the series of Greek scientists. Miletus, the richest Greek city of the Asiatic mainland, had a tyrant named Thrasybulus, who exchanged friendly messages with Periander. Afterward the city suffered a long period of internal strife, but sometime before 500 it achieved stability by inviting mediators from the island of Paros; by the settlement these mediators made, power appears to have been entrusted to men of landed wealth.

Ionian settlements of Asia

Phocaea, the northernmost city of mainland Ionia, did much to open the western part of the Mediterranean to Greek enterprise in the 6th century. The Phocaeans developed commercial relations with the flourishing kingdom of Tartessus in Spain (*c.* 620–*c.* 540). On the south coast of France the Phocaeans founded the colony of Massilia (the modern Marseille) *c.* 600; the Massiliotes in turn founded dependent colonies as trading stations in a westward line reaching into the northeast coast of Spain. The Phocaeans also founded a settlement in Corsica called Alalia *c.* 560. When Persian forces attacked Phocaea *c.* 540, the Phocaeans withdrew by sea and, although some returned, a large party sailed to Corsica and joined the colony of Alalia. But after practicing piracy for five years, the people of Alalia were attacked by the combined fleets of the Etruscans and the Carthaginians; although the Greeks claimed to have won the battle, they had to withdraw from Corsica, and, after a sojourn at Rhegium, they settled at Elea (Velia) in southern Italy. The Etruscans took Corsica, and the Carthaginians took Sardinia, which they subdued after a struggle with the natives; together the two powers exercised ascendancy in the western basin of the Mediterranean.

Greeks in Sicily and southern Italy

In Sicily the 6th century marked the beginning of a protracted conflict between Greeks and Phoenicians. The latter held three bases—at Motya, Panormus, and Solus—in the western part of the island; they were often joined by the people of Segesta in their opposition to the Greek advance from the east. The first known conflict occurred *c.* 580, when Pentathlus of Cnidus led a force from Cnidus and Rhodes to settle at Lilybaeum—a position commanding the harbour of Motya; he was driven out by the Phoenicians and Segestans. In the next decades Carthage gained leadership over the Phoenician settlements in Sicily. In 510 Dorieus, the half-brother of Cleomenes of Sparta, led a party of perhaps 1,000 men to settle at the foot of Mt. Eryx, but he was overcome by the combined forces of Carthage, Segesta, and the Phoenicians of Sicily.

In southern Italy Sybaris, an Achaean colony, built up a loose federation of Achaean colonies from *c.* 550. Croton, another Achaean city, became its chief rival. Soon after 530 Pythagoras the philosopher settled in Croton; his political teaching is not clear, but his followers gained predominant influence in the city and set about expanding its rule. In 510 the Crotoniates took advantage of an internal dispute in Sybaris to attack and destroy the latter; at the time of its destruction Sybaris was perhaps the most thriving of Greek colonies. Croton then became the leading power in southern Italy, although the alliance it created was not so extensive as that formerly led by Sybaris. The Italiote cities played a prominent part in Greek thought and culture in the late 6th century; they produced such men as the philosopher Parmenides of Elea and the poet Ibycus of Rhegium. Croton had a flourishing school of medicine; and one of its doctors, Democedes, served for a time at the court of Darius I of Persia.

RELATIONS AMONG THE GREEK POLEIS TO THE END OF THE 6TH CENTURY BC

The early Archaic period. Early in the Archaic period the structure of the *polis* was weak and therefore there was little official intercourse between *poleis*. Thucydides remarked that in early Greece there were hardly any wars sufficiently extensive to bring in many cities; he noted as an exception the war between Chalcis and Eretria, neighbouring cities on the island of Euboea, in which many other Greeks supported one side or the other. This struggle is called the War of the Lelantine Plain because it was in part a conflict for control of the plain of the Lelanton River in Euboea. The allies of Eretria included Miletus, and those of Chalcis included Samos. Chalcis also gained help from Pharsalus in Thessaly. (Some of the issues were local; Samos and Miletus went to war for control of Priene as late as 441.) The date, duration, character, and outcome of the Lelantine War are far from clear; a good case can be made for a date in the late 8th or early 7th century BC, although a later date can also be reasonably defended. If the earlier date is correct, rivalry for colonial sites probably exacerbated the struggle.

Local leagues

Although dealings between cities were slight, local leagues arose at an early date. These were predominantly religious, but they sometimes acquired a political character. An important example was the League of Amphictyones, comprising several powers of central and northern Greece from Boeotia to Thessaly. It arose to protect the cult of Demeter at Anthela near Thermopylae, but it acquired control over the sanctuary of Apollo at Delphi. The oath of its members included a promise not to destroy or cut off the water supply of any member-city, even during warfare.

Another local league included 12 Ionian cities—Samos, Chios, and ten cities on the Asiatic mainland. Members built a temple—the Panionion—on the northern slope of Mt. Mycale and gathered there for periodic festivals. When the Ionians felt themselves threatened by the Persian advance *c.* 544, they gathered at the temple for political deliberation.

The early tyrants in the Peloponnese brought greater cohesion to their cities and asserted themselves abroad. The colonies founded by the Cypselids and the dealings of Periander with Procles of Epidaurus have been noted above. Periander maintained good relations with Oriental powers. For example, after seizing 300 Corcyrean boys as hostages during a dispute with the island, he sent them as a present to King Alyattes of Lydia (the present did not arrive; the convoy put in at Samos and the Samians enabled the hostages to escape). Periander's nephew was called Psammetichus—a non-Greek name (Psamtik) borne by some pharaohs of the Saite dynasty (664–525), which suggests Corinthian dealings with Egypt.

First Sacred War

Cleisthenes of Sicyon fought a war against the Argives, but his great opportunity was provided by the First Sacred War. This war (*c.* 595–*c.* 586) concerned the Delphic sanctuary and the Phocian town of Crisa. The latter had a good harbour on the northern shore of the Corinthian Gulf; it controlled a fertile plain, through which ran the route taken by pilgrims to Delphi. According to the tradition—known from texts written more than two centuries later—the Crisaeans levied tolls on these pilgrims; and the Amphictyonic League, exhorted by a response of the oracle, went to war against the Crisaeans because of their impiety. The war developed into a siege of Crisa; the northern powers blockaded it on the landward side, but it received supplies by sea. Thereupon Cleisthenes joined in the war; he built a fleet and hence stopped the transport of supplies to Crisa. The town fell in 591–590, although pockets of resistance still held out. Cleisthenes received a share of the spoils and won a chariot victory at the Pythian festival of 582. The war brought him distinction in Greece, and his fleet brought him power.

The war led to reorganization of Delphic affairs. The previous condition is not clear. Thenceforth the Amphictyonic League had ultimate control over the sanctuary; the town of Delphi managed its own affairs and supplied the priestess and interpreters for the oracle. The Pythian

festival was reorganized on a larger scale, with athletic and other competitions; it was to be held every four years, and the year 582 was reckoned as the first Pythiad.

Reorganization of festivals

The Pythian reorganization seems to have prompted the reorganization or foundation of other panhellenic festivals. About 580 the Eleans finally gained ascendancy over the Pisatans and reorganized the Olympic festival, held likewise every four years; there had been a festival at Olympia before, but its early history is obscure. (In the second half of the 5th century, Hippias of Elis published a list of Olympic victors; he assigned the first celebration of the festival to 776 and all subsequent scholarship followed him, but the reliability of the entries in the early part of his list is an unsolved problem.) The reorganization of *c.* 580 may have caused the festival to attract visitors from a wider area than before. In Corinthian territory the Isthmian Games were founded *c.* 580 and celebrated every two years. In the territory of Cleonae the Nemean Games were founded in 573 and likewise celebrated every two years; it is not clear whether Cleonae, which lay between Sicyon and Argos, was under the influence of Cleisthenes or of the Argives at the time of the foundation.

In general it is disputed whether panhellenic festivals owed their expansion in the early 6th century to the tyrants or to other regimes. The fact emerges, however, that the expansion of the festivals reflects the same growth of wealth and ambition as do the early tyrannies. The four festivals—Pythian, Olympic, Isthmian, and Nemean—were panhellenic in that they admitted all Greeks without regard to such distinctions as that between Dorians and Ionians. They attracted visitors and competitors of all kinds, but their contribution to promoting panhellenic consciousness should not be exaggerated; they did not acquire political significance.

The later Archaic period. In the 7th and 6th centuries BC, the overseas activities of Greeks on the European mainland increased. The fortunes of the Asiatic Greeks, and later of those on the European mainland, were affected increasingly by the non-Greek powers of Asia Minor.

Lydian influence

Influence of non-Greeks. The kingdom of Lydia was rich in gold and silver and in an alloy of the two—electrum—which occurred there naturally. In founding the Mermnad dynasty at Lydia, Gyges (*c.* 680–648) seems to have filled a power vacuum. He made indecisive attacks on some Ionian cities; he raided Miletus and Smyrna, and he captured the citadel of Colophon. This policy was continued by his successors: the third and fourth members of the dynasty, Sadyattes and Alyattes, fought a war of 12 years against Miletus. In each of the first 11 years the Lydian forces plundered the Milesian crops before the harvest; but the sea routes to Miletus remained open, and in the 12th year Alyattes concluded a treaty of friendship and alliance with the city. His successor Croesus attacked Ephesus and then the other Greek cities of the Asiatic mainland and made them pay tribute, although Miletus retained its privileged status; regular tribute was more satisfactory to all parties than were intermittent raids. Under Croesus the Lydian kingdom reached its widest extent, stretching as far as the Halys River in the east.

In spite of the raids and the tribute, the Mermnad dynasty brought advantages to Greeks. Trade with Lydia allowed a steady growth in Ionian prosperity. Greeks seem to have travelled freely in Lydia; later tradition told of the hospitality shown by Croesus to the Athenians Solon and Alcmaeon; and although details are suspect, such stories attest the King's philhellenism. No Lydian garrisons are recorded in Greek cities. Looking westward beyond the mainland, Croesus achieved treaties of friendship with Ionians of the offshore islands. He sent gifts for dedication in Greek sanctuaries at Ephesus, at Branchidae near Miletus, at Thebes, and at Delphi. He exchanged presents with Sparta.

About 544 (the precise date is disputed) Croesus went to war against Cyrus, the founder of the Persian Empire. Cyrus drove the Lydian forces back to Sardis, besieged the city, and overcame Croesus. The Greek cities of the Asiatic mainland had to consider their attitude toward the new power approaching them from the east. Before Cyrus left Sardis, the Greeks sent envoys and asked him to let them continue in the same status they had enjoyed under Croesus. Cyrus confirmed the Milesians in their previous condition, but he would make no undertaking to the others because they had refused his request that they desert Croesus while the war was in progress.

After a short stay in Sardis, Cyrus hastened to Ecbatana in Media. The Lydians promptly rose in revolt and were joined by the Greek cities of the Asiatic mainland. Cyrus sent forces that reduced Lydia anew and then captured the Greek cities piecemeal; Miletus alone continued to enjoy special treatment. Thus, by *c.* 540 the Persian Empire had acquired the Greek cities of Asia Minor. These cities became subject to the nearest satrap, or provincial governor, such as the satraps resident at Sardis and Dascylium; and the imperial administration usually tried to maintain order by supporting a local man as tyrant in each city. The cities were required to pay tribute, but generally their burdens were not severe.

Persian rule

From the mainland of Asia Minor the Persian administration might have hoped to extend its authority to the offshore islands, but the steps taken are obscure. Details are available only for Samos. This island was ruled from *c.* 535 by the tyrant Polycrates, who raised it to unprecedented power; he practiced piracy extensively and maintained the strongest fleet in the Aegean. Polycrates seems to have taken advantage of a change in naval engineering; probably during his time the trireme was invented. His contacts were not only with Greeks. He exchanged presents with Ahmose II, the pharaoh of Egypt; later (in 525) Cambyses, the son and successor of Cyrus, launched his successful expedition to conquer Egypt, and Polycrates sent 40 triremes to help Cambyses. Toward 522 Oroetes, the satrap of Sardis, conceived a design for conquering Samos; he enticed Polycrates into a conference on the mainland and crucified him. But before Oroetes could proceed further, Cambyses was overthrown, and, after a struggle for the succession, the usurper Darius made himself king. Darius had Oroetes assassinated. Meanwhile, Maeandrius, the second in command to Polycrates, ruled Samos; but shortly afterward Darius sent a special force under Otanes to attack the island. The force was guided by Syloson, the exiled brother of Polycrates. Otanes sacked Samos and then entrusted it to Syloson.

How far Persian rule extended over Greeks *c.* 514 is known from Herodotus' account of the expedition that Darius led into Scythia. Darius conducted his forces across the Bosporus and thence northward and across the Danube; meanwhile the Greek tyrants from cities under his control sailed ahead to the Danube to bridge the river, and Herodotus gives a list of them. They included men from such cities of the Ionian and Aeolian mainland as Miletus, Phocaea, and Cyme, and also tyrants from several cities on the Asiatic shore of the Hellespont and Propontis, notably from Abydos, Lampsacus, Parium, Cyzicus, and the neighbouring island of Proconnesus. The only Aegean islands represented in the list were Samos and Chios; the tyrants present from the European mainland were Miltiades, the Athenian ruler of the Thracian Chersonese, and one from Byzantium. Elsewhere Herodotus remarks that Coes brought a force from Mytilene and that Darius made him tyrant of that city as a reward for his services on the expedition.

Spartan foreign policy. The foreign policy of Sparta in the 6th century was determined first by the city's position in the Peloponnese and later by its attitude toward developments across the Aegean. Sparta's wars with Tegea (*c.* 580–*c.* 550) and Argos (*c.* 544) and the growth of the Peloponnesian League were noted previously (see above *Sparta: The Peloponnesian League*). In its dealings with powers outside Greece, Sparta at first followed—consciously or otherwise—the practice of tyrants like Periander. Relations were opened with Croesus toward the middle of the century. The Lacedaemonians sent to Sardis to buy gold for a proposed statue of Apollo, and Croesus gave them the gold free. Thereafter the Lacedae-

Spartan relations with Lydia

monians sent a large ornamental bowl of bronze as a present to Croesus; the bowl only travelled as far as Samos, and the Lacedaemonians said that it was seized there by Samian pirates. Relations were opened likewise with Ahmose of Egypt. Shortly before the dispatch of the bowl to Croesus, Ahmose sent the Lacedaemonians an embroidered corslet of linen, decorated with gold; this, too, travelled no farther than Samos.

The tradition reaching Herodotus portrayed the dispatch of the bowl as the Spartan response to a request from Croesus for a military alliance against Cyrus. Likewise it said that when Croesus was besieged in Sardis by Cyrus, he appealed to Sparta for help, and, although the Lacedaemonians were engaged in their war with Argos, they prepared to send a fleet, but that the news arrived of Sardis' capture before the fleet could sail. These stories may have gained something in the telling. The historian should beware of statements of unrealized intentions; the fact emerging from the alleged preparation of a fleet is that Sparta did not send aid to Croesus. Even so, the exchanges of presents may have had political implications. There may have been more presents than are recorded, and at the least they indicate commercial possibilities.

Herodotus tells a tantalizing story of action taken by the Ionians immediately after Cyrus overcame Croesus. Allegedly they gathered at the Panionion and sent envoys to Sparta for help. The Spartans decided to give no help, but they sent a penteconter (50-oared galley) to Phocaea and one of its crew proceeded to Sardis. There he gave Cyrus the message of the Lacedaemonians—that they would not tolerate the Persians ravaging any Greek city—and Cyrus made a contemptuous reply. In this story it is not difficult to recognize an element of fiction. The account of the Lacedaemonian penteconter and message to Cyrus was surely invented later to gloss over the Spartan refusal of aid to the Ionians. But the Ionian appeal to Sparta may well be authentic; it attests the standing that the Lacedaemonians had achieved in Greece and the extent to which they had interested themselves in affairs beyond the Aegean.

Such a development of Lacedaemonian interests had been possible in the time of Croesus; accordingly it was checked by the Persian conquest of Lydia. A further check to Spartan enterprise in the eastern Aegean occurred *c.* 525. In response to the appeal of some Samian exiles, the Lacedaemonians and the Corinthians sent a fleet to try to overthrow Polycrates. The force besieged Samos for 40 days unsuccessfully; then it withdrew.

Decline of Spartan overseas operations

Modern historians have sometimes supposed that in consequence of the final subjugation of Messenia, Sparta concentrated on developing its power by land and declined to acquire interests overseas. This is incorrect. In the middle of the 6th century Sparta concerned itself with developments across the Aegean, but by 520 its attempts to look eastward had suffered more than one setback. Thereafter until 412, it made little attempt at naval enterprise and concentrated on extending its influence by land operations. Such a policy appears in the reign of Cleomenes I (*c.* 520–*c.* 490), but before considering his early activities, attention must be given to the foreign policy of Athens.

Athenian foreign policy. Late in the 7th and early in the 6th century, the Athenians scarcely developed foreign interests beyond border warfare with their immediate neighbours. There was a long struggle with Megara, the main issue being control of the island of Salamis. During this war Peisistratus led a campaign sometime before 560, in which the Athenians captured Nisaea, the eastern harbour of the Megarid; it is not clear when the Megarians recovered Nisaea. The main outcome of the fighting was that the Athenians won Salamis.

There are slight traces of Athenian enterprise farther afield. An Athenian contingent, commanded by Alcmaeon, took part in the First Sacred War; thenceforth, Athens had a vote in the Amphictyonic Council. A less reliable tradition said that the original resolution of the Amphictyones against Crisa was proposed by Solon, but this may be a later invention of Athenian pride. Many historians believe that late in the 7th century an Athenian force commanded by Phrynon fought the Mytilenaeans for control of Sigeum in the Troad. The historicity of this war depends on a complex problem of chronology: if indeed there was such fighting at so early a date, then it was probably not an official act of the Athenian state but the work of some Athenians. Certainly the question of Sigeum arose, or arose again, in the time of Peisistratus.

Athenian foreign policy may be said to begin with the final tyranny of Peisistratus and his sons (546–510). Peisistratus established an Athenian presence in the neighbourhood of the Hellespont, he asserted Athenian influence in the heart of the Aegean, and he maintained good relations with several powers of the Greek homeland. In the first of these spheres he captured Sigeum from the Mytilenaeans and entrusted it to Hegesistratus, one of his sons. Hegesistratus had to conduct further fighting against the Mytilenaeans, but he remained in control of Sigeum; indeed, the Peisistratids withdrew there when they were driven from Athens in 510.

Athenian presence in the Hellespont

The foundation of an Athenian settlement in the Chersonese on the shore of the Hellespont was still more ambitious and was probably carried out soon after 546. The settlement was invited by the natives of the Chersonese—the Thracian Dolonci—who desired reinforcements against the attacks of their neighbours, the Apsinthii. The settlement was led by Miltiades of the Philaid clan, which apparently belonged to Brauron because the deme in which Brauron stood was called Philaidae. After bringing Athenian settlers, Miltiades built a wall across the isthmus of the Chersonese and waged war indecisively against Lampsacus on the other shore of the Hellespont. At one stage in the war Miltiades was taken prisoner by the Lampsacenes, but he was released through the intercession of Croesus. At his death Miltiades entrusted the Chersonese to Stesagoras, the son of his uterine brother Cimon. The war with Lampsacus continued and in consequence of it Stesagoras was assassinated. Thereupon (*c.* 516) the sons of Peisistratus sent out from Athens another son of Cimon, who bore the name of his uncle Miltiades. The dispatch of the younger Miltiades shows that the Peisistratids were keen to preserve their connection with the Chersonese.

In the heart of the Aegean, Peisistratus had a political debt to pay. In 546 Lygdamis, an adventurer from Naxos, helped him with men and money in his final restoration. In return Peisistratus subdued Naxos and entrusted it to Lygdamis. (The latter helped Polycrates to make himself tyrant of Samos.) Peisistratus also carried out a ceremonial purification of the island of Delos, the main sanctuary of the Ionians, by digging up and removing all corpses buried within sight of the temple; by the purification Peisistratus took advantage of the Athenian claim—first attested in the poems of Solon—to be the metropolis of all other Ionian cities.

Several cities in the Greek homeland aided Peisistratus in his final restoration; they included Thebes, Argos, and Eretria. One of his sons bore the name Thessalus, which suggests that the family had ties with the Thessalians; Hippias' alliance with Thessaly was apparent in the last years of his rule, when Thessalian cavalry helped him against Lacedaemonian attacks. The Peisistratids seem to have also enjoyed the friendship of Sparta for a time; some years after the overthrow of Hippias the Spartans conceived a plan for restoring him and remembered that the Peisistratids had been their friends. (International "friendship" was a formal matter, akin to alliance, and Spartan recollection may have been correct.)

Athenian alliances

In large part the tyranny owed its foundation and its preservation for many years to the favour of other cities; neighbours of Attica, like Thebes and Eretria, and powers farther afield were keen to see a *persona grata* in control of Athens. Developments abroad eventually weakened the Peisistratids. A Spartan force overthrew Lygdamis of Naxos, perhaps during the return of the unsuccessful Spartan expedition against Polycrates of Samos, the friend of Lygdamis; the attack on Lygdamis may not have been intended to harm the Peisistratids, but it removed a friend of theirs. A few years later the Persians overthrew Polycrates.

Some time later the Plataeans were attacked by the Thebans; on the advice of Cleomenes, who happened to be near with a Lacedaemonian force, the Plataeans sought and gained the alliance of Athens. (The traditional date of concluding this alliance is 519; it has been disputed but cannot be proved wrong.) Herodotus, recounting the alliance, says that the Lacedaemonian aim was to create discord between Athens and Thebes. That may be an anachronistic inference from conditions obtaining in his own time, but the conclusion of the alliance did create discord between Athens and Thebes; the Athenians promptly sent a force that defeated the Boeotians.

If the Plataean alliance was concluded in 519, then the international position of Hippias had been impaired well before 514. After the assassination of Hipparchus, Hippias sought new friends abroad; he gave his daughter in marriage to the son of Hippoclus, the tyrant of Lampsacus. According to Thucydides' recording of the marriage, Hippias knew that the Lampsacene tyrants had influence with Darius. Hippias may also have recognized that the makers of Persian policy were showing a new interest in the West. At least Hippias secured the prospect of a refuge in the Persian Empire, should he be overthrown.

Spartan policy under Cleomenes. Spartan policy, as it developed in the early years of Cleomenes, followed recognizable principles. On the one hand Sparta gave up its attempts to extend its influence by naval enterprise across the Aegean. This meant that Sparta would not oppose the expansion of the Persian Empire, provided that it did not reach European Greece. Thus when the Persians under Otanes finally attacked Samos, Maeandrius sailed to Lacedaemon and appealed to Cleomenes for help; instead, Cleomenes advised the ephors to expel Maeandrius from Lacedaemon, and this was done. Again, when Darius had attacked the Scythians, the latter sent envoys to Sparta and offered an alliance for military operations against the Persian Empire, or so Herodotus says; the account may be imprecise, and the only result was that Cleomenes learned from the envoys the habit of drinking unmixed wine.

On the other hand, the Spartans tried to enlarge their ascendancy by land operations on the Greek mainland; this led them into conflict with friends of Persia, when Persian influence appeared to encroach on European Greece. The alliance of Hippias with Hippoclus of Lampsacus—a friend of the Persians—may well have induced the Spartans to adopt extreme measures against Hippias, measures that culminated in the expulsion of the Peisistratids from Athens. Whether Athens became a member of the Peloponnesian League in 510 is perhaps a question of terminology. Certainly in the ensuing decade the Spartans tried repeatedly to ensure that there should be a favourable regime in Athens. As related above (see above *Athens: The reforms of Cleisthenes*), some time after the Peisistratids' fall Cleomenes tried to support Isagoras against Cleisthenes, first by sending a herald and then by coming himself to Athens, where he attempted to dissolve the council; but the Athenians drove him out. Thus the Athenians had quarrelled with Sparta, and so they turned to the alternative source of support; they sent envoys to Sardis to seek an alliance with Persia, and, at the request of the satrap, the envoys gave earth and water, the tokens of submission. Hence for a time Athens was technically a vassel of Persia.

Spartan–Athenian antagonism

As also mentioned previously, Cleomenes responded to the rebuff he received at Athens by calling out the army of the Peloponnesian League and leading it against Attica, but at Eleusis the Corinthian contingent mutinied and the force disbanded. This operation caused a crisis in the league, and a congress of envoys from the member-states was summoned. Doubtless questions of authority and command were discussed; indeed, this may have been the occasion when a multilateral agreement was first accepted, superseding the bilateral treaties from which the league had arisen. For the congress the Spartans invited Hippias from Sigeum, and they proposed to the allies that he should be restored to Athens. But first the Corinthians and then the other allies rejected the proposal; it was abandoned and Hippias returned to Sigeum.

As a result of the congress, the Spartans gave up trying to control Athenian affairs. The Athenians, however, soon became perturbed because asylum was granted to Hippias within the Persian Empire, and they sent envoys to Sardis to complain. The satrap replied with a brusque instruction: they should restore Hippias, if they cared for their safety. The Athenians were not willing to comply, and thus their close relationship with the Persians came to an end.

6th-century changes in Greece. The 6th century saw two major changes in the balance of power in European Greece. One of these was the development of the Peloponnesian League; by 500 it was the largest single force in interstate affairs, capable of providing a nucleus for resisting a foreign invader and fit to serve as a model for other alliances. The other change was the rise of Athens to mature statehood. Before 600 the Athenians had done little to assert themselves beyond the borders of Attica, and for a long time afterward Athens was much subject to foreign influence; other cities played a large part in the final restoration of Peisistratus and even in the overthrow of Hippias. But the ambitious policy of Peisistratus had aroused new aspirations among the Athenians; in the decade following 510 they came to assert themselves against Sparta and Sardis, and thus they achieved full independence. (B.R.S.)

III. The 5th century BC

THE PERIOD OF THE GRECO-PERSIAN WARS

The Ionian revolt and its consequences. The sequel to the conquest of Lydia by Cyrus the Great was the subjection of the Ionians and other east Greeks. The Persians were completely alien and their capital more than two months distant. Not understanding Greek political attitudes, they based their control on local tyrants, despite the fact that any form of absolute rule had become an anachronism to the Greeks. It was thus more for political than for economic reasons that the Ionians revolted in 499 BC. This revolt, led by Miletus, spread from Caria to the Hellespont and, for the first two years, resulted in a remarkable degree of unity. It began with the expulsion of the pro-Persian puppet rulers and an appeal to the mainland for help. Sparta, the dominant military power in Greece, rejected the appeal, but Athens, which claimed to be the mother-city of the Ionian cities, sent 20 ships, which were joined by five more from Eretria. The united forces sacked the Lydian city of Sardis but were caught on their return near Ephesus, suffering heavy losses. The Athenians seem to have become convinced that the military prospect was hopeless, and consequently they withdrew; the Ionians, however, fought on. Not until 494 was their revolt crushed—by a naval defeat at Lade, followed by the reduction of Miletus.

The punishment of Athens now became a natural Persian objective, and in 492 a strong force was sent around the north coast of the Aegean; but the fleet was wrecked off Mt. Athos and the expedition was abandoned. Two years later a second force was sent, this time through the islands across the Aegean. Traitors opened the gates of Eretria, and the population was enslaved; the Persians then landed in the Bay of Marathon. The Athenians, roused by Miltiades, the most dynamic of their generals, decided to march out and meet the Persians on the Plain of Marathon. There they were joined by the Plataeans and by clever tactics and tough fighting won a decisive victory against more than twice their number. When they marched out they had sent a messenger to Sparta, but the Spartans waited for the full moon and arrived the day after the battle.

The Battle of Marathon (490 BC)

In the decade following Marathon there were keen political rivalries at Athens. Miltiades, the hero of Marathon, was discredited in the following year when an expedition against Paros, which he had advocated and led, failed miserably. The death sentence was commuted to a heavy fine, but he died shortly afterward. There followed a quick succession of ostracisms; in 487 and the next two years the victims were friends of the Peisistratids, who were suspected of treason at the time of

Marathon. Later, other issues became more important: the most critical was a struggle between Aristides and Themistocles, probably over naval policy, which resulted in the ostracism of Aristides in 482. This struggle was associated closely with a dramatic decision that, more than any other, influenced the course of Greek history in the 5th century. A particularly rich vein of silver had been discovered in the mining area of Laurium, and it was at first intended to distribute this windfall among the citizens. Themistocles, fully aware of the growing danger from Persia, persuaded the people to use the money to build triremes. His new Athenian navy was to prove one of the decisive factors in the repulse of the Persians.

The return of the Persians under Xerxes. The Persian force that was broken at Marathon had limited objectives and may not have exceeded 30,000: the aim of the next, much larger, expedition was the conquest of Greece. The Greek states met at the Isthmus in 481 to concert plans for their defense. But not all of the Greeks were prepared to join in active resistance. The Peloponnesian League followed Sparta's lead, but Argos remained neutral and suspected, and north of the Isthmus only Athens could be firmly relied on; Thessaly even reached an accord with the Persians; and the other states were not likely to expose themselves unless it became clear that they could be protected. The Greek army was eventually posted at Thermopylae to hold the narrow pass between mountain and sea, while the fleet, stationed at Artemisium in north Euboea, was to prevent the Persian fleet from moving south and landing troops behind the Greek lines. Some 4,000 men held up the vastly superior masses of Persians that Xerxes threw into battle, but the Greek position became untenable when a small Persian force was guided along a mountain path that brought them down behind the Greek position.

Victory of Xerxes at Thermopylae (480 BC)

The failure to hold Thermopylae meant the abandonment of Greece north of the Isthmus. Athens was evacuated, though a small company remained to defend the Acropolis. The Greek fleet assembled at the island of Salamis, while Xerxes moved south, ravaged Attica, and, after a short siege, took and sacked the Acropolis. Themistocles, who commanded the Athenian fleet, persuaded the Greeks that they could only hope to win at sea if they fought in narrow waters. He then sent a messenger to Xerxes, assuring him that the Greeks were on the point of flight and in no state to resist; Xerxes closed the western channel and sent his main fleet into the straits between Salamis and the mainland, expecting wholesale surrender. Instead, the Persians found the Greeks fully prepared for battle; in the narrow waters numbers were a handicap, ramming and boarding was the general pattern, and the Greek marines had better arms and a more robust morale. The victory was complete, and Xerxes withdrew with his fleet.

The Persian general Mardonius was left with a substantial army in Greece, and the next year, after raiding and ravaging as far south as the Isthmus, withdrew to a camp on the Asopus near Thebes. In August a Greek army of some 35,000 hoplites and more than 50,000 light-armed troops, led by the Spartan regent Pausanias, advanced to give battle. The decisive engagement was fought near Plataea, when Pausanias, having failed to draw Mardonius, ordered a general retreat by night from a position that the Persian cavalry had made untenable. Mardonius attacked in the early morning, expecting an easy victory, but the Spartan wing took the main shock and their superior arms and spirit decided the issue. Mardonius was killed. The remnants of the Persian army fled in disorder, and their camp was sacked. At roughly the same time news was brought that the Greek fleet, considerably reduced after Salamis, had won a great victory. King Leotychides, the Spartan commander, having heard that the Persians guarding Ionia were demoralized and that the Ionians were eager to revolt, crossed the Aegean to Samos. The Persians were encamped on Cape Mycale, where the Greeks landed unopposed and stormed the camp. The victory was the signal for a widespread revolt in Ionia.

The western Greeks. The Greeks of the west had not been able to help in the defense of Greece because they had troubles of their own. While the Phoenicians of the east formed the backbone of Xerxes' fleet, the Phoenicians of Carthage were hoping to drive the Greeks of Sicily out of the island. In the late 8th and early 7th centuries the Greeks had established colonies in the east of the island and the Phoenicians in the west at Motya, Solus, and Panormus. For more than 100 years no hostilities are recorded between the two peoples, but friction developed in the 6th century when Carthage—which by then was the strongest and richest Phoenician city in the west and which had made an alliance with the Etruscans—attempted to exclude Greeks from the western Mediterranean.

By 500 it was merely a question of time before a serious crisis arose. It came in the form of a quarrel between tyrants. Gelon of Syracuse had marriage alliances with Theron of Acragas. Their main enemy was Anaxilas of Rhegium, on the toe of Italy. He had seized Zancle on the opposite Sicilian coast and was allied with Terillus, tyrant of Himera, who was on good terms with the Phoenicians. Theron drove out Terillus and made his son ruler of Himera. Terillus appealed to Carthage, and the Carthaginians sent Hamilcar, one of their chief magistrates, with an army that was probably much larger than the Greeks could muster, though Herodotus' figures (300,000 men) are no doubt exaggerated. The Carthaginians landed near Panormus and proceeded to besiege Theron in Himera. Gelon marched across Sicily with 50,000 foot soldiers and 5,000 cavalry, and in a great pitched battle Hamilcar was killed (according to one account he sacrificed himself) and his army routed. The two tyrants were left in possession of a rich booty and thousands of prisoners. As a result of this decisive victory Sicily was to be safe from Carthaginian invaders for more than 70 years. But in 409 the Carthaginians returned and took their revenge. Himera was destroyed and Acragas sacked. Syracuse was saved by another tyrant, Dionysius I, who for 30 years maintained his power by equivocal tactics and saved the east of Sicily from Carthaginian control.

Battle of Himera (480 BC)

Gelon died two years after his victory, and the rule of Syracuse passed to his brother Hieron, who in 474 won a great naval victory off Cumae against the other main enemy of the Greeks in the west, the Etruscans. This victory was of much more than local significance. The Etruscans, who in the 6th century had extended their rule south of the Tiber and into the rich lands of Campania, had lost control of their land communications when they were defeated in a great battle near Aricia by an army of Cumaeans and Latins, which was soon followed by the expulsion of the last Etruscan king from Rome. The destruction of their fleet off Cumae meant that the Etruscans were cut off from Campania and would no longer be a threat to the Greeks of the Bay of Naples and farther south.

Greek offensives against Persia in Asia Minor. After the Battle of Plataea, the Persian army had abandoned Europe and was not to return. The battle of Mycale was the beginning of another chapter. What was to be the future of the Ionians, many of whom were now in revolt? The Spartans proposed that they should be transferred to the Greek mainland from which they had originally come and be settled on the lands of the states who had medized (collaborated with the Persians). From a military point of view this was good sense. History had shown that without strong help from outside they were subject to the power that controlled Asia Minor. The Ionians, however, had no wish to leave their good lands; they were supported by the Athenians, and the plan was abandoned. It was now near the end of summer, but the Athenians insisted on proceeding to siege Sestos, which was the Persian headquarters in the Chersonese; the Peloponnesians preferred to sail home. By the end of winter Sestos had been starved into surrender and the Chersonese, which was vital to the protection of the corn route from the Euxine, was once again under Athenian control.

Between the battle of Plataea and the summer of 478 the Greeks had decided to continue operations and take the offensive against Persia. The Spartan regent Pausanias was again given the command and led a force of some 100 ships to the island of Cyprus, where Persian garrisons were driven out and the Greeks of Cyprus were encouraged to take control of the island. From Cyprus the fleet sailed up to Byzantium, which commanded one of the two easiest passages from Asia to Europe and the entry to the Euxine. At Byzantium Pausanias became increasingly unpopular with the allies, and there were even rumours that he favoured the Persians, which led to his recall to Sparta. Meanwhile the Athenian commander Aristides had been invited by the Ionians to take over command of the united forces. History had shown that Sparta was ill-adapted to overseas commitments; Athens could claim to be the mother-city of the Ionians and had sent ships to them in the Ionian revolt. Admittedly, they had been withdrawn at the first serious reverse, but it was now a very different Athens. The victory of Marathon, the creation of the largest and most modern navy in Greece, and its major contribution to the destruction of Persian sea power had increased its confidence and stimulated its ambitions. The Spartan army was still the strongest in Greece, but in 479–478 the Athenians had succeeded in rebuilding their fortifications, despite strong Spartan protests. Considering these developments, then, Aristides probably had a shrewd appreciation of Athens' interests when he persuaded the Athenians to accept the leadership of a new league.

Formation of the Delian League

In the winter of 478–477 Aristides, no doubt in consultation with the leaders of the contingents from Lesbos, Chios, and Samos (who provided the largest of the allied fleets), worked out the basic structure of the new league; all Greeks who were interested were invited to attend an inaugural meeting in the summer of 477 on the island of Delos.

Thucydides describes the essentials of the organization:

> The Athenians decided which cities were to contribute money and which ships . . . The *hellēnotamiai* were then first instituted as an Athenian office and they received the *phoros*, which was the name for the money that was collected. The first assessment was four hundred and sixty talents; Delos was their treasury and the meetings were held in the sanctuary. The allies were at first autonomous and policy was discussed at meetings which all shared.

To symbolize the permanence of the association lumps of metal were sunk in the sea and oaths were exchanged. Aristides, on behalf of Athens, and representatives of the allies bound their states by oath "to have the same friends and enemies." From the outset, the influence of Athens, as the freely accepted leader, was paramount. It was understood that it would always provide the commander for military operations and, probably, the chairman of league meetings. It is doubtful whether any formal guarantee of independence was laid down, for the allies were not in a suspicious mood. They realized that without Athenian leadership they would again become a fringe of the Persian Empire, and their feeling was one of undiluted gratitude.

The original alliance included the Cyclades with the exception of Melos and Thera, which had been settled from the Peloponnese; most of the Ionian and Aeolian coastal towns from Miletus to Byzantium; and probably the Dorians to the south, comprising the three cities of Rhodes (Ialysus, Lindus, Camirus), Cos, and Cnidus. In southwest Asia Minor some Carian communities joined at once, but most of the Carians from the south coast and the interior were not won over until later. The rich cities of the Thracian coast may not have joined the alliance until the middle 470s, but most of the Greek colonies of Chalcidice seem to have followed the example of their mother-cities in Euboea and Andros. By the middle of the century the large islands of Lesbos, Chios, and Samos were the only ship contributors. This was because a much larger number had by then taken the easier option of paying an annual tribute instead.

For some ten years the Athenians continued to lead league forces against the Persians, liberating Greek cities and extending membership of the league. The operations, culminating in a spectacular victory at the mouth of the River Eurymedon (*c.* 466 BC) were carried out under the command of the Athenian general Cimon, and these years could fairly be called the age of Cimon. His series of victories over the national enemy made him the hero of the day, and his family background and his associates gave him a powerful political base. Meanwhile, Themistocles had steadily lost ground. Looking ahead, he advocated anti-Spartan policies, which had little appeal while Cimon, who believed in a dual leadership of Greece, was winning victories in the east.

Cultural developments. The cultural revival of Athens after the Battle of the Eurymedon was at least encouraged, if not led, by aristocratic patronage. The years immediately following the expulsion of the Persians from the Greek mainland had been very bleak. The Acropolis and the lower city had been razed to the ground; public and private buildings had been reduced to rubble and ashes. The main concentration at first must have been on new living quarters and the restoration of the buildings that were essential to the carrying on of public business, but before long architects had new opportunities. When Cimon brought back the bones of the legendary hero Theseus from the island of Scyros a new special shrine was built for them; and from the spoils of the Battle of the Eurymedon he built a new south wall for the Acropolis, enlarging its monumental area.

It is significant that the architects of the Cimonian buildings are now nameless, while the painters whose work they accommodated are remembered. For this was the period of the first blossoming of monumental painting in Greece, a period of bold experiment breaking away from the restricting formulas of the Archaic period. To later generations, Polygnotus was the greatest of these painters. Born in Thasos, the son of a painter, he was probably attracted to Athens by Cimon, who had campaigned in Thracian waters.

Achievements in sculpture

In the sculpture of the period 480–450 BC the same spirit can be seen as in the painting of Polygnotus and his contemporaries. Archaic conventions are discarded and the main concern of the sculptor moves from the surface and linear pattern to a study of solid form. The Archaic smile disappears, and the unreal Archaic symmetry is replaced by more realistic standing figures with the weight of the body unevenly distributed as in nature. A wider and more enterprising range of subjects is chosen, including, toward the end of the period, Myron's bronze figure of an athlete, with body tensed, ready to throw the discus—a bold and difficult subject that was still widely copied in the Roman period. The crown of this generation's achievement was on the Temple of Zeus at Olympia, which was completed by 456. The two pediments, with their contrasting scenes of calm and conflict, and the Labours of Hercules on the metopes, were the finest architectural sculpture that Greece had yet seen.

This was a leaner period for poets at Athens. There was much trivial versifying in honour of Cimon but nothing to match the brilliant circle of poets who had been attracted by the Peisistratids. Simonides of Ceos retained his association with Athens sufficiently long to celebrate its praises in verses on the battles of Artemisium and Salamis, but in 476 he moved to the court of Hieron at Syracuse. Pindar was still in his prime. Before the Persian invasion he had lived and learned at Athens, and he paid a handsome tribute to its share in the preservation of freedom, but the Medism of his native Boeotia strained his feelings toward Athens, and he saw dangers ahead in the development of Athenian policy. His world of aristocratic virtues and privilege was passing away, but there is magic in the rhythm and the imagery of the victory odes for his wealthy patrons in Sicily and Cyrene and for athletes from Aegina and other mainland states.

Athenian tragedy

The most exciting literary development in this period was the growing maturity of tragedy, which was to remain the particular pride of Athens. Aeschylus, who was always regarded later as the greatest of the early trage-

dians, had fought at Marathon and Salamis and was profoundly moved by what seemed to him the divine salvation of Greece. In his *Persae*, produced in 472, he presented the Persian defeat as a godsent punishment for the hubris of Xerxes, and throughout his career he remained convinced that the divine power who controlled the universe must be fundamentally just. His main concern was to explain the ways of God to man; his characters are cast in the heroic mold, and his language is vivid and colourful. Most of his plays were produced during the Cimonian period, but by the year of his *Oresteia* (first performed in Athens in 458) Cimon had been ostracized, and new democratic forces were transforming Athens.

THE ATHENIAN EMPIRE

The changing nature of the Delian League. Beneath the political calm of the Cimonian period there had been undercurrents that were soon to come to the surface. At the time of the Eurymedon victory there was already a growing change in the attitude of Athens to the alliance. In *c.* 472 Carystus, at the south end of Euboea, which was not an original member of the Delian League, had been forced by military action to join. When, a little later, Naxos wished to secede, it was besieged. Naxos capitulated, and terms were dictated that were incompatible with its independence. It is possible that the revolt of Naxos was instigated by medizing oligarchs, and its reduction may have been in the genuine interest of the league, but when Thasos revolted in 465 the main issue seems to have been Athenian encroachment on what Thasos regarded as its own economic interests on the mainland. Its navy was defeated and, after a two-year siege, the island surrendered. Thasos had to give up its fleet, pay a war indemnity, and bring annual tribute. Athens took over Thasian mining rights and other interests on the mainland, but the attempt to settle a colony of Athenians and allies at Ennea Hodoi on the Strymon ended disastrously. Penetrating inland, the settlers were defeated by a combined Thracian force, and the colony had to be abandoned.

When Thasos revolted, it had appealed to Sparta and, according to Thucydides, Sparta promised to help by invading Attica. This was one of the first signs that the peaceful coexistence of Athens and Sparta was becoming strained. Hitherto the Spartans had been too preoccupied with their own troubles to worry about the growing strength of Athens. After their resignation of the leadership against Persia, Sparta had sent King Leotychides, the victor of Mycale, to Thessaly to unseat the medizing dynasty of the Aleuads, but the expedition was ineffective and ended with the trial of the King for bribery and his exile from Sparta. There followed a period of political agitation in the Peloponnese. Sparta had first to face an alliance of Argos and Tegea and then an Arcadian alliance that only Mantineia refused to join.

Pausanias, after being acquitted of treachery at Sparta on his first recall, in 478, had sailed out privately and occupied Byzantium, from which he was forcibly expelled by Cimon. He then settled at Colonae in the Troad and from there seems to have made approaches to the Persian satrap at Dascylium. He was recalled to Sparta and, after a surprisingly long delay, incriminating correspondence with Xerxes was alleged to have been found; he was also suspected of stirring up trouble with the helots. Pausanias fled for refuge to the temple of Athena of the Brazen House, from which he was taken when on the point of death from starvation. It is impossible now to recover the true story of Pausanias' last years, but it is probable that the Spartan authorities were more concerned with his possible future plans for Sparta than for his alleged Medism. The Spartans also claimed to have found evidence implicating Themistocles in the designs of Pausanias, and his enemies in Athens brought a charge against him in his absence. He fled from Argos and eventually reached the Persian king, who made him governor of the Greek city of Magnesta on the Maeander. There he died.

When Thasos revolted against Athens in 465 BC, Sparta promised help but was distracted by a serious earthquake, which provided the occasion for the most serious helot revolt since the 7th century. The Spartans were able to subdue the helots in Laconia, but the main strength of the revolt was beyond Mt. Taygetus in Messenia. There the helots took refuge on the very defensible slopes of Mt. Ithome, from which the Spartans could not dislodge them. At this point they called for help to their erstwhile allies in the war against Persia and, among them, to Athens. In the Athenian assembly, Cimon, well-known for his sympathy with Sparta, urged support, but there was strong opposition from new men who were working for a more democratic Athens free from any association with Sparta. Cimon narrowly won the vote and led a strong hoplite force to Sparta, but the Spartans found the attitude of the Athenians suspicious and dismissed them, alone of their allies.

Revolt of the helots and the dismissal of the Athenian force by Sparta

Whatever reasons the Spartans may have had for dismissing the Athenians, the results of their action were far-reaching. Cimon was discredited and in 461 he was ostracized. His main opponent, Ephialtes, was able to carry a series of laws that vitally changed the character of the Athenian democracy. The aspect of these reforms that is most emphasized in tradition is the curtailment of the power of the Areopagus, or Areopagite council, which the archons joined at the end of their year of office, but neither Aristotle nor any of his successors was able to define specifically what powers had been lost. In the 6th century the Areopagus had been the main guardian of the constitution, but the reforms of Cleisthenes shifted the balance of power to the Council of Five Hundred and the Assembly, and when, in 487, the lot was introduced in the election of archons, the prestige of the Areopagus probably declined. The Areopagus must previously have been exercising powers that were considered undemocratic. The definition of the very limited cases, all of a religious nature, that they were henceforward entitled to try implies that they had been acting more widely as a judicial court. The emphasis in the new, more developed democracy of Athens on the people's control of the executive suggests that magistrates had previously been influenced by the Areopagus. New powers were now explicitly given to the people. The jury courts were reorganized on a popular basis, and court decisions no longer rested with the magistrates but with the jurors, who were paid for their services, a principle that was later applied to the Council of Five Hundred and to all offices of state; no citizen was to be barred from state service by poverty. All officials had to undergo an examination in a people's court at the end of their year of office, and public auditors were annually appointed to examine accounts. It is significant that from the 450s important decrees of the Assembly and the summary accounts of public works were normally inscribed on stone and set up on the Acropolis or in some other public place where all could see them.

The dismissal of Cimon's force of Athenians by the Spartans led to a reversal of foreign policy. The immediate Athenian reaction was to conclude an alliance with Argos, Sparta's traditional enemy, and with Thessaly, with which Athens had been allied in the 6th century. A dangerous situation became more tense when Megara, a member of the Peloponnesian League, under pressure from its neighbour, Corinth, was accepted into alliance by Athens.

Developments in the west. The 460s were a period of change in Sicily also. For two generations Sicilian history had been dominated by the tyrants of Gela, Acragas, and Syracuse—their cities had enjoyed a period of great prosperity, which was based primarily on military strength. The tyrant Gelon, who came to power in 491, had succeeded in making Syracuse the strongest and richest city in Sicily. A network of marriage alliances linked him with Theron, who had become tyrant of Acragas in *c.* 488, and he proceeded to build up an army and navy to extend his power. He built a wall to defend the extension of Syracuse on the mainland and increased the population at the expense of smaller cities.

Syracuse under the tyrant Gelon

With the exception of a northern pocket around Mes-

sana, Gelon came to control the east of Sicily, and by 480 his army was sufficiently powerful and strong to prove decisive at the Battle of Himera when, with his ally Theron of Acragas, he defeated a force of Carthaginian invaders led by Hamilcar. The rich booty from this victory enabled the two cities to build impressive new temples, and the magnificence of the two tyrants' courts became a byword throughout the Greek world; it was reflected in their chariot victories at Olympia and in their dedications at Olympia and Delphi. Gelon died two years after the great victory. Hieron succeeded to the tyranny of Syracuse, being replaced at Gela by the third of the brothers, Polyzelus. It is probable that Hieron was less popular than Gelon and more oppressive in his rule. In his relations with the other Greek cities of east Sicily he was as ruthless as his brother. He drove out the populations of Naxos and Catana and forced them to settle in Leontini, and near Catana he established his own new city of Aetna with settlers from the Peloponnese and Syracuse. His relations with his brother Polyzelus, however, became strained, and when Polyzelus took refuge with Theron at Acragas, the two allies came near to war. When Theron died in 472 his son Thrasydaeus seems to have thought that the best way to counter internal opposition was by war. He assembled a large army, but Hieron struck first, and in a hard-fought battle, in which 4,000 men of Acragas and 2,000 Syracusans are said to have been killed, Thrasydaeus was defeated and was forced to leave Acragas. He took refuge in mainland Megara but was there condemned to death. Hieron made peace and, though Acragas was to make another challenge in 446, Syracuse never lost the primacy in Sicily that Gelon had established.

The tyrant Hieron as patron of the arts

Hieron was not merely a man of war. Greek literature benefitted greatly from his generosity and taste. Poets need patronage, and Hieron followed the precedent of earlier tyrants, the Cypselids at Corinth, the Peisistratids at Athens, and Polycrates at Samos, on a more magnificent scale. In the desolation following the Persian sack, Athens was in no position to attract a literary circle. Pindar was glad to visit Hieron's court and write odes to celebrate his victories at Olympia. Simonides of Ceos, who had commemorated the victories over Persia, came to Syracuse in 476 and stayed there as a court poet; Bacchylides, his nephew, joined him. Aeschylus was also attracted and gave a special production of his *Persae* in the theatre that Hieron had built; his *Aetnaeae* was no doubt intended to commemorate Hieron's new foundation of Aetna.

Hieron died in 467 at his own Aetna. The youngest of the four brothers, Thrasybulus, who succeeded him, had neither his ability nor the support to maintain his position, and was before long forced to withdraw to Locri.

The Syracusans celebrated the end of their tyranny by establishing an annual Freedom Festival and setting up a colossal statue of Zeus the Liberator. There seems to have been no serious opposition to democracy, and a democratic crusade was led against the few remaining tyrants in the island. The fighting in Syracuse had repercussions in many other cities, but finally a general agreement was reached that those who had been uprooted by the tyrants should be restored to their own cities and that the mercenaries were to settle in Messana.

Of relations between the Greek cities of south Italy very little is known. After the destruction of Sybaris in 510, Locri was the strongest of the states, but the archaeological evidence suggests a fairly widespread prosperity. The descendants of the refugees from Sybaris attempted near the mid-century to resettle their old home, but they lacked the strength to hold their own and appealed to the mainland for help. The Athenian settlers who came to join them became a source of friction rather than of strength, and the result was the planting by Athens of a new Panhellenic colony on a new site at Thurii, in 443.

In the first half of the 5th century there was a considerable loss of life in both Sicily and Italy in battles between Greeks and between Greeks and barbarians and, in Sicily, great uprootings of populations; but in this same period the achievement of the western Greeks in peaceful fields was very remarkable and comparable with that of the east Greeks in the 6th century. Following the incorporation of the eastern Greeks in the Persian Empire, refugees from Ionia probably played an important part in stimulating the western Greeks. When the Persians came, a large body of Phocaeans sailed to Corsica and, when driven out, settled at Elea (Velia) on the west coast of Italy. Xenophanes of Colophon, a vigorous free-thinker, after much wandering, also settled in Italy. A little later Pythagoras left Samos for Croton, where his compound of philosophy and religion made a deep impression.

During this period, the west was the leader in intellectual speculation. Rival schools flourished. Pythagoras was a considerable mathematician and seems to have thought that numbers were the ultimate reality, but he was also strongly influenced by mystery religions. It is from this source that he based his belief in transmigration of souls, one of the few doctrines that can be certainly attributed to him.

Pythagoras and Parmenides

His followers, observing a rule of life that combined principles drawn from philosophy with a religious mysticism, exercised a strong influence on politics. Their stern morality was effective at first, especially at Croton, where Pythagoreanism had evolved toward the end of the 6th century. The movement spread to Metapontum and other cities, but by the middle of the 5th century the emphasis on moral reform savoured too much of oligarchy, and there was a wholesale reaction against Pythagoreans.

Parmenides of Elea was more important in the history of philosophy. The Milesian speculators had tried to explain the nature of the physical universe, but Parmenides turned from physics to metaphysics. The basic question that puzzled him was what lies behind what one says or thinks: what is the corresponding reality? He dismissed sense perceptions and by involved but logical deductive arguments concluded that reality was a unity—indivisible and unchanging. He established a considerable following, among whom Zeno was his most persuasive supporter, and his arguments, in verse, greatly influenced Plato.

Empedocles of Acragas was a colourful contemporary who, like Parmenides, explained his views in verse. He rejected Parmenides' approach and defended the senses, explaining their distortions in physical terms. He was closer to the Milesians; but instead of searching for a single substance to explain the world, he found four basic elements—earth, air, fire, and water—which, under the changing pressures of love and strife, took varying forms. But there was also a strain of mysticism in his teaching, for, like the Pythagoreans, he believed in the transmigration of souls and would not eat the flesh of any animal.

The poets of the 6th century BC, Stesichorus of Himera and Ibycus of Rhegium, had no distinguished successors, although Epicharmus established comedy in Syracuse independently of Athens. None of his plays survive, but in later tradition he was better known than his Athenian contemporaries. With democracy came an increase in the importance of public speaking; Corax and his pupil Tisias, both Syracusans, were regarded as the pioneers in the study and teaching of the art of rhetoric.

Visual arts of the western Greeks

Unlike the Greeks of the mainland, the western Greeks had no easily accessible marble suitable for building, but their shelly limestone is an attractive material in texture and colour, and their temples in a severe Doric style are impressive for their size and proportions; the temple of Olympian Zeus at Acragas was considerably larger than the Athenian Parthenon. The lack of marble helps to explain why little is heard of west Greek sculpture, and it is significant that Pythagoras (not to be identified with the philosopher), the only sculptor of the west who was later regarded as one of the great masters, came from Samos before settling at Rhegium. But there was one field in which the west Greeks were supreme. The coin engravers of Sicily deserve a place in any anthology of Greek art. There are few coins, ancient or modern, more beautiful than the Demareteion, a ten-drachma piece issued to commemorate the Battle of Himera and named for Gelon's wife.

The Greek legacy owes not a little to the west Greeks of the first half of the 5th century.

The first Peloponnesian War (460–445 BC). The ten years that followed the dismissal of the Athenians from Ithome by Sparta (462 BC) and the ostracism of Cimon witnessed a dramatic rise and fall in Athenian fortunes as the Athenians consolidated their democratic reforms and fought on two fronts—against Peloponnesians and Persians. In 460, 200 Athenian and allied ships sailed to Cyprus, which, since the expedition led by Pausanias in 478, had been partly recovered by the Persians. This fleet, however, was soon diverted to what seemed an even more promising opportunity. For Inaros, a Libyan prince who had raised a revolt in the Nile Delta soon after the accession of the new Persian king, appealed to Athens for support. The restoration of Egyptian independence would have been a more serious blow to Persia than the liberation of Cyprus. The rich grain resources of Egypt may also have influenced the Athenian decision to intervene. At first all went well. The Greeks defeated the small Persian fleet and won control of the Nile. The remaining Persian troops fell back on Memphis at the head of the Delta and were besieged; but, though the Greeks quickly occupied most of the town, a determined force of Persians held out stubbornly in the White Fort.

Meanwhile, hostilities had broken out in Greece. The brief surviving record does not explain the circumstances that led to the fighting. The narrative begins with an Athenian attempt to take Halieis, a port on the Peloponnesian coast beyond Troezen, which could have proved a useful naval base for the Athenian fleet for raids on the Peloponnese and for strengthening communication with Argos; but forces from Corinth and Epidaurus drove the Athenians off, though the attempt to destroy the fleet on its return journey resulted in an Athenian victory off the island of Cecryphaleia. At this point Athens' old rival Aegina determined to put out its full strength, but the Athenians, reinforced by league allies, won a decisive victory in a great naval battle. The Aeginetans were driven from the sea and, after a long siege, their city was captured. Aegina was forced to become a member of the Delian League and pay the high annual tribute of 30 talents, the highest of the assessments, shared only by Thasos. During the siege, Cornith had tried to relieve the pressure on Aegina by invading the Megarid but met with no success.

Direct conflict between Sparta and Athens (457 BC)

Hitherto the fighting had been between Athens and the members of the Peloponnesian League near the Isthmus. In 457 the Spartans intervened. Until 460 (and possibly longer) Sparta had been preoccupied with the resistance of the helots on Mt. Ithome, but they had now surrendered on condition that they could freely leave the Peloponnese. The Athenians gave them a home in Naupactus on the north shore of the Corinthian Gulf, which they had recently captured. In this strategic site, commanding the entrance to the gulf which Corinth regarded as its own, the helots were to repay abundantly the generosity of Athens. The desertion of Megara from the Peloponnesian League and its subsequent alliance with Athens had severely limited the range of Spartan action, for the Athenians had built a wall between Megara and Nisaea, effectively barring the only practical route for a Peloponnesian army invading Attica. The Athenians had also strengthened their position by building long walls from the city to the Piraeus and to Phaleron, within which the population of Attica could take refuge in the event of invasion. To demonstrate their power outside the Peloponnese, the Spartans took a strong force of some 11,500 Peloponnesians across the Corinthian Gulf. Their immediate objective was to defend the small state of Doris, a task that was soon accomplished. They now found that their way home was barred. The Athenians had sent a fleet into the Corinthian Gulf and had closed the mountain route over the Isthmus. The Spartans moved into Boeotia and encamped at Tanagra, threatening Attica and negotiating with extreme oligarchs in Athens, who were anxious to overthrow the democracy. The Athenians marched out, and the pitched battle that followed was evenly fought, but the Thessalian cavalry deserted and the Athenians had to admit defeat. The Spartans, however, did not feel strong enough to attack Athens itself and were content to return through the mountain passes of the Isthmus. Athenian morale was not badly shaken and two months later they returned under their general Myronides and won a decisive victory over the Boeotians at Oenophyta (457 BC). This victory gave them control over all Boeotia, with the possible exception of Thebes, and their control was soon extended over Phocis and Locris. They could now turn to the offensive against the Spartans; the Spartan dockyards at Gythium were burnt and Chalcis on the Gulf of Calydon was captured. This marked the high tide of Athenian success.

The tide first turned in the east. The Persian king had tried to relieve the pressure on Egypt by bribing the Spartans to act more vigorously against Athens. When this failed, a large army and navy were sent to crush the revolt. A squadron of 50 ships, sent out to relieve the Greek fleet or part of it, entered the Nile and was largely destroyed. The Greeks were driven from Memphis and fell back on Prosopitis, an island between two branches of the Nile. After 18 months the Persians dried up the canal linking the two branches, and the Greek position became untenable. Under an armistice the survivors were allowed to cross the western desert to Cyrene. The loss in men and ships was serious, and the effect on Athenian expansion decisive. During the early 450s Athens had aimed at bringing into the league Cyprus and all cities in the eastern Mediterranean that had Greek roots. The collapse in Egypt meant the abandonment of Cyprus and the eastern Mediterranean. In Greece itself the offensive against the Peloponnese was halted. Over the next three years the Athenians concentrated on building up their strength, but before a new expedition sailed east they wisely decided to secure themselves against Sparta. No one could have been a more acceptable mediator than Cimon, who had always advocated friendship with Sparta. Cimon was, therefore, specially recalled, shortly before his ten years' ostracism was due to expire, and he succeeded in negotiating a five years' truce early in 451.

Cimon could now resume command of league forces against Persia, and in 451 (or possibly 450) he sailed east with 200 ships. His main objective was the recovery of Cyprus, but he detached 60 ships to Egypt, where revolt was still smoldering. In Cyprus the campaign started well, but Cimon died while besieging Citium, the strongest Phoenician city in the island, and his colleagues in the command decided to take the fleet home. The Greek withdrawal from Cyprus marked the end of fighting between the Delian League and Persia. Both sides could now leave the struggle with some dignity, and both had good reason to do so. The Athenians realized that they had overstrained their resources and felt nervous for the stability of the league; the Persians had recovered control over the eastern Mediterranean and Egypt, although they were faced with a revolt in Syria. It is probable that a formal peace, the so-called Peace of Callais, was now made, in which the Athenians abandoned their ambitions in the eastern Mediterranean and the Persians agreed not to attack the members of the Delian League and to keep their fleet out of the Aegean; but there is no firm evidence, and the peace remains controversial. It is certain, however, that Athens decided to terminate hostilities.

Cimon's expedition to Cyprus

The years that followed the end of fighting against Persia were the most critical period for Athens, both at home and in relations with the allies, since the invasion of Xerxes. The most important problem was the future of the Delian League now that Persia could no longer be regarded as an active enemy. Athens was determined to maintain the league and did not hesitate to make this clear to the members. The Athenians' relations with the allies had, by 465, changed considerably, and they had used force to put down revolts. In the 450s, some of the cities were called upon to send ships or troops to fight against the Peloponnesians—something that had certainly not been anticipated earlier. Athens removed the league treasury from Delos to Athens. Henceforth the annual tribute was to be brought to Athens in early spring at the time of the Dionysia. The transfer of the treasury could be justified when it was made, for the Persian victory in Egypt might have encouraged the Phoenician fleet

to sail into the Aegean and raid Delos. But however honest the motive may have been, the transfer made it much easier for the Athenians to use the money for their own purposes.

After the death of Cimon, Thucydides, son of Melesias (not the historian), and probably Cimon's brother-in-law, set out to organize into a coherent party the extreme oligarchs and all those who might have an interest in reversing the tendencies of the democratic leadership. When the Assembly decided to use the tribute from the allies to build Athena's temple, Thucydides tried to persuade the people to repudiate the immoral use of the allies' money:

> Greece appears to be the victim of monstrous violence and manifest tyranny when she sees that with the money contributed under compulsion for the war we are gilding our city like a wanton woman, adorning her with extravagant stones, statues and thousand-talent temples.

But the pride of a new temple and the prospect of employment that it offered were sufficient to dull any tender consciences. Thucydides continued to attack his democratic opponents, but Athenian policies were not significantly modified.

Difficulties within the Delian League

Athens also had trouble from the allies. The tribute lists of the years from 450 to 446 show that this was an unstable period. Many cities paid late in the year; others made incomplete payments and some, including probably Aegina, did not pay at all. It was probably in this period that Colophon revolted and was suppressed. There had been trouble in Erythrae and Miletus before 450, and the Milesian oligarchs, with whom the Athenians at first tried to cooperate, now carried out a purge of their opposition. But by 440 democrats were in control of Miletus; they had almost certainly been installed in power by the Athenians.

Two important decrees that illustrate the new imperial tone are probably to be dated in these years. The first requires all the allies to use Athenian coins, weights, and measures and bans all minting of silver: now that the tribute was to be spent mainly in Athens, crews, contractors, and workers would naturally want to be paid in Athenian coin. But the move was also an open expression of empire. Another attempt to bind the cities together in an empire is alluded to in a second decree, the main purpose of which was to tighten up the collection of tribute but which refers in passing to a more important decree, recently passed, requiring all the allies to bring to the festival of the Great Panathenaea—held every four years—a cow and a suit of armour: colonies were traditionally expected to recognize in such ways the main festivals of their mother-cities. Athens also hoped to encourage loyalty to the empire by spreading the cult of "Athena, queen of Athens" in the cities.

Another important feature of this period was the settlement overseas of Athenian citizens of the two poorest classes. This policy of establishing what were called "cleruchies" in the territories of allied cities was one of the main grievances still remembered against Athens in the 4th century, although not all such settlements were unpopular. Some cleruchies were intended as garrisons and settled as penalties for anti-Athenian attitudes or actions.

Periclean democracy and imperialism. By the various measures taken between 450 and 446, Athens had succeeded in converting a league into an empire. The opposition in the Assembly led by Thucydides had been active but ineffective, and allied discontent had been met by firmness. There was no attempt to disguise the change of status, and the Athenians freely admitted that they no longer led autonomous allies. The strength of the new Athenian position was fully confirmed when Athens successfully weathered a succession of serious crises in *c.* 446, the year when the five years' truce with Sparta was due to expire. In spring 446 or summer 447 the Athenian general Tolmides underestimated the seriousness of a rising in Boeotia. He was surprised and defeated near Coronea, and to save the army the Athenians had to undertake to withdraw entirely from Boeotia, undoing all that had been won at Oenophyta. The Boeotians had been helped by Euboean exiles and revolt now spread to the main cities of Euboea. Pericles, now the leading Athenian politician and general, had taken an army over to the island when he learned that the Megarians had massacred most of their Athenian garrison and that a Peloponnesian army was marching toward Attica. He brought his army back and negotiated a Spartan withdrawal (allegedly by bribery). He could then return to Euboea, where the rebel cities were quickly reduced.

The Thirty Years' Peace

Meanwhile, an Athenian embassy to Sparta had negotiated the terms of a peace which was to last 30 years. The Athenians gave up Nisaea, Troezen, and Achaea. Aegina had also hoped to regain its independence but had to be satisfied with a clause guaranteeing freedom from Athenian interference provided that an annual tribute was paid. Athens' most important gain was the recognition of its empire by Sparta. Both sides undertook not to interfere with the alliance of the other, though neutrals could join either.

During the peace negotiations the Athenians had to draw up new tribute assessments. Some 30 cities (and probably more, for the evidence is not complete) had their assessments reduced, while only three increases are known; the natural inference is that Athens was reacting to the crises from which it had emerged by a policy of concessions. There is no firm evidence of the attitude taken by Thucydides and his followers to the events of these critical years, but in 443 there was sufficient feeling against him to secure his ostracism. With his fall, the party he had built up collapsed. The extreme oligarchs remained implacably hostile to the democracy but were not strong enough to come out into the open; most of the moderates were content to accept the leadership of Pericles, who, in spite of his political views, was an aristocrat.

Pericles, early in his political career, had been personally responsible for the introduction of state pay for state service, first to the jurors and later to the Boule (city council) and all branches of the executive. By the early 440s he was the most influential politician in Athens. He was the main architect of the conversion of league into empire and was almost certainly mainly responsible for ending the fighting against Persia.

Periclean building in Athens

With his firm belief in the need for maintaining a tribute-paying empire, Pericles combined imaginative ideas on the quality of Athenian democracy and culture. He began the transformation of Athenian public architecture, and it was he who formally proposed that the tribute reserve should be used for the rebuilding of Athenian temples. The public buildings of the Cimonian period had been in limestone; the Periclean temples were in marble from the quarries of Mt. Pentelicus. The most impressive of the new buildings were the Parthenon, with its splendid gold and ivory cult statue of Athena, and the new monumental western entrance to the Acropolis. Other fine temples were built in the same generation, among them, one to Hephaestus overlooking the Agora, to Poseidon on the headland of Sunium, and to Nemesis at Rhamnous. The program was not confined to religious buildings. A large concert hall, with its tentlike roof supported by a forest of columns, was built near the theatre on the southeast slope of the Acropolis, and to make the amenities of life available to poor at well as rich, public money was used to build public gymnasia and baths.

Pericles was said to have been a pupil of Anaxagoras, a philosopher who spent the greater part of his active life in Athens. To him he owed his rigorous grounding in the study of the physical universe and a lasting interest in philosophy; together they freed him from the restricting conventions of contemporary religion and superstition.

Pericles was reserved and did not mix freely with the people; but he was a commanding orator, and the Assembly learned to accept his judgment and follow his lead. After the ostracism of Thucydides he was elected general for 15 years in succession. But the real source of his power lay more in his personal authority. The historian Thucydides, in recording the funeral speech he delivered in 431 to commemorate those who died in the first year of the Peloponnesian War, outlines the main qualities of the democracy which Pericles did so much to create. Un-

Nature of Periclean democracy

like Sparta, inward-looking and strictly disciplined, Athens was a city wide open to the world. Pericles had himself stiffened the qualifications for citizenship by requiring Athenian parentage on both sides, but foreigners were encouraged to settle in the Piraeus or Athens itself and were better treated and had more profitable opportunities there than in any other Greek city. Athens welcomed them, unskilled as well as skilled, and they played a dominant part in Athenian trade. In the Periclean democracy, public service was not confined to a minority of activists but was the natural duty of all citizens, poor as well as rich, and most offices were filled by the lot. Five hundred men had to be found each year for the Boule, and, as no one could serve more than twice nor be under the age of 30, a large proportion of the citizen body must have served at least once. The Boule reviewed all state business and controlled the executive; and no business could be discussed in the Assembly unless it had been put on the agenda by the Boule. A year in the Boule was an intensive political experience, and for a tenth of the year every member had to be continuously available. The sovereign body was the Assembly, in which every citizen had an equal vote. Policies were normally discussed on the basis of resolutions drafted in the Boule (*probouleumata*), but it was also open to the Boule to make no formal recommendation and merely to bring a matter forward for debate. In either case there was a free vote; anyone could address the meeting; and amendments could be proposed from the floor. Perhaps the most surprising feature of the proceedings of the Assembly was the appointment by lot of the chairman, who changed daily and was chosen from the members of the Boule. That important policies could be discussed at large open-air meetings—at some of which a quorum of 6,000 was required—and result in rational decrees is a great tribute to the tolerance of the average citizen. Thucydides, looking back on what he regarded as the golden age of Pericles said that "it was in name a democracy, but in reality the rule of the first man." This should not obscure the fact that Pericles had to persuade the Assembly and that the Assembly was not an ignorant mob; he could not act arbitrarily without authority. For his actions in office he had to submit to the same public examination as others, and at any time his proposals could be rejected by vote.

Importance of the empire to Athenian prosperity

The high standard of living that the Athenian democracy provided for its citizens depended in no small part on the stability of the empire, the tribute of which paid directly or indirectly for much of Athenian public spending. Without the tribute reserve, Pericles' ambitious building program would have been out of the question, and without the annual tribute, Athens would have been unable to afford both state pay for state service and a large and active fleet. There is, however, no evidence that the allies were financially oppressed. There was no general increase in assessments before the Peloponnesian War, and more than half the cities kept the same assessment from 453 to 431 BC. For most cities the tribute was probably a small price to pay for the policing of the seas by the Athenian fleet. Too little is known of the pattern and volume of trading during this period to draw firm conclusions, but it is clear that the Piraeus became the busiest trading port in the Aegean and probably in the Mediterranean. A wide range of goods came in from the Euxine, Phoenicia, Egypt, and Carthage, as well as from the Greek world. There seems, indeed, to have been a considerable growth of trade following the end of hostilities against Persia, and, though Athens was the main beneficiary, the security of shipping benefitted the allies as well. The grievances of the allies were political rather than economic. They had lost their independence and were no longer allies but subjects.

In order to control subject cities, Athenian officials, *archontes*, were installed, sometimes singly, sometimes as many as five; with them went a small security guard, stationed on the local acropolis, capable of dealing with small-scale trouble but not strong enough to crush a serious revolt. Athens also sent out commissioners, *episkopoi*, to cities where trouble had arisen to examine the situation, make recommendations on the spot, and report back. Such officials were widespread by the early 440s. More important was the control exercised by the people's law courts at Athens. All cases involving the major penalties of death, exile, loss of citizen rights, and total confiscation of property had to be referred to Athens. But the most reliable means of control was the encouragement or imposition of democratic governments. It was the oligarchs who most resented Athenian rule; the burden of tribute fell mainly on the wealthy, and the powers of local dynasts were restricted. Most of the revolts for which there is evidence were engineered by oligarchs, and in the settlements that followed power was normally given to the demos. It was inevitable that oligarchs should look elsewhere for support, to Persia or Sparta, and when it came to a choice between rule by their own extreme oligarchs or Athens, the common people would tend to prefer Athenian control.

The revolt of Samos

After the Thirty Years' Peace had been negotiated, the Athenian Empire seemed secure. It was a considerable shock when, in 440, Samos, one of the three islands off the Asiatic shore that still contributed ships, revolted. Fighting had broken out between Samos, which at the time was controlled by oligarchs, and Miletus, where Athens had recently installed a democracy. Priene, which at various times had needed to fight against both for its independence, was the bone of contention. When an Athenian attempt at a political settlement failed, war followed, and the Athenians had to deploy their full naval resources and summon contingents from Chios and Lesbos. After a nine-month siege, Samos had to surrender and was made to give up its fleet, raze its walls, and agree to pay a substantial indemnity in installments. Samos had appealed for help to Sparta, and the Spartans went so far as to summon a meeting of the Peloponnesian League; but the peace had stipulated that neither side should interfere with the other's alliance, and the league voted against war. The Samian oligarchs had also appealed to the Persian satrap at Sardis and had received some mercenaries from him. Of the Athenian allies, Byzantium alone followed Samos but was recovered without serious fighting.

THE GREAT PELOPONNESIAN WAR (431–404 BC)

Five years after the surrender of Samos a train of events started in the northwest that led to the Great Peloponnesian War. Though the record is thin, it seems that in these years Athens was in an expansive mood, a mood likely to cause misgivings in Sparta. In 436 Athens succeeded in planting a large colony at Ennea Hodoi, now to be renamed Amphipolis, on the Strymon, a splendid base for the exploitation of the rich mineral and timber resources of the region. But Athens could not, without weakening its manpower dangerously, provide more than a nucleus of the colonists; the mixed character of the population, drawn largely from the Greek colonies of the area, was to prove a serious weakness. A little later Pericles himself led a spectacular expedition into the Euxine to demonstrate Athenian strength and their interest in the Greek cities of the south as well as the north coasts. At Sinope the local tyrant was expelled, and 600 Athenians were sent out to strengthen the Greek population.

Athenian intervention between Corinth and Corcyra

By 435 Athenian restlessness was causing general concern, and when fighting broke out between Corinth and its old colony Corcyra there was soon a danger that it would spread much further. For Corinth, humiliated by defeat in a naval battle, began to make intensive preparations for a larger fleet to teach Corcyra a lesson, and Corcyra appealed to Athens. Since Corcyra belonged to neither alliance, the Athenians would not be breaking the terms of the peace if they accepted Corcyra as an ally, although such an action would clearly invite the bitter resentment of Corinth. After an even debate in the Assembly, the Athenians decided to make a defensive alliance: Athens would help Corcyra if it was attacked and was in danger of defeat. Ten ships, shortly followed by a second squadron of 20, were sent out. In the Battle of Sybota that followed, the Athenian ships intervened when the Corcyraeans were in grave danger; the Corinthians withdrew. More bitterness was caused when the Athe-

nians, suspecting trouble from Potidaea in Chalcidice, a Corinthian colony but a member of the Athenian Empire, required the city to pull down its main defensive wall and give hostages. The Potidaeans, after failing to negotiate concessions from Athens, and relying on a Spartan undertaking to invade Attica if Potidaea was attacked, came out in open revolt. It was probably soon after this development that the Athenians charged Megara with cultivating borderland that belonged to the Eleusinian goddesses and with giving a refuge to runaway Athenian slaves. When no satisfaction was given, Pericles carried a decree banning the Megarians from the Athenian Agora (civic centre and market) and from all the ports of the Athenian Empire.

In 432, while an Athenian force was blockading Potidaea, the Corinthians and other members of the Peloponnesian League sent representatives to Sparta to press for action. Sparta was divided; King Archidamus pleaded for caution and delay, but a clear majority preferred the rousing demand for war from the ephor Sthenelaidas. To involve its allies Sparta needed a majority vote at a formal meeting of the Peloponnesian League. In the late summer of 432 the league was committed to war.

Thucydides' view of the war's origin

In his detailed account of these events Thucydides emphasizes the initiative of Corinth in bringing matters to a head, but he saw clearly that the cause of the war went far deeper than the trading interests of Corinth. "The true cause of the war . . . was the growth of Athenian power which compelled Sparta to fight." Other writers laid the main stress on the Megarian decree and on the refusal of Pericles to compromise. To Thucydides the real issue was not the trade rivalry between Athens and Corinth but whether Sparta or Athens should be the leading power in Greece. In the war, which opened in 431, the Spartans were technically the aggressors. They sent ultimatums to Athens over the winter, the terms of which were such that they cannot have expected Athens to accept them. Peace, however, could have been maintained if the Athenians had been more conciliatory. But Pericles had long since decided that Athens could not reach its full development while Sparta controlled the Peloponnese. His vision of Athens included the eclipse of Sparta.

Pericles led Athens into the war deliberately and with full confidence. In spite of the ambitious building program there was still a reserve of some 6,000 talents on the Acropolis which, when combined with annual income, seemed ample to sustain even a long war. The Athenian fleet, with 300 ships, was immensely superior to that of the Peloponnesians in numbers, experience, and skill. The Athenian fleet, Pericles thought, could maintain a firm hold on the empire and attack the enemy's coastline. The Athenian army was weaker in numbers and military reputation than that of the Peloponnesians, but it was sufficient to man the defenses and raid the Megarid. Pericles argued that the army should not be used to fight the Spartans and should avoid pitched battle; Attica must be abandoned and the country population take refuge in Athens, where they would be protected by the city walls and the long walls running to Piraeus. There should be no attempt to expand the empire during the war. It is difficult to see how Sparta could have been crushed by Pericles' strategy, but under continuous pressure the Peloponnesian League might have disintegrated, forcing Sparta to accept an unequal peace, virtually admitting Athenian primacy.

The great weaknesses on the Spartan side were their fleet and their finances. The Spartans still dealt in iron bars for currency, and most of their allies were agricultural states with lean resources. The coastal towns, particularly Corinth, were economically stronger, but they could not afford to raise and pay large fleets. The Peloponnesian army, however, could easily muster 30,000 (against an Athenian limit of 13,000).

The pattern of warfare

The first year of the war established the pattern that was to be expected. The Peloponnesian army, led by King Archidamus, invaded and ravaged Attica, while the Athenians watched helplessly from their walls. Meanwhile, a fleet of 100 Athenian ships sailed around the Peloponnese, raiding selected points. In 430 the strategies were repeated, but the most important event of the year was the arrival in Athens of a plague from the east that swept through the overcrowded city, killing roughly a quarter of the fighting men and an even larger proportion of women, children, and slaves. This had a depressing effect on Athenian morale; an embassy was sent to Sparta to negotiate a settlement and Pericles was dismissed from his command. Sparta, however, would not offer acceptable terms; the Athenian mood recovered, and Pericles was shortly re-elected. But in 429 he died.

The demagogic element in Athens. Pericles' death was followed by a change in the political climate. Among those who had been generals with Pericles there was no outstanding politician, and, as a consequence, policies became less consistent. The most disturbing factor was the emergence of new political leaders who no longer depended for their influence on their prestige as generals or on the distinction of their families but on their shrewd understanding of the common people and their debating skill in the Assembly. Cleon was the first of these new leaders. He first appears in the record in 431, attacking Pericles when the latter would not allow the Athenians to go out and fight. Like his successors, he rose to power as a critic, prosecuting oligarchs in the courts, seizing any opportunities that were offered when magistrates were publicly examined at the end of their year of office, and claiming to be the champion of the common man. Aristophanes caricatures him as a leather seller, as if he were some small-scale retail trader, but Cleon's father had supplied a chorus for a public festival and must therefore have been a man of more than average means. By his background he was better qualified than most of his political rivals to handle financial problems.

The rise of Cleon

Neither Thucydides nor Aristophanes was sympathetic to the new style, but even Thucydides admits that by 427 Cleon was "by far the most persuasive speaker in the Assembly." Thucydides also describes him as "most violent," and from Aristophanes it is known that he had a loud voice "like a mountain torrent." His qualities were demonstrated when Mytilene, which had been in revolt, surrendered in 427 and the Assembly had to decide what penalties to impose. Cleon convinced the people that the right policy was to put all adult males to death and enslave the women and children. At a second meeting, called to reconsider the decision, he stood firm by his original motion and was only narrowly outvoted.

Cleon's influence became even stronger in 425. An Athenian fleet sailing to Sicily had left a force on the promontory of Pylos in Messenia, hoping to encourage Spartan helots to desert. The Spartans, in alarm, brought back an invading army from Attica; in their operations against Pylos they occupied the neighbouring off-shore island of Sphacteria in order to deny it to the Athenians. But Pylos held out, and the Athenian fleet blockaded Sphacteria. When the blockade proved ineffective Cleon violently attacked the generals in the Assembly, demanding more vigorous action, with the surprising result that he was himself given the command. He took light-armed troops and used the advice of Demosthenes, the most enterprising of the generals. They landed a force on the island and finally forced the Spartans to surrender. Now Athens had hostages against further invasions of Attica, and Cleon's followers could introduce an extraordinary assessment in which the tributes of the allies were sharply increased to bring in a total of nearly 1,500 talents, more than three times the prewar figure.

The conduct of the war now became more vigorous. A raid was made on Corinthian territory, and in the summer of 424 the island of Cythera off the south coast of Laconia was captured, providing a useful base for raids on the mainland and for intercepting merchantmen coming to the Peloponnese from Libya and Egypt. In 424, however, the Athenians over-reached themselves. Cleon had been elected general, but it was Demosthenes and Hippocrates who planned the campaigns. Their first objective was to gain control of Megara by a combination of military action and political propaganda, but in this they failed. Demosthenes and Hippocrates then proceeded with an elaborate attempt to regain control of

Boeotia. There were to be democratic risings in the cities; Demosthenes was to land with a force at Siphae on the Corinthian Gulf, while Hippocrates led out the main Athenian army and occupied Delium. The plan was too complicated and could not be kept secret. Siphae was garrisoned when Demosthenes arrived; the revolts in the cities misfired; the army from Athens was isolated and, in a pitched battle near Delium, was decisively defeated. At roughly the same time, the Spartan Brasidas and a small force had reached Chalcidice and was attempting to undermine Athenian control of the area. Brasidas met with rather less success than might have been expected, but he succeeded in his most important objective by capturing Amphipolis, a very serious loss to Athens.

The Peace of Nicias. Athenian prospects had now completely lost the promise that the victory at Pylos had brought, but the Spartans were more anxious to recover their prisoners than to continue the fighting in the north. A year's armistice was therefore arranged from April 423; it was intended to pave the way to a permanent peace. But within a few days of the armistice Mende and Scione revolted, and Brasidas supported them. Mende was quickly recovered, but Scione held out into 421. In 422 Cleon was given command in the hope that he would repeat his success of 425; he did indeed start well, winning back Torone and some smaller places, but at Amphipolis he failed. He led out his force to high ground beyond the town in order to reconnoitre, and was caught by a surprise attack while returning. His army was beaten and he himself killed, but Brasidas also fell in the battle. Their deaths made it easier for the Spartans and Athenians to negotiate seriously for peace.

Terms of the peace

The main terms agreed between the two sides were that each should return its prisoners and that Sparta should recover Pylos, Athens Amphipolis. No provision was made for the restoration of Sollium and Anactorium, which the Athenians had taken from Corinth, nor of Nisaea, which they had occupied in 424 when they failed to win Megara. Boeotia was required to hand back Panactum, an Athenian border fort captured after the Battle of Delium. The Spartans had ignored the interests of their strongest allies and, when the terms were submitted to the Peloponnesian League for formal ratification, Corinth, Megara, Elis, and Boeotia all opposed acceptance; but they were outvoted by the smaller states, which had nothing to gain from war; nor were their interests seriously affected by Athenian imperialism.

The peace was named after Nicias, the most influential of the Periclean politicians since the death of Pericles, and the main enemy of Cleon. Nicias lacked Pericles' authority, however, and, though popular, was indecisive and ill-suited to lead Athens firmly to friendly coexistence with Sparta. His peace was doomed from the outset because the war had settled nothing, and too many cities were dissatisfied with the terms—especially Corinth, which had lost most and gained nothing. Internally, neither Sparta nor Athens was stable. When new ephors were appointed in the autumn at Sparta the board of five included two men who were anxious to renew the war. In Athens, Nicias had two powerful opponents who were not prepared to accept his policy. One, Hyperbolus, had inherited the mantle of Cleon; he had the same background, relied on the same following in the common people, and advocated similar policies. Cleon's fortune came from leather, Hyperbolus' from lamps; in Aristophanes' plays they are both warmongers. More dangerous was the young Alcibiades, perhaps the most brilliant Athenian of his generation. His father had died at the Battle of Coronea in 446 when he was only five years old, and he had been brought up in the house of his guardian Pericles. Strikingly handsome, with a quick intelligence and a cheerful contempt for convention, he fascinated women and could lead men. He combined great abilities with a fundamental lack of responsibility and, as Thucydides saw, his private life ruined his public career. When the peace was made he looked for opportunities to discredit Nicias and win the kind of position that Pericles had held. In so doing he roused the bitter hostility of Hyperbolus and his associates because his colourful conduct appealed to the common people. So developed a feud that was to be one of the main causes of Athens' ruin.

Breakdown of the peace: Athens' Peloponnesian alliances

The failure of the Peace of Nicias was soon manifest. Prisoners were exchanged, but Amphipolis was not handed back to Athens because the inhabitants were determined to remain independent, and so Athens continued to hold Pylos. In the uneasy years that followed there was a confusing pattern of negotiations and alliances. First Corinth attempted to build up a third power, winning over Argos, whose Thirty Years' Peace with Sparta was due to expire toward the end of 421, and some of the members of the Peloponnesian League; but an alliance between an oligarchic Corinth and a democratic Argos was bound to be insecure, and Corinth lacked the power and confidence to hold the alliance together. At the time, however, it seemed sufficiently dangerous to persuade Athens and Sparta to join forces in a new alliance to protect themselves. Before the end of 420, however, the influence of Nicias had been seriously eroded and Alcibiades was able to lead the Assembly away from Sparta into an alliance with Argos and two members of the Peloponnesian League that resented Sparta's high-handedness—Mantineia and Elis. This alliance was put to the test in 418 when the two armies faced one another outside Mantineia and Sparta was cut off from Corinth and Boeotia. The battle was hard fought, and at one point a picked corps of Argives broke through the Spartan line; but Spartan discipline finally prevailed, though the defeat did not become a rout.

The combination of Athens and Argos with discontented Peloponnesians near Sparta offered the only practical prospect of defeating Sparta decisively. But the policy failed because Athens' support was halfhearted. Its contribution to the allies' army—only 1,000 hoplites and 300 cavalry—was inadequate, and it was led by Laches and Nicostratus, who had been consistently associated with Nicias; Alcibiades, who originated the policy, had not even been elected general for the year. Elis also was to blame; when it disagreed with the priorities for the campaign, it withdrew 3,000 men.

Having failed in its Peloponnesian policy, Athens turned elsewhere. In 416 it sent a strong force to bring the island of Melos into the empire. Melos had been neutral at the beginning of the war and had resisted when Nicias landed in 426 with a strong force and ravaged the land. Though the Athenians now promised that there would be no victimization if Melos would join the other islands as a tribute-paying member of the Athenian Empire, the Melians stubbornly refused. After a stiff resistance they were forced to surrender; the men of military age were put to death, and the women and children enslaved. This was the fate that Cleon had advocated for Mytilene and had succeeded in imposing on Scione. But these two cities had revolted; Melos had merely tried to remain independent. From a playful allusion to the "Melian famine" in Aristophanes' *Birds*, produced in 414, it seems that the savage punishment of Melos did not weigh heavily on the Athenian conscience at the time. But Thucydides emphasized its significance, and it was widely remembered against Athens in the 4th century.

The expedition to Sicily and its aftermath. In 415 the Athenians embarked on an ambitious attempt to gain control of Sicily. The occasion was an appeal for help from Segesta in the west of the island, which was under pressure from neighbouring Selinus. Alcibiades saw in a Sicilian expedition the opportunity he needed for spectacular successes, and the people were attracted by the wealth of Sicily. Nicias pleaded for caution but was outvoted. In spite of his strong opposition he was elected to a joint command with Lamachus and Alcibiades. It was a bad compromise. The expedition was the most impressive that had left the Piraeus since the middle of the century. There were nearly 100 battle triremes, including 34 from the allies, with 40 more used as transports, and 5,100 hoplites, of whom only 1,700 were Athenians.

But the expedition sailed under a cloud. One night, shortly before it was due to depart, most of the figures of Hermes in the city were defaced. The outrage was widely regarded as a sinister omen, and rewards were

offered to informers who brought evidence about the Hermae or any other acts of sacrilege. Nothing was immediately discovered about the Hermae, but reports were brought about other offenses, including parodies of the Eleusinian Mysteries in private houses, in which Alcibiades was implicated. This opportunity was eagerly seized by Androcles and other political enemies of Alcibiades, who roused popular feeling against him. Alcibiades urged that his case should be tried at once, but his enemies, who were afraid that he would have the support of the expeditionary force, insisted that the case should be postponed until further evidence was collected. Soon after operations had begun in Sicily Alcibiades was summoned home. Realizing that the scales were weighted against him, he gave his escort the slip and soon was in Sparta putting his knowledge and advice at its disposal.

Defacement of the Hermae and the defection of Alcibiades

It was this action against Alcibiades that was largely responsible for the Athenian disaster in Sicily. Morale was badly shaken by the recall of the driving force behind the expedition, and not long afterward Lamachus was killed in battle. Nicias, whose indecisiveness was made worse by his poor health, was left in control. Progress had at first been promising, although too slow. The Athenian fleet controlled the sea, and a wall around the city was begun in order to complete the blockade. But Gylippus, a vigorous Spartan general, brought new confidence to the defenders, and Corinth also sent help. The circumvallation wall was cut off and the Athenians fell back on the defensive. Nicias, frightened to return home unsuccessful, sent for reinforcements, which arrived under Demosthenes. He made a bold night attack on Epipolae, the rocky plateau overlooking Syracuse; but his units became confused in the dark, and the attack had to be called off. Demosthenes was now anxious to leave; but Nicias hesitated, and an eclipse of the moon persuaded him to wait further. A great naval battle in the harbour was lost, and the only hope was to lead the forces overland to friendly country. But the roads were blocked, and after grim harrassment the survivors of both divisions surrendered. Nicias and Demosthenes were put to death and the men were imprisoned in quarries from which some were released for reciting verses from Euripides; others were ransomed, but many died.

Consequence of the defeat in Sicily

The almost complete destruction of the fleet and army that went to Sicily was a crippling blow to Athens. Few ships and little money were left. Urged on by Alcibiades, Agis, the Spartan king, had brought a force into Attica and was encamped at Decelea, only 12 miles from Athens itself. As a result Attica had to be completely abandoned; the silver mines at Laurium could not be worked, and some 20,000 slaves took refuge with the Spartans. Widespread revolt could be expected among the allies. The survival of Athens for eight further years is a great tribute to its courage and determination, but the Spartans, as so often before, were slow to press home their advantage. The Athenians were still safe within their walls provided that they could import enough food; this the Spartans could not prevent until they achieved decisive superiority at sea.

In order to preserve what they could of their empire, the Athenians made Samos their chief naval base, and most of the fighting shifted to the east side of the Aegean. The Spartans soon found that their problems were more complex than they had anticipated. While they were able by 412 to build up, with the help of their allies, a fleet sufficiently large to match that of the Athenians, they lacked the financial resources to maintain their crews and had to appeal to the Persians for help. This, however, posed an embarrassing dilemma. The Persian price was naturally the recovery of the Greek cities that had once belonged to the Persian Empire, and Sparta had claimed to be the liberator of the Greeks. It is not surprising that the first agreement with Persia, which recognized the Persian king's right to all that he had formerly ruled, was modified twice within six months, and that Persian pay became very irregular. Spartan relations with Persia also made the east Greeks less anxious to revolt, and Athens still had considerable support from democratic parties that knew that both Sparta and Persia favoured oligarchy.

Oligarchy in Athens. Sparta lost its best chance of an early victory in 411 when Athens was torn by political upheavals. Before the Syracusan disaster there had been no serious threat to the democracy, but conditions were now greatly changed. Periclean democracy depended on state pay for state service, and there would soon be no money to pay. The need for some restraint on the democracy had been recognized in 413 when the Assembly agreed to the appointment of ten elderly commissioners to ensure economies and guide policy. Toward the end of 412 there was open talk of the need for more substantial reform. In the fleet at Samos some of the generals and officers began to plot and approached Alcibiades, who had outstayed his welcome at Sparta and was now exercising his charm on Tissaphernes, the Persian satrap at Sardis. Alcibiades knew that Androcles and his other enemies were irreconcilable, but his family background assured him some support from his own social class. His main hope, however, rested on his assurance that he could persuade Tissaphernes to support the Athenians financially, if they changed their form of government. The oligarch Pisander led representatives of the fleet to put the case for reform before the people, and the prospect of Persian money proved decisive. The Assembly agreed in principle to constitutional changes; Pisander was sent back to complete negotiations with Alcibiades.

Cooperation of the oligarchs with Persia

When it came to the test Alcibiades could not secure the flow of Persian money, but the oligarchs had gone too far to draw back. Pisander returned to Athens, where a revolutionary situation was developing. There was much talk of a government of the 5,000 best qualified in purse and person to serve the state, but in the streets the most determined enemies of oligarchy, including Androcles, were assassinated. Pisander carried a motion that ten commissioners should be appointed to submit proposals to the Assembly on a specified day. The meeting was called at Colonus outside the walls, where, owing to the Spartan presence at Decelea, the common people would feel insecure. The commissioners merely recommended that there should be no state pay for state services, and that the normal safeguard against unconstitutional proposals should be waived. At this point, Pisander, by prearrangement, proposed that a council of 400, appointed by a combination of nomination and co-optation, should have full powers for the duration of the war with authority to convene the Five Thousand for consultation whenever they thought fit. There was no opposition, but, since delay might be dangerous, the Four Hundred entered the council house before the day appointed, with followers prepared to use force, and dismissed the democratic Five Hundred after giving them their salary for the remainder of the year.

The seizure of power was cleverly manipulated by Antiphon, an intellectual who had kept out of the public eye in politics but had helped oligarchs in the courts and in the pursuit of office. The revolution, however, had inherent weaknesses. The voting power behind it was provided by moderates who had no wish to confine real power to a small minority; the government of the Four Hundred was created by and for extreme oligarchs who would have wished to overthrow the democracy even if the treasury was full. They had no intention of sharing power with the Five Thousand. But the Four Hundred could only remain in power if they had the sympathy of the fleet at Samos, on which Athens depended for the protection of its corn ships and the collection of tribute.

They looked to the enemy for support and planned to admit a Spartan fleet into the Piraeus, but this proved the signal for a counter-revolution led by Theramenes, who was to become the recognized leader of the moderates. The Spartan fleet sailed on to Euboea, and the small Athenian squadron guarding the straits between the mainland and the island was overwhelmed; Euboea, which had been in touch with the Spartans, now openly revolted. This was a catastrophic disaster, for a significant part of Athenian food supplies came from the island; it meant the end of the Four Hundred, whose government was dissolved by a special meeting of the Assembly. In

Revolt of the Euboeans

further meetings a moderate constitution was built up, which Thucydides considered the best form of government he had known, although it lasted less than a year.

Meanwhile, the fleet from Samos had won a surprising victory at Cynossema, in the Hellespont. This success was largely due to Alcibiades, who had been recalled by the fleet. After dividing forces over the winter, the united Athenian fleet sailed into the Hellespont and surprised the Spartan fleet outside Cyzicus. The victory was complete, Sparta was swept from the seas, and the Athenians proceeded to recover the cities of the Hellespont and Propontis, over which they had lost control. To raise money quickly a station was established at Chrysopolis near the mouth of the Euxine, which exacted a toll of 10 percent on ships entering and leaving the Euxine. A further consequence was a restoration at Athens of the full democracy in the summer of 410.

By 407 Alcibiades felt sufficiently confident to return to Athens, where his reinstatement had been formally decreed. His first conspicuous gesture was to lead by land the procession to the celebration of the sacred mysteries at Eleusis, which in previous years had gone by sea in fear of the Spartan force at Decelea. He was now given supreme command with full authority to carry on the war against Sparta. Less than a year later a subordinate whom he had left in command of the fleet at Notium, with instructions not to give battle, was drawn into an engagement in which 15 ships were lost. His enemies at home seized the opportunity to stir up feeling against him, and the Assembly, which was becoming increasingly unstable as nerves became more strained, elected a new board of generals. Alcibiades retired to a castle in the Chersonese and from there watched the ruin of Athens.

Lysander and the victory of Sparta. The Battle of Notium (406 BC) had been won by Lysander, the ablest Spartan commander of the war. Intelligent, incisive, and ruthless, he succeeded, where his predecessors had conspicuously failed, in assuring adequate financial support from Persia. He won the confidence of Cyrus, the Persian king's younger brother, who was sent down to supersede the two western satraps, and with his generous help was able to restore the strength and spirit of the Spartan fleet. The Spartan naval command lasted only a year, however, and Lysander's successor was a more typical Spartan. Resenting the humiliation of dependence on Persia, he broke off relations with Cyrus. In a major sea battle off the Arginusae islands, with some 200 ships on each side, he lost his life, and his fleet was crushingly defeated. But 12 Athenian triremes went down with most of their men, and it was thought at Athens that more should have been done to save them. A stormy sea may have been the decisive factor, but scapegoats were needed, and Theramenes and Thrasybulus, who commanded triremes in the battle and had been sent to save the men, helped to steer the blame onto the generals. The Assembly, in a fit of hysteria, insisted that instead of having the individual trials that the law required, they should all be tried together. All six who were present were condemned to death.

The mishandling of this affair aroused bitter feelings at Athens and undermined the confidence of the fleet at Samos; the new generals elected for the next year commanded little respect. The Spartans had meanwhile sent Lysander back to the fleet, nominally as a subordinate but actually to command. He moved up to Abydos in the Hellespont to threaten Athens' lifeline from the Euxine; the Athenians had to follow. They encamped near the mouth of the Goat River opposite Abydos, but after failing to bring the Spartans to battle they grew careless, and Lysander was able to make a surprise attack when most of the crews were dispersed on land. All of the Athenian ships but nine were lost. Sparta now closed the route of the corn ships and the fall of Athens was inevitable. Of the Athenian allies only Samos remained loyal and refused to surrender. A generous decree was passed by the Athenian Assembly offering Athenian citizenship to all Samians, but both cities were doomed. When Athens was near starvation Theramenes was sent to negotiate with Sparta. The terms he brought back were humiliating, but Sparta had resisted the demand of Thebes and Corinth that Athens should be destroyed. The long walls were to be pulled down; all triremes except 12 were to be surrendered; Athens was to follow the same foreign policy as Sparta; and a commission of 30 was to be appointed, of whom ten were to be nominated by Lysander. This commission was to work out the details of a more oligarchic form of government that would be acceptable to Sparta.

Athens besieged: negotiations for peace

The oligarchs at Athens now had a second opportunity, but once again there was a divergence of aim between extremists and moderates, and the extremists, led by Critias, dictated events. The lesson they thought they had learned from 411 was that they must be more ruthless with the opposition, and they extended their murders from political opponents to rich citizens whose money they needed. Realizing their insecurity, they appealed to Sparta to send a garrison, but this increased their unpopularity. Meanwhile, some democrats had found refuge in Boeotia, where the leading politicians were now hostile to Sparta, and a small force under Thrasybulus occupied the border fort of Phyle as a rallying point and from there made a surprise attack on the Piraeus, which as a trading centre was firmly democratic. The population of the Piraeus welcomed them, and they successfully resisted an attack from the city; but what seemed to be the beginning of a civil war was ended by the mediation of the Spartan king Pausanias, whose primary concern was to prevent Lysander from taking control. In the settlement that he encouraged, the leading oligarchs were allowed to withdraw to Eleusis, and the Assembly resolved not to be vindictive but to bury the past. Their bitter experience under the Thirty had ensured that there would be no internal challenge again to democracy for a long time; but the Athenians had to resign themselves to the loss of their empire and to rely once again on their own resources.

THE CULTURAL LIFE OF ATHENS DURING THE WAR

The continuing tensions of the Peloponnesian War hastened changes in the intellectual climate of Athens, the beginnings of which could be discerned in the 430s. This was the generation of the Sophists, who disturbed long-standing traditions and challenged their contemporaries to extend the rationalism that already had been applied to the physical world to man and the state. The Sophists were primarily teachers who taught for pay. They professed to teach the art of politics, and the study of rhetoric was one of their main tools. The development of democracy had increased the importance of public speaking in the Assembly and in the law courts and encouraged the study of rhetoric, which included the right use of words, the emotional rhythm of a speech, and the presentation of arguments. The Sophists knew, as Aristophanes stated in a clever parody in his *Clouds,* how to make the wrong seem right and the right, wrong. Some of the Sophists were little more than fluent salesmen, but others encouraged serious thinking. By raising such basic questions as the difference between what derives from nature and what is man-made convention they questioned traditional morality and undermined faith in established religion, but they paved the way for the constructive philosophers of the 4th century.

Influence of Socrates

The general influences that produced the Sophists also produced Socrates, who was to have more influence on succeeding generations than any of his Greek contemporaries. Unlike the Sophists, who professed to equip their pupils for the practical problems of politics, Socrates, who was himself a poor man, did not charge fees and was concerned to make men work out for themselves true values and to consider ends before means; his method was to move toward the truth by rigorous cross-examination. Though despising current political practice, he regarded state service as a citizen's duty and himself served in the Boule; but, true to his character, when the Assembly, against existing law, insisted on trying six generals together after the Battle of Arginusae, he refused to put the proposal forward. He attracted some of the ablest young Athenians of the day, including Critias,

Alcibiades, and his cousin Charmides. The cruelties of Critias when he directed the oppressive policies of the Thirty and the selfish ambitions of Alcibiades must have been a bitter disappointment to him—their association with him was not forgotten when they were dead and he was brought to trial.

Thucydides, the historian, though very different from Socrates in character and interests, reflects with him the intellectual boldness of this generation. His passion for antithesis shows his keen interest in the rhetoric that the Sophists were teaching, but his mind was tougher and his thinking more profound than that of the Sophists. His *History of the Peloponnesian War* is a penetrating analysis of human nature and political motivation. He was particularly fascinated by the study of power, and from the outset in his summary of early history he emphasizes that it is inevitable that the strong should control the weak; and this assumption pervades his attitude to the Athenian Empire. In interstate relations expediency alone governs policies. He discarded the gods from his history, and for him oracles were only for the superstitious. Though less than a full generation separates him from Herodotus, he thus belongs to a different world.

Thucydides attached considerable importance to accuracy in observation and recording. In this he shared the mental attitude of Hippocrates and the medical writers who followed him. They too had removed the religious framework from their calling and looked to physical causes for physical symptoms. Epilepsy was not a "sacred disease" but a maladjustment of the brain. They built their medicine on a detailed study of cases.

Euripidean tragedy

Euripides, the third of the great Athenian tragedians, was a contemporary of Thucydides and members of the new school of medicine, and he had much in common with them. Like them, he could not be satisfied with traditional religion, but whereas Thucydides quietly ignored the gods, Euripides argued with them; the considered piety of Sophocles was replaced by a restless agnosticism. Euripides was profoundly interested in the roots of human behaviour, and in such characters as Medea and Phaedra he provided psychological studies of considerable power. But Aristotle was not being merely old-fashioned when he complained that tragedy lost something when heroic characters were modernized. Euripides also modified the form of tragedy. His plays tended to be less organic, and the chorus, whose importance was already declining, sometimes served simply as a musical interlude. The same loosening of structure can be seen in his use of the dithyramb, which adopted a freer form and developed the lyric solo, thus giving more play to the emotions.

Similar tendencies toward realism and individualism can be seen in contemporary sculpture, which tended to react against the disciplined restraint of the full Classical style and became increasingly concerned with the decorative treatment of drapery and a wider range of subjects. Of architecture too little remains to judge, but the emphasis on exquisite decoration in the Erechtheum is significant; it would have been out of place in Periclean temples. It is also no coincidence that the most famous painters of the late 5th century, Parrhasius and Zeuxis, carried realism to extremes.

Rationalism, realism, and individualism were the keynotes of this generation, but the attacks on the free-thinkers Anaxagoras, Protagoras, Diagoras, and Socrates are a reminder that conservative religious forces were still strong. Aristophanes made great fun, not always good-humoured, of the academic cleverness of the Sophists in his *Clouds* and *Wasps* and looked back wistfully on the simple instinctive virtues of the men of Marathon, but he knew in his heart that the men of Marathon would have been dull company and he delighted in his own cleverness, which was a match for any Sophist; he would have liked to have the best of both worlds. The new attitudes weakened the close bonds of the city-state, but they were to have a fertilizing influence far beyond the city-state. In Abdera, meanwhile, which had been the home of Protagoras (the greatest of the early Sophists), Leucippus and Democritus laid the foundations for an atomic theory that owed more to the Ionian physicists of the 6th century than to the Sophists. It is astounding that while Greece was torn by the most destructive war in its history, it should have produced such a wealth of creative achievement. (Ru.M.)

IV. The Greek world from 404 to 323 BC

THE SPARTAN HEGEMONY AND DECLINE

Spartan policy toward the Greek states. After 27 years the Peloponnesian War had wound to a close. Sparta had overcome Athens' maritime empire and had destroyed the Delian League. The decisive battle had been fought at Aegospotami, on the European side of the Hellespont, and the defeated Athenians saw their naval and military power melt away. Blockaded and starving within their walls, they sent the wily negotiator Theramenes to Sparta to sue for peace. Peace had been rejected several times during the war by each side, and the so-called Peace of Nicias (421) had barely lasted a few deceptive years. But finally, in the spring of 404, peace was signed by the warring states of Greece at a moment when the vast Persian Empire began to be troubled by the death of Darius II, the man who had finally tipped the balance of the war in favour of Sparta. In 404 the Greek world, divided as never before, despite the peace, entered a new stage of its history.

The peace of 404

Would Sparta, victorious but weakened, succeed where Athens had failed? Sparta was a town without walls whose defense lay in the strength, moral and physical, of its soldiers. Its salient characteristics were toughness, tenacity, and insularity. The city was ruled by a narrow-minded oligarchy that totally lacked imagination. But the Athenians, with all their boast of intelligence and creative energy, had shown themselves incapable of pursuing a long-term policy. Fortunately for the Athenians, they had an oligarchic party traditionally devoted to a Spartan alliance, while Sparta itself was divided into two factions: that of Lysander, victor of Aegospotami, the implacable war leader, obstinately hostile to Athens, and that of Pausanias, the king, perhaps jealous of his rival's prestige but also wise or generous enough to realize that the total destruction of Athens would create a dangerous imbalance of power in Greece.

Sparta's allies, especially Corinth and Thebes, wanted Athens annihilated once and for all. The Spartans would not go so far, but their terms were nevertheless severe. Athens kept Attica and Salamis but had to surrender what was left of its fleet and demolish the fortifications of the Piraeus, the city's port. Further, the city was to raze the long walls that defended it, recall the exiles, abandon all foreign possessions, and conclude an offensive and defensive alliance with Sparta. Once the head of a maritime empire, Athens was henceforth merely a member of the Peloponnesian League under the leadership of Sparta.

As soon as the peace was signed, Lysander made a triumphal entry into the Piraeus. He ordered the immediate demolition of the walls and called upon the pro-Spartan party to take over the government of Athens. In September 404, backed by a vote of the terrorized Assembly, he put in power a group of thirty Athenians, which included the peace negotiator Theramenes and Critias, Socrates' former pupil and first cousin of Plato's mother.

The Thirty and their regime were destined to leave behind unpleasant memories. They reduced the citizen body to 3,000 privileged persons and for the rest behaved as tyrants. Lysander had chosen the right men to complete the dissolution of the city he hated, but Sparta sent him on a new campaign overseas, and the Thirty held power only for eight months. They reigned through terror, and their rule was one long succession of arrests, political trials, and profitable confiscations. Fifteen hundred citizens were put to death, guilty only of political opposition, and pressure was put upon the Persian satrap Pharnabazus to have the exiled Athenian leader Alcibiades murdered.

Complicity in crime makes men stand together—for a time. But, while dissension was growing among the Thirty, while Theramenes was falling out with Critias, civil

war was on the point of breaking out in Attica and being loosed upon Athens. Opposition to the Thirty was led by the exile Thrasybulus, chief of the democratic party at Athens. Surreptitiously helped by Thebes, his little army grew day to day, and in May 403 he won a decisive victory over the Thirty in the Piraeus, Critias perishing in the battle.

Deposition of the Thirty

The surviving tyrants were deposed and took refuge at Eleusis, where two years later they were massacred in an ambush. Lysander reappeared and for a moment was ready to blockade the Piraeus, until Pausanias hurried from Sparta to re-establish order. After defeating Thrasybulus' forces, Pausanias was wise enough to set himself up as arbitrator between the two parties: that of the city, as it was called, the more or less faithful followers of the Thirty, which had Athens as its seat of government; and that of the Piraeus, the democrats united around Thrasybulus. Pausanias managed to bring the two parties together, and in autumn 403, under his auspices, the Athenians voted for a general amnesty, from which only the Thirty and the most heavily compromised of their officials were excluded. The old regime was restored, and in the following year (403–402) the Athenians undertook a general revision of the laws and a reorganization of the citizen body, which had suffered much from the two wars, external and civil. In 401–400 the amnesty was confirmed. Socrates, however, did not benefit from it, and he in his turn drank hemlock in 399.

Athens had thus lost its empire and its leadership of the Greek world. But, if the Greek cities thought that the time had come for them to recover or obtain their freedom, they were soon disabused. Sparta, short both of ideas and of manpower, impoverished by a long war, and haunted by the spectre of a helot revolt, proved incapable of fashioning a new system and merely imposed its own empire in place of that of Athens.

In Thessaly the Spartans put down a civil war; in the Peloponnese they strengthened their own domination. In particular, they invaded and destroyed Elis, leaving that city nothing but its traditional responsibility for the Olympic Games. Sparta, however, was directly threatened by trouble at home. In 397 a plot led to a massacre of citizens. Supported by Lysander, who was used to plots, the new king, Agesilaus II, destined to become the great man of Sparta and friend of Xenophon, drowned the conspiracy in blood, and Sparta was free to complete the task of establishing its own domination over the Greeks. Lysander made them realize that they had merely changed their master.

It was Lysander who, since the peace of 404, had been organizing a Spartan empire through blood and war methods. He brought under Spartan hegemony nearly every Aegean government that had once been controlled by Athens. Athenian cleruchs (colonies placed in conquered territory) were replaced by Spartan garrisons, Athenian *episkopoi* by harsh governors known as "harmosts." The islands, including the sacred island of Delos, were reduced to servitude, and in the cities that had formerly belonged to the Delian League he installed oligarchic governments loyal to Sparta; ten magistrates were invested with supreme power and instructed to exact the same tribute the islands had paid to Athens. In Greece the new system was merely a copy of the old, under a different master. In Persia, however, there lived a king, not a Greek, who might have something to say about Greek affairs.

Relations with Persia. The services that the younger Cyrus had rendered to Lysander from 408 onward had not engendered any gratitude toward the Great King, and when Darius II died, in 404, the victorious Spartans no longer needed either his financial or his military support. The treaties between Sparta and the Persian king, concluded without good faith on either side, had put the Ionian Greeks at the mercy of Persia. Now Sparta, wishing to consolidate its new empire, wanted to rally under its banner all Greeks, including those of Asia. On this point the Spartans risked the hostility of Persia.

Caught between two obligations, Sparta proceeded cautiously, profiting from Persian dynastic quarrels over the succession to the throne. The younger Cyrus had mounted an expedition in Lydia to depose his brother, the new king of Persia, Artaxerxes II. By extravagant promises he had persuaded 10,000 Greek mercenaries to go with him across the deserts, first against the satrap Tissaphernes but ultimately aiming to reach the capital city, Susa, in the heart of the empire. Sparta helped Cyrus in his attempt (401), sending a small fleet and a few hundred hoplites. It was a ridiculous escapade, though it allowed Xenophon to distinguish himself by leading the survivors back to Ionia after two years of hardships. The real end of the enterprise came only eight months after the expedition set out, at the Battle of Cunaxa, where, although the King's army was defeated, Cyrus himself fell, thus depriving the expedition of any point it may have had. In any case, a local wound had no effect on the huge body of the Persian Empire. The Ten Thousand had shown, however, that with determination Greeks could venture far from the sea, cross unknown lands, and challenge the Great King with impunity. The lesson would not be forgotten.

The Ten Thousand

Nevertheless, the Greek cities of Ionia had asked Sparta, in which they saw the champion of their liberties, to defend them against the satrap Tissaphernes. The return of what remained of the Ten Thousand allowed Sparta to economize on its own citizens and to send only a small body of troops into Asia, with an inexperienced general, Thibron, who soon had to be replaced by Dercyllidas. A considerable number of Greek cities were thus freed from Persian control. The King, however, finally tired of these provocations and prepared for full-scale war. In spring 396 Sparta had to send a large army, commanded by Agesilaus. He was a brilliant tactician, and Xenophon, who served under him, invests him with every virtue both as a man and as a general. He created a body of cavalry, organized fleet and infantry, and in a two-year campaign in Ionia went from success to success at the expense of the satraps Tissaphernes and, later, Tithraustes. But Susa was still far away, across the desert, and the empire could not be shaken. Though too big to be easily defended, the empire was also too big to be conquered.

Agesilaus, moreover, was obliged to retrace his steps, furious at heart, and had to abandon any attempt to follow up his victories: ten years after Aegospotami, in 395, Sparta was again threatened in Greece itself and recalled the King to meet the new emergency.

The Corinthian War (395–387). The peace of 404, far from satisfying Thebes, had merely intensified its bitterness against its Spartan ally. Discontented, Thebes naturally sought a rapprochement with Athens, which could now be of assistance in upsetting the unbearable domination of Sparta. While Persian gold once more flowed into Greece to stir up the Greeks against Sparta, the old enemies Thebes and Athens entered into an alliance and launched a campaign in central Greece that cost Sparta the life of Lysander, drove Pausanias into exile (395), and brought into being against Sparta a coalition of Argos, Corinth, Thebes, and Athens, whose interests for the moment coincided.

Alliance of Thebes and Athens

Agesilaus, hastening back from Asia, won a brilliant victory over the forces of the coalition at Coronea in Boeotia in 394. The victory, however, was not followed up, because, at the same time, the Athenian admiral Conon, the defeated commander at Aegospotami who had since entered the King's service, crushed Sparta's fleet at Cnidus, in Ionia. On the strength of his victory, Conon returned in triumph to Athens, where he set about rebuilding the walls in defiance of the peace of 404. Thus, both in Greece and in Asia Minor, Sparta's empire suffered severe blows at the hands of the Greeks, while that of Athens seemed capable of rising from its ashes.

To save its empire, Sparta took the easy way out. Without further hesitation, it changed policy once again and sought the help of the barbarian against the Greeks.

The King's Peace (386). Once again the internal conflicts among the Greek cities made the Great King the arbiter of Greece. There was a rush of embassies to Sardis, on the banks of the Pactolus, capital of the southern Ionian satrapy—embassies from Sparta, on the one

side, and from Athens, Thebes, and Argos, on the other. To stop the Athenians, who dreamed of re-establishing their empire, the Spartan envoys supported the autonomy of the Greek cities but at the same time proposed that the Greek cities of Asia Minor come under the Great King's authority. Thus, in 392 they proclaimed their pro-Persian policy. The following year another congress was held, this time at Sparta, and again the Spartans proposed autonomy for all the Greeks. This proposal was deceptive and was not carried out, since it aimed simply at separating Athens from its new allies. The Corinthian War flared up again, and hostilities began again both in Greece and in Asia. Athens, however, was not taken unawares; under the influence of Iphicrates the city restored its fleet and modernized its army.

While Agesilaus was occupied with a hard struggle against the Argives and Corinthians in Acarnania, Iphicrates went from success to success. Another Athenian, Chabrias, was sent in 390 to Cyprus to support the petty king Evagoras against the Great King. This interference was unwise at a time when money was scarce and the courts were working full-time to make citizens pay their war tax. It presumed upon Athens' strength and at the same time pushed the Great King more toward the side of Sparta, which, in addition, received help from the west, that of the elder Dionysius, tyrant of Syracuse.

Sparta, now confident of success, sent Antalcidas on a second embassy to Sardis, then to Susa (387). The result was the King's Peace (or the Peace of Antalcidas; spring 386). It bore the stamp of Sparta and Persia, which had agreed to divide up the world. Representatives from Athens, Argos, Corinth, Thebes, and, for form's sake, Sparta were summoned to Sardis to hear the terms of the peace that the King in Susa was pleased to grant. The west was to belong to Dionysius of Syracuse; the east, with the Ionian Greeks, betrayed by Sparta, to Artaxerxes; and Greece itself passed once again under Spartan hegemony. Finally, if any city refused to sign, the King would make war on it.

Aftermath of the King's Peace; Sparta's decline. Thus, the power of the Achaemenids was imposed on all the Greek cities, both in Europe and in Asia, and even on Sparta, whose complicity merely concealed its subservience. This proud city could maintain its precarious hegemony over the Greeks only by showing itself pliable enough to deserve the Persian king's support.

But, if Sparta was pliable toward Persia, it showed a new rigidity toward the Greeks. Doubtless the King had laid down that all Greek cities should be "autonomous." But if Sparta could accept this clause, which really meant autonomy for itself and for no one else, the other cities could not accept a system that stopped them banding together against Spartan tyranny.

Spartan lack of leadership

Sparta itself, if only it had been able to escape from its ossified principles and take a clear and balanced view of the realities of world politics, would have realized that its own mistakes, aggravated by its own deficiencies, made the King's Peace unworkable. Sparta was perpetually short of men, of citizens, even of generals. Agesilaus was still on hand, no doubt, wherever his services were needed, but the hidebound system provoked inevitable conflicts between the ephors and the kings. Sparta, the military city *par excellence*, had produced no general capable of modernizing its methods of warfare, as Iphicrates had done at Athens. The obscure figures who directed Sparta's destiny could imagine no way save that of brute force to keep order in Greece. They did not realize that the Athenians were silently working to rebuild their forces. Time itself was working against Sparta, blinded by its deceptive and doomed hegemony.

The Greek cities of Asia Minor had been under Persian rule for a half century—indifferent to liberty and slumbering in commercial prosperity. The King intervened in Egypt to put down disturbances and in Cyprus to reduce Evagoras and thus deprive Athens of its last supporter in the east. Meanwhile, Agesilaus, in Greece, applied the most inflexible principles of Lysander. He laid an iron hand on Corinth, Mantineia, and Megara, and suppressed any movement for independence outside the Peloponnesian League. Conversely, autonomy was granted to the cities of Boeotia, to undermine the supremacy of Thebes.

Sparta did not realize that its successes in fact masked serious defects. Passing through Boeotia on his way north to conduct operations in Chalcidice, the Spartiate Phoebidas, secretly backed by the Spartan government, seized the Cadmea, the citadel of Thebes. This outrage, which caused a sensation in Greece, was followed by a revolution in Thebes, where Sparta took the measures necessary to ensure that no help came from Athens. The presence of Peloponnesian armies in Chalcidice was equally directed against Athens, which had to be prevented from helping the Chalcidian League. Ever since the time of Brasidas, Sparta knew how important it was to Athens to maintain its presence in these Thraceward regions. The Spartan generals sent north at this time met many difficulties, but in the summer of 379 they secured the surrender of Olynthus, a city destined to play a large role in the future history of Athens and of Macedonia.

Sparta had never appeared more powerful, but it was only in appearance. In Xenophon's words, the Spartans "could at this time believe that their complete domination was gloriously and solidly established," but, he adds, "the gods do not forget men who violate both divine and human laws . . .; those who had sworn to leave cities autonomous were about to suffer their first punishment." Excess in fact brings nemesis.

Theban revival

In December 379 Thebes awoke with a start. Two Thebans, Epaminondas and Pelopidas, organized a conspiracy against the Spartan garrison of the Cadmea. The Spartans, taken by surprise, had to surrender. An army promptly came up from Sparta, but it, too, was defeated in front of Thebes. One of its generals decided to imitate Phoebidas' surprise attack by risking an attack on the Piraeus, which he almost captured. Greece was scandalized by this second attempt contrary to international law, and the acquittal of Sphodrias when he was put on trial at Sparta opened the eyes of all those who had blinded themselves to Spartan intentions.

Animated by a common hatred of Sparta, Athens and Thebes again concluded a defensive alliance (378). Agesilaus appeared before Thebes with a powerful army, but his failure merely strengthened the tie between Athens and Thebes that marked the end of the Spartan hegemony. It had taken Sparta a quarter of a century to bring down Athens. The same length of time had now proved sufficient for Aegospotami to be wiped out.

The year 378 marked the failure of Sparta's policy in Persia as well. Although individual Greeks had long advocated a rational crusade against the Persians, Artaxerxes was beginning to doubt the wisdom of supporting Sparta. There was little point in interfering in Greek affairs. The Greeks hated one another and could be relied upon to destroy themselves. Their threat to Persia was negligible.

The Second Athenian League; the restoration of democracy (378–371). The Athenian democracy, destroyed and then restored in 404, had never let the flame of its traditional imperialism die down completely. Helped by the satrap Pharnabazus, the Athenians had profited from Conon's victory at Cnidus (394), which destroyed Sparta's new naval supremacy, by recovering a number of islands, such as Lemnos, Imbros, and Scyros. Three years later, Andocides delivered his speech "On the Peace," in which he developed the theme of an Athens whose strength was based on the Piraeus, the walls, and the fleet, without alienating Sparta, and of prosperity through power. In 389 the theory was put into practice with Thrasybulus' campaigns in the north of the Aegean, which were hampered by the emptiness of the treasury but which aimed to re-establish an Athenian League and thus to bring money into the state's coffers. The King's Peace in 386 had lulled Sparta's anxieties by checking this policy of patient rebuilding. But in 378 the Theban alliance with Athens revived the latter's imperial ambitions. In the intervening period they had never missed a chance of keeping open relations and, where possible, of maintaining alliances with the Aegean islands. The islands, on their side, from 386 onward saw in Athens their own defense

against Persian domination. Athens had signed a pact with Chios in 384; it now formed an alliance with Byzantium, Lesbos, and Rhodes (378).

Constitution of the league

It seemed a suitable moment to find a constitutional formula that would replace these separate alliances and would encourage other new allies to join together into a single organization. Negotiations lasted from autumn of 378 through spring 377. This shows how much care went into them. Finally, the decree of Aristoteles gave the Second Athenian League its constitutional form.

The leaders of Athenian policy were basically well aware of the abuses to which Pericles' principles of imperialism had given rise, although it cannot be shown that they wished to guard against their repetition. Nevertheless, for the sake of form at least and perhaps to reassure the new members of the league, the constitution was based upon theories of federalism that were interesting by their novelty and that showed an impulse toward reform or at least a real intention of it.

The new federal organization respected the terms of the King's Peace as far as Persia was concerned but invited all peoples not under the King's rule to join the league. Their autonomy was guaranteed, putting them rigorously on an equal footing with Athens and giving Sparta no cause to interfere. No city had a foreign garrison or foreign governor. At the Synedrion, or Council, which met at Athens, each member had one vote only. On the financial side the "tribute," of bitter memory, gave place to a "contribution" to the federal treasury. These were the essential features of this first attempt in Greek history to form a representative international system with the cities sending delegates to a permanent assembly. But Athens, of course, kept its own Assembly, alongside the Synedrion, so that there existed two assemblies of equal standing in law, with that of Athens in fact exercising considerable influence. As it was, however, the organization was well-enough planned to last for 40 years, until 338, after Philip of Macedon had defeated the Greek forces at Chaeronea.

Borne up by new hopes, stirred as always by their spirit of initiative, the Athenians turned to domestic reforms affecting the Council, the law courts, the fleet, and above all—thanks to Callistratus of Aphidna—the financial system. Since there was to be no more tribute from the allies, the basis of taxation was revised, and a census of private wealth was taken. The citizens were divided into a hundred *symmories*, each of which was responsible through its own tax collectors for paying to the treasury 1/100 of the tax levied by the state.

The lawmakers having done their job, it was time for the men of action to do theirs. Among the more prominent of them were the generals Iphicrates and Chabrias and a first-class admiral, Timotheus, son of Conon and follower of Isocrates. It was thanks to Athenians of this calibre that the new league got under way. The most extravagant hopes seemed justified, whereas Spartan disquiet grew proportionately. The Spartans had no success in operations against Thebes nor in an attempt to rebuild a fleet to regain the mastery of the Aegean. Chabrias and Timotheus, on the other hand, were winning victories everywhere, and each victory joined new cities to the league, which, young as it was, thrived to the point where it recalled the Delian League a century earlier. Nothing was missing save the Greek cities of Ionia, which the peace of 386 had abandoned to the King.

Sparta felt threatened and beneath this threat succeeded with the help of the King and of the elder Dionysius, tyrant of Syracuse, in concluding a new treaty with Athens (374): Athens recognized Sparta's supremacy in the Peloponnese, which was no great sacrifice, and Sparta, in return, recognized the Athenian League. Then Sparta changed its policy, broke the treaty, and again intervened against Athens in the west. It was merely a brush fire, however, for Timotheus, Callistratus, and Iphicrates, although bickering among themselves, soon brought Sparta to see reason.

Sparta was in full decline and no longer feared. Athens, however, had a new enemy on its hands and another in view on the horizon. In Thessaly, Jason of Pherae, thinker and man of action alike, succeeded in the difficult task of uniting the country and thus making it powerful. A still graver danger threatened in Boeotia, where at Thebes, slowly but surely, Epaminondas and Pelopidas had reorganized the army and indeed reorganized the whole country around the army, turning the old Boeotian League into a powerful and well-organized federal state. Wisdom suggested that peace in Greece should be set on a more solid basis.

Rise of Thessaly and Thebes

Sparta wanted peace, while Athens, prey to new financial troubles and worried by the growing disharmony among its best generals, was also interested. Athens, moreover, could count on the support of a league now 75 strong, though this was primarily moral support, since the members of the league did not have the financial resources to wage a war and were not prepared to sacrifice their own money once the danger from Sparta was gone.

It was thus the moment for peace. In 371 there met at Sparta a congress not merely of all the Greek states but one on a truly worldwide scale, since in addition to Dionysius of Syracuse the barbarians were also represented, notably Amyntas of Macedonia and Artaxerxes of Persia. Agreement was reached, and peace seemed assured for many years to come. But, at the last moment, one of Epaminondas' demands caused the Boeotians to be excluded from the treaty, to their great pride at this distinction. On the one side stood the world and on the other Thebes, not caring that it stood alone, because with its outstanding generals and its present strength it felt itself in a position to take over from Sparta and Athens the hegemonies they had long exercised.

Theban expansion and containment. With the stubborn patience of the peasant used to the inevitable cycle of the seasons, the Thebans had been waiting for their moment to come since 404. They had experienced the bitterness of the realization that in helping Sparta to crush Athens they had helped the most ungrateful of allies, who had then refused to share the harvest they had reaped. The King's Peace had shown them, moreover, that Sparta was capable of any treachery to consolidate its own supremacy in Greece. The peace had forced them to dissolve the Boeotian League; the seizure of the Cadmea by Phoebidas was the last straw, proving, as if further proof were needed, how little respect Sparta had for its staunchest allies. Thebes was ready for revenge as soon as the hour should strike.

Thebes could stay aloof of the peace of 371 without danger. In merely eight years Pelopidas and Epaminondas had made Thebes the most powerful city of Greece: working together, they had reorganized the army, had created the famous Sacred Band composed of 150 pairs of young men from the leading families, and had given an unusual flexibility to military tactics by inventing the charge in oblique order, by echelons, thus permitting the army to pierce the opposing line like a trireme with its ram. They also re-established the Boeotian League on a new basis and in defiance of the King's Peace.

At the beginning of July 371 the Spartan king Cleombrotus, relying on the reputation of his hoplites, unwisely invaded Boeotian territory. He supposed that with his army of 10,000 men he would have no difficulty in forcing Thebes to dissolve the league, which was intolerable to Sparta and which made a mock of treaties. But surprise carried the day. At Leuctra, west of Thebes, Epaminondas inflicted on the invading forces a blow from which Sparta never recovered. Leuctra was the first great defeat of the Spartan infantry.

Battle of Leuctra

All Greece was stupefied and flocked to join the victor. The Boeotian League was strengthened, the Athenian Confederation enlarged, the Peloponnesian League dissolved. The Spartan harmosts who still remained were driven out or killed. Soon Sparta felt itself threatened in the very heart of the Peloponnese, as the vice slowly tightened. The Argives rebelled, Elis recovered the territories Sparta had stolen from it, and Mantineia raised its head and welcomed the advances that were made by its old enemy Tegea. At Thebes's instigation a new league of Greek cities, the Arcadian League, was planned and indeed realized. A new capital was established, Mega-

lopolis, at the foot of Mt. Lycaeus, and a new federal constitution was introduced, followed by a police force. The first act of the new league was to call upon Epaminondas for help against Sparta.

Epaminondas came down into the Peloponnese and carried fire and slaughter to the very gates of Sparta. As Xenophon says, "The women of the city, who had never seen an enemy in arms, found the smoke of the fires lit by the enemy unbearable." Two Peloponnesian campaigns (a third was to follow) sufficed for Epaminondas to free Messenia. In 369 he again founded a capital, Messene, a new town with magnificent ramparts that made Sparta regret its pride in having no other defense than, as has been noted, the stalwart breasts and shields of its hoplites.

By climbing at the first blow into first place, Thebes upset the balance of Greece, which was always precarious. Its only difficulties were in the north, in Thessaly and Macedonia. Thessaly had revolted after the assassination of the brilliant Jason of Pherae, the ally of Boeotia, and Thebes intervened against his successor, who was allied to Athens. In Macedonia, Iphicrates seemed likely to establish Athenian supremacy. Thebes skillfully manoeuvred to secure an alliance with Macedonia, and the alliance was guaranteed by the despatch to Thebes of a hostage destined to a great future, the young prince Philip of Macedon, the future Philip II.

Everywhere else Thebes's successes were instantaneous and so widespread that they had two serious repercussions, in Asia as in Greece. Faced with the menace of Thebes, Greek envoys were sent to Susa in 367 to beg for the help of the King of Persia. Artaxerxes chose the stronger party, and by a rescript issued from Susa he opted for Thebes, against Athens and above all against Sparta, which was terrified of losing the advantages of the King's Peace. Athens, for its part, was forced to choose between Sparta and Thebes. Two years earlier, Iphicrates had helped Sparta, and Athens had granted the Spartans an alliance. In 367 the Athenians decided to stand by it, and backed it up by an understanding with the elder Dionysius of Syracuse, to assure its own security in the west.

General warfare in Greece

Despite these treaties and despite the King's intervention, the balance of power remained uncertain, and the Greeks feared a general conflagration. In 367 Thebes tried to summon a peace congress but failed; for Thebes itself would have been the arbitrator of peace. The enmity of the Greeks rekindled the war by sea and by land. By sea Athens sent a fleet to Asia under the command of Timotheus to put pressure on Persia, to obtain some alleviation of the rescript of Susa, and to support one of the satraps against the King. Epaminondas, on the other hand, built a fleet to challenge Athens' naval power and dared to launch a campaign right up to the Bosporus. Theban daring knew no bounds.

By land, war spread everywhere. The Thessalians were again restless, and Thebes had once again to intervene. The Theban victory at Cynoscephalae in 364 cost Pelopidas his life but secured peace in the north. In the south, however, the situation was becoming serious as the result of a local conflict between Elis and the Arcadians, which quickly assumed major proportions throughout the Greek world, since the sanctuary of Olympia lay in the territory of Elis. Every city took sides, and the Arcadian League itself split. This was playing Thebes's game.

In the spring of 362 Epaminondas decided on a fourth campaign in the Peloponnese, and on July 4 two Greek armies faced each other at Mantineia, north of Sparta. On the one side were contingents from Sparta, Athens, Elis, and the northern Arcadians, a total of 20,000 men. Epaminondas faced them with an equal number of Thebans, southern Arcadians, Messenians, and Argives. By skillful tactics the Theban general came within an ace of a great victory, but his death at the height of the battle left the result indecisive.

Only exhaustion stopped the war. Sparta was at the end of its tether, Athens had lost confidence in everything except the traditional supremacy of its triremes, and Thebes, with the deaths of Pelopidas and Epaminondas, had lost all chance of keeping its position as the leading state of Greece. The Boeotians could do no more than cast a regretful glance on their brilliant past as they went back to their fields. Untroubled peace confirmed a status quo of exhaustion among the Greek cities.

Peace and the balance of power in Greece (362–355). Plutarch relates that the last advice of his compatriot Epaminondas to the Thebans as he lay dying on the battlefield of Mantineia was to make peace. Peace was made but, as noted, for the simple reason that the Greeks had no strength left to make war and not because they had decided to abandon their quarrels and renounce war for good. Sparta, like Thebes in 371, kept aloof from the treaty of 362, because in its case the recurrent danger of helot revolt did not allow it to recognize the independence of Messenia. Nevertheless, while dreaming of its glorious past, Sparta did actually keep the peace.

Like Sparta and the Peloponnesian cities, Thebes turned in upon itself. Far from the battlefield, the soldier-peasant of the Boeotian League once more observed the succession of work and days. But Epaminondas and Pelopidas had left an example of how to combine force with flexibility, and this example was not lost on the young Greek–barbarian prince, Philip of Macedon, who had come to the great Thebans as a hostage and remained as their disciple and friend.

Until this young prince and, later, his son and successor Alexander had shown them the way, the Greeks in the first half of the 4th century BC conceived of no pattern of international relations except groupings of cities around one of their number that was for the moment powerful. The Athenian hegemony had ended in 404, the Spartan in 378, the Theban in 362. Moreover, none of these cities had been able to keep its pre-eminence for any considerable period except by an alliance with the next-strongest. The balance of power subsisting after the Battle of Mantineia rested solely on an equal degree of exhaustion all round. Moreover, Greece had, as it happened, nothing to fear for the moment from Persia, which was disturbed by the revolt of the western provinces of its overgrown empire.

Collapse of the Athenian League

Athens, however, no doubt because its league extending overseas gave it a fleet, seemed for the moment, at least in theory, the least feeble of the Greek cities. The empire was vital to Athens' existence, but its extension created problems, and before long the Athenian League caused Athens grave worry.

The chief anxieties came from the north, from the lands far beyond Thebes, lands that always played a role in Athenian history. In Thessaly, Alexander, the successor of Jason of Pherae, was beginning to challenge Athens even by sea; but the aristocratic Thessalian League was scarcely to be feared as long as the ancient family of the Aleuads counterbalanced the ambitions of the tyrants of Pherae. Moreover, Athens' fleet was still more powerful than Alexander's.

Nevertheless, this fleet had need of bases around the Aegean and of free access eastward to bring the grain of the Black Sea regions to the Piraeus. Athens, however, could not succeed in regaining control of Amphipolis, now a member of another league, that of Chalcidice, under the protection of the kings of Macedonia. Another enemy of Athens was Cotys, King of Thrace, who was waging war against them in the Hellespont. Only his assassination, in 359, delivered them from the annoyance of this petty barbarian chieftain. In the direction of Magna Graecia, there were also storm clouds on the horizon. Corcyra, torn apart by its eternal factional quarrels, had seen the oligarchs get back into power and in 361 had left the Athenian League.

The Athenians in their nervousness were all too ready to turn to the old remedy of blaming the generals for the deficiencies of popular policy. The black days of the trial of the victorious generals after Arginusae seemed to have come back. The best generals were accused, arrested, and sentenced to fines, exile, or death.

Plots against the national security were often facilitated by Thebans working under cover and helped by the existence at Athens of a pro-Theban party. In 357 Thebes

stirred up trouble in Euboea, the island that was Attica's natural shield and essential to the Athenian supply route. The revolt was at once suppressed, but it showed that things were sadly amiss in the league. Faced with the problem of tightening or relaxing the ties that united the allies, Athens tightened them, and they broke, resulting in the Social War, which lasted two years until 355.

In Autumn 357, Chios, knowing Athens' need for money, calmly refused to pay its contribution to the league. Urged on by the ruler of Caria, Mausolus (whose tomb was later among the Seven Wonders of the World), Chios allied itself with Rhodes to the south and Byzantium to the north. So disquieting was this threefold defection that Athens sent its best generals into the Aegean. At the Battle of Embata, near Chios, the fleet failed to carry the day, which led to a trial at Athens, wherein Iphicrates was acquitted but Timotheus condemned to exile, whereupon he died. The third general, Chares, stayed in Asia to stir up dissension among the satraps and trouble the new king of Persia, who was proving difficult. But the young Artaxerxes III Ochus feared nothing; he sent Athens an ultimatum: either recall Chares or face war.

Athens, no longer in a position to choose, gave in to the demand. Thus ended the last struggle between Greeks who were supposed to be allies before they were brought into line by Macedonia. Once more, it took the Great King's intervention to bring the Social War to an end. Athens was ruined, suffering hunger and thirst. It gave up the struggle with Mausolus, recognized the independence of Byzantium, Chios, Rhodes, and of the neighbouring island of Cos, in the Aegean; of Corcyra, in the Ionian Sea; and shortly afterward of Mytilene, on the coast of Asia. All Athens kept in its possession were some tiny Cyclades, a few harbours in the north, and the right to sail freely in the Aegean. Athens had lost another empire, 50 years after the first.

The end of Athenian power

Athens had lost not only its empire but its illusions and ambitions as well. The city lived from day to day, forced to restore its finances, rebuild its economy, replace its triremes by cargo vessels. Eubulus was probably the man it needed, in 355, to recover its balance and its good sense. He was an economist and financier, scrupulously honest, a man of peace. In their weariness the people accepted him as administrator in every area of government. He struggled against fraud, waste, peculation. He balanced the two treasuries, the one reserved for the army, the other for public entertainments, somewhat to the benefit of the latter, the *theōrikon*, which helped him to maintain his popularity and thus stay in power. The improvement in the finances permitted him to undertake an extensive and useful program of public works. Athens was, however, finished as a military power.

This, however, exposed the city to danger, and a new orator, Demosthenes, saw this and began to be disturbed. For, whereas leagues and confederations had everywhere failed, the Greek world saw the rise on all sides of princes, dynasts, tyrants, and kings, both great and small, intelligent and bold, such as the elder Dionysius in Sicily, Archytas of Tarentum, Jason and Alexander in Thessaly, Evagoras in Cyprus, Cotys in Thrace, and Mausolus in Caria, not to mention Artaxerxes III in Persia. Perhaps their strength was not firmly based, but they had dared raise their heads against Athens and had on occasion shaken it.

And now appeared on the scene Philip II, he who had meditated on the example of Pelopidas and Epaminondas, overcoming dynastic problems and seating himself firmly on the throne of Macedonia, just at the moment when Eubulus' policies closed the eyes of the Athenians to the danger he presented. The year 355, like 404, opened a new era in history. It marked the end of the Athenian Empire, along with the end of the Social War. It closed an era that had seen all dreams of Greek unity brought to nought. And with the new age of Macedonia it opened new horizons.

THE RISE OF MACEDONIA

Early Macedonia. United or otherwise, the Greek cities were a mere shadow, alongside which a new state had been gradually taking shape since the beginning of the 4th century—Macedonia, a backward country of hunters, drinkers, fighters, and peasants, whom the Greeks regarded as barbarians. The language of the country was basically Greek but so mixed with Illyrian and Thraco-Phrygian that it was incomprehensible to Athenians. Because of their violence and appeal to madness, Dionysiac rites were much celebrated. The form of government was that of a hereditary monarchy under the family of the Argeads, who enjoyed the dubious support of a great landowning aristocracy. With each generation, the kings of Macedonia tried to introduce more and more Greek civilization into their wild land.

During the Peloponnesian War, Athens had made great efforts to secure the alliance of King Perdiccas II, son of Alexander I. Macedonia could be a valuable ally. The region was rich in gold and shipbuilding timber and also lay upon the chief route for the transport of grain to several Greek cities, including Athens. The Athenians, however, might have done better to have Perdiccas as their enemy. He proved an inconstant friend and changed his coat several times before his death in 413. His son Archelaus proved, on the contrary, a great ruler, a Philhellene, and a friend of literature and the arts. He moved his capital to Pella and made it an intellectual centre to which he attracted Greek poets and musicians, such as the great tragedian Euripides, who conceived his tragedy, the *Bacchae*, at the court of this enlightened despot. Archelaus reorganized the government, centralized power, and fashioned his troops into a strong regular army. Under his reign, Macedonia ceased to be convulsed by its endemic political crises, and the historian Thucydides—a severe critic—praised him as a great builder and administrator.

Achievements of Archelaus

But, when Archelaus was assassinated in 399 by a favourite, Macedonia was plunged into 40 years of palace revolutions. Apart from its internal problems, Macedonia was also threatened from all sides: by the Paeonians to the north, the Illyrians to the west, and the Thracians to the east, while the Greek settlers in Chalcidice, to the southeast, could scarcely be considered allies; furthermore, the country lacked an outlet to the Aegean.

Amyntas III (reigned *c.* 393–370/369) had great difficulty in consolidating his throne and sought help first from Sparta, then from Athens, whose rights to Amphipolis he recognized in 371, one year before his death. His elder son and successor, Alexander II, was killed by his mother Eurydice's lover, Ptolemy, and the pair of them ruled as regents until Ptolemy, in turn, was assassinated by the second son of Amyntas III, the young Perdiccas III, then aged 20. This young king, a Philhellene and lover of philosophy, called on the exiled Athenian Callistratus to reorganize his treasury and followed the example of Archelaus in making Macedonia a strong power, until he was killed in 359 after a reign of six years in a campaign against the Illyrians, who were occupying part of his kingdom.

Problem of the succession

Macedonia was again in danger; but it can be supposed that these trials were tempering the character of the Argeads and forming a dynasty that was to produce Philip and Alexander. The problem of the frontiers was serious, but that of the succession was critical. In 359 several claimants sought the throne, supported by foreign armies. Perdiccas' son Amyntas was too young to be king, but the throne was claimed by his paternal uncles: Archelaus, Arrhidaeus, Menelaus, and Philip. Philip, the youngest, had spent three years as a hostage at Thebes, the friend of Epaminondas and Pelopidas. Philip was appointed regent for his nephew Amyntas and thus represented the legitimate power. Few could have guessed that this young Macedonian prince, aged 23, would, in less than 20 years, shape a Hellenic nation united under his own absolute authority.

The rise of Macedonia under Philip II. Unscrupulous, intelligent, determined, backed by no assembly, Philip succeeded where no purely Greek people had done so. In the past the cities of Greece had merely formed alliances or leagues under temporary hegemonies that masked or failed to mask the subjection of the weak.

Philip, by imposing a new domination on the Greeks, achieved for the first time a new unity whereby all were equally enslaved.

At 23 Philip was already experienced in politics and administration, having governed one of the provinces of Macedonia after his return from Boeotia. It took him only three years to oust his nephew from the throne. When in 356 the princess Olympias gave him his hoped-for heir, Alexander, he exchanged his regency for the title of king. This gave him the green light for his hopes and desires. He could devote himself to his many passions, of which the foremost was the greatness of his country.

He was an exceptional character, who held all the trump cards. Educated, civilized, Hellenized, indefatigable, he was also a *bon vivant* who loved wine and women and who knew how to use his charm on strangers. He had the flexibility of the diplomat, the steadfastness of the soldier, and all the qualities of leadership. Patiently and methodically, he tackled his problems one by one. He began by re-establishing order in his enormous kingdom. (Macedonia was at that time the largest and most populous state in the Greek world.) With power centralized in his own hands, he made Macedonia even larger, at the expense of its neighbours, and Hellenized the lands he conquered. Towns that resisted him were destroyed, and new ones were founded in their stead. He favoured urbanization, built roads, and encouraged agriculture. His peasants made excellent soldiers—trained, disciplined, and full of admiration for their commander in chief.

Philip's primary need was money. He balanced his budget in the simplest and most effective way by conquering Mt. Pangaeum, whose gold mines produced 1,000 talents a year. He then founded the nearby town of Philippi in place of Crenides. He gave his name to the golden staters that came from the mines, for he now began to coin money, and the handsome "philipps" became an instrument of his policy. He understood and practiced the art of buying consciences.

Reorganization of the army

His closest care was reserved for the army, in which area he was assisted by his faithful general Parmenio. Compulsory service was introduced, each region furnishing its quota of men. Three recruiting areas were established, each one producing a unit of light infantry, one of heavy infantry, and one of cavalry. The tactics, based on those of Epaminondas, combined flexibility of manoeuvre with the thrust of light and heavy troops. The keystone was the famous Macedonian phalanx, bristling with the long lance known as a *sarissa*, which presented to the enemy an impregnable wall of iron. Once the opponent was checked and held by the phalanx, the mobile troops had merely to attack in the rear. Siege tactics also progressed. Engineering and artillery now contributed to the speedy capture of the besieged town.

At the head of this superb army, Philip II took part of Epirus and extended Macedonia's southern frontiers at the expense of Thessaly. To guard his western flank against the Illyrians, he had recourse to a diplomatic marriage with Olympias, the daughter of an Illyrian king. Philip also realized that Macedonia needed an outlet to the sea. As regent he had recognized Athens' right to Amphipolis, though with mental reservations. Now, as king and sure of his army, he attacked the town without hesitation. It was vital to Athens and had already seen much Athenian bloodshed. Philip took it, promised the Athenians to give it back in exchange for Pydna, and finished by keeping both Amphipolis and Pydna. Paralyzed by the Social War, the Athenians could do nothing but accept a *fait accompli*. Nor did they even intervene in time to save Olynthus or Potidaea. Olynthus, capital of Chalcidice and of the Chalcidian League, threw itself into Philip's arms, and he bought the Olynthians' loyalty at no cost to himself by making them a present of the territory of Potidaea, which he had had destroyed.

While Philip, almost as soon as he was on the throne, became master of a unified, powerful, and populous Macedonia, the Athenians remained blinded by the pacifist policy of Eubulus. Only the orator Demosthenes, now entering on his political career, realized the danger. He believed that Athens should keep at peace with Persia in order to concentrate all its forces against Macedonia. Only Athens could stop Philip. The Athenians, however, would not face the danger that grew clearer day by day in the north, despite the importance of this region for their grain supply.

The Third Sacred War. Philip bided his time, waiting for a chance to intervene in Greece. He found his pretext in the so-called Third Sacred War, between the Phocians of Delphi and a coalition of Thebans, Thessalians, and Locrians. Ostensibly fought to defend the rights of an outraged god, Apollo of Delphi, the war in fact was fed by an old and deep-seated hatred between Thebes and Phocis. But the religious character of the war threatened to engulf all Greece, instead of uniting the Greeks against a common enemy.

In 356 the Phocians had laid sacrilegious hands on the gold and silver in the treasuries of the Panhellenic sanctuary of Delphi, which lay in the middle of their territory. With this they made war, raising and maintaining an army of 10,000 men, which was for some time the best in Greece. Under energetic commanders this army dared invade Thessaly and Boeotia, with more successes than failures.

This attracted the wolf into the sheepfold. In 354 Philip had taken the town of Methone, at the foot of Mt. Olympus, and in Athens Demosthenes had realized the gravity of the danger from Macedonia. Philip, moving down into Thessaly, lost a first battle against the Phocian army but soon had his revenge, and all Thessaly came under his sway. Thebes, the enemy of Phocis, had naturally taken his side, Athens and Sparta that of Phocis.

Philip and Demosthenes

The war ranged Phocis against Thebes at the front of the stage, with Macedonia versus Athens behind them. It also ranged policies and men against each other; the great duel between Demosthenes and Philip was to last almost 30 years. It was a dramatic duel, if ever there was one, but unequal, since Philip had the support of his army, his diplomacy, his undivided aims and control over his own decisions, whereas Demosthenes was armed only with his eloquence and was surrounded by other opponents, the worst of all among his own compatriots. At Athens an age of generals had given place to an age of orators, some of whom, such as Aeschines, had been bought by Philip, while others, such as Eubulus, supported by Isocrates, did not wish to see the danger and played on the people's apathy. At each step Philip made, Demosthenes tried in vain to shake the Athenian Assembly from its inertia by a speech compounded of violence and reason, but his eloquence was powerless against the strength of the King of Macedonia.

The latter's intentions were clear, at least to those who were willing to see, the day when he crossed Thessaly, which he had annexed, and appeared before Thermopylae (353). This bold stroke produced a reaction in Greece, and in a reminiscence of the glorious days of the Persian Wars Philip found himself faced by the Phocian army, reinforced by 10,000 Greeks from Sparta and above all from Athens. With the way forward barred, Philip saw that the fruit was not yet ripe. He withdrew, patiently awaiting a better opportunity.

Meanwhile, he strengthened his position in the north and east, pushing into the Chersonese and the Hellespontine regions, reaching as far as Byzantium, where he opened negotiations designed to undermine Athenian influence. At the same time, he obliged the King of the Odrysians in Thrace to sign a treaty of alliance. With his hands free on that front, he could turn on a new prey, his supposed allies, the Chalcidians. He in fact needed to get the Greeks of Chalcidice into his power, not only because its promontories offered threefold access to the sea but also because its geographic situation made it an intolerable barrier between Philip's own possessions, Amphipolis, Philippi, and Pangaeum, to the east, and Pydna and Methone, to the west.

Hoping for assistance, the Chalcidians concluded a treaty with Athens. Demosthenes delivered his first "Philippic" (351), followed by the three "Olynthiacs" when Philip revealed his intentions on Olynthus, the most powerful of the Chalcidian cities. To stop Athens from in-

terfering, Philip in machiavellian style formented a revolt in Euboea. Athens in fact sent three expeditions to Olynthus, but it still surrendered (348). Philip razed it to the ground for daring to resist, sold the inhabitants into slavery, destroyed 32 other Chalcidian cities, and incorporated the country into Macedonia. The Athenians saw their access to the north definitely cut off, and there was nothing to stop Macedonia replacing them as a maritime power.

Philip was then clever enough to make people believe that he would not abuse his victory. Like a good player, he sheathed the sword and turned upon Athens a friendly countenance. Many Athenians, following Aeschines, did not wish to undertake the necessary effort to keep independence and preferred to see Philip as a friend and come to terms with him. But all the rest as well, whatever their party or persuasion, equally desired an agreement with Macedonia, even Demosthenes himself, who realized how weak his country was at this time.

Negotiations were therefore opened, and the two governments played out a diplomatic comedy at Athens' expense. Athens sent an embassy to Pella, made up of Philocrates and of the two rivals in eloquence and opponents in policy, Aeschines and Demosthenes. The splendid reception that the King gave them won them over, except perhaps Demosthenes, who, however, lost his wits, either from illness or emotion, and was unable to speak. Philip's charm had done its work on the others. In return, a Macedonian delegation was sent to Athens to come to precise terms. These were debated by the Assembly, which in the confusion voted for the status quo between the two states. This meant recognizing the loss of Amphipolis and Chalcidice, while at the same time the Phocians were excluded from the treaty, which allowed Philip the latitude to continue or halt the Sacred War. But the peace was not yet signed, as the King's oath was still lacking.

Thus, a second embassy, made up of the same men as the first, set off for Pella. Demosthenes had realized that Athens must bring the affair to a swift conclusion, since it was in Philip's interest for it to drag on. He was in the process of completing his conquests in Thrace, and each day his share of the status quo grew larger. He also knew how to spend his money to cause delays. The Athenian ambassadors spent a month and a half running after him. It was only in July 346, a year after Plato's death, that Philip signed the peace known as the Peace of Philocrates. He signed in the name of the Macedonians and their allies, including the Thebans, with Athens alone as the other party. Although he was now Athens' ally, Philip could still complete the conquest of Phocis, thus becoming master of Thermopylae and of the sanctuary of Delphi, from which he expelled the Phocians permanently. His political supremacy was thus strengthened by a moral and religious authority in Greek eyes, since he now controlled the oracle of Apollo and presided over the Pythian Games of 346.

The Peace of Philocrates

Such was the result of the Sacred War. Philip's triumph, which he owed to his diplomacy and his army, ensured his complete sovereignty in northern and central Greece, and at Athens itself he increased the number of his supporters. Isocrates, the teacher of rhetoric, saw in him the man of destiny capable of uniting all the Greeks and leading them in a great crusade against the King of Persia, although the danger from Persia had ceased to exist for Athens, at least compared with that from Macedonia. Demosthenes was not deceived; but he realized that Athens, weakened as it was, had no alternative but peace, unreal though it might be.

Renewal of Athenian resistance. So Athens and Philip made peace. They even became allies. But the causes that had made the two states enemies and would make them enemies again had not been removed. Philip was still eaten up by his ambition to become supreme lord of the whole of Greece. In all Greece he found not one single city to oppose him; and Demosthenes was a man without support, save that of his own intransigent patriotism.

Isolated and obstinate, Demosthenes fought on every front. In the courts he launched a case against Aeschines over the embassy that had negotiated the Peace of Philocrates, accusing him of treason. But the citizen jury, afraid of arousing Philip's anger, acquitted Aeschines. In the Assembly Demosthenes once more denounced the Macedonian peril, courageously delivering the second "Philippic" (344). He was also active on the diplomatic front, to south and north. He sought to draw the cities of the Peloponnese into a union against Macedonia and judged it essential also to erect a living barrier between Philip and Athens. For this he had to effect a great reversal of alliances, forget the grievances against Thebes, forget that Thebes had profited from the Peace of Philocrates as ally (since 354) of Macedonia, and obtain at any cost an alliance with Thebes.

Such a reversal could not be achieved in one day, and bit by bit, while waiting, the meshes of the Macedonian net tightened. Philip negotiated with the King of Persia, stirred up fresh trouble in Euboea, and extended his threatening shadow toward the coast of Ionia and, bypassing Athens, up to the Isthmus of Corinth. Demosthenes, however, stood in the breach, persuading the cities to conclude defensive alliances with Athens. With characteristic flexibility, Philip did not insist but changed his front. Turning toward the Bosporus, he reduced Thrace to a Macedonian province (341). Next, he launched a campaign against the Thracian Chersonese, Athens' last possession in the northeast. He went in fact as far as to lay siege to Byzantium, which, thanks to Demosthenes, had rejoined the Athenian alliance. This intolerable audacity finally shook the Athenians out of their apathy, and they decided to send a fleet into the Hellespont. The Peace of Philocrates was truly at an end. Demosthenes now redoubled his activities: he delivered the last two "Philippics," brought into being a Hellenic league, improved the situation of the war chest, and restored the strength of the Athenian fleet, thanks to a reform of the trierarchy system. Byzantium was saved.

In 339 a fourth sacred war, called the Amphissean War, broke out in Greece as the result of a sacrilege committed by some men of Amphissa against the Delphic god. Apollo had to be avenged. Philip accepted the bargain. Moreover, the command of the army charged with punishing the guilty Amphisseans was conferred upon him. He secretly outflanked Thermopylae and by a surprise gained possession of Elatea, in northern Boeotia. Panic seized the Athenians: Philip was three days' march from the frontier of Attica; he had only to cross Boeotia, and his army would be in front of the walls of Athens.

The Amphissean War

In the general consternation, Demosthenes kept his head. Philip had sent to Thebes envoys loaded with promises. Demosthenes got himself sent there as well and proved to the worried Thebans that Philip's advance must be stopped. His eloquence won the day: Thebes chose Athens. Their common enemy could not tolerate such an alliance, and war broke out openly between Philip and the new allies. Fortune seemed at first to favour the Greeks during the winter campaign; the armies of Thebes and Athens won two minor victories, which had no follow-up. Instead, there ensued a fierce battle in April 338 on the plain of Chaeronea, in Boeotia, where the Macedonian phalanx routed the ill-led allied troops. It was the end of Greek liberty.

Philip's hegemony over Greece. Thebes was occupied by a Macedonian garrison. Athens got off more lightly: by what is known as the Peace of Demades, Philip, no doubt influenced by what he owed to Athenian civilization, paid homage to the conquered city and to the dignity of its resistance by granting easy conditions. He compelled Athens to sign an alliance with him and took the Chersonese; but neither the city nor Attica was occupied, the Athenians kept their fleet, and their ports remained free. Demosthenes' anti-Macedonian policy may be considered to have been justified by the leniency of the peace. If Athens had listened to Aeschines, it would have been humiliated without a fight. With Demosthenes it won the respect of a conqueror who was more Greek than barbarian. Alexander would not forget the lesson in moderation his father had given him.

After his victory Philip did not halt. Master of Athens

and of central Greece, he conquered Euboea and then descended upon the Peloponnese, where he imposed his will without a fight. Greece lay at his feet.

To succeed in his program, Philip attempted to establish a permanent organization of the Greek cities under Macedonian hegemony. He summoned to Corinth, the central city, delegates from all Greece. Apart from Sparta, all accepted the invitation to this extraordinary congress. There, in 337, there came into being a league truly "Panhellenic," since it included, apart from the Spartans, all those who henceforth called themselves officially Hellenes. Philip thus realized the ideal of Isocrates, though with one major reservation, namely that the Hellenes, though united, were united only under a foreign dominion, that of the King of Macedonia, now become their *hēgemōn* and *stratēgos* and wielding executive power. The league was represented by a council, the first example of a supranational institution or league of nations, but was entirely in Philip's hands, beneath the banner of Hellenism.

The states that adhered to the League of Corinth were declared autonomous. They paid no tribute, and their military obligations were reduced, consisting only of an obligation to provide a contingent to the federal army and fleet; it was forbidden to take up arms against Greeks, since all Greeks were henceforth linked in a general peace.

The new institutions were skillfully arranged, and Philip was diplomat enough to cover his iron hand with a velvet glove. He was also realistic enough to realize that a common enemy was needed to strengthen the ties among men so diverse and to free the Asiatic Greeks. In 336 he proposed at Corinth a general crusade against the barbarian. A Macedonian army of 10,000 men set out at once as an advance guard under the orders of Parmenio and Attalus. Penetrating Ionia, it seized Ephesus. The Achaemenid Empire seemed to be nearing its end.

Assassination of Philip

But Philip in his universal victories had counted without fate. At the beginning of the summer of 336, when he was 48, during the magnificent celebration that he had organized for the wedding of his daughter Cleopatra to the king of Epirus, he fell beneath an assassin's dagger. Philip was dead, but Hellenism, on the contrary, had a chance to survive. It was not extinguished in the country of Isocrates and Demosthenes, and it vibrated in the heart of the young Alexander, Philip's son and heir. Alexander was 20 years old. He had been 18 at the battle of Chaeronea and 13 when Philip had appointed Aristotle his tutor. Aristotle's pupil was to Hellenize the east. But, on the other side of Greece, Hellenism still shone, with its defects and its virtues, among the western Greeks.

THE WESTERN GREEKS

Conflict with Carthage. After the Peloponnesian War, the cities of mainland Greece continued jockeying for supremacy and the king of Persia never hesitated to intervene. It took Philip of Macedon to stop the process. The history of Greeks and barbarians in western Greece (*i.e.*, in Magna Graecia, southern Italy, and Sicily) reflected in its record of internecine warfare and barbarian intervention that of their mother cities in Greece itself. To understand the history of the 4th century, one must go back to 480, when the Carthaginians were defeated at Himera in Sicily. At the same time, the Persians were attacking the mainland Greeks. In 413 the Athenian disaster at Syracuse again produced a similar twofold barbarian intervention against the Greeks. While the King of Persia, with his satraps in Ionia, was working against both Athens and Sparta to ensure his own domination by the exhaustion of both rivals, the Carthaginians, who had been temporarily threatened by Alcibiades' plans, now on their side, breathed new life into their own Sicilian ambitions. This was a serious threat, since Sicilian unity had not survived the victory over Athens in 413.

Hermocrates

Hermocrates, the leader of the aristocratic party at Syracuse, had emerged by luck and the help of Sparta as the brilliant architect of victory. Scarcely had he turned his back to go to the Peloponnese—there to continue the struggle against Athens—when the ungrateful Syracusans exiled him and called in the democrat Diocles. On a wider scale, the same conflict also set one city of Sicily against another. Syracuse turned on Catana, Selinus on Segesta. And the Segestans called on Carthage for help against their fellow Greeks.

Carthage did not miss this chance of avenging the insult that the petty tyrant of the petty town of Gela had inflicted on it at Himera 70 years before. In 409 a Carthaginian army under Hannibal, son of Gisco, disembarked in western Sicily. It had no difficulty in beating the Selinians, whose town was promptly sacked. Himera, threatened in turn, was helped by Diocles of Syracuse but fell to superior numbers and was razed. Hermocrates, returning home, recaptured Selinus but died at Syracuse in 407. His supporters, including a young officer named Dionysius, were exiled. The following year the Carthaginians, aiming to end all resistance of the Sicilian Greeks, sent out a new expeditionary force under Hannibal and his grandnephew Himilco. They laid siege to Acragas, where Hannibal died, but Himilco's gold bought the treachery of Sicilian generals both at Syracuse and at Acragas itself, and Himilco took the town in December 406. At this moment, a saviour arose in the person of Dionysius, the young officer who had served his apprenticeship in arms with Hermocrates.

The rise of Syracuse under Dionysius. Seizing his opportunity, Dionysius, known as Dionysius the Elder, with the help of others of Hermocrates' supporters (such as the rich Philistus and Hipparinus, the father of Plato's young friend Dion), began by denouncing the treachery of the Syracusan generals. With nine new colleagues (whom he was soon to get rid of), he was elected general. He recalled the exiles, married one of Hermocrates' daughters, and organized a plebiscite. With the assistance of a group of supporters who shared his conviction that Syracuse needed a firm government based on the army, he surrounded himself with a bodyguard, by means of which in the summer of 405 he seized absolute power.

Struggle against Carthage

To retain power, he needed to remove the Carthaginian menace. Himilco had continued the conquest of Sicily, defeating Gela and Camarina. Dionysius did not rush to their help with any great haste, perhaps to leave open the possibility of an agreement with Carthage. In his absence, however, the Syracusans rebelled and killed his wife. When he returned, he put down the rebellion and succeeded in concluding an advantageous treaty with Himilco. Half of Sicily was abandoned to Carthage, but the independence of the cities in the eastern half was guaranteed and strengthened by the Syracusan tyranny, which Dionysius was to retain for 38 years, until his death, in 367.

Dionysius' first task was to establish his power on a firm basis. He reorganized the army by introducing mercenaries and fortified the royal palace on the island of Ortygia (which almost completely shuts in the Great Harbour) and fortified the Great Harbour itself. He erected defenses for the whole town by surrounding with enormous walls the extensive plateau of Epipolae, where the fortress of Euryalus became recognized as a masterpiece of military engineering. The philosopher Plato was to stay in this palace on several occasions from 388 or 387 onward.

He needed also to ensure the succession, since he proposed to turn his tyranny into a hereditary monarchy. With this in mind he turned bigamist, marrying on the same day Hipparinus' daughter Aristomache and Doris of Locri, who was destined to produce the future heir Dionysius II.

If the elder Dionysius was almost wholly devoid of scruples, nevertheless it should be said that, on the whole, he used his power with moderation, once he felt that it was assured, after a final Syracusan revolt in 403.

As master of Syracuse, his ambitions grew. He wanted to rule all Sicily and make it, in Plato's phrase, "one single city." In this he merely anticipated on a smaller scale Philip's plan to make mainland Greece a single state. To this end he reduced Catana, Naxos, Leontini, and Messana and became, under the title of "archon of Sicily," the head of the citizens of the Sicilian Greek cities and

also the protector of the original Sicilian inhabitants, insofar as the latter were not under Carthaginian rule. In this he anticipated Alexander as well, since he did not hesitate to deport entire communities in order to realize the fusion of peoples and races.

Projects in southern Italy

Since he still had plans for southern Italy, he proposed, without giving up the struggle against Carthage, to place some of the Italian cities under the control of Locri, home of his wife Doris; with the others, he would not deprive them of their liberty but would take them under his protection by bringing them together in a league presided over by Tarentum, under the aegis of his friend Archytas. He therefore allowed the latter, who combined the role of politician with those of Pythagorean philosopher and mathematician of genius, to give Tarentum a mixed constitution that made it the leading city of southern Italy. Then, after concluding pacts with the Messapians, Campanians, and Celts, he founded the towns of Ancona and Adria on the Adriatic. He was anticipating not only the two great kings of Macedonia but also the Romans, since he would doubtless have brought about the unity of Italy if throughout his reign he had not had to cope with several Punic wars, as the Romans were also obliged to do later.

The treaty of 405 had not in fact finally put an end to the danger from the Carthaginians. Dionysius began by calling on Carthage in 398 to evacuate the Greek cities of Sicily, and after a siege he captured Motya, which was defended by Himilco's fleet. Himilco, however, took his revenge the following year by destroying Messana and defeating Dionysius in front of Catana, which enabled him to besiege Syracuse. But Dionysius in 396 regained the initiative, destroyed Himilco's fleet, and allowed him to escape to Carthage, where he committed suicide, unable to bear his defeat. Dionysius then took Catana, rebuilt Messana, and occupied Tauromenium (present-day Taormina), founded by Himilco five years earlier.

A second Punic war (383–376) went less well for him. He defeated the Carthaginians at Cabala, where Mago was killed; but Mago's son, the younger Himilco, got his revenge at Cronium. The elder Dionysius was forced to ask for peace and to allow a third of Sicily to pass once more under barbarian rule. A third Punic war, toward the end of his reign, proved indecisive. The status quo was maintained, and Syracuse and Carthage shared the rule over Sicily.

Relations with mainland Greece

The elder Dionysius did not, however, have to do exclusively with Italy and North Africa. The mainland Greeks, like those of Sicily itself, kept their eyes always fixed on this notable tyrant who dared to intrude upon their affairs. He remained faithful to the Syracusan alliance with Sparta, closely followed Persia's intervention in Greece at the time of the King's Peace (386), and sent a representative to the congress at Sparta (371). Athens tried to seduce him from his Spartan alliance and to get the help of his mercenaries. It crowned one of his tragedies, *The Ransom of Hector*, which he had had presented at Athens during the Lenaean Festival of 367. Although Lysias had spoken harshly of him at the Olympic Games in 388, Isocrates in 369 wrote him an open letter to invite him, as he was later to invite Philip, to head a crusade against Persia. After his death, Xenophon followed with the treatise known as the *Hieron*, ending with an encomium of the enlightened despot. Even Plato made his condemnation of tyranny less harsh on his account, and it was his realization of the impossibility of achieving anything in Athenian politics that made him undertake in 388/387 his first journey to Syracuse, where he hoped to find the seat of the philosopher-king or king-philosopher. There he met the tyrant's brother-in-law, the young and brilliant Dion, aged 21, on whom he was to found so many hopes. His journey ended badly, but on returning to Athens he founded the Academy and continued to exchange letters both with Archytas of Tarentum and with Dionysius the Elder.

This remarkable tyrant may have had excessive literary pretensions and thought himself a greater poet than he was. But his political achievements were considerable. He was a great statesman who made Syracuse the richest and most populous city in the world. His example had some influence on Alexander, since Dionysius accomplished in the west what Alexander was to repeat on a larger scale 40 years later in the east. Like Alexander, Dionysius followed the principle of bringing together Greeks and barbarians.

The western Greeks to the beginning of the 3rd century BC. In Dionysius the Younger, or Dionysius II, the elder Dionysius did not have a worthy successor. The younger man was cultured but had no morality, nor had he any talent, either political or military. He welcomed Plato, who had accepted Dion's invitation to visit Syracuse a second time, still haunted by his ideal of the philosopher-king. But Dion, whose crime was to have tried to keep his nephew the tyrant from a life of debauchery, was exiled, and Plato, once more disappointed by Syracuse, had to leave a court that was wholly given over to intrigue, in order to take up again his teaching at the Academy. Dion followed the courses, while keeping in touch with the leaders of the opposition at Syracuse.

The visits of Plato

Hoping to reconcile Dionysius and Dion, Plato risked a third journey to Syracuse, with the idea of demonstrating to the tyrant the primacy of the soul over the body and of creating with him the republic of his dreams. Once more disappointed, he hurried back to Athens (361/360). Three years later Dion recruited mercenaries and assembled a fleet to obtain a return by force. He received a triumphal welcome at Syracuse, besieged Ortygia, won a naval victory over Dionysius, and after various ups and downs had himself made general with full powers. He thereupon declared that he was applying Plato's principles but in practice seemed to forget somewhat that he was his pupil. He got rid of a dangerous subordinate but fell victim to his Athenian friend Callippus, his host at Athens, and a year after taking power at Syracuse he was assassinated by his own soldiers (June 354).

Once again anarchy reigned in Sicily. Callippus, although an Athenian, made himself tyrant of Syracuse for 13 months. He had to fight against Dion's family and their supporters under Hipparinus, who took the town and regained power until his death, two years later. Hipparinus' brother Nysaeus reigned for five years (until 347), when the younger Dionysius returned and regained the tyranny for two years. In 345 the Syracusan exiles appealed for help to their mother city, Corinth, and secured the despatch of the Corinthian envoy Timoleon, who in 344 forced the younger Dionysius' abdication. The work of the elder Dionysius was destroyed, and Sicily, following a course only too typically Greek, returned to its discords.

Timoleon

Timoleon, however, surprised everyone. This Corinthian was a great man of the type celebrated by Plutarch, perhaps painted better than he was by history, probably enamoured of the ancient virtues; once master of Syracuse, he tried to re-establish peace in the city and to restore Sicilian unity. The initial success of his program reawakened Carthaginian fears, resulting in a new Punic war. Timoleon was lucky enough to win a great victory near Segesta that compelled the Carthaginians to ask for peace (341). He could then give himself entirely to his work for peace and civilization. He freed the cities of Sicily, brought in new blood with 60,000 settlers, distributed land, and established a wise and moderate regime in Syracuse. After seven years, considering that Sicily no longer needed him, he signed his own abdication, respected by all (337).

Timoleon had restored Sicilian unity, but his influence had not spread to southern Italy, where trouble continued. Despite this, Hellenism made steady progress, gradually winning over the barbarians by spreading among them moral and intellectual ideas. Hellenism had also reached Africa, where Cyrene shone by its prosperity, its schools, and its trade, as well as Gaul, where the Provençal centres of Saint-Blaise, Olbia, Antipolis, and Agde maintained a flourishing trade with Greece and Sicily.

Before losing its independence, Greek Sicily had one last fling. While the Greco-Macedonian monarchies were taking shape in the east after Alexander's death, the freebooter Agathocles temporarily halted the decline of the

island, which was doomed, with southern Italy, to annexation by the Romans. In 318/317 he seized power in Syracuse, had himself given the title of king, reopened with some success the Punic War, and was summoned by Tarentum to restore order in southern Italy. He was the man to save the Greek west and to establish a Greek "Kingdom of the Two Sicilies."

But Agathocles left it to the Romans to complete the job and to rekindle in the new capital of the world the fire of Hellenism that had burned brightly but fitfully at Syracuse.

GREEK CULTURE AND SOCIETY IN THE 4TH CENTURY BC

The changing style of life of the polis. Philip's success in uniting the Greek cities under Macedonian domination was the result, above all, of subtle diplomacy linked to force of arms. What he had laid low, however, was merely a giant already shaken by the struggles that had scarcely stopped tearing apart the Greek peoples, separately or in their leagues, from the Persian Wars to Philip's own time.

Since the victories never lasted, nor did the peace, the conquerors and the conquered suffered equally from the ills that war brought about: the conscription of farmers into the army, the devastation of the countryside, the flight from the land. The peasant and small landowner tended to disappear. Men returning from war were unwilling to take up the plow and instead hired themselves out as soldiers; after living dangerously but well in times of pillage, after seeing new, wider horizons, a man lost the taste for a narrow existence on land that demanded daily toil or felt himself stifled by being shut in within city walls. Mercenary soldiering was an inevitable evil if it was the means whereby alone men could live, but it contributed to the death of both country and city.

Decline of the city

The city in itself, moreover, was leading a precarious existence. Perpetual warfare slowly but surely brought economic stagnation, and the maritime leagues no longer brought in the easy tribute of the previous century. At Athens, the rich citizens were obliged to band together in order to meet the crushing charges that taxation imposed. The poorer classes expected the state to provide for them, and the level of public morality declined. The thousands of citizens who formed the juries in the lawcourts lost the habit of working, since they were paid for performing their duties as jurymen. The number of cases multiplied, while the number of informers living on blackmail and confiscations increased. Speakers had no difficulty in getting the people to vote the re-establishment of the Theoric Fund destined to pay for the people's pleasure, and this same people henceforth received a salary for being present in the Assembly. The 4th century provides the spectacle of the slow ruin of public spirit. Perhaps the life of the city-state was already moribund at the time of Philip's conquest.

The incessant wars between Greek cities and even within cities undermined by civil strife showed clearly that no regime, whether oligarchic, such as Sparta, or democratic, such as Athens, had been able to maintain equilibrium in Greece. After the death of Socrates, guilty, despite having done his duty on the battlefield, of rising above the city walls to think of man instead of defending the democracy, historians and philosophers had clearly defined the social and political problem. For the philosopher Antisthenes, founder of Cynicism, Greek and barbarian were equal, as were slave and free citizen. Among the intellectuals of the period and among those men of action who reflected upon the historical scene in which they were acting, there was born and took shape the idea that the separateness of the city-states had had its day.

Already in 392 the Sophist Gorgias took the occasion of the Olympic Games to proclaim the need to bring about a union of all Greeks, a position later taken up also by Lysias and Isocrates. The latter had at first thought the Greeks could be united under the leadership of Athens, but the history of his times gradually converted him to the idea that Greece would give up its divisions only under the direction of one single man.

The idea of Greek unification under a strong individual was also taken up by Plato, who thought for a time that he had found his philosopher-king, in Sicily, in the person of Dionysius the Elder, then of Dionysius the Younger, then of Dion. Isocrates placed his hope in Jason of Pherae, then turned his eyes on the son of the king of Sparta, Archidamus, and then again on Dionysius the Elder, who, tyrant though he was, succeeded in uniting the Sicilian Greeks in the face of the Carthaginian peril, a union that he made more lasting than any in Greece. And while Isocrates, the intellectual pure and simple, was idealizing another prince, Evagoras of Cyprus, Xenophon, with his experience of exile, travel, and war, was painting in his *Hieron* the portrait of the perfect monarch, whom he thought he had found in flesh and blood in the person of the king of Sparta, Agesilaus. He completed the exposition of his views by showing in the *Cyropaedia*, by the example of Cyrus the Elder, what the education of a prince should be and the benefits that his people can expect as a result. Isocrates finally came back to reality, a reality that endangered his country's liberty, when he decided that he had found in Philip of Macedon the man of destiny who could bring Panhellenism out of utopia into the realm of reality.

The desire for a philosopher-king

Philip had set his own statue beside those of the gods and thought of having the Greeks worship it in the sanctuary of Olympia. Alexander, persuaded of his divine parentage, instituted the cult of the ruler and demanded that he be made a god while he was still alive.

The arts and architecture. The same effort to escape from tradition, the same tendency to break the bounds of the city in order that the individual might forget his sufferings, showed in the arts in 4th-cenutry Greece. But the main principles held firm, and the combination of old and new still produced marvels of art, closer to man and his sufferings than in the past. Artists conveyed the uncertainty of a world in transition. Men sought to escape the anguish of the fleeting present by creating an ideal world. Their attention was concentrated less on the solid past, sometimes put in doubt today, than on daily life, even among the humble and the have-nots, and on the human personality and the passions that shake it. Thus developed the taste for analysis.

Developments in sculpture

The sculptors grew away from the city and forgot the existence of the gods. They felt the influence of painting, which renders shadows, reflections, and transparencies and translates the movements of the soul, and they set themselves to study man, no longer in what is universal in him but in his fears and weaknesses. Hence, they sought to reproduce the expression of the face and of the eyes down to the finest shades of meaning, as well as interpreting gestures and bodily attitudes of suffering or emotion. Scopas expressed the pathos of existence in heads looking backward, in mouths twisted or half open, in quivering muscles. Praxiteles, more sentimental, interpreted voluptuous revery through the sweetness of a smile of invitation or resignation; his subjects no longer have the strength to hold themselves up, their bodies drooping softly and supporting themselves on a column. He was interested in languid youths and dared to bare completely the female body, even of goddesses, who appeal to the pleasures of the senses.

A similar grace, deliberately indiscrete, inspired toreutic art and still more the delightful figurines of Tanagra, little girls or young women captured in the very moment of a light thought or passing fancy, now flirtatious and laughing, now sad and melancholic, wrapped in transparent draperies or sauntering beneath a parasol.

A new movement developed in the second half of the century. Lysippus turned from women to athletes and was also interested in monarchs. Philip lured him to Macedonia, and he accompanied Alexander to Asia; he was the first court artist. But there is nothing formal about his art. He has an eye for detail, seizes the act of movement, and shows man as he is, in his trade or in history.

In architecture, novelty abounded. Theatres multiplied, and stone tiers made their appearance at Syracuse and Epidaurus, arranged in conformity with laws whose secret is lost today, to produce unequalled acoustics. In the religious sanctuaries, round buildings developed, *tholoi*,

set above a crevasse giving access to the divinities of the underworld. Religious feeling remained strong in the Greek world wherever it was the expression of a community spirit. Cities and individuals gave considerable sums to reconstruct the great Doric temple of Apollo at Delphi, destroyed in an earthquake in 373. Later, thanks to Philip and Alexander, who were perhaps more interested in propaganda than in expressing genuine religious faith, Olympia was enriched with new buildings.

Ionian architecture

It was in Ionia, however, that architecture particularly flourished; it aimed both at ornament and at grandeur. Everywhere temples were built or rebuilt—at Sardis, Priene, Miletus, Xanthus. Indeed, on the Asiatic shore of the Aegean, already the home of the Ionic order, two of the Seven Wonders of the World were created: the temple of the goddess Artemis at Ephesus and the giant Mausoleum at Halicarnassus, the resting place of Mausolus of Caria, to whose apotheosis both Scopas and Praxiteles contributed.

Literature and oratory. In literature even more than in art, Athens remained the great capital of the Greek world. Writers who were not from Athens came there to learn its lessons. The Athenian political regime offered an example of what not to imitate, but in literature, as in art, the age of masterpieces was not yet over. But the masterpieces were no longer inspired by the same spirit as in the previous century, which had seen tragedy, comedy, and history blaze into glory.

Except in the theatre, poetry, in decline, gave way to prose. As was natural at a time when man was more worried about his future than about his destiny, the output of drama continued, especially where the theatre was under the protection of tyrants, but the tragedies of this period have not been preserved. It is known, however, that they were in the same line as those of Euripides, poet of anxiety and of passion. Aristophanes continued to write but produced a new style of comedy, either plunging into utopia to escape the harshness of the times or taking the direction that was to be that of New Comedy by depicting in realistic fashion the manners of everyday life, drawn particularly from the common people, and by subtly analyzing situations rather than individual characters.

In the lawcourts and the world of politics, the spoken word extended its domain, since it was necessary to work upon the citizens in their double capacity as judges and as masters of their country's destiny. The orators stayed in the city to defend their clients in court and influence the decisions of the people but left it to appeal to Greek opinion and put forward great ideas.

Isaeus remained the specialist in inheritance taxes. Lysias, as previously noted, was not simply a speech writer for the benefit of those who could not speak in public: a panegyric at Olympia gave him the chance of addressing all the Greeks. Isocrates went still further; having made a fortune as a lawyer, he became a professor of the highest form of eloquence, that for state occasions, insisted on a broad culture for his disciples, and left his school to urge Panhellenism, first upon the Greeks and then upon Philip of Macedon, when Greece became for him more important than Athens.

Demosthenes

On the opposite side, with a higher flame of eloquence, Demosthenes continued his incessant struggle against the rulers of Macedonia. By his public speeches and political addresses, he fought obstinately in defense of Athens, of its liberty and its brilliant past, with a settled ardour and a passion of logic that finally defeated the skilled talent of Aeschines. But he was to pay with his life for his courage in opposing the power of Macedonia.

Demosthenes' life and work are one with the history of his times. There remained, however, some professional historians. None had the force or greatness of Thucydides, although one is in danger of misjudging, on the basis of fragments or mere echoes, historians who are known mostly by name only, such as Theopompus, Ephorus, or that Ctesias who was also a doctor at the court of Susa. On the other hand, the immense output of Xenophon has survived complete. An Athenian who often, though not always, admired Sparta, he left an account of 50 years of Greek history, finishing the narrative of the Peloponnesian War that Thucydides left incomplete and continuing his researches down to the Battle of Mantineia, which reduced the cities of Greece to greater chaos than ever. Full of curiosity, more percipient than he is usually given credit for, though suffering by comparison with Thucydides as a historian and with Plato as a philosopher, he stirs and interests his readers by the diversity of his talents. His troubled life took him to the crossroads of the civilizations of Asia and Greece. He appeared on the battlefields of both Asia and Greece, then gave up a soldier's life to become a country dweller, horseman, and hunter. Faithful to the memory of his master Socrates, he created both biography with his life of Agesilaus and the historical novel with his *Cyropaedia*, which foretold the coming of Alexander.

Philosophy and political thought. The philosophers in their schools also, as was natural, invited men to reflection, whether it led subsequently to action or to meditation. All the major philosophical schools were influenced by Socrates, who had directed his powerful mind to search for the good and the beautiful—*i.e.*, the true—and who had drunk hemlock with calm courage to show the justness of his principles.

In Athens, Antisthenes, founder of the Cynic school, taught that neither happiness nor unhappiness existed in themselves but rather are subjective states. The Cynics believed the happiest creatures are the savage and the animal, since they suffer from none of the prejudices burdening man. They are lucky enough to know nothing of honours, country, religion. In short, to attain true happiness, one should "lead the life of a dog." Such was the blessed state that Diogenes was to attain in his barrel.

If the Cynics are the forerunners of the Stoics, the Epicureans derive from Aristippus of Cyrene, theoretician of hedonism. For this teacher and his disciples, everything in human life goes back to the senses. Happiness lies in pleasure; thus, the greatest happiness is the greatest pleasure. The wise man, however, is not insensible to the quality of the pleasure, and it is in his interest to remain master of his passions. Regarding the love he felt for a courtesan, Aristippus summed up in a striking phrase the teaching of the Cyrenaics: "I take; I am not taken."

Plato and the Academy

Like Xenophon, Antisthenes, and Aristippus, Plato was first molded by Socrates; their master perhaps taught them in the last analysis to be men more than citizens. That does not in any way mean that Socrates' teaching was harmful from the point of view of the state. On the contrary, Plato, before turning to philosophy, had wished to serve the city, and all his life he remained haunted by the problem of politics.

Socrates' death turned Plato away from active politics. After this, he combined the experience of travel with reflection in an attempt to discover the ideal regime of a philosopher on the throne. As has been noted, he thought he had found it in Sicily. Disappointed in this, he expounded the theory of it, first in *The Republic* and later in the *Laws*. Realizing that individualism was the death of the city, he sought to locate sovereignty in an all-powerful republic, authoritarian enough to abolish classes, and later in pure reason, creator of unchangeable laws. Plato would have liked to give concrete form to his abstract theory and suffered all his life from his inability to put his ideas into practice. Nor did he have the pleasure of seeing certain of his disciples write constitutions for cities after his death.

Since the regime and policies of Athens denied him a career as a statesman, he was a philosopher, having as his aim the formation of men for political life. On his first return from Sicily, in 387, he founded the Academy, a school of political science, where the listeners worked together under the direction of the master, aiming toward an ethical and scientific training whose ultimate aim was the reform of the state. Without ever repudiating Socrates, Plato went beyond him, broadened the field of reflection, and speculated on the realm of the absolute. Surrounded by his disciples, the most brilliant young Athenians of their generation, who live in his dialogues alongside Socrates, and in the company, too, of the Soph-

ists, whom he delighted to confound, Plato sought passionately after truth in all fields, from mathematics to metaphysics. His dialectical method came to him from Socrates. It allowed him, through questions often tinged with irony, to lead his partner in the conversation by stages to the discovery of the solution. Often the dialogue resolves itself into connected exposition, and, when only imagery can transmit the subtlety of the supreme reality, Plato, the antagonist of poetry as an agent of decadence in the city, himself has recourse to the poetry of myths.

Socrates convinced Plato of the reality of virtue, and Archytas of Tarentum and the Pythagoreans showed him that the universe was founded upon the ever-new beauty of numbers. He believed that the world was a mere illusion. Thus, it is desirable to free oneself from one's mortal body and, thanks to the soul that survives it and that, by virtue of the reincarnations, remembers its past lives, to climb from illusion to belief and from belief to the world of ideas, the only reality, since it is the image of God. Borne upon the wings of love, the soul finally achieves its happiness in the divine contemplation of the beautiful, which gives it no longer belief but actual knowledge of the good and the true.

Plato goes further and much higher than Socrates, and it has been said that all subsequent philosophies are merely footnotes of his thought. He retains, however, the secret he learned from Socrates of always providing the fascinating spectacle of a thought in the process of being born. At the same time realist and mystic, he is the father of the New Academy and of Neoplatonism. He opens the way for the Fathers of the Church and for Christian thought. The first in time of his famous disciples is, however, Aristotle.

Aristotle and the Lyceum

Aristotle had less charm than Plato but is more accessible. Where Plato opened up the lofty road of the idea, Aristotle opened up the earthly track of the fact. The two, however, make one whole—unique, incomparable, and profoundly Greek—in the sense that they settle forever the two complementary aspects of man's speculation.

Aristotle was born at Stagira, in the region of Chalcidice coveted by Philip of Macedon. His life, like that of Demosthenes, spans the middle of the century, from 384 to 322. For 20 years he was Plato's disciple, until the latter's death in 348/347. Five years later he accepted Philip's offer to take charge of the education of the young Alexander, then aged 13.

Aristotle, after living in Macedonia and touring Asia, founded a school known as the Lyceum at Athens in 335. There, scholarly discussion took place while walking, whence the name of "Peripatetic" for the school. In the afternoon the lectures were public. The morning was for work, in which Aristotle directed teams of his disciples. This is the only part of Aristotle's work that survived. For only the notes, fortunately copious, taken by Aristotle's pupils give us an idea, admittedly extensive, of the body of his work.

He left to Plato the realm of mathematical speculation but took in the rest of knowledge and established an encyclopaedic body of research on a combination of observation and syllogistic logic. In his eyes concrete objects alone exist, though they are constantly changing. He classified them, both flora and fauna, by genera and species, assembling an astounding mass of observations and conclusions. For him the life of species is determined by the action of a final cause, and motion is transmitted by a chain of events whose origin goes back to a god, perfect, unique, indifferent to the world, though not totally divorced from the world, since he passes on his energy to matter whose forms he shapes.

In ethics, Aristotle is distinguished from Plato by his realism, as the latter distinguishes himself from Socrates by his idealism. Aristotle considers that virtue lies in a just mean, a sort of equilibrium that is obtained, like the pleasure of watching a tragedy in the theatre, by a purging of the passions. But, before being a moral creature, man is a political animal, and the first of all skills is political skill. Here again, though influenced by Plato, Aristotle differs from his master in not constructing an ideal city. He studies actual existing constitutions and arranges and classifies them as he classified animals and plants, following the same method that allows him, through critical observations, to work out definite laws for the great literary genres.

It was natural that a mind of this quality, this universality, should have left its stamp on Alexander; it was natural, too, that so exceptional a pupil should have shown his gratitude by sending his master money for his research and rare specimens for his collections from the depths of Asia. The Greeks soon saw that the young disciple had replaced encyclopaedic research with conquests up to the limits of the unknown, and substituted for the spirit of inquiry a determination to impose balance and order on conquered humanity.

THE CONQUESTS OF ALEXANDER THE GREAT

Relations between the Greeks and Macedonians. When, at the beginning of summer 336, Philip II of Macedon fell beneath the assassin's knife, there was an explosion of joy in Greece: the national enemy was dead. As for his successor, Alexander, the Athenians could believe that he was too young—a mere 20 years old—to follow in his father's footsteps. They knew that he was brought up on Greek and trained by Aristotle. They could also know that, before taking part in the Battle of Chaeronea at Philip's side, he had studied passionately Homer, Pindar, Herodotus, and Euripides; they could suppose that his encyclopaedic knowledge might possibly direct him toward the things of the spirit.

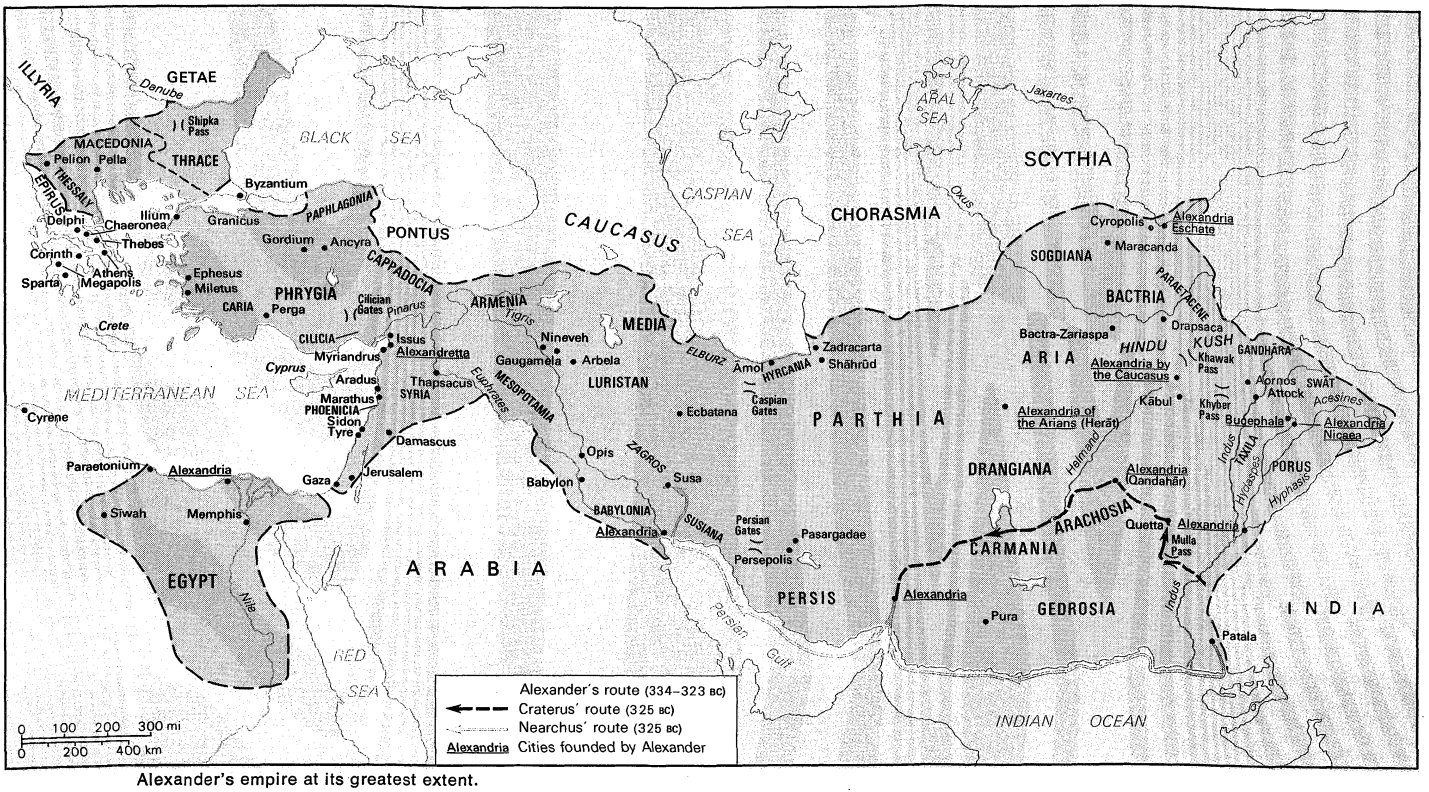
Alexander's background

Alexander had inherited from his father a taste for warfare, however, and from Homer and Herodotus he had drawn warlike lessons, as well as the example of a great struggle to be led against the barbarians of Asia. He had also listened to the advice of the orators; he knew of the crusades preached by Gorgias, Lysias, and Isocrates. He had not forgotten the march of the Ten Thousand across Asia nor the campaigns of Agesilaus; he knew that the Greeks had for too long allowed their quarrels to be settled by the barbarian king. As a Hellenized monarch, Alexander could believe he had every chance of bringing the Greeks finally into agreement beneath the dominion of someone not a barbarian. His father had shown him the way: Philip had created the League of Corinth in order to impose a general harmony under the aegis of Macedonia. Except for Sparta, all the Greek cities, members of the new league, had accepted in the spring of 337 the idea of a great war of revenge against Persia, by means of which Philip meant to cement their union.

Alexander took up Philip's program but turned it around: waging war in Asia was for Philip a means of ensuring his own sovereign authority over the Greeks; for Alexander, animated by an appetite for glory and for conquest, the war was itself the end. But, to attain such an end, he must necessarily have peace in his rear. His first act, despite his youth, was to intimidate the Greeks: he descended like a thunderbolt upon Thermopylae, haunted by the spirit of Leonidas, and won the succession to his father's seat on the Amphictyonic Council, whereupon the League of Corinth named him commander in chief of the Greeks.

A danger now became apparent on the other flank, in the north, in 335. There was trouble in Thrace, and beyond, among the Triballi and the Illyrians. Alexander, with his army, reached the northern bank of the Danube and re-established Macedonian order among the recalcitrant barbarians. Nevertheless, when a rumour spread that he had died in Illyria, the effect was seen of the embassies and of the gold that the King of Persia had sent into Greece to check the policy of Alexander's father and of Alexander himself. At Thebes the exiles returned and dared to kill the Macedonian governors. Thebes requested the support of the Arcadians, the Eleans, and, in particular, the Athenians, among whom Demosthenes was keeping alive the sacred flame of the struggle for liberty. They decided to send help secretly into Boeotia. But Alexander lost no time in showing that he was truly still alive.

From Illyria, he made a dizzy swoop into Greece: 12 days sufficed for him to appear before the walls of



Alexander's empire at its greatest extent.

Destruction of Thebes

Thebes. The Thebans were dumbfounded, and the city fell. An example had to be made of them. The city was razed; its inhabitants, including the women and children, were slaughtered or sold into slavery. The punishment was so cruel that Alexander was struck with repentance; he made the pilgrimage to Delphi to beg Apollo's pardon and to cleanse himself in the god's presence from the stain of this bloody repression. He had commanded that naught be spared except the descendants of Pindar and the poet's own house. The terror was effective: the Greeks saw that it did not pay to take such a master lightly, even if he was flexible enough to measure out his vengeance sparingly, showing himself less severe toward Athens, a city for which he had always had a weak spot.

Now undisturbed either by barbarians or by Greeks, Alexander could turn toward Asia. He planned to make a bridge between the barbarian East and the civilization of the West, a project that presupposed replacing the Achaemenid Empire by a Macedonian monarchy. In the spring of 334 he took charge of a small but experienced army of 30,000 infantry and 5,000 cavalry and set off for the Hellespont. He had left behind his turbulent mother Olympias, who hated Antipater. But he could count on his faithful lieutenant to ensure the regency of Macedonia and the government of Greece.

The conquest of the Persian Empire (334–330). One might speculate about Alexander's aims as he crossed over from Europe into Asia. Did he intend merely to repeat the Persian Wars? to liberate from the Persian yoke the Greek cities of Ionia? to sow in the East the benefits of Hellenism? His ideas were large enough to take in all these goals, but it is certain that his sense of reality told him that he must crush Persia in order to put an end to the interventions of its arrogant diplomacy and hidden subsidies in the affairs of Europe. The hour had come for Macedonia to play the game up to the limits of the world. Alexander realized clearly what was necessary from a political point of view, but he also felt beating in his breast the heart of one of Homer's heroes; he wished to bring the *Iliad* to life.

Once he had crossed the Hellespont, Alexander made a sacrifice on the tomb of Achilles, whom he believed to be his ancestor, and then impetuously attacked the Persians. In 334, on the banks of the Granicus, after a crazy charge without a battle plan, he won a brilliant victory over the lieutenants of the Persian king. From the spoils of the barbarians he sent trophies to the Athenians that they might be consecrated in the Parthenon and adorn the Acropolis. He liberated the Greeks in the region of Troy from the King's yoke and exempted them from all the taxes imposed by his satraps. In a few months Ionia, land of the bards and fatherland of Homer, was conquered. At Sardis he restored to its inhabitants their ancient laws. At Ephesus he pacified the rival factions and gave the funds necessary to rebuild the temple of Artemis, one of the Seven Wonders of the World. Returning to northern Phrygia, he reached its capital, Gordium, on the road to Susa and there, according to legend, cut the famous Gordian knot that promised the empire of Asia to whoever should loose it. Alexander then moved south to cut Persia off from the Mediterranean, but in all the territory from the Hellespont to the Nile he wished to appear more liberator than conqueror and used force only where generosity failed.

Battle of Granicus

After experiencing serious difficulties in Cilicia in the autumn of 333, he penetrated into Syria and this time defeated the King himself in November at the Battle of Issus. Darius succeeded in escaping and reached Babylon, but he abandoned his dependents, his harem, and his family. Alexander respected his captives, and, when the Queen died in his camp as a prisoner, he ordered a funeral so magnificent that Darius considered leaving his throne to the Macedonian if he were finally defeated.

There was, however, no question of accepting a ransom or of negotiating. Alexander went his own way. Instead of making for Babylon, however, he completed the division of the empire into two halves, north and south, in order to break its naval power. Sidon opened its gates, and Tyre fell after seven months. Alexander escaped an assassin's knife and seized Gaza. Without a blow struck, Egypt fell into his hand and welcomed him as liberator. In the winter of 332/331, he offered sacrifice at Memphis, founded Alexandria, which was to be the cradle of Hellenistic culture, and advanced across North Africa toward Carthage.

Alexander next turned back toward the very heart of Persia. At Tyre he offered sacrifice to Heracles and also organized in passing a dramatic contest in the Athenian

manner. He received from Athens the homage of an embassy that landed from a state trireme, charged with obtaining the freedom of the mercenaries from Athens whom he had captured at Issus serving in the Persian army. Since Athens had just refused its support to the king of Sparta, Agis III, who was trying to subvert the Greeks against Macedonia, ruled by Antipater in the absence of its king, he granted the Athenian prisoners their liberty. After this curiously literary and diplomatic interlude, he took up arms again, crossed new deserts, and passed over the Tigris; and on October 1, 331, at Gaugamela, not far from Arbela, he crushed Darius in a third and decisive battle. At the same moment, in the Peloponnese, in front of Megalopolis, Antipater was annihilating the forces of Agis.

Battle of Gaugamela

Reassured as far as the Greeks were concerned and now conqueror on the Asiatic front, Alexander made a magnificent entry into Babylon. A whole month of festivities allowed the soldiers to relax and enjoy themselves. Victors and vanquished celebrated alike, with a feeling of relief that the Achaemenid Empire had come to an end. The complete success gave substance to the idea of one single new empire beneath a monarch who abolished frontiers to try to bring about a fusion of East and West.

Instead of following Darius, who had taken refuge in Ecbatana, Alexander advanced toward Susa, which opened its gates before him. To symbolize the end of the age-long hostility of Greeks and barbarians, Alexander adopted Persian costume and beliefs but at the cost of alienating his own men. He celebrated games, offered sacrifices, and freed the captive princesses, the mother and daughters of Darius, together with the young prince Ochus; he granted them Susa as their place of residence and had them taught Greek.

Advancing into Iran, he entered the holy cities of Persepolis and Pasargadae. He punished the resistance of the satrap Ariobarzanes by giving Persepolis over to pillage (apart from the royal palaces) and allowed his soldiers unprecedented loot. For his own part, he seized a fabulous treasure of 120,000 talents. At Pasargadae, he went to meditate before the tomb of Cyrus the Great and listened to the message of the dead conqueror. He had to adopt Eastern habits if he was to take the place of the Great King, even if it displeased part of his own army.

In the spring of 330 he organized at Persepolis an immense banquet, accompanied by music, songs, and dances. Abandon seized everyone. In a moment of exaltation, the son of Olympias, egged on by the courtesan Thais, mistress of Ptolemy, the future king of Egypt, set on fire the palace of the kings of Persia, which until that time had been spared. Darius, grown old, exhausted by his long flight, finished by falling into the hands of his satrap of Bactria, Bessus, who coveted the throne. He was put to death by the traitor; Alexander did not arrive in time to save him. He wept over the body of his enemy, had the last honours paid to him, and eight months later killed Bessus, whom he had taken prisoner. It was the end of the Achaemenids. There remained only one king of Persia, Alexander.

Death of Darius

The conquests in Bactria and the Indus Valley (330–323). Once Darius was dead, Alexander had the right to conclude that he had brought to a victorious end his mission as champion of the Panhellenic idea. He ceased to consider himself the delegate of the League of Corinth; he was no longer commander in chief of the Greeks but King of Kings, the successor of Cyrus the Great. He adopted the ceremonial of the Persian court, took a harem, and wore the tiara—a posture that led some to surmise that one Oriental despot had been exchanged for another.

Alexander went so far as to proclaim himself a god and demand from the Greeks abasement in his presence. In the army, anxiety gave place to anger. Plots were formed, and those suspected of complicity were executed, even if they were the King's old friends.

At a victory celebration in January 327 Alexander noticed Roxana, the daughter of his vanquished enemy; he eventually married her, thus realizing more than symbolic union of Greece and Asia.

There is no stopping on the high road of conquest. Mysterious India attracted Alexander because it held the traditions of his ancestral gods Dionysus and Heracles and because a pupil of Aristotle could there satisfy his curiosity as a geographer and his urge for exploration. What is more, the bearer of civilization would open up for the Greeks new commercial routes to the East, and his soldiers would restore their morale in guerilla warfare and high life alternately. The great adventure went on.

With an army of 120,000 infantry and 15,000 cavalry, he marched for 18 months until he reached the Hyphasis (Beās), an eastern tributary of the Indus. He suited his movements to the difficult country and the unknown climate; he adapted his tactics to the elephants of Porus, rajah of Lahore; he built a small fleet to sail on the Indus. In July 323 he finished off the resistance of Porus on the banks of another tributary of the Indus, the Hydaspes (Jhelum).

The final stage was to be the Ganges, at the very limits of the world, which scholars and legend said was bordered by the ocean. But his soldiers were upset by the tropical rain, his officers suffered from homesickness, and the army would go no farther. It was a bitter disappointment for the conqueror; he could not go on alone, and to the joy of the others he gave the order to return.

At the end of the autumn of 326 he launched a fleet, this time of 2,000 ships. Himself convalescing from a wound, he descended the Indus, a river that, instead of flowing into the Nile as was believed, has its own delta, as was discovered in July 325; thus, it flows into the ocean. To reach Susa, the army was divided into three sections. In the north, Craterus was to march by the land route across the country of Arachosia; in the south, by the sea route, Nearchus would sail with the fleet; Alexander chose for himself the central route, across the fearsome desert of Gedrosia, in the hope of maintaining contact with the fleet.

The northern army made its march without incident. The parallel march by the King across the desert and the voyage of Nearchus, braving a terrible sea with a river fleet along an unknown shore bristling with reefs, nearly ended in disaster. Human energy won the day. Army and fleet first made contact again, against all hope, in Carmania; their meeting was celebrated in the autumn of 325 by an astonishing orgy lasting seven days. They met for good six months later at the head of the Persian Gulf in the delta of the Euphrates. They had thus opened up the sea route linking East to West, which the great sailors of the future would follow.

The survivors of the expedition were at last reunited at Susa. Alexander decided to reward them and at the same time to crown his policy of joining the races. In February 324 he organized an astounding marriage celebration at which the sound of the trumpet orchestrated all the movements. Ten thousand mixed marriages took place at the same time between Greek soldiers and Asiatic women; all the King's lieutenants received chosen Eastern brides. He himself, who had lost a son of Roxana in India, celebrated a new marriage with the eldest daughter of Darius, the princess Barsine (Stateira).

Greco-Persian marriage at Susa

After this he could disband part of his army, those who were tired of the country; he replaced it by native troops to whom he taught the Greek language and Macedonian tactics. He then incorporated them into what remained of his old troops. He did not, however, forget Greece and wished to bring about a higher union: having, as he thought, obtained a reconciliation in Asia, he had to impose it on Greece. He signed two decrees at Susa and published them at the Olympic Games in September 324. By the first, he ordered the Greek cities to recall their exiles, and all accepted this general amnesty except Athens, where the anti-Macedonian spirit was still alive. By the second, he demanded to be accorded divine honours; the Greeks recognized him as the new Dionysus, brother of Apollo and son of Zeus. In 323, at Babylon, his sovereignty became that of a king and god; the Greek cities of the entire world sent their representatives to celebrate his apotheosis.

Alexander's ambition was insatiable. He envisaged new

explorations and studied fresh conquests, from the mouths of the true Nile to the Pillars of Hercules, Africa following upon Asia. But Nemesis lay waiting for him. His body had suffered too much from orgies, from wounds, and from the trials of war. Fever took him, increasing daily, and on June 13, 323, death struck the god who was not immortal.

The empire and achievements of Alexander. It is difficult to say what would have become of the empire of Alexander if it had been given him to reach the Ganges and finish his work. One's judgment must limit itself to what this exceptional man tried to do and to the trends that had already manifested themselves.

He did not live to see the known world united under his sovereignty, nor did he give the world a single capital. Greece stayed Greek, with its internal conflicts, beneath the rule of Antipater, Alexander's representative in Europe and governor of Macedonia. Asia remained Asian without having imposed upon it great innovations. The conqueror had the intelligence to preserve all that was workable and healthy. He was content to correct or refine the Achaemenid administration. He reorganized the satrapies but kept them in existence in Syria, in India, in Egypt: he gave each satrap a deputy, with a general as military commander. He set in order the payment of taxes, since the treasures of the kings of Persia were not inexhaustible, and issued a new coinage that covered the known world with his portrait. There was no area that did not bear the master's mark: justice functioned; circulation of money was encouraged; canals were dug and roads opened or repaired; town life and agriculture throve alike.

The master, king and god, might have chosen Babylon as capital, but he remained the pupil of Aristotle. He believed that it was the task of the West to enlighten the East, to stir up its masses, to energize its softness and delays. He protected artists, scholars, poets, and writers trained at Athens, whence came his admiration for the capital of the arts and of literature. Knowing by experience the vital strength of Greek language and civilization, he founded across the world 34 Alexandrias, future centres of Hellenism, on African or Asian soil. It is from Alexandria in Egypt and the Alexandrians that the world possesses all that Greek civilization from Homer onward had bequeathed.

Such indeed was the master plan of this young genius, and it succeeded after his death. As if he had realized that the immediate question of the succession would cause internal strife, he sought to ensure for the generations to come the survival of Hellenism. He went far beyond the utopian and superficial Hellenism preached by Isocrates, which Philip had almost brought about. If Alexander imposed his monarchy by divine right upon the world that he had made to yield or had conquered, it was not to leave side by side brothers who were still enemies or races separated by mutual hatred; it was in order to mold these divers elements into one single unit and to pour the best of Greek thought into an Eastern mold, where authority from on high would in no way derogate from the freedom of equals or inferiors.

When he married Roxana, when he gave his lieutenants Eastern princesses for wives, when he gave his soldiers Persian women, he was only setting an example or rather mildly demanding one. He meant to bring about a marriage between two civilizations, and he was certain that the fruit would have the best elements of both. Dead at the age of 33, after 12 years of action, Alexander had made history of a new sort, that of the conqueror who brings peace, who pardons the vanquished, who forces nations to accept his rule, only to help them to live and to unite them.

Ideas rule the world. Alexander passed on his ideas to the world that he had conquered. Before him, neither Sparta nor Thebes had been able to dominate Greece by arms; even Athens had not succeeded, either by force or by intelligence. With Alexander the rule of factions was over, the cities were broken, leagues were dissolved, nations cast into the melting pot, and races intermingled, and the time of great men itself was over.

While Aristotle was drawing up a catalog of the products of earth and man and was building up a systematization of the Greek world, his Macedonian pupil was saving the Greek heritage, was opening the Alexandrian Age, and was allowing Hellenism to diffuse throughout the world. (E.D.)

V. The Hellenistic Age (323–30 BC): Greece in the Roman period

THE ESTABLISHMENT OF THE HELLENISTIC KINGDOMS (323–276 BC)

Alexander's career gave rise to a new Greek world, in which the city-states played a role subordinate to territorial monarchies but in which the genius of the Greek people found fresh outlets in every field of culture and political experimentation. The three centuries from Alexander to the establishment of the Roman Empire under Augustus were among the most productive and influential in the whole of Greek history.

From Alexander's death to the death of Perdiccas, 323–321. Alexander's death (323) produced a grave political crisis over the succession; in a compromise solution the army vested power jointly in Philip's feeble-minded bastard, Arrhidaeus, who was an epileptic, and the unborn child of Alexander and Roxana, should it prove a boy (as it did). These two became Philip III and Alexander IV. Powers and provinces were apportioned. Antipater was confirmed in his control of Macedonia and the European possessions, including Greece. In Asia Perdiccas was made chiliarch (or grand vizier); Craterus was declared guardian of the kings. Ptolemy received Egypt (where Cleomenes of Naukratis had usurped power) and gained prestige by seizing Alexander's body, which was being conveyed to Macedonia, and diverting it to Alexandria. Antigonus Monophthalmus (the One-Eyed), satrap of Phrygia, received western Anatolia (Greater Phrygia, Lycia, and Pamphylia), and Lysimachus received Thrace (hitherto an appendage of Macedonia). Alexander's Greek secretary, Eumenes of Cardia, was sent to oust Ariarathes from Cappadocia and Paphlagonia. The satrap of Hellespontine Phrygia, Leonnatus, soon perished bringing reinforcements to Greece during the Lamian War. Of all these men Ptolemy, Antigonus, Eumenes, and Lysimachus were the most outstanding and played the greatest part in the struggles for power that quickly ensued.

Political crisis over succession

News of Alexander's death provoked a rising in Greece known as the Lamian War (from the siege of Lamia). The two main disaffected factions were, first, the Athenian democrats under Hyperides, who voiced the widespread resentment felt at Alexander's decree recalling exiles, and, second, a body of mercenaries back from Asia who had provoked disturbances at the mercenary market of Taenarum in Laconia and, under the Athenian Leosthenes, now brought help to Athens. Aetolia and Thessaly joined the movement, soon followed by other Greek cities. Their forces besieged Antipater in Lamia; but Leosthenes fell in battle, reinforcements reached Antipater, and the Athenian fleet was crippled in a defeat at Amorgos. In 322, under pressure from both Antipater and Craterus, Athens negotiated; in the peace it lost Oropus and had to pay an indemnity and accept a Macedonian garrison in Piraeus. Both Hyperides and Demosthenes perished in the reprisals, and an oligarchic government was established under Phocion and Demades. Greece was now bound more tightly than ever to Macedonia, without even the pretense of alliance that the League of Corinth had offered. Aetolia alone escaped because Antipater and Craterus were recalled to Asia.

In Asia, in Craterus' absence, Perdiccas had usurped guardianship of the kings and was making a bid to unite the empire under his control. Antigonus of Phrygia hated Perdiccas; and personal issues exacerbated the conflict. Though married to Antipater's daughter Nicaea, Perdiccas was tempted by the offer of the queen mother Olympias to give him her daughter Cleopatra, Alexander's sister. Perdiccas' equivocations helped provoke a coalition of hostile satraps: Antipater, Craterus, Antigonus, Lysimachus, and Ptolemy all united against him.

Coalition against Perdiccas

But war was averted when Perdiccas, invading Egypt, was assassinated (321). Ptolemy, who had had the usurper Cleomenes murdered, was now firmly in control there and strengthened by the addition of Cyrenaica to the west; he was wise enough to decline an invitation to take Perdiccas' place. Perdiccas' death brought the first period of manoeuvre to an end. It also isolated Eumenes, who was closely linked to Perdiccas; but a drive against him proved a fiasco, though it brought about Craterus' death.

The career of Antigonus Monophthalmus, 321–301. The two decades following Perdiccas' death were dominated by Antigonus' attempt to succeed him as the unifier of Alexander's empire.

The elimination of Eumenes, 321–316. A meeting of Perdiccas' opponents at Triparadisus in north Syria (321) declared Antipater guardian of the kings in his stead. Babylonia was assigned to Seleucus, one of Perdiccas' murderers. Antigonus was entrusted with the task of hounding down Eumenes, whom the allies had condemned to death; having appointed Antigonus general of Asia, Antipater returned to Europe with the kings.

During the next two years (321–319), in the drive against Eumenes, Antigonus rode roughshod over his colleagues in Asia Minor and was virtually master of the whole area. Eumenes was penned up in Nora in Cappadocia, when Antigonus learned of Antipater's death (319). Antipater had arbitrarily appointed as regent to succeed him Polyperchon, an old officer of Philip II, instead of his own son Cassander. Cassander, an able and ambitous man, promptly crossed into Asia, there to organize a coalition of Lysimachus, Antigonus, and Ptolemy against Polyperchon. Seduced by these new hopes Antigonus rashly offered to give Eumenes his satrapy back in return for his collaboration—an offer Eumenes readily accepted without any intention of keeping his word. Meanwhile, Ptolemy, on hearing of Antipater's death, had launched an attack on Syria–Phoenicia, an act less important for what it achieved than it was as an indication that he had now made both the kingdom and the strategy of the pharaohs his own.

In Europe Polyperchon, opposed by the other governors, attempted to improve Macedonian relations with the Greeks. Athens was promised the return of Oropus and Samos, and the events of the Lamian War were expunged in a formal proclamation; the oligarchies set up by Antipater were to be abolished and exiles restored. These gestures were halfhearted and short-lived. At Athens a brief spell of democracy (during which Phocion and others were executed) ended in negotiations with Cassander's troops in Piraeus as soon as it became clear that Polyperchon was losing ground.

An agreement made in 317 established the Peripatetic philosopher Demetrius of Phaleron as master of Athens, where he remained in power for the next ten years. Under his guidance Athens enjoyed peaceful and efficient government, in which some of the precepts of Aristotelian political thought were put into practice; the presence of Cassander's garrison stifled opposition. Polyperchon himself, meanwhile, had been expelled from Macedonia; having lost his fleet in a defeat by Antigonus near the Bosporus and with Cassander gaining ground in Greece, Polyperchon fell back on the Peloponnese, where he still commanded some support.

Power struggle in Macedonia

Meanwhile, events in Macedonia had ended all pretense of loyalty to the family of Alexander the Great. The quarrel between Polyperchon and the other dynasts had been reflected in the fortunes of the kings. Eurydice, the wife of Philip III, had joined Cassander and proclaimed him regent; and Polyperchon, who still held Alexander IV, now recalled Olympias from Epirus to strengthen his claims. Olympias had both Eurydice and Philip III killed; but she was herself imprisoned by Cassander shortly afterward, tried and condemned by the Macedonian army assembly, and executed. To improve his own position relative to Polyperchon, Cassander married Thessalonice, a half sister of Alexander the Great (and sometime later named the city he founded on the site of Therma after her).

Meanwhile, Polyperchon had taken the obvious step of allying himself to Eumenes and as regent had assigned to him the generalship of Asia. From 318 onward Eumenes fought several impressive and successful campaigns against his united enemies—in Asia Minor, Phoenicia (where he recovered some of Ptolemy's conquests), Babylon (which he took), and Persia. But in 316 in Persia he was betrayed by his own troops, handed over to Antigonus, tried, and executed. Over several years Eumenes had employed skill and resilience in the name of the kings (though whether indeed with the selfless loyalty alleged by the ancient sources may be questioned). His death left Antigonus free to act against the satrapy of Iran, where anarchy was rife, and to pursue on his own behalf the unity of the empire. In so doing Antigonus became the rival and hated enemy of the other generals; thus Eumenes' death marked a crucial step in his struggle to win the succession of Alexander.

From 316 to the peace of 311. Antigonus gained control of the whole area from Asia Minor to Iran, and in 315 he turned southward to expel Seleucus from Babylonia. As a refugee in Ptolemy's court, Seleucus urged action on the other generals, and an ultimatum was delivered on Antigonus in north Syria by Ptolemy, Cassander, and Lysimachus. Because Antigonus' action against Eumenes had been on behalf of them all, they called upon him to restore Babylonia to Seleucus, to abandon Syria to Ptolemy, to hand over Hellespontine Phrygia to Lysimachus, and to surrender Cappadocia and Lycia to Cassander; further, they demanded that Eumenes' treasure be shared with the rest. Rejecting these demands, Antigonus continued his annexations; soon he held all southern Syria except Tyre, and he turned thence to seize Bithynia and Caria. Like Eumenes before him, he also allied himself with Polyperchon, whom he recognized as general of the Peloponnese.

Antigonus' manifesto of 315

In 315 at Tyre, Antigonus published a manifesto recording the condemnation of Cassander by his army assembly for the "murder" of Olympias and the seizure of Alexander IV and his mother; he also published his own appointment as guardian of the surviving king, thus stressing his role as defender of the legitimate line. Further, the proclamation declared that the Greek cities should be free, autonomous, and ungarrisoned—a demand to which Monophthalmus was to remain consistently faithful; he followed it up (probably in 315–314) with the creation of a confederation of the Aegean islanders (Nesiotes), engineered a revolt of Delos from Athens (it was to remain independent until 166), and sent agents to Greece to intrigue against Cassander.

Leaving his son Demetrius to guard Phoenicia against Ptolemy, Antigonus planned to attack first Lysimachus in Thrace, then Cassander in Macedonia. But Ptolemy, after some delay caused by revolts in Cyrene and Cyprus (where he had now gained a footing), yielded to the pressure of Seleucus and, in 312, attacked and defeated Demetrius at Gaza, thus enabling Seleucus to recover Babylonia and drawing Antigonus southward. Seleucus' change of fortune, however, suggested that negotiations might profit both Antigonus and Ptolemy (who had returned to Egypt), and after some preliminaries an uneasy peace was agreed (311).

This peace between Antigonus and Cassander and Lysimachus, on the one hand, and Ptolemy, on the other, represented a compromise based on the status quo. Cassander was to remain general of Europe during Alexander IV's minority; and Antigonus, general of all Asia. Lysimachus' control of Thrace and Ptolemy's of Egypt were confirmed. Seleucus, no party to the peace, was quickly excluded from all mention (he remained at war with Antigonus for two more years); nor did the peace concern Polyperchon. A clause underwriting the liberty of the Greek cities was destined to furnish each signatory with a convenient *casus belli* against any other who could be shown to have ignored it. In about 310 Cassander removed the limiting clause on his own powers by assassinating Alexander IV and his mother. For Antigonus the peace merely afforded a breathing space before his next attempt to absorb the other four territories.

From the peace of 311 to the death of Antigonus, 311–301. The next ten years reveal a complicated story because the general alignment against Antigonus did not prevent his rivals from intriguing against each other or from making temporary accommodations with him. For both Antigonus and Ptolemy naval power was assuming increased importance; Antigonus had his eyes on Macedonia, and Ptolemy's control of Cyprus and Syria–Phoenicia turned on the possession of a navy. In 310 Ptolemy made his brother Menelaus general of Cyprus, and it was perhaps in 306 or even earlier that the Egyptian ruler entered into a long-lasting alliance with the maritime commercial city of Rhodes. Meanwhile, Seleucus recovered the upper satrapies, inflicted a defeat on Antigonus, and made a peace requiring Antigonus to surrender his claim to Iran but leaving him free to fight against the Mauryan king Candragupta in India.

About the same time, Cassander made a rapprochement with Polyperchon (who abandoned his support of Heracles, an alleged bastard of Alexander). That accord led Antigonus and Ptolemy to patch up an agreement, which may have been linked with Ptolemy's assassination of Polemaios, Antigonus' agent in Greece. The background is obscure, however, and Ptolemy's reason for this turnabout can only be surmised. The mainland Greek cities, faced with a coalition of Cassander and Polyperchon, appealed to Ptolemy, who invaded the Peloponnese in 308; but failing there, he came to terms with Cassander (though Ptolemaic garrisons remained installed in Corinth and other Greek cities). The following year (307), while Cassander was busy in Epirus, Antigonus' son Demetrius Poliorcetes sailed to Athens, seized it, and expelled Demetrius of Phaleron, who was superseded by a democracy. When Demetrius Poliorcetes seized Cyprus, however, the friendship with Ptolemy terminated. In 305 Demetrius began his famous siege of Rhodes, which lasted a year and ended in a compromise peace. Rhodes accepted the Antigonid alliance provided it entailed no disloyalty to Ptolemy; the outcome of the siege was celebrated by the Rhodian erection of the Colossus in the harbour at Rhodes and by the title of Poliorcetes (the Besieger), thenceforth borne by Demetrius.

Conquests of Demetrius Poliorcetes

The year 306 was marked by a spate of kingship claims. After Demetrius' seizure of Cyprus, Antigonus assumed the title of king for both himself and his son—a clear implication that they were kings of Alexander's empire. A year later Ptolemy also took the title—no doubt implying "king of Egypt" (where he was already pharaoh to the native Egyptians). Cassander, Lysimachus, and Seleucus quickly followed suit. In proclaiming a Seleucid era from October 312 (April 311 in the Babylonian calendar), Seleucus had already perhaps taken a step in this direction; but his regnal years date only from 305–304.

Demetrius was now master of Athens; and after gaining the Isthmus region he resuscitated the Greek confederacy, with himself and Antigonus as presidents. Its constitution, known from an inscription found at Epidaurus, owed much to Adeimantus of Lampsacus. Like the league of Philip II, it was intended primarily as a tool of Macedonian domination. (Shortly afterward Polyperchon disappears from the records and was probably dead.)

Antigonus' enemies now prepared seriously to oppose him. A new coalition of Cassander, Lysimachus, Ptolemy, and Seleucus (who had ceded India to Candragupta in exchange for a troop of invaluable war elephants) made ready to confront Monophthalmus, who recalled Demetrius from Athens. Father and son met the combined forces of Lysimachus and Seleucus (with his elephants) at Ipsus in Phrygia (301). Antigonus lost the battle, perishing in the melee; Demetrius escaped.

The Battle of Ipsus and death of Antigonus

The victors shared the spoils. Lysimachus took Asia Minor to the Taurus (except parts of Lycia and Pisidia, which became Ptolemaic, and Cilicia, which was governed for a time by Cassander's brother Pleistarchus). Seleucus declared his claim to Syria, but he did not care to press it against his benefactor Ptolemy, who held all south of Aradus and Damascus. Cassander remained satisfied with his European possessions. The battle at Ipsus marked the end of all pretense that the empire would be united; despite Lysimachus' realm astride the straits, Europe and Asia were thenceforth to go different ways.

The failure of Demetrius Poliorcetes, 301–286. Though defeated at Ipsus, Demetrius still possessed the islands, his fleet, and several cities in Greece and Asia; but he lost Athens, which had been offended by his outrageous behaviour and had swung over to Cassander as a nominally free city under the government of Lachares. Demetrius' first chance came when Ptolemy made a double marriage alliance with Lysimachus; Seleucus, in consequence, turned to Demetrius (rather than Cassander) to make a counteralliance (at Rhosus in Syria), by which Seleucus married Demetrius' daughter Stratonice and Demetrius received Cilicia. It proved short-lived, however. Attempting to take advantage of Cassander's death in 297 (or possibly 298), Demetrius started in 296 to regain a foothold in Greece and retook Athens, which he held from 294 until 288; but he lost his remaining Asian possessions—Cyprus to Ptolemy, Cilicia to Seleucus, and his Ionian cities to Lysimachus. In 294, however, he successfully invaded Macedonia, killed one of Cassander's young sons, expelled another, and was proclaimed king of Macedonia by the army. Soon afterward he celebrated his new dignity by founding Demetrias in the Gulf of Pagasae (modern Gulf of Vólos, in Greece).

Demetrius' volatile temperament was inconsistent, however, with any firm policy. In 292–291 he invaded Asia, only to be forced to return to Europe by risings in Boeotia and Aetolia stimulated by Pyrrhus, the young king of Epirus whom Ptolemy had restored to his kingdom in 298–297 to maintain pressure on the Macedonian frontier (see below *Epirus and Sicily, until their absorption by Rome*). Demetrius suppressed the Boeotian rising and in 291–290 recovered Corcyra, which Pyrrhus had received as dowry from Agathocles of Syracuse, whose daughter Lanassa he married in 303. Demetrius' conflict with Pyrrhus went on for two more years, ending with a peace in 289. From then onward Demetrius' position deteriorated. By about 287 he had lost all the Aegean islands to Ptolemy; worse still, in 288 Lysimachus and Pyrrhus had combined to fall upon Macedonia and expel Demetrius, while Ptolemy's fleet liberated Athens. Thenceforth Demetrius was a wanderer without a base. He attacked first Lysimachus, then Seleucus, who took him prisoner in 285 and put him under house arrest. Demetrius, who had become an anachronism in a world of solidifying frontiers, died from drink in 283.

The expulsion of Demetrius

The end of the struggle for succession, 286–276. Antigonus' death at Ipsus had left Lysimachus the most serious challenger to the throne of Macedonia. He now held territories on both sides of the straits, where already in 309–308 he had built the stronghold of Lysimacheia. In 288–287 he had annexed northern Macedonia (having expelled Demetrius with Pyrrhus' help); and in 285, having broken with Pyrrhus, he seized the rest of Macedonia and Thessaly—though Demetrius' son, Antigonus Gonatas, still held Demetrias, Chalcis, and Corinth, later to be known as the "fetters of Greece" and certainly the bastions of Macedonian rule. To these for a time was added Piraeus.

Lysimachus was brought down at the height of his power, thanks partly to a domestic drama. In the interest of her children, his third wife, Arsinoe, Ptolemy's daughter, persuaded Lysimachus to execute his son Agathocles as a traitor. Thereupon Agathocles' widow, Lysandra, and her brother Ptolemy Ceraunus (Ptolemy's children by an earlier marriage) stirred up Seleucus to make a bid for Macedonia. Seleucus, perhaps also encouraged by Lysimachus' governor in Pergamum, who now went over to him, invaded Asia Minor in 282; Lysimachus was defeated at Corupedium and perished.

Seleucus, the last of Alexander's generation, seized Lysimachus' possessions in Asia, crossed into Europe, and was promptly assassinated by Ptolemy Ceraunus. Seleucus' death did not threaten his realm, where his son Antiochus I already reigned as co-monarch. The deaths of Lysimachus and Seleucus thus offered the greatest opportunity to Antigonus Gonatas, who could

not, however, stop Ceraunus from being accepted as Macedonia's king. Ceraunus' reign, however, was violent and brief. To strengthen his claim to the throne, Ptolemy Ceraunus married Lysimachus' widow, Arsinoe (his own half sister); but when he murdered two of her sons, Arsinoe fled to Egypt and married her own full brother, Ptolemy II (ruled 285–246), who had succeeded their father. Soon afterward (probably in 280) Macedonia was invaded by a band of Gauls (Celts) migrating across Europe and quick to penetrate frontiers weakened by Lysimachus' defeat. Ceraunus perished at their hands, probably in January 279; a Gaulish kingdom of Tylis was established in Thrace, and one group reached Delphi, where the Aetolians brought about their destruction. Later other bands crossed into Anatolia (see below *Bithynia, Pontus, Cappadocia, and Galatia*).

Ceraunus' death was followed by short weak reigns in Macedonia and (apparently) by a period without kings at all. Gonatas, who had been weakened by his failure to check Ceraunus, faced revolts in Greece, where Sparta rose under Areus and where Argos and Megalopolis expelled his garrisons. But after a short campaign in Asia and the striking of what was to be a lasting alliance with Antiochus I (Gonatas married Phila, Antiochus' half sister), Gonatas returned to Europe to defeat the Gauls in Thrace at Lysimacheia. This success, widely publicized in the propaganda of the dynasty, enabled him to make himself master of Macedonia and Thessaly by 276; a king since 283, he had at last found a kingdom. Thus, in just less than 50 years from the death of its founder, Alexander's empire had settled down into the three territorial states that along with Pergamum (see below *Pergamum*) were to constitute the great powers of the Hellenistic world until the Romans overthrew them: the Ptolemies in Egypt, the Seleucids in the composite state based on Syria and Mesopotamia, and the Antigonids in Macedonia. Those three states were the survivors of the dynastic struggles of the successors; and each dynasty had its own special problems.

The three great powers of the Hellenistic world

THE HELLENISTIC MONARCHIES IN THE 3RD CENTURY BC

Ptolemaic Egypt. Many Greeks had entered Egypt in the 4th century as mercenaries and traders; and, after Alexander founded Alexandria, their numbers were swollen by Greeks and by half-Hellenized Thracians and Anatolians who poured in as mercenaries.

Hellenization. Settled in the few Greek cities—Alexandria, Naukratis, and Ptolemais—or on plots throughout the countryside, where as cleruchs they constituted a reserve army and there organized themselves in their own communities (*politeumata*), the Greeks built gymnasiums and wrestling schools, formed clubs, and read Greek books. This Greek minority formed the base of Ptolemaic rule. Alexandria was an exception: besides Greeks it contained Jews (only superficially Hellenized) and Egyptians; and, although it housed the palace and central administration, it was officially separate from Egypt and never a Greek city in the traditional sense. In the countryside, moreover, though encouraged by the early Ptolemies, Hellenism was a wasting asset; as the influx of immigrants declined, native pressures grew. Intermarriage produced mixed families, and the cultural traditions of uprooted Greek immigrants gradually gave way to the centuries-old social patterns of the native Egyptians. From about 200 BC onward Egyptian traditions began to prevail in all spheres. Nevertheless, so long as Ptolemaic rule endured, there remained a strong incentive to acquire the hallmark of Greek culture. Thus in Egypt as elsewhere, Hellene came to be a cultural term, valued especially because the Greeks remained the privileged class on whom the administration rested.

The character of Ptolemaic government was linked closely with foreign policy. The security of Egypt was assured by outposts in the eastern Mediterranean and Aegean and by an expensive naval supremacy. Southern Syria, seized in 301, remained Ptolemaic until 200. Cyprus, too, after some dispute with Antigonus I and Demetrius I, became permanently Egyptian. For most of the 3rd century, the Ptolemies controlled the Cyclades (and Samos to 201), much of the Asian coast from the Calycadnus to Ephesus, and much of the Hellespontine and Thracian coasts with Lesbos and Samothrace, together with outposts in the Peloponnese and Crete.

Though perhaps conceived defensively, the acquisition of the Ptolemaic Empire led to conflicts with both Antigonids and Seleucids (see below *Ptolemic policy in the Aegean and Asia Minor*); nevertheless, it brought economic gain to the early Ptolemies, who pursued a mercantilist policy, perhaps primarily in support of their costly imperial program. Essential metals, timber, and manpower were lacking in Egypt, together with many of the immigrants' basic needs. Thus the Ptolemies were led to develop a highly centralized bureaucracy, which was the most individual feature of their kingdom.

From 200 onward the bureaucracy became less efficient, and a revival of Egyptian influence occurred in many fields—in the army after 217, in the adoption of Egyptian customs, and in the predominance of the Egyptian calendar. Nevertheless, Egypt was the last of the Hellenistic states to be absorbed by Rome (see below *Roman annexation of Egypt*).

The Seleucid kingdom. The Seleucid dominions covered three distinct areas—Asia Minor (Anatolia), Mesopotamia (with Babylonia, Assyria, northern Syria, and, after Antiochus III's victory at Panium in 200, Coele Syria [Palestine]), and Iran. Their straggling and heterogeneous character created rival claims to attention, which made for weakness. Asia Minor contained a variety of states and peoples. The Seleucids controlled Hellespontine Phrygia, Phrygia proper, Lydia, inland Caria, eastern Cilicia, and for a time southern Cappadocia; several minor dynasts acknowledged them as overlords, but only the royal road to Sardis held the area together. Between the ancient trading and manufacturing districts of Mesopotamia and the Syrian and Phoenician coastal cities, which had long been exposed to Mediterranean influences, were the nomads, shepherds, or cultivators, including the Jews. In this predominantly Semitic area, with its worship of Bel, Marduk, Yahweh, and many Baalim, the Seleucids encouraged the revival of Babylonia, where the old religion and cuneiform writings underwent a renaissance. Farther eastward a mixed population of nomads, shepherds, farmers, and, in the cities of Media and Persia, traders shared an Iranian culture resistant to Hellenism. Failing there, the Seleucids gradually fell back upon the centre, where Antioch was to outlast Sardis and Babylon as the capital; but the Seleucid attempt to unite this disparate empire was an experiment not wholly fruitless.

Three distinct Seleucid regions

Hellenization: the Greek cities. The amorphous Seleucid realm was unified only by personal allegiance to the king and by the Hellenization he promoted. Alexander's foundations were supplemented both by full cities—often with dynastic names, like Antioch-on-the-Orontes, Seleucia-in-Pieria, or Laodicea-on-Sea—and by military settlements (which later sometimes achieved the status of cities), the inhabitants of which manned the phalanx. Many of the cities enjoyed nominal independence; the degree to which this was achieved in reality reflected the goodwill or weakness of the king. Antiochus III claimed full sovereignty over the Asian Greek cities; yet in 196 Miletus and Magnesia could engage in warfare. Many towns had a royal governor, and freedom often meant only freedom from tribute.

The cities and settlements Hellenized the surrounding areas, sometimes accepting non-Greeks as citizens or in corporate bodies with defined rights. Greco-Syrian law also promoted Hellenism: thus, in the 1st century, leases between men with Persian names in Kurdistan are in Greek, and, except in Babylonia, Greek was the common language, though it was rarely the native tongue east of Phrygia. Native religions were preferred to Greek; and Greek culture grew more tenuous, although its strength in the early Hellenistic period is impressive.

Government and foreign policy. The Seleucids had a double task—to reconcile the Greek settlers with the Iranians, who had previously been masters in the land, and to defend the eastern frontier against a substantial

power in Chorasmia (modern Turkistan). By 303 Seleucus I (ruled 312–281) had lost Gandhāra, eastern Arachosia, and Gedrosia to the Mauryan Candragupta; and, although Antiochus I, as co-ruler, had special responsibilities in the east, after the battle of Ipsus (301) western pressures constantly diverted the Seleucids from the east. Later dynastic conflicts and problems raised by Egypt and Pergamum prevented a consistent eastern policy; this led to Iranian irredentism and Greek disaffection.

Seleucid clashes with Egypt

The earlier Seleucid clashes with Egypt are badly documented. On Seleucus I's death (281), Ptolemy II fomented a revolt near Apamea but made peace in 279; Antiochus I (ruled 281–261) was then occupied against the Galatians introduced by Nicomedes of Bithynia, until in 275–274 he defeated them and settled them in the later Galatia. The First Syrian War (274–271) brought Ptolemy II some success, and Antiochus I had to accept the independence of Pergamum. The Second Syrian War (*c.* 260–255 or 253) brought Ionia and many lost territories to Antiochus II (ruled 261–246); it ended in his marriage to Ptolemy II's daughter Berenice and led to a Seleucid revival. But on Antiochus II's death, Ptolemy III (ruled 246–221) championed his sister Berenice, Antiochus' widow, and her young son against Antiochus' former wife, Laodice, and her son, Seleucus II (ruled 246–225). In the Third Syrian (or Laodicean) War, Ptolemy III crossed the Euphrates but without lasting effect. About this time the people later known as Parthians seized Parthyene, and Bactria seceded. Seleucus II was distracted by civil war with his brother Hierax, but he made a compromise peace (236) and soon invaded the eastern provinces, with small result. His eldest son, Seleucus III (ruled 225–223), was fully occupied against Attalus I of Pergamum. He was assassinated in 223. His brother Antiochus III (ruled 223–187) launched the Fourth Syrian War (219–216) against Ptolemy IV. Antiochus lost the Battle of Raphia (217), but an Egyptian rising that followed permanently weakened the Ptolemaic kingdom. Although between 212 and 205 Antiochus III marched as far eastward as Paropamisadae (see below *Roman entrance into Hellenistic affairs*), by the end of the 3rd century the Seleucids were more directly involved in the west than at any time since Seleucus I.

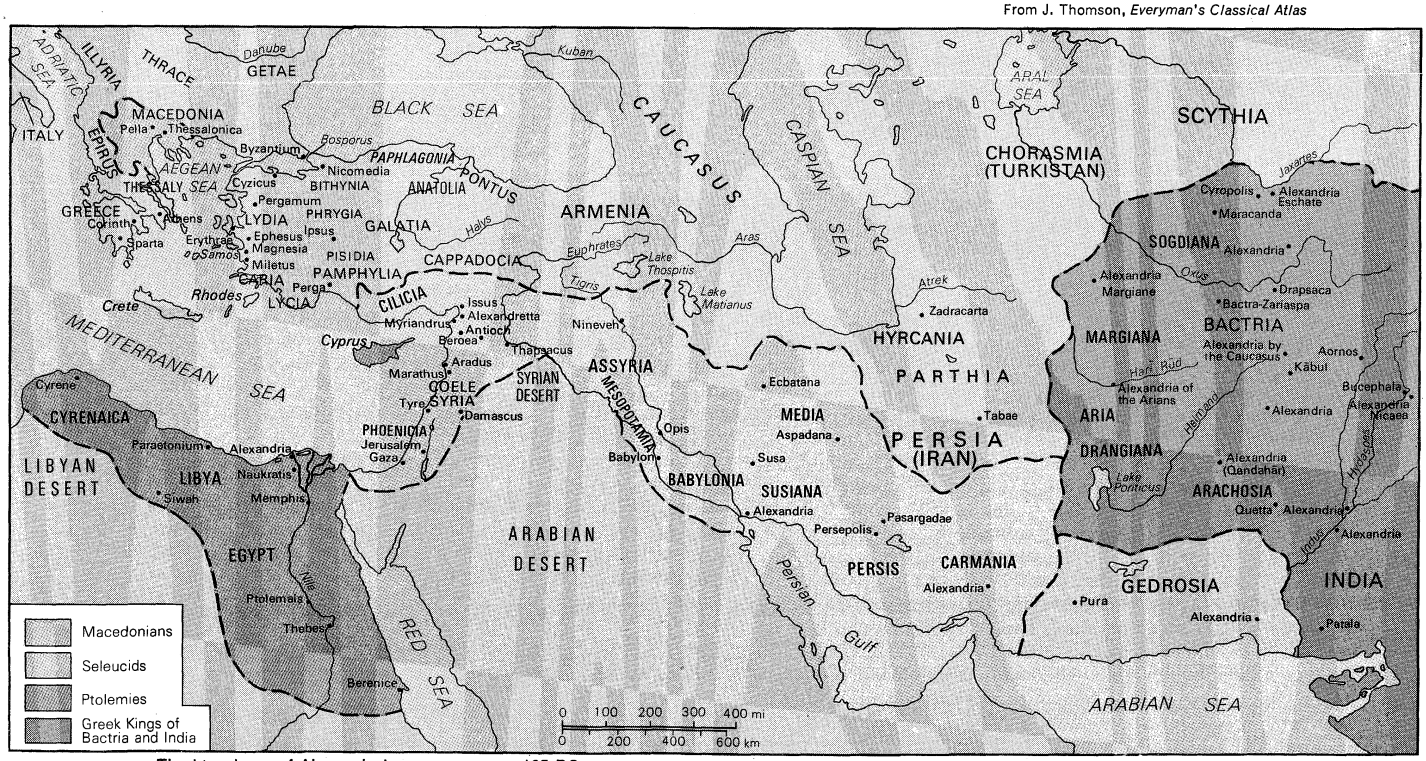
The Greeks in Bactria and India. About 239 BC Diodotus, satrap of Bactria, took advantage of Seleucid weakness to set up an independent Greco-Macedonian kingdom in Bactria, Margiana, and Sogdiana, supported by Iranians who feared a nomad invasion. His son was overthrown by Euthydemus, whom Antiochus III recognized as king after a siege of Bactra (208–206); and Euthydemus' son Demetrius annexed Aria, Arachosia, and perhaps Gedrosia and Carmania. Sometime after 187 another Demetrius of Bactria reached Gandhāra (Punjab); and in about 171 King Eucratides united all the Greek areas around Bactria. Eucratides' son Heliocles was defeated by the nomadic Yüeh-Chih around 135; but there were Greek princes on the Indus and farther eastward much later, the most famous in Greek and Indian tradition being Menander (others are known only from coins). Though inadequately documented, the story of the Greeks in the Far East exemplifies the vitality of the Hellenic tradition.

Pergamum, the smaller Anatolian kingdoms, and Rhodes. *Pergamum.* Pergamum, a stronghold on the Caïcus River in northwestern Asia Minor, was entrusted by Lysimachus to Philetaerus, who maintained good relations with the Greek world. He bequeathed Pergamum to his nephew Eumenes, who defeated Antiochus I near Sardis and declared himself independent. Eumenes' nephew, Attalus I, defeated Antiochus Hierax's Gaulish allies (*c.* 238) and took the title of *sotēr* ("saviour") and, shortly afterward, that of king. In 133 the last Attalid, Attalus III, left the kingdom to Rome; at its height, through Roman favour, Pergamum had come to embrace much of Asia Minor.

The Attalids of Pergamum

Like the Ptolemies, the Attalids zealously pursued personal gain. Their lands were rich in pitch and timber and they manufactured parchment from hides imported from the Black Sea area. They founded many cities, especially in the newer territories, and even more military colonies for their mercenaries; the cleruchs (soldiers who settled on land allotments) paid a 10 percent tax on produce, but their other subjects paid a fixed amount of corn and a heavy burden of other taxes. Pergamum itself became a splendid city with outstanding amenities and public-health provisions. The Attalids patronized learning, and their library was second only to that of Alexandria. Agricultural experiments were fostered, and industry (resting more than elsewhere upon slave labour) was developed. The Attalids posed as democratic rulers, especially in their capital; but they were widely detested by the Greeks, who regarded them as instruments of Rome.

From J. Thomson, *Everyman's Classical Atlas*



The kingdoms of Alexander's successors c. 185 BC.

Bithynia, Pontus, Cappadocia, and Galatia. Bithynia, astride the lower Sangarius, had eluded conquest by Alexander. In 298 or 297 its prince, Zipoetes, declared himself king. His successor Nicomedes I joined the Greek cities against Antiochus I but later brought the Gauls (Galatians) over into Asia Minor as mercenaries; in about 260 he founded Nicomedia. The later kings cultivated Greek friendship by generous gifts and founded many Greek cities, mainly on sites already inhabited. The population, largely Thracian, was substantially Hellenized. Of the later kings, Prusias I supported Rome against Antiochus III, and Prusias II played an ambiguous role in the Third Macedonian War; after a career as a noteworthy flatterer of Rome, the latter fell victim to a dynastic imbroglio (149).

Pontus, on the southern shore of the Black Sea, east of the Halys, was seized by Mithradates, the nephew of a tyrant of Cios, in 302; he made himself king and cultivated friendly relations with the Seleucids. To the south, Cappadocia, stretching from Lycaonia to the Euphrates and as far as the Taurus Range, had also remained independent under its satrap, Ariarathes; about 255 Ariarathes III became king and cemented good relations with Seleucus II. Both Pontus and Cappadocia remained feudal and mainly Iranian in outlook and custom.

The Galatians, intruders in the Greek world, were a branch of the same Celtic peoples who had invaded Italy in the early 4th century. Following their invasion of Macedonia and their attack on Delphi, a group including the Tectosages, Trocmi, and Tolistobogii (Tolistoages) was brought into Asia Minor by Nicomedes I of Bithynia in 277 and attacked Cyzicus, Erythrae, and Didyma. Settled by Antiochus I around the upper Sangarius and middle Halys, they were feared and hated by the Greeks. (Attalus I's victories over them were later commemorated in the frieze of the great altar of Zeus at Pergamum.) The Galatians kept their language, customs, and tribal organization down to the Christian era.

Rhodes. Its skilled navy and commercial strength enabled the island city of Rhodes to play an independent vigorous political role, especially in defense of the freedom of the seas. In 220 it fought Byzantium to keep the straits open, and it later made war on the Cretan pirates. In 305–304 the Rhodians successfully withstood the siege of Demetrius Poliorcetes. About 250 they defeated Ptolemy II off Ephesus in circumstances that remain obscure; generally, however, Rhodes was closely aligned with Egypt and inherited its control of the Aegean. Donations from other states to help repair the damage caused by a serious earthquake of *c.* 227 indicated Rhodes's high prestige throughout the Greek world. The richer families held power in a limited democracy and used their wealth to stave off social troubles; the 1,000,000 drachmas raised annually from import and export duties in 170 are an indication of Rhodes's wealth. After 167 Rhodes fell foul of its friends in Rome and suffered greatly in consequence. The Rhodian schools of philosophy and rhetoric were famous, and the city possessed many works of art; its maritime law may be partly incorporated in the Byzantine code known as the Rhodian Sea Law.

Macedonia: government and foreign policy. The Antigonids retained some of the traits of "heroic monarchy" evident under the Argeads. The king was the state; but the army assembly elected a regent and tried cases of treason. The monarchy was neither absolute nor personal; the king was first among his peers, neither a conqueror nor (to the Macedonians) a god. Macedonia was a poor land: the land tax raised only 200 talents annually. It was a country of peasant landowners (though the kings granted conquered land to settlers and veterans); mines and forests were royal possessions. The capital, Pella, became a Hellenized city and nominally autonomous. The upper classes spoke Greek and worshipped Greek gods. Among the few new cities were Thessalonica and Cassandrea. Antigonid power, solidified by Antigonus II Gonatas (ruled 276–239), rested on the citizen army; Macedonia avoided the problems of mercenary armies familiar to the Ptolemies and Seleucids.

The Antigonids' "heroic monarchy"

Not until the death of Pyrrhus of Epirus (272)—who had almost conquered Macedonia in 274—did Gonatas feel secure. For 50 years Macedonia tried to prevent any strong power from arising in Greece. To that end Gonatas maintained garrisons in Corinth, Demetrias, Chalcis, and Eretria; friendly governments in Argos, Megalopolis, Elis, and Megara; and a tacit agreement with Aetolia. A coalition raised by Athens and Sparta and backed by Ptolemy II took four years to suppress (266–262) in the Chremonidean War, named after Chremonides, who introduced the war measure at Athens; Gonatas' defeat of the Egyptian fleet off Cos may have occurred in 262. Ten years later, Alexander, governor of Corinth, revolted; and, although Gonatas recovered the city on Alexander's death, he soon lost it again to the Achaeans. Both he and his successors—Demetrius II, Antigonus III, Philip V, and Perseus—were much concerned with repelling the northern barbarians. But in Greece the policy of those rulers turned on their relations with the Achaean and Aetolian confederations, which were to involve Macedonia with the growing power of Rome (see below *The Greek leagues and the Antigonids in the 3rd century BC*).

The Greek states. The Hellenistic Age saw a number of changes affecting the Greeks, both on the mainland and overseas.

Social and political changes in the polis. The particularism of the *polis* underwent modification. In the mainland cities the machinery of government still functioned; but many were controlled by Macedonia, and relations with Macedonia became the main political issue alongside the rival interests of rich and poor. Elsewhere much of the content had gone out of political life. There was considerable material prosperity; the economic centre had shifted to Asia (especially to Rhodes), but Corinth, Delos, Pagasae, and Ambracia all flourished. In many ways life had improved. Attempts were made to humanize the practice of war. Many cities gained neutral status as holy places; and inscriptions record grants of immunity from the widespread custom of reprisals. Arbitration was common, and cities frequently invited outside commissions to settle lawsuits.

Freeing of slaves was frequent, some slaves buying their own freedom. Greater wealth led to new and more elaborate festivals and to an increase in social clubs; in some areas, like Boeotia, excessive social life became an abuse. Though depopulation was not serious before the 2nd century, some family limitation was practiced, probably through infanticide or abortion. In the 2nd century, however, the Roman wars brought a deterioration to most Greek cities and utter ruin to some.

The Achaean and Aetolian leagues. In the 3rd century federalism increased, thus providing compensation for the weakness of the separate cities. The Boeotian and Arcadian leagues were both important, but the most effective leagues were those in Achaea and Aetolia.

The Aetolian cantons were federally organized by the early 4th century, and after 300 the league included most of central Greece. Outlying areas enjoyed a loose form of citizen exchange (*isopoliteia*), and both Delphi and the Delphic amphictyony (association of neighbouring states) were under Aetolian control. The league had a representative council and a primary assembly meeting in spring and (at Thermum) in autumn. A cavalry leader, secretary, and other magistrates assisted the general, who was military leader; but a board of 30 *apoklētoi*—a council committee under the general—directed policy. The land was poor; this encouraged mercenary service abroad and piratical expeditions, especially as the accessible seaboard grew. In the First Macedonian War the Aetolians fought with Rome against Macedonia.

An Achaean league existed in the 5th century, but it had lapsed. In 280 Dyme, Pharae, Patras, and Tritaea reformed it; and by 272 the league of ten cities, including Aegium with the federal centre of Zeus Homarios, was complete. The accession of Dorian Sicyon under Aratus in 251 introduced an anti-Macedonian policy, which lasted until the rise of Cleomenes of Sparta (see below *The Greek leagues and the Antigonids in the 3rd century*

BC). Achaea, like Aetolia, had a primary assembly and a representative council. In 255 its two generals gave place to one, who might not serve in consecutive years; there were subsidiary magistrates, including a cavalry commander and secretary, and a ten-member board meeting under the general. The organization of the assemblies is still controversial; but apparently during the 3rd century the assembly met four times a year at Aegium, together with the council and magistrates, for routine business and elections. These meetings (*synodoi*) were restricted in the 2nd century to the council and magistrates. Special meetings (*synklētoi*) could always be summoned for special business, and after 200 they became mandatory to decide peace or alliance or to hear communications from the Roman Senate. There were federal laws and courts (as well as those of the cities) and, in the 2nd century, federal coins.

The Achaean League eventually embraced the whole Peloponnese. Its failure to strike a satisfactory compromise in its relations with Rome and an overweighting in favour of the propertied classes, who were unable or unwilling to make concessions to the increasingly radical poor within the cities, led to the league's downfall; but this does not detract from what it achieved during the 3rd and early 2nd centuries.

From W. Shepherd, *Historical Atlas*

The Aetolian and Achaean leagues.

Athens and the other Greek states. Such cities as Athens, Thebes, and Sparta found it hard to accept a diminution in scale and opportunity in the Hellenistic Age. For 60 years after Alexander's death, Athens aspired to an independent policy despite its defeat in the Lamian War (322). It had ten years of conservative administration under Demetrius of Phaleron, but after its "liberation" (307) it indulged in wild adulation of Antigonus I and Demetrius I. The Athenian and Spartan revolt against Antigonus II (the Chremonidean War) was crushed in 262; subsequently Macedonia controlled and garrisoned Athens until 229, when the governor Diogenes sold the city its freedom. Thenceforth it pursued a modest role under a conservative democracy, enjoying Ptolemaic protection. Under both the Antigonids and the restored democracy, Athens enjoyed high repute because of its past and even more as the home of the philosophical schools and the New Comedy.

Aspirations of the large cities

Thebes, destroyed by Alexander, was restored in 316 by Cassander; but its position on the fringe of Aetolian- and Macedonian-held areas restricted its political life. A supple policy, mainly based on friendship with Macedonia, kept it independent; but the Aetolians broke its military power in 248, and internally it suffered from inadequate administration, social conflict, and extravagant expenditure, foreshadowing its early-2nd-century clashes.

Sparta, consistently anti-Macedonian, warded off both Demetrius I and Pyrrhus. King Areus joined in the Chremonidean War but fell at Corinth; and under Agis IV (ruled 244–241) Sparta was briefly allied with Achaea against Aetolia. Agis was the first to attempt to deal with social ills found elsewhere but most evident at Sparta, where wealth was in the hands of the few and where a citizen body that depended on the possession of land had dwindled to a few hundred. Agis cancelled debts but was murdered before he could divide up the land as he proposed. His program was taken over and put into effect by Cleomenes III (ruled 235–222), whose imperial ambitions led the Achaean Aratus to call in Antigonus III. After Cleomenes was defeated at Sellasia and fled to Egypt, Sparta became a constant source of friction with Achaea. Revolutionary policies were revived under Machanidas and Nabis but later they degenerated into faction; and Sparta declined into a sterile imitation of its Lycurgan past, becoming a tourist centre under the Roman Empire.

Epirus and Sicily, until their absorption by Rome. By the middle of the 3rd century BC, the western Greeks were drawn irrevocably into the current of Roman history. In 317, after much faction, Agathocles, a man from Thermae, made himself tyrant at Syracuse. Engaged in a Carthaginian war, which was going poorly, he slipped out of Syracuse to land in Africa; there Ophellas of Cyrene joined him but was soon murdered by Agathocles. The war was inconclusive, but Agathocles on returning to Syracuse made a peace that established the Halycus River as the boundary with Carthage in Sicily. In 305 Agathocles took the title of king; he later campaigned in Italy and gained Corcyra, which, however, he gave to Pyrrhus of Epirus as dowry with his daughter Lanassa. Dissension in his family over succession caused Agathocles on his death in 289 to restore freedom to Syracuse. His reign had wasted Sicily by inconsequential policies and savage massacres.

The western Greeks

Pyrrhus, the Molossian king of Epirus (ruled *c.* 307–272), came nearer than anyone to bringing southern Italy and Sicily within the Hellenistic sphere. A relative of Alexander, he was perhaps the stormiest figure of his generation. Expelled from Epirus in 302, he was restored by Ptolemy I and Agathocles and set about giving a Hellenistic stamp to the monarchy of Epirus. His aim was Macedonia; and he seized part of it, with Thessaly, in 288 but was driven out by Lysimachus in 285. In 280 Tarentum invoked Pyrrhus' help against Rome; but, after victories at Heraclea (280) and Asculum (279), he crossed to Sicily, where anarchy had followed Agathocles' death. He almost drove the Carthaginians from the island; friction with the Greeks, however, led to his return to Italy and, after a drawn battle at Beneventum, to Greece. Failing in attacks on Antigonus II and Sparta, he perished in a night melee in Argos (272). Pyrrhus' policy was opportunist, and his real aims, if any, remain unfathomable; his return to Greece once more, however, severed the threads linking East and West.

At Syracuse Hieron II (ruled *c.* 270–215) seized power and took the royal title after defeating the Mamertini, Campanian mercenaries of Agathocles, who had seized Messana (Messina). The Mamertini invoked Roman aid. Hieron at first allied himself with Carthage; but in 263, after a defeat, he made a peace that initiated a period of some 50 years in which he ruled as a successful client prince of Rome. Thenceforth southern Italy and Sicily remained part of the Roman world.

RELATIONS AMONG THE HELLENISTIC STATES, 275 TO 27 BC

Ptolemaic policy in the Aegean and Asia Minor. Together with Coele Syria, the Ptolemaic overseas possessions were valuable for their wealth and formed an empire for the defense of Egypt; under Ptolemy IV (ruled 221–*c.* 204) and Ptolemy V (ruled *c.* 204–180), the possessions were mostly lost to Syria, or they either asserted or were granted independence. By 195 Egypt held only Thera and a few Cretan towns, having also lost Coele Syria, the main object of the long series of 3rd- and 2nd-century wars between Syria and Egypt.

Of these wars the first four (see above *The Seleucid*

kingdom: Government and foreign policy) left Coele Syria Egyptian; but the weakness of Ptolemy IV after the Battle of Raphia (217) and Antiochus III's experience and prestige made Syrian retaliation inevitable. By 203 Antiochus was interfering in Caria; his secret agreement with Philip V of Macedonia in 203–202 to dismember the Ptolemaic possessions after the accession of the boy king Ptolemy V probably assigned Caria to Philip. After advancing to Gaza and retreating to the sources of the Jordan, Antiochus won a victory at Panium (200), thereby gaining Coele Syria, which thenceforth was Selucid and under a general of Coele Syria and Phoenicia. In 195, having tried unsuccessfully to annex Cyprus, Antiochus made peace, marrying his daughter Cleopatra to Ptolemy V. Peace lasted 25 years, during which (in 186) Ptolemy V at last suppressed rebels who had held out in Upper Egypt since early in the previous reign. Antiochus, following on a defeat by Rome (see below *Roman entrance into Hellenistic affairs*), lost his western provinces; he was succeeded by his son Seleucus IV in 187. Seleucus was assassinated in 175 and succeeded by his brother Antiochus IV Epiphanes, who ruled until 163.

The Syrian–Egyptian wars

Antiochus had seized the throne with Pergamene help and did much to restore the kingdom. In 170 the regents of Ptolemy VI Philometor (ruled 180–145), the younger son of Ptolemy V and Cleopatra, declared war on Antiochus, hoping to recover Coele Syria. Both sides appealed to Rome; but the Senate, by then at war with Perseus of Macedonia (see below *Roman conquest of Macedonia and Greece and the acquisition of Pergamum*), delayed a decision. In 169 Antiochus invaded Egypt, besieged Alexandria, then returned home, leaving Ptolemy VI in control; Ptolemy, however, joined his sister Cleopatra II and his brother Ptolemy VIII against Antiochus and once again appealed to Rome.

The next year Antiochus seized Cyprus and again invaded Egypt. By then, however, Rome had defeated Perseus, and it ordered Antiochus to evacuate both Egypt and Cyprus. Antiochus yielded. The incident marked a decisive stage in Syrian decline; Egypt, too, was shaken, and thenceforth it could pursue an independent policy only through Roman indifference.

Syria was further weakened by a revolt of the Maccabees against the Hellenizing Judaean aristocracy, a movement that eventually ended in the establishment of a Jewish kingdom. In 150 Ptolemy VI married his daughter to the Syrian pretender, Alexander Balas; and another son of Seleucus IV, Demetrius I (ruled 162–150), was defeated and killed by Alexander Balas. Three years later Demetrius' son, Demetrius II (ruled 145–139; 129–125), landed in Cilicia to challenge Balas, whereupon Ptolemy transferred support to him in the hope of receiving Coele Syria; Demetrius defeated Balas in the Battle of Oenoparas (145), and Coele Syria remained Seleucid. In 132 Ptolemy VIII successfully raised a usurper against Demetrius II, who was tortured to death in 126 or 125; later, however, Ptolemy supported Demetrius' son, Antiochus VIII Grypus.

Dissolution of Seleucid Syria

The years 123–83 witnessed the final dissolution of Seleucid Syria, rent with dynastic strife and prey to Jews and Arabs within and to Parthians without. Tigranes of Armenia seized the remnants of the Seleucid kingdom in 83, which by then was ripe for Roman annexation. Ptolemaic Egypt survived semi-independent for another half century.

The Greek leagues and the Antigonids in the 3rd century BC. Soon after bringing Sicyon into the Achaean League, Aratus in a peacetime coup seized the Acrocorinth. Antigonus II Gonatas made no attempt to recover this position in southern Greece, but he leaned more heavily on the friendly tyrants in the Peloponnesian cities. In 241 Achaea made peace with Macedonia (and also with the Aetolians, who had recently expanded into central Greece and had been raiding the Peloponnese); nevertheless, Aratus launched a series of attacks on Argos and Athens.

Upon succeeding his father Antigonus, Demetrius II (ruled 239–229) made an alliance with Epirus, marrying the princess Phthia (Philip V's mother). This development provoked an Achaeo-Aetolian alliance, and, in 239–238, war broke out between Macedonia and the leagues. The Aetolians coveted Epirote Acarnania, and Aratus aimed at bringing all the Peloponnese under Achaea. Aratus seized Cleonae and Heraea, but he failed at Argos, where in 235 Aristomachus succeeded his brother Aristippus as tyrant. That same year, however, Lydiades resigned his tyranny at Megalopolis, which joined the Achaean League, as did Orchomenus and Mantineia. Demetrius, meanwhile, was busy fighting the Aetolians; in 237–236 he entered Boeotia and took Megara, thus driving a wedge between the leagues. In 229 Demetrius died while fighting in the north. His son, Philip (later Philip V), was only nine.

Macedonia was imperilled. The Aetolians seized Phthiotis, Thessaliotis, and Hestiaeotis; but Antigonus Doson, a nephew of Gonatas, was elected regent by the army and restored the position. In three years Antigonus Doson re-established the northern frontiers, recovered most of the Aetolian conquests, and seized part of Phocis. Doson was recognized as king (Antigonus III), but he loyally held the position in trust for Philip. In 227 he made a naval expedition to Caria, an obscure episode. Meanwhile, the monarchy in Epirus had been swept away, and Illyrian attacks caused the state to disintegrate. Ambracia and Amphilochia went with Aetolia, Athamania became independent, and Epirus itself eventually joined the Illyrians. Farther south, Demetrius' death led to the freeing of Athens (229–228), and Aristomachus surrendered his tyranny to join Achaea (228). Under Argive and Megalopolitan influence, Achaea became more hostile to Sparta, where the revolutionary Cleomenes III had succeeded in 235. Shortly before, perhaps as compensation for its greater burden in the war, Achaea had ceded Tegea, Mantineia, Caphyae, and Orchomenus to the Aetolians; in 229 they were given to Cleomenes.

Cleomenes' invasion of Megalopolitan territory initiated the Cleomenean War with Achaea (229–222), which quickly developed in his favour. In 227 he deposed the Spartan ephors, raised the citizen body to 4,000 by radical land redistribution, and introduced Macedonian tactics. Aratus, seeing the league dissolve and fearing social revolution, appealed to the Macedonian Antigonus Doson, agreeing in 225–224 to surrender Corinth in return for Macedonian help. With the Macedonian army confronting Cleomenes at the Isthmus, Argos revolted from Cleomenes and forced him to withdraw into Laconia. In 223 Cleomenes' Arcadian gains fell away; and, though in winter (223–222) he seized and destroyed Megalopolis, his paymaster Ptolemy (who had abandoned Achaea a little before) deserted him. Defeated at Sellasia (222), Cleomenes fled to Egypt, where he perished in a rising shortly afterward. Antigonus occupied Sparta, but a Dardanian invasion soon drew him back to the north; after a victory there, he died of consumption in 221.

The Hellenic Alliance

In 224 Antigonus had created a new organization to control Greece—the Hellenic Alliance, a loose body of leagues (not cities), including Achaea, Epirus, Phocis, Boeotia, Acarnania, Opuntian Locris, Euboea, Thessaly, and (nominally) Macedonia. The Macedonian king was president; a council made all decisions, which each state had to ratify. This alliance threatened Aetolia with encirclement, and in 220 the Achaeans clashed with Aetolians operating in Messenia. The ensuing Social War was essentially a conflict between Achaea and Aetolia, with Antigonus' successor Philip V (ruled 221–179) and the alliance playing reluctant parts. Elis and Sparta joined Aetolia, and various Cretan cities aligned themselves on the two sides for domestic reasons. An impressive list of demands was presented to Aetolia. In the three years of fighting Philip revealed tactical skill and personal energy —crushing internal opposition among his ministers and sacking Thermum. But when peace was concluded at Naupactus (217), both sides kept what they held.

Already Philip's eyes were elsewhere. In 221 the Illyrian chieftains, Demetrius of Pharos and Scerdilaidas, had broken the terms imposed by Rome in 228 by sailing southward on a piratical foray. In 219 a speedy policing

expedition (the Second Illyrian War) had crushed Demetrius, who, as an exile at Philip's court, now urged him to pursue Macedonian (and Illyrian) interests in the Adriatic.

Roman entrance into Hellenistic affairs. Through the Hellenic Alliance, most of Greece was drawn into a new conflict between Macedonia and Rome. At first Philip enjoyed mixed fortunes in Illyria: in 215 he approached Hannibal of Carthage, and a treaty was made in very general terms to secure Philip's Illyrian aims. In 216–212 Philip suffered a naval setback but reached the Adriatic coast by land; in Messenia his inept policy alienated Achaea. In 211 the Romans engineered an Aetolian alliance, under which the Aetolians were to have conquered territory while the plunder went to the Romans or was shared. Soon Elis, Sparta, and Messenia came in on the Aetolian side, along with Attalus of Pergamum (to whom the Aetolians sold Aegina, taken from Achaea). In 209 and 208 Philip was characteristically active defending his allies, and Attalus retired to Asia to meet the attack of Prusias of Bithynia. Neutral attempts at mediation—by Egypt, Rhodes, Chios, and Athens—were fruitless. In 207 and 206 Roman inactivity allowed Philip to invade Aetolia and force it to a separate peace; meanwhile, the Achaean army, reorganized by Philopoemen, had destroyed the Spartan tyrant Machanidas at Mantineia (207). The Peace of Phoenice, made with Rome in 205, represented a limited success for Philip, who then turned his attention to the Aegean.

Simultaneously Antiochus III was looking in the same direction. After Raphia (217) he had spent three years crushing the revolt of his cousin Achaeus and recovering some of his territory in Asia Minor. He then led his forces eastward, covering Media, Parthia, Bactria, Paropamisadae, and Arachosia and ending at Gerrha in Arabia. Antiochus thereby won wealth and the title of great and reasserted Seleucid authority in Media. His treaties with rulers farther eastward, however, merely disguised their virtual independence. In 204–203 he took Amyzon in Caria; but Ptolemy IV's death and the accession of a boy, Ptolemy V Epiphanes, changed the whole situation.

In winter 203–202 Philip, who had already been treacherously attacking Rhodes and raising money by piracy, compacted with Antiochus to divide the overseas possessions of Ptolemy; and in 200 Antiochus recovered Coele Syria (see above *Ptolemaic policy in the Aegean and Asia Minor*). In 202 Philip campaigned in Thrace, seizing the Aetolian possessions of Lysimacheia, Chalcedon, and Cios; in 201 he sailed a new fleet across the Aegean, attacking Rhodes and Pergamum and campaigning in Caria. Attalus and Rhodes appealed to Rome, and in 200 a Roman embassy declared war on Philip as he was besieging Abydos. Roman motives have been variously assessed: Philhellenism, fear of Philip, fear of Philip and Antiochus together (in the light of exaggerated accounts of their pact), and pure imperialism have all been suggested. Probably motives were mixed; but irrational alarm undoubtedly figured prominently among them.

Roman declaration of war against Philip

Though isolated, Philip resisted for three years (200–197). In 198 the Roman Titus Quinctius Flamininus defeated him on the Aous in Illyria, forcing him back into Macedonia. Aetolia and Achaea (with some opposition from Argos) joined the Romans. There were negotiations in winter 198–197, but, once assured that his command would be renewed, Flamininus made sure they collapsed. In June 197 Philip was decisively beaten at Cynoscephalae in Thessaly, the Aetolians contributing greatly to the victory.

The Roman demands had been gradually stepped up until they included the general requirement that all Greeks be free; the proclamation of this policy at the Isthmian Games of 196 aroused tremendous excitement. Philip was restricted to Macedonia; much of Thessaly was organized in federations; Aetolia received some territories but emerged discontented. The Greeks were freed; but the Romans expected their willing collaboration (failure to appreciate this was later to cause disaster). Nabis, the tyrant of Sparta, was obliged to free Argos (made over to him by Philip) but kept his throne. In 194 the legions left Greece.

Antiochus, meanwhile, had reached the Hellespont (the Rhodians having withdrawn opposition upon the news of Cynoscephalae). Smyrna and Lampsacus appealed to Rome, and Antiochus was ordered to withdraw. But when at a conference at Lysimacheia (summer 196) the Romans bade him refrain from attacking Greek cities or Ptolemy's possessions, Antiochus parried this with a pertinent reference to the Greeks in Italy and announced his forthcoming alliance with Ptolemy (see above *Ptolemaic policy in the Aegean and Asia Minor*). In 195 Hannibal fled to Antiochus' court; and in 193, through a Syrian embassy at Rome, Antiochus was ordered to stay out of Europe or see the Romans intervene in Asia. Probably neither side sought war. But in 192 the Aetolians tried to raise a coalition against Rome, and, though Philip wisely declined and Nabis was soon assassinated, Antiochus felt he must seize the opportunity; in autumn 192 he crossed, inadequately prepared, to Greece.

Elis, Boeotia, and Amynander of Athamania joined Antiochus; but Achaea and Philip both fought alongside Rome. In 191 Antiochus was defeated at Thermopylae and returned to Asia. The Romans granted the Aetolians a truce, which was renewed in 190 when Lucius Scipio as consul, with his brother Africanus as his legatus, crossed to Greece and marched northward through Macedonia to the Hellespont. Three naval victories—at Corycus (191) and at Side and Myonnesus (190)—gave Rome's allies, including Rhodes and Pergamum, command of the seas. Antiochus evacuated Thrace; and in winter 190–189 his army was defeated by the smaller but more disciplined Roman force at Magnesia-by-Sipylus (Magnesia ad Sipylum).

In 189 the Aetolians were given terms—the first recorded example of a treaty requiring the other party to "preserve the majesty of Rome." In Asia the new consul, Manlius Vulso, turned a nominally punitive expedition against the Galatians into a large-scale plundering of Asia Minor. The Peace of Apamea (188) fixed Antiochus' boundary at the Taurus Range and limited his fleet and armaments. Excluded from Asia Minor (except eastern Cilicia), his realm was thenceforth firmly centred in Syria. The program of liberation was necessarily compromised. Cities that had been free or had abandoned Antiochus before Magnesia remained free; the rest, along with large parts of Asia Minor (excluding Lycia, Caria, and the Maeander Valley, which went to Rhodes), were assigned to Eumenes II of Pergamum, the main beneficiary of the peace.

Roman conquest of Macedonia and Greece and the acquisition of Pergamum. Despite Philip's discontent with the outcome of the peace, his reorganization of Macedonia between 188 and his death in 179 (he built up the royal revenues by taxes, the encouragement of trade, and the exploitation of mines) was not necessarily with a view toward war on Rome, as some sources suggest. Constant complaints to Rome from the Greeks, especially in Pergamum and Thessaly, resulted in decisions invariably to Philip's disadvantage. He was obliged to relinquish Aenus and Maroneia in Thrace, which he had seized. From 184 onward, he campaigned and intrigued in Thrace, but his plan to raise the Bastarnians against the Dardanians fell through upon his death in 179. On succeeding, his son Perseus (ruled 179–168) revised Philip's policy and cultivated friendly relations with the Greek states and the amphictyonic council and made marriage alliances with the Seleucids and with Prusias of Bithynia. The Seleucid alliance was upset, however, in 176–175, when Perseus' enemy Eumenes sponsored Antiochus IV as Seleucus IV's successor (see above *Ptolemaic policy in the Aegean and Asia Minor*). In 172 Eumenes visited Rome and accused Perseus of hostility to Rome; the Romans resolved to eliminate Perseus, perhaps fearing a repetition of the situation of 201 because Antiochus IV was beginning to loom large in the Middle East. The Third Macedonian War (172–168) began in the winter of 172–171; in 171 a Roman force crossed over to Greece. For three years the Romans made little headway.

End of the Antigonid monarchy

Generally sympathy was with Perseus, and Epirus and the Illyrians under Genthius joined him; both Rhodes and Eumenes himself appear to have been compromised. In June 168, however, Lucius Aemilius Paullus defeated Perseus at Pydna; and the Antigonid monarchy came to an end.

Macedonia was divided into four separate tribute-paying (if nominally independent) republics with capitals at Amphipolis, Thessalonica, Pella, and Heraclea Lyncestis. Athens was rewarded for its loyalty by the gift of Lemnos, Imbros, Scyros, Delos, and Haliartus. But Epirus was savagely crushed, its population enslaved as an example to others.

Greece was disturbed and uneasy after this war. In Achaea from 189 onward there had been constant trouble with Sparta (brought into the league in 188) and Messenia (where a revolt was crushed in 184). Roman indecision and occasional malevolence heightened the general feeling of unease. After Perseus' defeat, pro-Roman politicians like Callicrates gained power, and 1,000 leading citizens were deported to Rome and kept there until 151–150; they included the historian Polybius. Despite this, internal problems continued to arise, and at each step the contenders appealed to Rome.

In Macedonia the new republics were popular only with the richer classes. In 149 a pretender, Andriscus, took the name of Philip and carried Macedonia before him. He destroyed one legion (148) but was defeated and sent to Rome by Metellus. Macedonia was then made a province, and its proconsul was given responsibility also for Illyria. About the same time general political and social discontent precipitated revolt in Achaea. Further trouble arose over Sparta; and Diaeus, a popular Achaean leader, adopted a truculent attitude toward Rome. In 147 Lucius Aurelius Orestes was sent out to Greece and demanded that Sparta and also Corinth, Argos, Orchomenus, and Heracleia-in-Trachis be made independent of the league. Further envoys found the Achaeans stubborn and bent on war with Sparta. In 146 a general conflict flared up, including Boeotia, Phocis, and Locris; but Metellus defeated the Achaean force in central Greece, and Lucius Mummius sacked Corinth as an act of deliberate punitive terrorism. The Achaean League was temporarily dissolved and, together with those states that had supported it, was put under the control of the proconsul of Macedonia. Rome had now firmly established itself in the Balkans, and Greek political freedom was at an end.

In Asia the war with Perseus had left Eumenes II under a cloud. The Galatians and Prusias II of Bithynia had exploited this fact by attacking him; but he was succeeded by Attalus II (ruled 159–138), his brother, who recovered the goodwill of Rome. Prusias was forced to desist from war in 156, and Pergamum grew in prosperity. Attalus III (ruled 138–133), a son of Eumenes II, succeded his uncle; and on his premature death for unknown reasons left his kingdom (apart from Pergamum itself and its territory) to the Roman people. Attalus III's death precipitated a civil war because Aristonicus, a bastard son of Eumenes II, claimed the throne. Pergamum and most of the cities supported Rome; Aristonicus, with some following among the Greco-Macedonian population, was mainly supported by the rustic and slave elements. He cancelled debts, freed slaves, and set up a centre called Heliopolis in Mysia, the significance of which has been much debated: he may have been trying to establish some kind of mystical utopia; at least it served as a means to rally supporters.

The disappearance of Pergamum

In 130 the rebels were defeated and Aristonicus was taken prisoner. In 129 Manius Aquilius and a commission settled the fate of the Pergamene territories. Many fringe lands in the interior were handed over to such other kingdoms as Pontus and Cappadocia. The Thracian Chersonese and Aegina were placed under the proconsul of Macedonia. But the heart of the kingdom—Mysia and the Troad, Lydia, southwest Phrygia, and perhaps parts of Caria—became the Roman province of Asia. The disappearance of Pergamum at the very moment that the Seleucid kingdom had just lost Mesopotamia to the Parthians under Mithradates I (who had taken Demetrius II prisoner in 140–139) marked a further stage in the disintegration of the Hellenistic world and the transformation of the Greeks from allies to Roman provincials.

Rome and Mithradates VI. The kingdom of Pontus had gained some prominence early in the 2nd century, when Pharnaces had attempted to expand but had been forced to surrender most of his gains in a peace underwritten by Rome (182–179). Mithradates V Euergetes (ruled *c.* 150–*c.* 120) was given part of Phrygia for helping the Romans against Aristonicus, but upon Mithradates' assassination the Romans revoked the gift—a source of bitterness to his successor, Mithradates VI Eupator (died 63 BC), who became effectively king of Pontus in 112. After gaining the realm of Bosporus, north of the Euxine, and expanding his territories eastward to Colchis and Trapezus, Mithradates VI agreed with Nicomedes III of Bithynia to attack Paphlagonia and Cappadocia. Rome intervened, compelled the evacuation of both countries, and placed Ariobarzanes on the Cappadocian throne (95). After being expelled and restored by Sulla (92), Ariobarzanes soon became a refugee at Rome along with Nicomedes IV of Bithynia, whom Mithradates then replaced with a puppet. A Roman commission restored both. Later, when the Romans provoked an invasion of Pontus, Mithradates decided on war (88). Asia was seething with hatred toward Rome because of its oppressive system of tax collection, both in the cities and the countryside. Mithradates was therefore welcomed everywhere. Three Roman armies were overthrown, and from Ephesus Mithradates organized a massacre of 80,000 Italians. His fleet crossed the Aegean to Athens, which had joined him; in Asia, only Rhodes resisted him.

The Roman general Sulla recovered Athens in 87–86, and, after two Roman victories at Chaeronea and Orchomenus, the war in Europe was over (86). A second Roman army, sent out by the supporters of Sulla's rival, Marius, was successful in Bithynia; and in 85 Sulla made an agreement of doubtful validity with the Pontic general Archelaus—the Peace of Dardanus, by which Mithradates surrendered all his gains since 88. Nicomedes and Ariobarzanes were restored, and collaborating cities in Asia were subjected; Rhodes was rewarded with additional territory. Effectively, this was the end of any freedom for the Greek cities of Asia.

Between 84 and 74 Mithradates was subject to some provocation from Roman officers; after Sulla's death the Romans broke off negotiations with him. They were increasingly concerned, however, with the problem of piracy in the Mediterranean; its centre in Cilicia Trachea was excluded from the province of Cilicia, which was set up in 80. Hostilities with Mithradates broke out again in 73, when he invaded Bithynia. Between 73 and 70 Lucius Lucullus defeated him, took over Pontus, and carried out a humane reorganization of Asia (thereby antagonizing financial circles at Rome). In 69–68 Lucullus advanced into Armenia, where Tigranes had given asylum to Mithradates; but his army refused to go farther, and by 67 Mithradates was back in Pontus, and Lucullus was without a command.

The arrival of Pompey

Intrigues at Rome had brought about the appointment of Gnaeus Pompeius (Pompey), first, to act against the pirates—which he did in 67—and then to take over the Mithradatic War with powers far greater than those of Lucullus. In 66 Pompey marched from Cilicia, where he had ended the piratical war, over Taurus to occupy Cappadocia; and by the end of the summer he held Pontus. Mithradates fled to Colchis and later to the Crimea, where he committed suicide in 63. Pompey meanwhile settled Asia Minor, now consisting of four Roman provinces—Asia, Cilicia, Bithynia, and Pontus—and a number of client princes, notably in Cappadocia, Galatia, and Paphlagonia. In 66–65 Tigranes submitted, and Armenia became a client state. After campaigning in the Caucasus, Pompey in 64 entered Syria, which was made a province; evidently the decision had already been taken at Rome. A last Seleucid, Antiochus XIII, briefly restored by Lucullus, was deposed and murdered by the Arab shaykh Sampsiceramus of Emesa.

In Judaea, where the high priesthood had developed royal characteristics and civil war over succession had been in progress since 76, Pompey gave his support to John Hyrcanus II and expelled his younger and more vigorous brother, Aristobulus; Judaea, however, became tributary, and Hyrcanus was styled ethnarch. Pompey's settlement in this region was on similar lines to that in Anatolia. Commagene took its place beside Armenia, Galatia, and Cappadocia as part of the cordon of client kingdoms between Roman territory and Parthia. Tarcondimotus of Kastabala in Amanus covered the communications between the provinces of Cilicia and Syria; and Judaea was a buffer to the south, with the Ituraean and Nabataean kingdoms flanking it.

This settlement—the first to be carried out by a Roman general without a senatorial commission—brought Pompey great prestige and a vast patronage, to which he was later to turn in his war with Caesar. It also marked the real end of the Hellenistic order. The contrast was thenceforth between a Mediterranean world, under Rome, and the Iranian East including Mesopotamia. The one exception was the still nominally independent kingdom of the Ptolemies in Egypt.

Roman annexation of Egypt. Upon the death of Ptolemy VIII (Euergetes II) in 116, the kingdom was divided between his three sons—Ptolemy IX Philometor (Soter II), who took Egypt; Ptolemy X Alexander, who took Cyprus; and a bastard, Ptolemy Apion, who took Cyrene. In 96 Apion died, leaving Cyrene to Rome (but it was made into a quaestorian province only in 74); and in 88 Ptolemy IX murdered Ptolemy X and reunited Egypt and Cyprus. During the Mithradatic War he pursued a cautious neutral policy, in view of the fact that Mithradates had gained possession of his two sons, who were in Cos when the Pontic king seized it. On the death of Ptolemy IX in 81, Sulla sent the son of Ptolemy X (who had escaped to Rome) to succeed him; as Ptolemy XI his reign was short (19 days) and important mainly for his will authorizing the Romans to annex Egypt and Cyprus when they wished.

Ptolemy IX's sons, however, soon appeared at Alexandria. The elder, Ptolemy XII—usually known as Auletes, the Fluteplayer—spent 20 years and vast sums of money in bribes to get his position sanctioned at Rome. Thenceforth the main importance of Egypt was as a factor in the internal political rivalries at Rome. In 64–63 Ptolemy sent an embassy to Pompey at Damascus; and at Rome Cicero prevented the passing of a land law that would have included the annexation of Egypt (in the interest of Crassus and the commercial class). At last in 59 Caesar was won over, and Ptolemy XII was recognized as king; Cyprus, however, was detached from Egypt and made into an independent province. In 58, a rising in Egypt caused the expulsion of Ptolemy, who was restored forcibly (for a large sum of money) by Aulus Gabinius, the governor of Syria, in 55. To achieve the restoration, Egypt was mulcted, its people were harassed, and many were murdered.

The succession of Cleopatra VII

On his death (51) Ptolemy Auletes left his kingdom to his children Ptolemy XIII (aged ten) and the famous Cleopatra VII (aged 17), as consorts. The ministers Pothinus and Achillas set the brother against his sister; and during her flight Pompey arrived in Egypt as a fugitive after his defeat at Pharsalus and was assassinated. Upon Caesar's arrival, Cleopatra returned to Alexandria and gained his support. In the ensuing civil war Caesar was hard pressed but eventually victorious, and Ptolemy XIII perished in 47. Cleopatra's sister Arsinoe later appeared in Caesar's triumph. Cleopatra, who was married to a second brother, Ptolemy XIV, went with him to Rome, where she remained until after Caesar's murder in 44. Some time later she replaced Ptolemy XIV as co-ruler with Ptolemy XV (Caesarion), allegedly her son by Caesar.

Within Egypt Cleopatra relied largely on the native element. She could speak Egyptian, an unusual accomplishment for a Ptolemy. It was also essential to have a strong friend at Rome. In 41 she was summoned to Tarsus by Mark Antony (Marcus Antonius), now in charge in the East; but the ensuing liaison was broken in 40 when Antony was reconciled to Octavian (later the emperor Augustus), whose sister Octavia he married.

Between 40 and 37 Roman armies in the East were fighting the Parthians, who had swept over Syria and Anatolia; in 38 the Romans drove them back to the Euphrates, and in 37 Herod, the son of the Idumaean king Antipater, expelled them from Judaea and established himself on the Judaean throne.

Antony resumed his liaison with Cleopatra, sending Octavia back to Italy; and in 37–36 at the so-called Donations of Alexandria, a last short-lived organization of the Hellenistic East took place. Asia and Bithynia remained provinces; but most of Asia Minor was assigned to the three augmented kingdoms of Pontus, Galatia, and Cappadocia (Cilicia Campestris was added to Syria, and the Lycian cities remained independent). Farther southward Nabataea and Judaea were client kingdoms, while Egypt was given southern Syria, Cyprus, and part of Cilicia Trachea. In 34 Cleopatra was designated queen of kings; Caesarion, king of kings; and the three children Cleopatra had borne to Antony were assigned satellite kingdoms—Armenia and lands beyond the Euphrates to Alexander Helios; the lands west of the Euphrates from the Hellespont to Phoenicia to Ptolemy Philadelphus; and Libya and Cyrenaica to Cleopatra Selene. These fanciful plans were all destroyed in 31, however, when Octavian defeated the Antonian and Egyptian fleets at Actium. By 30 Octavian was in Alexandria and the Ptolemaic monarchy dissolved. Egypt was thenceforth a province of Rome, enjoying very special relations with Octavian and his successors in the principate. The Hellenistic world had become part of the Roman Empire.

HELLENISTIC POLITICAL, SOCIAL, ECONOMIC, AND CULTURAL INSTITUTIONS

Hellenistic monarchy and royal administration. Hellenistic monarchy united features taken from Macedonian kingship, in which the god-descended king claimed the personal allegiance of his peers, and from the absolute monarchies of Persia and Egypt. It built up a set of fairly homogeneous institutions, which varied slightly from state to state. The outward marks of Hellenistic monarchy common to all the kingdoms included dynastic rule, often with co-regency to ensure the succession; a divine pedigree; the use of the royal diadem, purple robes, and seal; the king's portrait on the coinage; and reckoning by years of the reigns. Dynastic intermarriage was normal and polygamy not unknown, but only in Egypt was brother–sister marriage usual. The wives of the kings frequently exercised great and independent power.

In the new realms (excluding Macedonia) the king was the state and his powers were absolute. His claim to this position rested on conquest of the land and his capacity to rule. But his position was reinforced by the adoption of ruler cult, an institution with mixed origins. To the native population of Egypt the pharaoh was always a god; but the official cults were something different and more Greek. In 324 Alexander had demanded worship from the Greek cities. The main step, however, was taken by Ptolemy II, who in 283 consecrated the dead Ptolemy I as the "saviour god," adding his wife to the cult on her death. In 270 he consecrated his own late wife Arsinoe II as the "brother-loving goddess," and he later set up a joint cult of himself and Arsinoe as the *theoi adelphoi* ("brother and sister gods"). His successors added themselves to this growing cult embracing all the Ptolemies; Alexander was set at the head, and Ptolemy IV incorporated Ptolemy I and his wife (the saviour gods) in the sequence. Royal cult was introduced into the Seleucid kingdom, probably by Antiochus I; and all the other kingdoms quickly followed suit. The Greek cities also instituted cults, separate from those of the states in which they were situated.

Mixed origins of the ruler cult

The precise meaning of such cults is unclear. God-kings were the object of vows but not of prayer. Yet the view that deification was designed to give the king a footing in the Greek cities is not supported by evidence. There was

a strong political element, a means of uniting often very disparate areas and people in a common loyalty; the Greeks had always been familiar with gods who had mortal parents (like Apollo or Dionysus) or who had actually been mortal (like Asclepius or Heracles), and they were ready to equate achievement and service to mankind with godhead. The institution was later to be taken over by the Roman emperors.

The courts and administration of the various kingdoms shared certain features. The king had a council of friends (later elaborately subdivided into various grades) with advisory duties; these and the "kinsmen" were of Achaemenid origin. As the fount of law, the king possessed a secretariat to draft the decrees and letters in which law was formulated; and there was a secretary who wrote the official journal. From these functions a chancery developed with its own protocol and language sufficiently distinctive to influence the style of contemporary writers.

Other institutions common to most of the kingdoms were the guard (*agēma*), the corps of royal pages, and the bodyguards (*sōmatophylakes*), all inherited from Alexander. Normally there would be a finance minister (*dioekētēs*)—like Apollonius under Ptolemy II—and sometimes (perhaps only for an emergency) there might be a minister of affairs. The various districts within the boundaries of the state were usually governed by generals (*stratēgoi*) with military powers, responsible directly to the king (though the Antigonids used them rarely in Greece and not at all in Macedonia and Thessaly); in the Seleucid kingdom, down to the reign of Antiochus III, satraps were found, except in Asia Minor. There were admirals (navarchs) to control naval forces and, often, city governors (*epistatai*).

The army-assembly tradition

The traditional army assembly continued to be a factor in Macedonia, and some of its rights—the acclaiming of a new king, the appointing of a regent when the king was a minor, the approbation of the king's will and testament, and the judging of those charged with high treason—were sporadically exercised under the immediate successors of Alexander. Occasional political acts of the Seleucid and Ptolemaic armies in Antioch or Alexandria may be based on this Macedonian tradition, though often they seem to have acted more like a praetorian guard. Those armies ceased to contain any genuine Macedonian elements, except, of course, in Macedonia itself. In general, the administrative machinery was over centralized, and, in consequence, far too much had to be done (or was left undone) by the king in person. Especially in Ptolemaic Egypt, the king faced an overwhelming volume of paperwork as petitions and references travelled up and decisions travelled down the chain of control.

The old and new Greek cities. Though really independent *poleis* were rare, the Greek city played a fundamental part in all the Hellenistic monarchies except perhaps Egypt. It was pre-eminently through the cities that Hellenism was maintained. King and city were interdependent, but their relationship was ill defined and rested ultimately on a basis of power. Although the machinery of an independent state was usually maintained through its council, assembly, and magistrates, royal domination was frequently assured by a king's party, by uniting several towns or villages into a single community to create virtually new cities out of old, and by the presence of royal governors and garrisons. The king's attitude toward the cities was based mainly on expediency, and the slogan of "liberation" was cynically exploited.

Ultimately only a city such as Rhodes, capable of military resistance, could be truly independent; for the rest, freedom from taxation was the nearest approach to liberty within their grasp. Many of the cities of Greece proper and the Aegean maintained a theoretical independence, which in practice was diminished by the presence of Macedonian garrisons at key points and, in some periods, by local tyrants in Macedonian pay. The development of leagues and other federal bodies compensated for this weakness (see above *The Greek leagues and the Antigonids in the 3rd century BC*) unless, as frequently, such bodies were themselves the instrument of a king (*e.g.*, the Islanders' League or the Hellenic Alliance of Antigonus Doson). Because Macedonian domination was always resented, the "liberation" of Greece by Flamininus in 197 was greeted with joy.

Under such restrictions men turned from politics to social and private life; clubs became more important than the state, and the main magistrates came to be those concerned with the food supply and the gymnasiums. The reduction in the number of small wars was a positive gain, an advantage that was increased by the kings' role in assigning foreign judges or making grants of asylum to shrines or even cities.

New Asian cities

The new cities in the kingdoms of Asia differed from the old city-states. Though often Macedonian military settlements in origin, they became centres of Hellenism, even if the racial basis of citizenship was less rigorously enforced. They were usually built on the gridiron pattern, and their population was divided in the old Greek way into tribes. As already mentioned, these cities played an important role in Seleucid Asia; in Egypt, they were rare and scarcely essential to the Ptolemaic pattern of government (apart from Alexandria, which was hardly a normal Greek city). The Attalids emulated the Ptolemies in maintaining a strict control of the cities within their dominions. But nowhere did the Greek cities have any say in policy; their function was to radiate Hellenism and to provide manpower reservoirs from which the kings could draw their administrators.

Hellenizing of non-Greek lands. Alexander's campaigns had initiated a period of Greek colonization comparable to the early migrations and to the movement of the 8th to 6th centuries; during the late 4th century thousands found new homes in Asia or Egypt, the more easily because the new political order facilitated movement. With them they took their political institutions, their language, and their way of life. Throughout the new monarchies Greek was the language of the army and the bureaucracy. In its Hellenistic form (the Koine) Greek became a world language, spoken from Spain to Afghanistan. Other Hellenizing institutions were Attic law, which was widely adopted in forms modified to suit local traditions, and especially Greek education. To have passed through the gymnasium—usually a private institution, though occasionally aided by royal endowment—was to have entered the gateway to Hellenism and material success. Out of the old military training (the *ephēbeia*) had also grown a new physical and intellectual regime designed to inculcate Greek values and produce Greek gentlemen and bureaucrats capable of serving in the administration.

For a century the Greeks, constantly reinforced from the homeland, remained exclusive in their culture. Then gradually upper class Asians became accepted and, when properly Hellenized, would live like Greeks and take Greek names. The values of the gymnasium were reinforced by the performances in the Greek theatre, which was to be found as far away as Babylon by the mid-2nd century. The guilds of travelling actors, on the fringe of upper class life—the *technitai* of Dionysus—found a new field of activity in the monarchies and travelled widely throughout the expanded Greek world. Greek, too, were the many private social clubs on which so much of men's interests now centred and that served as an avenue into society for foreigners arriving in a new city.

Class structure in Greece and eastward

For a few the new kingdoms brought great wealth. The higher officials in the army, the navy, or the court were well-off, indeed. In the cities of mainland Greece and the Aegean islands, wealthy landowners, shipowners, and owners of workshops employing slave labour were still important; but farther eastward the upper layers of society were filled rather by the professionals employed by the kings to run the state. Professionalism was strengthened in many fields, such as warfare, by the availability of technical treatises. As a result, it took the place of the amateurish organization of the city-state, as befitted an age that fostered the systematic recording of knowledge and experience. Both the upper class and those immediately beneath were Greek or Hellenized natives who made a substantial livelihood as settlers, merchants, craftsmen, and soldiers, or practiced the profession of

architect, engineer, doctor, or teacher. These people formed the active middle class in the new Greek cities, and social and economic life in the new lands rested largely upon that class.

At the bottom were the labouring classes—usually made up of the native population, whose status varied from place to place; they could include freemen, serfs, and slaves. They were mainly non-Greek (though mixed populations were found, especially in Syria and Egypt), and their status depended on the tradition of the various lands. In general, however, they were poor and oppressed, though there was no racial or nationalistic policy directed against them. Their hostility and, in Egypt, their frequent resort to flight were reactions to the hardship inherent in their situation. Slavery was not especially significant, except in Greece proper; there were domestic and temple slaves. Serfdom was far more widespread in both Seleucid Asia and Ptolemaic Egypt. In a society where all were the king's subjects, this lack of personal freedom was not, however, greatly important.

Economic life. Until the campaigns of Sulla in 87–86, the upper classes in Greece enjoyed considerable economic prosperity; not all areas, however, shared equally in this. Athens fell behind its earlier standards of wealth until it recovered in the late 2nd century; and Sparta was rent with social struggles. Northern Greece prospered, especially Aetolia and Ambracia and the port of Pagasae under Macedonian control; and evidence points to expanded trade and a high standard of living in the cities of Asia Minor, where riches were far greater than anything recorded from Greece proper. This prosperity is reflected in the amount of tribute raised by Rhodes from its mainland possessions, in the size of gifts or dowries or subscriptions to clubs in a variety of cities, and not least in the amount of plunder eventually seized by the Romans. Evidence from Corinth and Messenia shows mainland Greece also sharing in this prosperity, though to a lesser degree. A progressive fall in interest rates in the early 3rd century may be a partial indication that money was plentiful. But while their upper classes were rich, the cities themselves were often poor and living from hand to mouth. Most needs were met by raising loans (which were often tardily repaid), and public works frequently languished. A property tax was rare; cities preferred to raise funds by indirect taxes on imports and exports, pasturing fees, harbour dues, and the like.

Conditions were less good for the little man and the artisan. For the free worker available figures suggest hard times in the 3rd century, as money depreciated in value, and wages failed to keep abreast of rising prices for food and housing. The gap that thus grew between rich and poor created unhealthy tensions; and many cities tried to ease conditions for the indigent by distributing free grain. Although strikes were virtually unknown, revolutionary risings occurred in several cities. The call for debt cancellation and land redistribution was sometimes reinforced with demands for the liberation of slaves (to serve as troops in the revolution). Such a pattern is most clearly evident at Sparta under Agis and Cleomenes and later Nabis, as well as elsewhere, including Achaea around 150–146.

Conditions within the Hellenistic kingdoms

Within the Hellenistic kingdoms conditions were different. Those regimes were organized as largely closed economies with a high degree of governmental control. Especially the Ptolemies, themselves active in commerce, operated a strictly centralized economy outside the operation of the market; thus, ultimately, against the heavy burden imposed by the bureaucracy, the only remedy open to the peasantry was flight. The other monarchies, if to a lesser extent, also employed a similar system. In Asia much of the wealth released by Alexander's campaigns together with other capital went to promote trade farther eastward until the initial impulse died down after about 250. In Egypt in the 2nd century, inflation was widespread and contributed to a growing inefficiency in the bureaucratic machinery. The centralized controls within the monarchies allowed agriculture to benefit from some improved techniques, more intensive exploitation of the land (which was sometimes added to by draining, as in the Fayyūm in Egypt), and the introduction of new plants and crops together with a few new domesticated animals. Large estates, devoted to the enrichment of a minority, also afforded opportunities for experiment and more scientific farming. Though a few large slave-manned establishments were found in such cities as Pergamum and Alexandria, industry remained (as in the Greek cities) on a small scale; as in agriculture, the main advantages went to the government through heavy taxation or through the licensing of monopolies for the production of such commodities as salt, oil, papyrus, and grain. Trade was burdened with heavy customs dues, and foreign trade tended to be largely in luxury goods and slaves. Production for the market was rare.

The declining economic life of the Hellenistic world suffered heavily from the ravaging that accompanied the Roman conquest. From 150 onward, the growth of piracy and slave dealing further disrupted economic life, and recovery had to await the Augustan peace and the incorporation of Egypt, Asia Minor, and Syria into the Roman Empire.

Hellenistic culture. The Hellenistic world was culturally one: extending from the western Mediterranean to Central Asia, it was linked by the use of the Koine form of Greek and by new facilities for travel. A lively atmosphere of curiosity prevailed, and a large public, even though not highly educated, turned eagerly to popularized knowledge and to a wide range of reading, often of indifferent merit. Ideas circulated, and among the cultural minority controversy stimulated research. There was cross-fertilization between the various philosophical schools; and in the arts masters created their own following, often associated with particular cities. The barriers of the *polis* had broken down and with them the old division between Greek and barbarian. In the ferment of such centres as Antioch, Pergamum, and Alexandria, the East made its contribution no less than did the old Greek cities such as Athens.

A great role was played by royal patronage. The library and museum at Alexandria fostered literature and scholarship: the systematization of all kinds of knowledge, already pursued enthusiastically within the school of Aristotle, was there developed into a science. Modern texts still owe much, both for good and bad, to the Alexandrine philologists, whose prototype is perhaps the famous Didymus (*c.* 83–10 BC), author of 3,500 books. A vast literature grew up in all the main areas of the Hellenistic world; almost all of it is lost, but some of the New Comedy plays of Menander (*c.* 342–*c.* 292 BC) are among the works that have been recovered on papyri from the sands of Egypt. Writers showed a growing interest in personality, reflected in such works as Theophrastus' *Characters* (*c.* 300 BC) and a host of biographies, which culminated in the *Lives* of Plutarch in the 1st century AD. The end of political independence led to a diminution of political oratory but not rhetorical studies. The sensational and dramatic aspects of the historiography of the 3rd century came under heavy criticism in the next century by Polybius, the historian of Rome's rise to world power. New genres appeared, such as literary and cultural history and art history; chronology was scientifically studied, and Polemon of Ilium (2nd century BC) made use of inscriptions. The widening of frontiers brought with it a growing interest in geography, both descriptive and scientific; here the works of Eratosthenes (*c.* 276–*c.* 194 BC), Pytheas (*c.* 300 BC), and Polybius (*c.* 200–118 BC) were to lead on through Poseidonius (*c.* 135–*c.* 51 BC) to the work in Augustan times of Strabo. Vast works of compilation and encyclopaedias were balanced at the other end of the scale by romantic novels and scurrilous works of scandal.

Literature and scholarship

In the visual arts there was a similar variety. A general restlessness encouraged change and the exploration of new concepts. Sculpture lost its formal composure and became tortured or realistically down-to-earth, portraying the individual rather than some idealized type. Romantic themes occur, and there is an interest in children. Famous schools grew up at Rhodes that were lively and

technically very competent; of Chares' "Colossus," unfortunately, no clear account survives. The school of Pergamum, deriving largely from Scopas (4th century BC), is famous for such violent and emotional pieces as "The Dying Gaul" and above all the great frieze on the altar of Zeus depicting the battles of the gods and titans, the symbol of a world in struggle. Of painting only the faintest idea can be gained from such sources as the gravestones of Pagasae, the mummy cases of the Fayyūm, and a remarkable mosaic representing Alexander and Darius, probably at Gaugamela. Hellenistic painting was clearly an important art form, which was to be influential (along with sculpture) in fertilizing the arts of the East during imperial times.

Oriental traits in religion

Reactions to the new world after Alexander are reflected especially in the growth of Oriental traits in religion. The Olympians, associated closely with the old city-states, had ceased to mean anything to ordinary people; and attempts to revive their cults, especially in the later 2nd century, proved ineffective. The Greeks, as they travelled and settled, sometimes brought their own gods along but often adopted those of the native people. Worship became more personal and linked with club life rather than the city. The combining of beliefs was widespread: there was felt to be one god, no matter how many names he bore.

The multitude of gods in Syria had a wide following, especially Atargatis (who was associated with Artemis); many were personalized cult objects, stones, or meteorites. Above all, men worshipped the great Anatolian nature goddess in her many guises. Of the older gods Dionysus was the most popular; and he was sometimes identified with Sarapis, the great creation of Alexandria, intended to link Greeks and Egyptians, who, however, rejected it. Isis, Sarapis, and Anubis formed a triad, worshipped outside and inside Egypt; Isis especially had perhaps the most widespread and far-reaching cult in the Hellenistic world and was later to influence Christianity through the figure of the Virgin Mary. But mystery religions that offered personal salvation flourished everywhere, as did magic, the shortcut to the achievement of one's immediate and often trivial desires.

Philosophy appealed to a different level of the population. Athens remained a great centre and gave hospitality not only to its own Academy (the school of Plato) but also to the Peripatetics (Aristotle's school) and later to Epicurus (341–270 BC) of Lampsacus and Zeno (*c.* 335–263 BC) of Citium, founders of the two most important Hellenistic schools—the Epicureans and the Stoics. After the work of Theophrastus and Strato, the Peripatos had lost its momentum and counted for little by 250; and the Academy under Arcesilaus took over much of the teaching of the Skeptics, who advocated the suspension of judgment, so that it became largely identified with the criticism of Stoicism.

Both Epicurus and Zeno were concerned with personal conduct rather than with abstract truth—with the individual rather than the nature of the outside world. They showed small interest in politics or indeed in the learning and science of their age. Both set out to equip men to deal with the blows dealt by fortune in an age of violent change—Epicurus by a doctrine of quietism and happiness, resting on virtue in a universe where the random movement of atoms was the ultimate causative force and the gods were remote and aloof; and Zeno by preaching the overriding force of universal law, the power of destiny, that man's greatest goal was to become the Stoic "wise man," and to live "according to nature." Of these, Stoicism was to live on, modified by Panaetius (*c.* 180–109 BC), into the Roman Empire.

Scientific development

At the other end of the spectrum, the age was one of scientific development and of progress in the arts that impinge on the sciences. Systematic work in botany, zoology, geography, ethnography, and hydrography was pursued in the Peripatos. The description of animals was furthered by the availability of zoos in such cities as Alexandria; and Theophrastus wrote a *History of Plants;* both zoology and botany were handicapped, however, by the lack of any scientific classification. Long controversy raged between supporters of the heliocentric and geocentric theories of the universe: the incorrect but more convincingly argued Earth-centred theory of Hipparchus (fl. between 146 and 127 BC) of Nicaea carried the day against the Sun-centred theory of Aristarchus (*c.* 270 BC) of Samos, and it was to persist until the Renaissance. Much headway was made toward creating a world map, despite the inability to solve the problem of detecting longitude. Eratosthenes, however, succeeded brilliantly in estimating the size of the Earth's circumference. Mathematics was developed by Eratosthenes and by Archimedes (*c.* 287–212 BC), who worked out the value of π and who also made a reputation (which he despised) as a practical mechanic, with such inventions as the screw for raising water. On the whole, although progress was made in siege engines, water clocks, eventually a water mill, a water organ, and the diopter (an improved form of water level), the Hellenistic world tended to agree with Archimedes in rating these activities below pure speculation. Some fields were thereby seriously handicapped—*e.g.*, physics and chemistry, which languished for want of optical glass. But progress was made in medicine, with increased knowledge of the nerves and arteries (though no one managed to detect and describe the circulation of the blood).

In one field, however, progress was linked up closely with the practical application of knowledge. The new cities gave wide scope for architects and engineers. The gridiron pattern originated by Hippodamus of Miletus (5th century BC) was everywhere reproduced (with appropriate concessions to the contours of the natural site); and the temples, marketplaces, and wide streets of Priene, Pergamum, or Miletus can still be reconstructed. Fortifications were devised to counter the increasingly effective artillery of the age; and many cities installed impressive water and sewerage systems, thus providing agreeable living conditions for large populations.

Commerce, travel, and exploration. Alexander's campaigns had widened the horizon of the Greek world, and his successors carried exploration further. Ptolemy II, in search of ivory and elephants, opened up the Red Sea along the Trogodyte coast and explored the Arabian coast (about 280); and the later Ptolemies pushed the boundaries of Egypt up the Nile to beyond Wadi Halfa and explored the African coast down to Somaliland. The Seleucids were active in the region of the Caspian, and farther eastward the Bactrian kings colonized Fergana and made contact with Chinese Turkistan. In the West, Pytheas of Massilia, probably a contemporary of Alexander, circumnavigated Britain and reached Norway or Jutland, but he met with widespread disbelief, among others from Polybius, who himself made a voyage in the Atlantic (146).

Trade by land and sea with India

Such journeys were undertaken partly in the interest of trade, and trade fostered knowledge of the outer regions. The Seleucids were interested in the route to India—by sea up the Persian Gulf to Seleucia, where it was joined by caravans coming overland from the Punjab through Taxila, Bactra, Hecatompylos, and Ecbatana; thence several ways led down to the coast, that by Antioch going forward along the old Royal Road through Tarsus to Ephesus. The Ptolemies encouraged the development of the route around southern Arabia, especially after Ptolemy V had lost Coele Syria; and toward the end of the 2nd century the collapse of the power of the Sabaeans in the Yemen opened up the way beyond. Eudoxus of Cyzicus was probably the first European to sail direct to India and back along the coast (*c.* 130 BC). Farther northward the Nabataeans at Petra built up a strong power by controlling the desert routes and sea trade in the Gulf of Aqaba.

Within the Hellenistic world itself, trading was active. Grain from Egypt, Cyrenaica, and the Crimea (and later Numidia) came to the larger cities of Greece and Ionia, largely through depots at Rhodes and Delos. North Syrian and Ionian (and island) wine went everywhere. Textiles were produced in most areas that reared sheep, and silk from wild silkworms was a valued luxury; by the first century Chinese silk may have been reaching

Egypt. There was an adequate supply of metals—iron in many parts, gold from new Nubian mines, silver from Asia Minor and Spain, quicksilver from Cappadocia. Many places had their specialties—Attic oil and honey, Bithynian cheese, salt fish from Byzantium, fruits and nuts from Pontus, and dried fruit from the Levant. Papyrus from Egypt vied with parchment from Pergamum. Glass, pitch, marble, bitumen, timber, granite, purple dye, and ivory were all well-attested articles of trade. But above all, it was the slave trade, centring in Delos from about 160 onward, that brought riches and misery as it grew along with Roman imperial expansion and the prevalence of piracy. (Delos, however, never recovered from the massacre carried out by Mithradates VI in 87.) Especially prized were the gems, spices, and frankincense from the East—from India and Arabia as well as from Palestine. For these Rhodes and Alexandria were important distribution centres.

Commerce contributed to the ferment of ideas as well as to the exchange of commodities and played a large part in the knitting of the Hellenistic world into a cultural whole. In general, this was a time when travel was not unusual. Among the many who travelled about the world were soldiers, especially mercenaries, professional men (teachers, philosophers, doctors, architects, and engineers) in search of patronage, actors, official envoys from kings and cities, some members of the royal courts and bureaucracies, and, not least, uprooted men (exiles, brigands, and pirates). But the majority, as always, stayed at home.

MACEDONIA AND GREECE UNDER ROMAN RULE (TO C. AD 395)

Social distress and slave uprisings

After 146 BC the decline of Greece continued. Social distress was accentuated by economic exploitation at the hands of the rich, both native and Italian. Athens was an exception, so long as it held the thriving port of Delos, but there were slave uprisings in Attica in 134–133 and 104–103, and in 115 Dyme was rent with class conflict. Sulla's campaign against Athens during the Mithradatic War brought widespread ruin, and during the 1st century BC the western coast of Asia Minor became the real centre of a Greek culture that continued to flourish despite political disasters. The civil wars between Caesar and Pompey and later those against Caesar's murderers and between Antony and Octavian bore hard on Greece: the battles of Pharsalus (48), Philippi (42), and Actium (31) were all fought on or around Greek soil. But under the early empire, Nicopolis, Patras, and Corinth (refounded as a veteran colony) became flourishing centres of new life. Athens was in decline; but Sparta, under its tyrant Eurycles during the Roman civil wars, revived some semblance of its old Lycurgan regime, if mainly for the tourist trade. Delphi was impoverished, and the amphictyonic council counted for little until its revival under the emperor Hadrian (ruled AD 117–138). From 27 BC onward, southern Epirus, the Ionian islands, and the Cyclades were joined with Greece proper to form the senatorial province of Achaea under a proconsul of praetorian rank resident at Corinth and without a garrison.

On November 28, AD 67, Nero aroused wild enthusiasm by liberating Greece and freeing it from all tribute. The Peloponnese was renamed the Neronese, and Nero himself was worshipped as Zeus Eleutherios (Liberator). Nero's successors, the Flavian emperors, however, quickly reversed this gesture and restored taxation to the province. Prosperity revived to some extent under the emperors Trajan (ruled AD 98–117) and Hadrian, for although the upper class in Macedonia was somewhat mulcted to produce supplies for Trajan's wars in Dacia and Parthia, Greece generally benefitted from these conflicts and also from Hadrian's favour and enthusiasm for building. Athens received a whole new suburb, new buildings, and Panhellenic games were instituted; a new Athenian era was dated from the first of Hadrian's three visits in AD 124. The high-water mark of the revival of Athenian prosperity came under the Antonine emperors.

In the second half of the 2nd century AD the shadows lengthened. A plague brought back from the East by Lucius Verus' armies decimated Greece, and the barbarian Costoboci burnt Eleusis. Under Commodus and the Severi in the late 2nd and early 3rd centuries, tension between rich and poor grew greater and the institution of the *dekaprōtoi*, responsible for extracting taxes from an increasingly impoverished upper class, brought a final end to all pretense of free city institutions. In 251 the death of the emperor Decius opened the gates to barbarian invasion; in 267 the Heruli penetrated the Peloponnese and ravaged Corinth, Sparta, and Argos, until, after taking Athens, they were defeated by the historian Dexippus and a force of 2,000 men. Despite these disasters Athens saw some sort of revival coinciding with the teaching of Plotinus (*c.* 205–269/270) and the reign of Gallienus (ruled 260–268). Diocletian's reign (284–305) strengthened the central bureaucracy. Achaea and Macedonia, which now formed part of the diocese of the Moesiae, both decayed further. When the last Olympic festival was held in 393, few Greeks any longer took part. The whole peninsula had long been a backwater of small villages and large estates. (F.W.W.)

BIBLIOGRAPHY

Greek civilization from c. 1200 to 500 BC: ANTONY ANDREWES, *The Greeks* (1967), presents the historian's view; C.M. BOWRA, *The Greek Experience* (1957), approaches the Greeks through their literature. N.G.L. HAMMOND, *A History of Greece to 322 B.C.*, 2nd ed. (1967), gives a full account and is mainly devoted to political history. See also *The Cambridge Ancient History*, vol. 3–7 (1925–28), and some relevant chapters in the new edition of vol. 2, which is appearing in fascicles (1970–). MICHAEL GRANT (ed.), *The Birth of Western Civilisation: Greece and Rome* (1964), contains essays by different scholars on Greek history, art, and thought (fully illustrated). (*Geography of the Greek homeland*): MAX CARY, *Geographic Background of Greek and Roman History* (1949), is a useful treatment; and J.L. MYRES, *Geographical History in Greek Lands* (1953), contains essays including studies of geography and colonization. (*Sources for the study of Greek civilization*): MICHAEL GRANT, *The Ancient Historians* (1969), is of much value. P.L. MACKENDRICK, *The Greek Stones Speak* (1962), contains a survey by periods and sites of archaeological discoveries in Greece. The principal ancient historical sources, all available in translation, are HERODOTUS (Archaic period), THUCYDIDES (Peloponnesian War), DIODORUS (5th–4th century), ARRIAN (Alexander), XENOPHON (4th century and the East), PAUSANIAS (description of Greece), and PLUTARCH (biographies). (*The Early Archaic period*): V.R.d'A. DESBOROUGH, *The Last Mycenaeans and Their Successors* (1964) and *Protogeometric Pottery* (1952), contain detailed studies of the full range of archaeological evidence. J.N. COLDSTREAM, *Greek Geometric Pottery* (1968), includes a survey of the archaeological evidence for the history of the period. A.M. SNODGRASS, *The Dark Age of Greece* (1971), provides a full archaeological synthesis of the evidence. C.G. STARR, *The Origins of Greek Civilization, 1100–650 BC* (1961), gives a historian's view of the period. M.I. FINLEY, *The World of Odysseus*, rev. ed. (1962), projects Homer's world into the Dark Ages. (*The Greek colonizing movement*): JOHN BOARDMAN, *The Greeks Overseas* (1974), provides a survey of the archaeology of colonizing and trading posts. T.J. DUNBABIN, *The Greeks and Their Eastern Neighbours* (1957), contains lectures on relations and trade with the East. M.M. AUSTIN, *Greece and Egypt in the Archaic Age* (1970), is a short but detailed study of mercenaries and trade in Egypt. T.J. DUNBABIN, *The Western Greeks* (1948), gives a full survey of all sources for south Italy and Sicily. (*Archaic Greek culture*): G.M.A. RICHTER, *Archaic Greek Art Against Its Historical Background* (1949), is a survey by regions and periods; and JOHN BOARDMAN, *Pre-Classical: Style and Civilization* (1967), a brief study of art and society in the Archaic period. A.R. BURN, *The Lyric Age of Greece* (1960), is a good study of all sources with accounts of literature, art, and thought, as well as political and social history. See also W.K.C. GUTHRIE, *A History of Greek Philosophy*, vol. 1, *The Earlier Presocratics and the Pythagoreans* (1962); G.E.R. LLOYD, *Early Greek Science: Thales to Aristotle* (1970); and KARL SCHEFOLD, *Frühgriechische Sagenbilder* (1964; Eng. trans., *Myth and Legend in Early Greek Art*, 1966).

Development of the Greek poleis from c. 750 to c. 500 BC: HERODOTUS' *History* is the most valuable source for the period. ARISTOTLE's *Constitution of the Athenians* is useful, especially on Solon and Cleisthenes. PLUTARCH's lives of Lycurgus, Theseus, and Solon preserve some valuable facts. Fragments of the poems of Tyrtaeus and Solon with translations

are accessible in J.M. EDMONDS, *Elegy and Iambus*, vol. 1 ("Loeb Classical Library," 1931). Twentieth-century scholarship begins with K.J. BELOCH, *Griechische Geschichte*, 2nd ed., 4 vol. in 8 (1912–27); the first volume deals with the period before the Persian Wars. J.B. BURY, *A History of Greece*, 3rd ed. rev. by RUSSELL MEIGGS (1951), has still to be surpassed as a one-volume survey. ANTONY ANDREWES, *The Greeks* (1967), offers a good account, more descriptive than narrative. W.G. FORREST, *The Emergence of Greek Democracy, 800–400 B.C.* (1966), provides a brief and thoughtful introduction. *The Cambridge Ancient History*, vol. 3–4 (1929–39), though old, is still useful, especially on interstate relations. (*Tyranny and hoplite tactics*): ANTONY ANDREWES, *The Greek Tyrants* (1956), collects together plentiful information. H.T. WADE-GERY, "The Growth of the Dorian States," ch. 22 of *The Cambridge Ancient History*, vol. 3, presents admirably one theory of tyranny. A.M. SNODGRASS, "The Hoplite Reform and History," *Journal of Hellenic Studies*, 85:110–122 (1965), supersedes previous work on the beginnings of hoplite tactics. The same author's *Arms and Armour of the Greeks* (1967) gives a more discursive account of hoplite tactics. (*Sparta*): H.T. WADE-GERY, "The Spartan Rhetra in Plutarch, *Lycurgus VI*," *Classical Quarterly*, 37:62–72 (1943) and 38:1–9, 115–126 (1944), reprinted in *Essays in Greek History* (1958), is a good starting point for the study of early Sparta. ANTONY ANDREWES, *Probouleusis, Sparta's Contribution to the Technique of Government* (1954), offers a theory of conflict between an aristocracy and a wider class. G.L. HUXLEY, *Early Sparta* (1962), is provocative. W.G. FORREST, *A History of Sparta 950–192 BC* (1968), is a brief survey. ANTONY ANDREWES, "The Government of Classical Sparta," in E. BADIAN (ed.), *Ancient Society and Institutions: Studies Presented to Victor Ehrenberg on His 75th Birthday* (1966), makes important points. (*Athens*): CHARLES HIGNETT, *A History of the Athenian Constitution to the End of the Fifth Century B.C.* (1952), offers a view on most issues. H.T. WADE-GERY, *Essays in Greek History* (1958), includes several articles on constitutional questions. B.L. BAILEY, "The Export of Attic Black-Figure Ware," *Journal of Hellenic Studies*, 60:60–70 (1940), has fundamental importance for the economic history of Archaic Athens. ALFRED FRENCH, *The Growth of the Athenian Economy* (1964), is a good treatment of a difficult subject. Two valuable studies of the sources for Athenian constitutional history are: FELIX JACOBY, *Atthis, the Local Chronicles of Ancient Athens* (1949); and JAMES H. DAY and MORTIMER CHAMBERS, *Aristotle's History of Athenian Democracy* (1962). Two specialized studies have brought considerable advance in understanding Dracon and Solon: EBERHARD RUSCHENBUSCH, "Φονος zum Recht Drakons und seiner Bedeutung für das Werden des athenischen Staates," *Historia*, 9: 129–154 (1960) and Σολωνος νομοι: *Die Fragmente des solonischen Gesetzeswerkes* (1966).

The Greek world from c. 500 to 404 BC: The main sources for the period are HERODOTUS (trans. by G. RAWLINSON, introd. by F.R.B. GODOLPHIN, 1942) and THUCYDIDES (trans. by R. CRAWLEY, introd. by J.H. FINLEY, 1950). Herodotus records in detail the Persian invasion of Greece (Books VII–IX), with a long introduction on the events that led up to it. He had to rely largely on oral tradition and prejudiced sources and is unreliable on strategy and tactics, but his narrative is vivid, colourful, and very readable. Thucydides, writing a generation later, is a more mature and critical historian. His theme is the Peloponnesian War, with a brief introduction on the period between the two great wars. His main interests are the nature of power and the reaction of people to events, but he attached great importance to accuracy in the detail of his narrative. These literary sources are supplemented by inscriptions recording decrees, dedications, financial accounts, and casualty lists, especially from Athens; texts of the most significant, with commentary by RUSSELL MEIGGS and DAVID LEWIS, are in *A Selection of Greek Historical Inscriptions to the End of the Fifth Century B.C.* (1969). PLUTARCH, writing some 500 years later, in his lives of Aristides, Themistocles, Cimon, Pericles, Nicias, Alcibiades, and Lysander (*Plutarch's Lives*, trans. by JOHN DRYDEN), preserves important material from earlier sources that are lost, though he is primarily interested in the characters of his heroes and is reluctant to dismiss a good story. There are two good recent studies of Xerxes' invasion: A.R. BURN, *Persia and the Greeks* (1962); and CHARLES HIGNETT, *Xerxes' Invasion of Greece* (1963). DONALD KAGAN, *The Outbreak of the Peloponnesian War* (1969), discusses the policies that led up to the war, which are differently interpreted by G.E.M. DE ST. CROIX, *The Origins of the Peloponnesian War* (1972). RUSSELL MEIGGS, *The Athenian Empire* (1972), analyzes the evidence for the growth and character of the Athenian Empire. Of general histories of Greece, GEORGE GROTE, *History of Greece*, new ed. (1888, reprinted 1971), is still worth reading; N.G.L. HAMMOND, *A History of Greece to 322 B.C.*, 2nd ed. (1967), is detailed and up-to-date, but compressed; VICTOR EHRENBERG, *From Solon to Socrates* (1967), is also comprehensive and easier to read. At shorter length, J.B. BURY, *A History of Greece to the Death of Alexander the Great*, 4th ed. (1974), has been revised to take account of new evidence. For the economic background HUMFREY MICHELL, *The Economics of Ancient Greece*, 2nd ed. (1957), is a useful review of the evidence; ALFRED FRENCH, *The Growth of the Athenian Economy* (1964), studies Athens in more detail. CHARLES HIGNETT, *A History of the Athenian Constitution* (1952), is a good critical review, often unorthodox, of Athenian politics and constitutional changes. W.G. FORREST, *The Emergence of Greek Democracy, 800–400 B.C.* (1966), is the most refreshing new look at Athenian politics and can be usefully supplemented by the examination of the mechanics of Athenian democracy in A.H.M. JONES, *Athenian Democracy* (1966), and the detailed analysis in P.J. RHODES, *The Athenian Boule* (1972). The best general account of Greek living conditions is ROBERT FLACELIERE, *La Vie quotidienne en Grèce au siècle de Périclès* (1959; Eng. trans., *Daily Life in Greece at the Time of Pericles*, 1960); the Athenian scene is gaily illustrated in the comedies of Aristophanes, which combine an excellent sense of theatre with strong political satire, fantasy, and boisterous bawdry.

The Greek world from c. 404 to 323 BC: A select bibliography of the history of the Greek world in the 4th century must necessarily concentrate on general works, which themselves contain more detailed bibliographies. The basic works for the history of 4th-century Greece in French, English, and German, are: GUSTAVE GLOTZ and ROBERT COHEN, *Histoire grecque*, vol. 3, *La Grèce au IV^e siècle* (1936) and vol. 4 (pt. 1), with the assistance of PIERRE ROUSSEL, *Alexandre et le démembrement de son empire*, 2nd ed. (1945); *The Cambridge Ancient History*, vol. 4, 3rd ed., *Macedon (401–301 BC)* (1953), better informed than the preceding on the most recent works; HERMANN BENGTSON, *Griechische Geschichte*, 3rd ed. (1965). ROBERT COHEN, *La Grèce et l'hellénisation du monde antique*, new ed. (1948), is rich in ideas and precious for its indication of the sources and the present state of the questions. For the literary history of the period, still of use is the old and monumental *Histoire de la littérature grecque*, by the brothers ALFRED and MAURICE CROISET, 4th ed., vol. 4 (1928), but ALBIN LESKY carries forward the essential material in his volume of the *Geschichte der griechischen Literatur*, 2nd ed. (1963; Eng. trans., *A History of Greek Literature*, 1966), and his bibliography is more important, more precise, and more up-to-date than that of the Croisets. The diplomatic history is studied more particularly, and with much justice, by the Swiss Hellenist VICTOR MARTIN, *La Vie internationale dans la Grèce des cités, VI^e–IV^e s. av. J.-C.* (1940). On the civilization in the largest sense of the term, see the two volumes, whose text and illustrations are equally remarkable, of PIERRE LEVEQUE, *L'Aventure grecque* (1964); and of FRANCOIS CHAMOUX, *La Civilisation grecque* (1963); although dealing with nearly identical subjects, the two books, without supplanting one another, complete one another very well. The following are more detailed or more specialized works: The history of Demosthenes and of Philip is explained with finesse and clarity, despite the complications, by PAUL CLOCHE in *Un Fondateur d'Empire: Philippe II, roi de Macedoine* (1955); and WERNER JAEGER, *Demosthenes: The Origin and Growth of His Policy* (1938). The problems of the education of the era are studied thoroughly by H.I. MARROU, *Histoire de l'éducation dans l'antiquité*, 5th ed. (1960; Eng. trans., *A History of Education in Antiquity*, 1956, reprinted 1964), but not without some prejudices. In the matter of art, out of a superabundant bibliography three works stand out: one old but not out-of-date book that explains the evolution of the art of Greece in all of its forms in relation to its history, ANDRE DE RIDDER and W. DEONNA, *L'Art en Grèce* (1924; Eng. trans., *Art in Greece*, 1927, reprinted 1968); the great work of CHARLES PICARD, *Manuel d'archéologie grecque, la sculpture*, vol. 3–4 (1948–63); and a survey work—intelligent, well informed, and well illustrated—by FRANCOIS CHAMOUX, *Art grec* (1966). On Plato the book that can give the best general idea about his policy and philosophy is that of the great specialist AUGUSTE DIES, *Autour de Platon*, 2 vol. (1927), to which it is necessary to add the more summary *Platon*, by the same author (1930). EDOUARD DELEBECQUE, *Essai sur la vie de Xénophon* (1957), studies the relationships between this disciple of Socrates and his times, and attempts to fix the chronology. The best general work on Alexander is GEORGES RADET, *Alexandre le Grand* (1931, reprinted 1950); the bibliography has been brought up-to-date by W. SESTON.

The Hellenistic Age—323–30 BC: The Cambridge Ancient History, vol. 7–9 (1928–32), by various authors, with good bibliography; MAX CARY, *A History of the Greek World*

from 323 to 146 B.C., 2nd ed. rev. (1951); W.W. TARN and G.T. GRIFFITH, *Hellenistic Civilisation*, 3rd rev. ed. (1952, reprinted 1966), a good conspectus; PIERRE JOUGUET, *L'Impérialisme macédonien et l'hellénisation de l'Orient* (1926; Eng. trans., *Macedonian Imperialism and the Hellenization of the East*, 1928). The best recent account of the political history, with full references, is EDOUARD WILL, *Histoire politique du monde hellénistique (323–30 av. J.-C.)* (1966–67). (*Hellenistic kingdoms—Egypt*): E.R. BEVAN, *A History of Egypt Under the Ptolemaic Dynasty* (1927); P.M. FRASER, *Ptolemaic Alexandria* (1972). (*Seleucid Asia*): E.R. BEVAN, *The House of Seleucus*, 2 vol. (1902, reprinted 1966); ELIAS BICKERMAN, *Institutions des Séleucides* (1938). (*Bactria and India*): W.W. TARN, *The Greeks in Bactria and India*, 2nd ed. (1951), fundamental if rather imaginative; A.K. NARAIN, *The Indo-Greeks* (1957). (*Pergamum*): E.V. HANSEN, *The Attalids of Pergamon*, rev. 2nd ed. (1971); R.B. MCSHANE, *The Foreign Policy of the Attalids of Pergamon* (1964). (*Macedonia*): W.W. TARN, *Antigonos Gonatas* (1913); F.W. WALBANK, *Philip V of Macedon* (1940, reprinted 1967). (*Greek states*): J.A.O. LARSEN, *Greek Federal States* (1968); W.S. FERGUSON, *Hellenistic Athens* (1911); HUMFREY MICHELL, *Sparta* (1952). (*Hellenistic politics, institutions, and society—monarchy*): LUCIEN CERFAUX and J. TONDRIAU, *Le Culte des souverains dans la civilisation gréco-romaine* (1957). (*Organization*): HERMANN BENGTSON, *Die Strategie in der hellenistischen Zeit*, 3 vol. (1937–52). (*Hellenization*): MOSES HADAS, *Hellenistic Culture: Fusion and Diffusion* (1959). (*Economy*): M.I. ROSTOVTZEFF, *The Social and Economic History of the Hellenistic World*, 2nd rev. ed. (1957). (*Cultural activities*): MARGARETE BIEBER, *The Sculpture of the Hellenistic Age*, rev. ed. (1961); T.B.L. WEBSTER, *Hellenistic Poetry and Art* (1964), and *Hellenistic Art* (1967); R.E. WYCHERLEY, *How the Greeks Built Cities*, 2nd ed. (1962). (*Warfare*): W.W. TARN, *Hellenistic Military and Naval Developments* (1930); E.W. MARSDEN, *Greek and Roman Artillery: Historical Development* (1969), and *Greek and Roman Artillery: Technical Treatises* (1971). (*View of world*): J.O. THOMSON, *History of Ancient Geography* (1948). (*Roman period*): HERMANN BENGTSON, *Griechische Geschichte von den Anfängen bis in die römische Kaiserzeit* (1969).

(Jo.Bo./B.R.S./Ru.M./E.D./F.W.W.)

Greek Language

Greek is an Indo-European language whose history can be followed from the 14th century BC to the present day. Its documents cover a longer period of time (34 centuries) than those of any other Indo-European language. There is an Ancient phase, subdivided into a Mycenaean period (texts in syllabic script from the 14th to the 12th centuries BC) and Archaic and Classical periods (beginning with the adoption of the alphabet, from the 8th to the 4th centuries BC); a Hellenistic and Roman phase (4th century BC to 4th century AD); a Byzantine phase (5th–15th centuries AD); and a Modern phase.

Separate transliteration tables for Classical and Modern Greek accompany this article. Some differences in transliteration result from changes in pronunciation of the Greek language; others reflect convention, as for example the χ (*chi* or *khi*), which was transliterated by the Romans as *ch* (because they lacked the letter *k* in their usual alphabet). In Modern Greek, however, the standard transliteration for χ is *kh*. Another difference is the representation of β (*bēta* or *víta*); in Classical Greek it is transliterated as *b* in every instance, and in Modern Greek as *v*. The pronunciation of Ancient Greek vowels is indicated by the transliteration used by the Romans. Υ (*upsilon*) was written as *y* by the Romans, indicating that the sound was not identical to the sound of their letter *i*. Modern Greek υ (*ípsilon*) is transliterated as *i*, indicating that the sound used today differs from the ancient υ. (See the transliteration tables for values of all the Greek letters.)

GENERAL CONSIDERATIONS

In the course of the 2nd millennium BC, groups of Greek-speaking Indo-Europeans established themselves by stages on the Greek peninsula, on most of the islands of the Aegean, and on the west coast of Anatolia; with few exceptions that is still the area occupied by the Greek language today. In the second quarter of the 1st millennium BC a vast "colonial" movement took place, resulting in establishments founded by various Greek cities all around the Mediterranean and the Black Sea, especially in southern Italy and Sicily. This extension of the linguistic area of Greek lasted only a few centuries; in the Roman period, Latin, more or less rapidly, took the place of Greek in most of these ancient colonies. "Colonial" Greek survived longest at Byzantium, as the official language of the Eastern empire.

Relationship of Greek to Indo-European. Ancient Greek is, next to Hittite, the Indo-European language with documents going furthest back into the past. At the time when it comes within view in the 2nd millennium BC, it has already acquired a completely distinct character from the parent Indo-European language. Its linguistic features place it in a central region on the dialect map that can be reconstructed for Common Indo-European; the ancient languages with which it has the most features in common are little known ones such as Phrygian or Macedonian. In the study of Indo-European dialectology, phonetic data are the most readily available and provide the most information. In this respect the position of Ancient Greek is as follows. The original Indo-European vowels of *a* and *o* quality, both short and long, remain distinct, whereas they are completely or partially confused in Hittite, Indo-Iranian, Baltic, Slavic, and Germanic. Greek is the only language that distinguishes by three different qualities (*ĕ*, *ă*, *ŏ*) the secondary short vowels resulting in certain positions from the three laryngeal sounds, $*H_1$, $*H_2$, $*H_3$, of Indo-European. (An asterisk preceding a sound or word indicates that it is not attested, but is a reconstructed, hypothetical form. For a discussion of these laryngeal sounds, see INDO-EUROPEAN LANGUAGES.) Greek keeps the distinction between the original voiced stops and voiced aspirated stops of Indo-European (*e.g.*, Indo-European **d* becomes Greek *d*, and Indo-European **dh* becomes Greek *th*), whereas Iranian, Slavic, Baltic, and Celtic confuse them. Greek avoids the general shifts of stop consonants that are displayed, independently, by Armenian and Germanic, as well as the palatalization that affects guttural stops in Indo-Iranian, Armenian, Baltic, and Slavic. In these respects, Ancient Greek is conservative, as are, generally speaking, the western Indo-European languages (Italic and Celtic). On the other hand, it does show innovations. One of these, the devoicing of the original voiced stops, is shared with Italic, although it is realized in different ways (**dh*- yields Greek *th*-, Latin *f*-, Osco-Umbrian *f*-); but others are foreign to Italic: for example, the weakening of spirants and semivowels at the beginning of words before a vowel, the evolution of **s*- to *h*- (pre-Mycenaean), and **y*- to *h*- (contemporary with Mycenaean).

Comparison of the sounds of Ancient Greek with other Indo-European tongues

Morphological criteria must, of course, be taken into account in defining the position of a language. It should be noted that there are few grammatical innovations shared by Greek and Italic, apart from the extension to nouns of the pronominal ending of the genitive feminine plural **-āsŏm* (Greek *-āōn;* Latin *-ārum*, Umbrian *-aru*, Oscan *-azum*) and of the pronominal ending of the nominative masculine plural **-oi* (Greek *-oi;* Latin *-ī*). The last innovation, however, is not shared with Osco-Umbrian, but is found instead in Germanic (in the strong declension of adjectives) and partly in Celtic. The dialectal individuality of Greek is very clearly marked in the organization of the verb (see below), which is without parallel except for an approximation in Indo-Iranian.

Greek syllabaries. Starting from a foreign script known as Linear A (used in Crete to record a native language known as Minoan), the Greeks devised, toward 1400 BC at the latest, a syllabic script to record their own language. Known as Linear B, this script was deciphered in 1952 by the British architect Michael Ventris and the British classicist John Chadwick. At present just over 100 very short Linear B inscriptions painted on vases have been found at Khaniá, Knossos, Tiryns, Mycenae, Eleusis, Orchomenus, and especially at Thebes. The major source of Linear B inscriptions are the 3,000 to 4,000 unbaked clay tablets found at Knossos (1400–1350 BC—this date has been questioned), at Thebes (probably 1350–1300 BC), and at Mycenae and Pylos (1250–1150 BC). There are no literary texts, and hardly any continu-

ous texts (there is only a small number of real sentences); all that is currently known, and that only in part, is the accounts of the great Mycenaean palaces and their dependencies, compiled in the Greek language.

Signs of Linear B

The Linear B syllabary consists of about 90 signs. There are signs for the vowels *a, e, i, o, u,* but these are hardly used except for initial vowels of words. There are no signs noting consonants in isolation, only signs noting consonant + vowel combinations; thus there is no sign for *t-*, but five different signs for *ta, te, ti, to, tu*. The script does not distinguish *r-* and *l-*; with the exception of *d-*, it does not distinguish between unvoiced, aspirated, and voiced stops (so the sign *ka* can be read in Greek as *ka, cha,* or *ga*). In addition, the scribes used a shorthand spelling and saved time by omissions, mainly of certain consonants (in particular, those that end syllables or words). Consequently, the spellings are often clumsy and ambiguous, such as *ka-po* for *karpos, a-re-ku-tu-ru-wo* for *alektryōn, ka-sa-to* for *xanthōi*. This inconvenient script and the nature of the documents make Mycenaean inscriptions harder to use and less rich in data than the later alphabetic inscriptions; but the information that can be gathered on the state of Greek five centuries before Homer, incomplete as it may be, is of capital importance.

Another syllabary, distantly related to Linear B, was in use in Cyprus much later (7th–3rd centuries BC) to record a native language of the island (Eteocypriot) as well as Greek.

The Greek alphabet. The Mycenaean script dropped out of use in the 12th century when the Mycenaean civilization was destroyed by the Dorian invasions. For nearly four centuries the Greeks seem to have been illiterate.

In the 8th century at the latest, starting from a Semitic model (which had separate signs for the consonants, but none for the vowels), a new system of writing was created by Greeks—the alphabet. For this purpose the list of Semitic consonants was adapted to the needs of Greek phonology, but the major innovation was the invention of five letters with the value of vowels—α(*a*), ε(*e*), ι(*i*), ο(*o*), υ(*u*). The use of the alphabet spread very quickly from east to west across the Greek world. The earliest datable inscriptions, both from around 725 BC, come from Athens (the Dipylon vase) and the colony of Ischia in the Tyrrhenian Sea (the so-called Nestor's cup).

During the period from the 8th to the 5th centuries BC, local differences caused certain details in the forms of the letters to vary from one city to another. Moreover, the primitive Greek alphabet underwent various reforms —the creation of new letters, first φ(*ph*), χ(*ch*), ξ(*ks*), and ψ(*ps*), and η(*ē*) and ω(*ō*). From the 4th century BC on, the alphabet became uniform throughout the Greek world as the result of the general adoption of the form it had taken in Asiatic Ionia.

Greek alphabetic inscriptions

Greek alphabetic inscriptions are numbered in tens of thousands: dedications, epitaphs, decrees, laws, treaties, religious rules, judicial decisions, and so forth. The majority are of Hellenistic or Roman date. The less numerous Archaic inscriptions (8th–5th centuries BC) are of particular interest for their contribution to the knowledge of the dialects (see below). It is only in Hellenistic papyri, and later in Byzantine manuscripts, that the great works of ancient literature (the originals of which have disappeared) come into view in the form of copies, some further and some less far removed from the originals.

The Greek alphabet, still in use today in Greece in the form it reached in the Hellenistic period, has enjoyed an extraordinary success as a direct or indirect model for other alphabets (notably the Latin alphabet); on it are based the writing systems employed in a great part of the modern world.

ANCIENT GREEK

History and development. Only from the 4th century BC, in the Hellenistic period, did Greek approach great unity throughout the area it covered (see below *Koine*). In the preceding ten centuries there were numerous Greek dialects, which differed in phonetic and morphological details, but which were mutually intelligible. The features shared by the local speech of different regions allow the delineation of dialect groups, of which the Greeks themselves were aware. The classifications of modern scholars modify in various ways the classifications made by the ancients, but still retain these as their basis. Among the dialects there are a West group, an Aeolic group, an Ionic-Attic group, and an Arcado-Cypriot group (the last group was neglected by the ancient Greeks because neither Arcadian nor Cypriot gave rise to a literary language). Modern scholars have never questioned the isolation of the West group, but they have tried in various ways to combine the other three into two divisions (*e.g.*, by considering Aeolic and Arcado-Cypriot as varieties of "central" Greek, or by considering Arcado-Cypriot and Ionic-Attic as varieties of "southern" Greek).

In regard to the dialects, two very different situations must be distinguished: that established for the period between the 14th and the 12th centuries BC and that for the period between the 8th and the 4th centuries BC.

In Mycenaean times the carriers of "West Greek" had not yet reached Greece; they did not irrupt into it until the end of the 2nd millennium. In continental Greece (north and south of the Isthmus of Corinth) and on certain Aegean islands (notably Crete), only varieties of Greek other than West Greek were spoken. The tablets reveal a somewhat artificial chancellery language current in the palace offices and taught as a written language in scribal schools. Based essentially on a dialect of the type that was eventually called Arcado-Cypriot, it shows great uniformity in time (during the two centuries or thereabouts covered by documents) and in space (from Knossos to Thebes). Certain fluctuations in details, however, which can be shown to vary between scribes (even at the same site and at the same date), permit the assumption that, behind this official written form of Greek, there must have been various forms of spoken Greek. The problem of the genesis of the dialects other than West Greek does not now present any provable solution.

Influence of Dorian invasions and Greek colonization

There followed two great events that upset the dialectal distribution within the Greek world. First, the Dorian invasions brought speakers of West Greek into northern Greece, then into the Peloponnese, and finally into the Aegean. Some pre-Dorian Greek populations were expelled from their homes and emigrated eastward to the west coast of Anatolia and to Cyprus. Others, who remained where they were, became more or less thoroughly Dorian in speech. It has long been thought that some of the features that Thessalian and, even more, Boeotian (both of which are Aeolic) shared in the 1st millennium with West Greek can be attributed to "recent" influences; on the other hand, some Doric dialects of the 1st millennium (*e.g.*, in Crete) show sporadic traces of features attributable to an Arcado-Cypriot substratum. The other subsequent event, which is of a different sort, was the great colonization movement that began in the 8th century BC. Each group of emigrants took with them the speech of their mother city and planted it in the new foundation. Thus there developed on the shores of southern Italy a totally new grouping of Greek dialects, side by side—Asiatic Ionic at Siris; Euboean Ionic at Rhegium and Cumae; Laconian Doric at Tarentum and Heraclea; Achaean at Sybaris, Croton, and Metapontum; Locrian at Locri Epizephyrii; and so on.

Toward the middle of the 1st millennium BC the geographical distribution of the dialects (insofar as they are known directly through inscriptions) is briefly as follows:

West Group: (1) Doric proper: Messenia, Laconia (colonies—Tarentum, Heraclea); the Argolid; the territory of Corinth (colonies—Corcyra, Anactorium, Syracuse); the Megarid (colonies—Megara Hyblaea, Selinus, Byzantium); the Sporades (colony—Cyrene); Crete; Rhodes (colonies—Gela, Acragas). (2) North-West Greek: Elis, Achaea (colonies—Ithaca, Sybaris, Croton, Metapontum); Aetolia; Phocis; Locris (colony—Locri Epizephyrii).

Aeolic Group: (1) Boeotia; (2) Thessaly; (3) Lesbos and Asiatic Aeolis.

Ionic-Attic Group: (1) Attica; (2) Euboea (colonies—Catana, Zancle, Rhegium, Cumae); (3) Cyclades; (4) Asiatic Ionia (colonies—Siris, Phocaea, foundations in Pontus [Black Sea]).

Arcado-Cypriot Group: (1) Arcadia; (2) Cyprus; (3) Pamphylia.

Literature and dialects

This linguistic situation in the first half of the 1st millennium BC resulted in literature developing on a dialect basis. The Homeric epic in the state in which it became fixed by writing displays a mixture of Aeolic and Ionic features. Choral lyric is especially Doric in colouring. Prose developed first in Ionic surroundings (Herodotus, Hippocrates), then in Attica (Thucydides, Plato). Attic is the language of dialogue in tragedy, but alongside Attic comedy there also developed in Sicily a Doric comedy. Personal poetry employs, depending on the author, Ionic (Hipponax), Lesbian (Alcaeus, Sappho), Boeotian (Corinna), and other dialects. It was only in the Hellenistic and Roman periods that Ionic-Attic became clearly dominant, though in poetry of the later periods there were artificial imitations of the early genres.

Within the alphabetical period of Ancient Greek (8th–4th centuries BC), previous to Koine, there is no break between what is termed Archaic Greek (8th–6th centuries) and what is termed Classical Greek (5th–4th centuries). The Classical period is that in which the progressive elaboration of Archaic data brought Greek literature, as well as Greek art, to perfection.

In the linguistic subdivision of Ancient Greek the effects of substratum languages played only a minor part. In their penetration into Greece toward the beginning of the 2nd millennium BC, the Hellenic peoples found earlier populations established there, about whom Greek tradition gives only vague hints, and whose language or languages are unknown. From this "pre-Hellenic" stratum, Greek vocabulary made numerous borrowings (*kyparissos* "cypress," *pyrgos* "tower," and so on), and it received from it a number of place names (*e.g.*, Korinthos); but there is no reason to think that the divergent characters of the Greek dialects (in phonetics and morphology) could be connected with different substrata. The native "barbarian" languages also had little effect on colonial Greek in the 1st millennium, and these contacts show up only in a few local borrowings.

On the other hand, there is a connection between the facts of civilization (in the political and cultural fields) and the evolution of the language. In the Mycenaean period an evident unity of civilization and the organization in the palaces of record offices and scribal schools allowed the use of a stable and uniform chancellery language. In the first half of the 1st millennium, political subdivision and rivalry between cities allowed dialectal peculiarities to strike deep roots. The special conditions in which epic developed, however, resulted in presenting the "noble" literary genres from their inception with a model of dialect mixture. From the 5th century BC onward, the prestige of Ionic and Attic literature and the political authority of Athens opened the way to Ionic-Attic predominance, and this was eventually imposed by the Macedonian conquest.

Linguistic characteristics. *Phonology.* The phonological systems of Ancient Greek differ noticeably from one period to another and from one dialect to another. The system that has been chosen to serve as an example here is that which may be attributed to Old Attic of the 7th–6th centuries BC.

In Old Attic, there are seven vowel qualities: *i*, open and closed *e*, *a*, open and closed *o*, and *u*, each of which has a

long and a short form, except open *e* and open *o*, which have only the long form. Diphthongs originally included *ei*, *ai*, *oi*, and *eu*, *au*, *ou*, but very soon *ei* began to evolve toward long closed *ē* and *ou* toward long closed *ō*. In addition, there is a rare diphthong *ui*, and usually at the end of words the diphthongs *-ēi*, *-āi*, *-ōi*, with preponderant first elements, which later were reduced respectively to long open *ē*, long *ā*, and long open *ō*.

The consonantal structure is characterized by relative richness in stops (sounds produced by momentary complete closure at some point in the vocal tract): unvoiced *p*, *t*, *k*, aspirated *ph*, *th*, *ch*, voiced *b*, *d*, *g*; and by few spirants: only *s* and *h* sounds (*h* restricted to initial position before a vowel). There is also a voiced affricate sound, *dz*; two liquid sounds, *l* and *r*; and two nasals, *m* and *n*. The guttural nasal is not distinctive, but is only a variant of the sound *n* in front of a guttural stop. Neither *y* nor *w* occur as distinctive sounds. All of the consonants except *h* and *dz* can be doubled between vowels. The only consonant sounds normally allowed at the end of the word are *-s*, *-n*, and *-r*.

Word accent

Apart from some unaccented monosyllabic or disyllabic terms of minor importance, each word is marked by a rise in the musical pitch of the voice (accent) on one of the vowels (one of the last three vowels, if the word has more than three syllables). Short vowels, if they carry the accent, have only a rising tone (noted from the Alexandrian grammarians onward by the sign of the acute accent); long vowels or diphthongs may have either a rising tone (noted by the acute accent) or a rising tone followed by a falling tone (noted by the circumflex accent). Within a phrase the vowel of a final syllable with a normally rising tone is weakened in accent (noted by the grave accent). The position and nature of the accent in the word are governed by rules so strict that they do not usually permit variations that would serve to differentiate two otherwise identical forms. There are, however, examples of such a differentiation: *oîkoi* ("houses") is a nominative plural form, and *oíkoi* ("at home"), an adverb of place; *tómos* means "a cut" and *tomós* "cutting"; and so on.

The accent (which is not associated with stress) does not play any part in the rhythm of the language. This rhythm (and that of poetry, which is a stylized form of it) is based upon the distribution in the sentence (and in the verse) of short and long syllables. For a syllable to be short, it must end in a short vowel; syllables ending in a long vowel, or closed syllables (*i.e.*, those ending in a consonant), are long. The rhythm of Ancient Greek is therefore quantitative.

Morphology. Every nominal (noun) or verbal form combines a "root" that carries the sense of the word and a certain number of grammatical markers that serve principally to define the function of the word in the phrase.

The category of gender, which differentiates masculine, feminine, and neuter, is expressed only in the substantive (noun), adjective, and pronoun. The category of person (1st, 2nd, and 3rd person) is restricted to the personal pronoun and the verb. There are three numbers—singular, dual, and plural—that are distinguished in both the noun and the verb. The survival of the dual is an archaism; although a living form in the Mycenaean period, it tends to be replaced by the plural in the 1st millennium. Attic is one of the dialects in which it is best preserved down to the threshold of the Hellenistic period.

Not counting the vocative case, the Greek declension in the Mycenaean period still contained at least six cases: nominative, accusative, genitive, dative, locative, and instrumental. Between the Mycenaean period and the 8th century the locative and the instrumental ceased to exist as living cases, their functions having been taken over by the dative.

Role of aspect in the Greek verb

The most original feature of Greek morphology is the structure of the verb system, which is determined fundamentally by the category of aspect. It is organized around three principal themes (or tenses) for each verb: the "present" theme for the durative aspect, the aorist theme for the punctual aspect, and the perfect theme for the aspect of completion. Each of these themes provides an indicative and, apart from the imperative, two nonassertive moods (subjunctive and optative). The expression of time exists only in the indicative; there is, on the one hand, a future theme, and on the other, an aorist indicative theme (which always represents past time). There are also past tenses attached respectively to the present indicative (imperfect) and to the perfect indicative (pluperfect). The past tense has as its distinguishing marks a certain set of endings, called secondary (which it shares with the optative), and the presence of a special preverb called the augment. The Greek verb has two voices (active and mediopassive), which are expressed (leaving aside the aorist passive) by the opposition of two series of endings. Finally, in each voice, complete series of participles and infinitives were established corresponding to the present, future, aorist, and perfect themes.

Syntax. A relatively free word order occurs in Greek. Above all, the creation of the definite article (post-Mycenaean and post-Homeric), and the various ways in which the nominal forms of the verb (participles and infinitives) come into play, confer on the Greek sentence a suppleness unmatched in other languages.

Vocabulary. If one considers the roots of words, it seems that, although the essential basis of the vocabulary is of Indo-European origin, a fairly considerable number of terms are borrowings. Most of these loans were taken from the idioms of the populations living in Greece prior to the arrival of the Greeks; many such words had already penetrated into Greek in the 2nd millennium, for there are forms found in Mycenaean that correspond to plant names such as *elaia* "olive," *pyxos* "box tree," and *selinon* "celery"; animal names such as *leōn* "lion" and *onos* "ass"; names for objects such as *asaminthos* "bathing tub," *depas* "goblet," and *xiphos* "sword"; and names of materials such as *elephās* "ivory," *chrysos* "gold," and *kyanos* "dark blue enamel."

The most important fact is that from the verbal and nominal roots (of whatever origin) the language extracted a vocabulary full of nuances and of great scope (by using preverbs, and by forming compounds and derived words). At all periods the lexical creativity of Greek has been very active, thus giving it a vocabulary of extraordinary richness. (M.Le.)

KOINE

The fairly uniform variety of spoken Greek that gradually replaced the local dialects after the breakdown of old political barriers and the establishment of Alexander's empire in the 4th century BC is known as the Koine (*hē koinē dialektos* "the common language"), or "Hellenistic Greek." Attic, by virtue of the undiminished cultural and commercial predominance of Athens, provided its basis; but as the medium of communication throughout the new urban centres of Egypt, Syria, and Asia Minor, it absorbed numerous non-Attic elements and underwent some degree of grammatical simplification. Numerous inscriptions enable scholars to trace its triumphant progress at the expense of the old dialects, at least as the language of business and administration, although some rural dialects are reported to have survived as late as the 2nd century AD. Other sources of information for the Koine are the translation of the Septuagint made in the 3rd century BC for the use of the Hellenized Jewish community of Alexandria, the New Testament, and the writings of a few people (*e.g.*, the historian Polybius and the philosopher Epictetus) who favoured it over Attic. As the everday colloquial language of urban Egypt it may be studied in papyri going back to the 4th century BC. The Koine may be dated very crudely from the period of Alexander's conquests in the 4th century BC to approximately the reign of Justinian in the 6th century AD.

Sound changes from Ancient Greek to the Koine

The Koine replaced the Attic sound *tt* by the *ss* characteristic of Ionic and other dialects (*e.g.*, *glōssa* for *glōtta* "tongue") at an early date, but its main phonological significance lies in its gradual simplification of the rich vowel system of Classical Greek. Ancient *ei* (ει), *i*(ι), and *ē*(η) sounds merged as *i*, and *ai*(αι) was monophthongized to *e*; *oi*(οι) became pronounced as the sound symbolized

by *ü*, thus merging with simple *y* (pronounced as in French *tu*). The second element of *au* (*αυ*) and *eu* (*ευ*) was changed to *v* or *f* (compare ancient *autós* to modern *aftós* "he"). These shifts, combined with the loss of length distinctions, led to a new six-term system of vowel sounds: *i, u, ü, e, o, a*. The loss of *h* also belongs to the Koine period, and there is evidence that the change of the ancient aspirates and voiced stops to fricative (spirant) sounds was well under way. As a result of this latter process, Classical *ph, th, ch* (pronounced as in English "pin," "tin," "kin") acquired the fricative articulations of "fin," "thin," and the final element of Scottish "loch," (or German *Buch*); *b, d, g* became the voiced fricative sounds *v, dh* (as in "that"), and *gh* (as in Spanish *fuego*).

Grammar too began to move in the direction of Modern Greek in this period. Nouns in consonant stems acquired the endings of the *-a* declension; *e.g., thygatēr*, "daughter," accusative *thygatera*, was remodelled after items such as *khōra, khōran* "country." The dual number was lost in nouns, verbs, and adjectives, as was the optative mood of verbs. Confusion arose between the perfect and aorist tense forms, leading to the loss of one or the other (the former in most verbs).

In vocabulary there were numerous borrowings from non-Attic dialects, and Attic words acquired new meanings; thus *opsaria* "fish" and *brechei* "it rains" for Classical Greek *ichthyes* and *hyei* both occur in the New Testament (*cf.* Modern Greek *psárya, vrékhi*).

This gradual divergence from the language of Plato and Demosthenes was viewed as a species of linguistic decadence by an influential school known as the Atticists, who unceasingly castigated the use of Koine forms by writers. It was thus that there developed a rift between the everyday spoken language and an archaizing, specifically written language. It became fashionable to publish manuals of "good usage" in which the Attic equivalents of Koine innovations were recommended for the student's imitation.

BYZANTINE GREEK

During the period of the Byzantine Empire (*i.e.*, until the fall of Constantinople in 1453) the language of administration and of most writing was firmly rooted in the Atticist tradition; it is this archaizing style that is often referred to as "Byzantine Greek." The spoken language continued to develop apace, however, and its course can be followed to some extent in the writings of the less educated chroniclers (such as Malalas, 6th century) and hagiographers. Furthermore, the increasing political and military disintegration characteristic of the last few centuries preceding the fall of Constantinople brought with it a general decline in educational level, and works appeared that reflect quite closely the colloquial language of the time, although learned and pseudolearned elements are never absent. While the differences between the *Chronicle of the Morea* (13th century), for example, and present-day spoken Greek are quite minor, Byzantium failed to produce a writer of the stature of Dante, capable of establishing once and for all the living vernacular as a worthy vehicle for great literature.

Changes occurring in the Koine

Most of the phonological and grammatical developments that separate present-day Greek from the Koine occurred during this period. The frequent misuse of the dative case of nouns shows that it went out of use in the spoken language, and the infinitive was replaced by various periphrastic constructions. (Periphrastic constructions involve the use of function words and auxiliaries.) In the early period numerous words (mostly Latin) were imported: the chronicler Malalas has (in their modern form) *pórta* "door," *kámbos* "plain," *saíta* "arrow," *paláti* "palace," *spíti* "house" (from *hospitium*), and hundreds of other borrowings, not all of which have survived. The later period is characterized by the richness of its compound words, usually from native roots. Some of these continued ancient patterns, such as that in which a modifying noun is linked to its head noun by *-o-* (*thalassovrákhi* "sea rock," *vunópulo* "mountain lad"); but coordinative compounds of the type common today are also found (*e.g.*, Modern Greek *andróyino* "man and wife," *makheropíruna* "knives and forks"). Semantic shift was another source of innovation: *álogho* "horse," previously meant "irrational"; *skiázome* "I fear," earlier was "I am in shadow"; and *(u)dhén* "not," was, in Classical Greek, "nothing."

MODERN GREEK

History and development. Modern Greek derives from the Koine via the local varieties that presumably arose during the Byzantine period, and is the mother tongue of the inhabitants of the Kingdom of Greece and of the Greek majority in the Republic of Cyprus. Before the exchange of populations (1923) there were Greek-speaking communities in Turkey (Pontus and Cappadocia), and it remains the language of the Greek community of Istanbul. Certain villages in Calabria in southern Italy are also Greek-speaking. Three main varieties may be distinguished: (1) the local dialects, which may differ from one another virtually to the point of mutual unintelligibility, (2) the standard colloquial Greek spoken in all the urban centres of Greece, known as demotic, and (3) Katharevusa (from *katharós* "pure"), a strictly literary language.

Local dialects. Of the local dialects, Tsakonian, spoken in certain mountain villages in eastern Peloponnese, is quite aberrant and shows evidence of descent from the ancient Doric dialect (*e.g.*, it often has an *a* sound for the early Greek *ā* that went to *ē* in Attic, later to *i*). The Asia Minor dialects also display archaic features (*e.g.*, Pontic *e* for ancient *ē* in certain word elements). It is not certain whether southern Italian Greek represents a survival from ancient times or was reimported there during the Byzantine period. Apart from these peripheral varieties, the modern dialects may be grouped for practical purposes as follows:

Divisions of the modern dialects

1. Peloponnesian, differing but slightly from the dialects of the Ionian isles, forms the basis of standard demotic. It shows very few specifically local innovations in its phonology, although its verb morphology is less conservative than that of the island dialects.

2. Northern dialects, spoken on the mainland north of Attica, in northern Euboea, and on the islands of the northern Aegean, are characterized by their loss of unstressed *i* and *u* and the raising of unstressed *e* and *o* sounds to *i* and *u*. Thus, standard *kotópulo* "chicken" becomes *kutóplu, émine* "he stayed" becomes *émni*. They also mark certain 1st and 2nd person plural past tense verb forms with *-an* (*ímastan* "we were," Athenian *ímaste*) and use the accusative for indirect object pronouns in instances in which the southern dialects have the genitive (*na se pó* "let me tell you," standard *na sou pó*).

3. Old Athenian was spoken in Athens itself until it became the capital of the modern state (1833), and on Aegina until early in the 20th century; it survives in Megara and in the Kími district of central Euboea. Its salient feature is the replacement of the Byzantine *ü* sound (from ancient *y, oi*) by *u* rather than normal *i*; it changes the *k* sound before the vowels *e* and *i* to *ts* and fails to contract the vowels *i* and *e* to a *y* sound before vowels (ancient *sykéa* becomes *sutséa* "fig tree," standard *sikyá*).

4. Cretan softens *k* to a *č* sound (as in "church"), *kh* to *š* (as in "she") before *i* and *e*, and *y* to *ž* (as the *s* in "pleasure")—*e.g.*, *če* "and," *šéri* "hand," *žéros* "old man," standard *ke, khéri, yéros*.

5. The southeastern dialects of Cyprus, Rhodes, Chios, and other islands in the area soften *k* to *č* as in Crete, drop voiced fricative consonants between vowels, and retain the ancient final *-n* (*láin* "oil," standard *ládhi*). They also retain the contrast between long and short consonants (*fíla* "kiss!" but *fílla* "leaves"). As is done in Cretan and Old Athenian, they add *gh* to the *-ev-* that occurs at the end of many verb stems (*dhulévgho* "I work").

Demotic. Demotic is the language used for everyday conversation in the towns of mainland Greece, and is understood without difficulty by all speakers. Differences within the demotic form as it is spoken in the various parts of the country are so minor that it may be regarded as the standard spoken language. In all essential respects

Table 2: Modern Greek Alphabet

Greek letters			name	equivalents	approximate pronunciation
capital	lower case	combinations			
A	α, ά*		álfa	a	bother
		αι		ai	bed
		αυ		av	Slav, laugh†
B	β		víta	v	van
Γ	γ		ghámma	g before α, ο, ου, ω and consonants other than γ, ξ, and χ; y before αι, ε, ει, η, ι, οι, υ, and υι; n before γ, ξ, and χ	wit, yet, sing
		γκ		initial, g; medial, ng	go, finger
Δ	δ, ∂*		dhélta	dh; d between ν and ρ	then, wondrous

Ω	ω		oméga	o	bone

*Old-style character. †Pronounced with long *a*. ‡Final, *s*.

its phonology and grammar follow average Peloponnesian practice, but it has absorbed a vast number of vocabulary items from learned sources. It is also used as the vehicle of poetry and, since the beginning of the 20th century, of fiction, although, except for certain genres such as drama and detective novels, the spoken language is not necessarily reproduced with any fidelity. Indeed, one may speak of a specifically literary demotic that differs from the spoken language in its extensive use of words culled from local dialects, its fondness for innovation in compound formation, and its somewhat eclectic verb morphology.

Use of Katharevusa

Katharevusa. Katharevusa is the purist, archaizing written language of administration; it is also used in technical publications, newspapers, and public notices. Its role in education has varied with the policies of successive governments; since 1967 it has been the official language of education beyond the elementary school. Although the concept of a distinctive written language based on earlier usage goes back to the Atticists, Katharevusa originated in the 19th century as a result of the effort to purify the local dialects of foreign elements and to systematize their morphology (inevitably on the Classical Greek model). Thus, Katharevusa is characterized by its exclusive use of Ancient Greek roots and much Classical inflection, while its syntax and idiom differ but slightly from those of demotic (this is true, at least, of the "simple Katharevusa" current in today's newspapers and periodicals). Katharevusa elements abound in demotic, often with a specialized role; for example, *édhra* (from the Ancient Greek word for "chair") means "professorial chair," the demotic word for "chair," *karékla*, being the term for the article of furniture. Many Katharevusa terms appear almost exclusively in print: *zíthos* "beer" and *ínos* "wine" are common in advertisements, but everyone says *bíra* and *krasí*. Words of Katharevusa origin often show ancient inflections: *kathiyitís* "professor" has the vocative form *kathiyitá*, *fititís* "student" is in the plural *fitité* (*cf.* demotic *traghudhistís* "singer," plural *traghudhistés*, *traghudhistádhes*). Because of its use in newspapers and news bulletins, most Greeks have a good passive knowledge of Katharevusa and it is easily accessible to foreigners with reasonable competence in the classical language.

Linguistic characteristics. *Phonology.* Modern Greek has five distinct vowel sounds (*i, e, a, o, u*) and the glide *y*, most of which are indicated in Greek orthography in more than one way. The consonant sounds are:

Voiceless stops	*p*	*t*		*k*
Voiced stops	*b*	*d*		*g*
Voiceless fricatives	*f*	*th*	*s*	*kh*
Voiced fricatives	*v*	*dh*	*z*	*gh*
Nasals	*m*	*n*		
Liquids	*l*	*r*		

The sounds *f*, *th*, and *kh* derive from ancient aspirated consonants, and the voiced fricative sounds *v*, *dh*, and *gh* from *b*, *d*, and *g*. Modern *b*, *d*, and *g* are usually created by the voicing of *p*, *t*, and *k* after nasals; thus Ancient Greek *pénte* "five" becomes *pénde*. These also occur at the beginning of words in place of ancient nasal + stop sequences (*boró* "I am able" from *emporó*). Other important combinatory changes linking Ancient and Modern Greek include the following: (1) Ancient stop clusters and aspirate clusters both become fricative + stop; *e.g.*, *hepta* "seven," *oktō* "eight," *ophthalmos* "eye" become *eftá*, *okhtó*, *ftarmós* ("evil eye"). (2) Double consonants are simplified except in the southeast, thus *thalassa* becomes *thálasa* "sea." (3) Nasal sounds assimilate to following fricative sounds; thus *nymphē* becomes *níffi* and then (except in the southeast dialects) it changes to *nífi* "bride." (4) The sound *l* is replaced by *r* before consonants; *e.g.*, *adelphos* becomes *adherfós* "brother." (5) Before a vowel, *i* and *e* change to *y*; thus *paidia* becomes *pedhyá* "boys," *mēlea* becomes *milyá* "apple tree." Except for the simplification of double consonants, these statements do not apply to words of Katharevusa origin. Thus in *simfonía*, meaning "symphony" or "agreement," statements (3) and (5) are violated (the true demotic form would be *sifonyá*).

Stress in Modern Greek

Modern Greek has dynamic stress (as in English) and not the ancient musical accent, so that while words may be distinguished by stress placement (*fíli* "friends," *filí* "kiss"), the old distinction between grave, acute, and circumflex is lost (but still represented in written accents).

Grammar. Much of the inflectional apparatus of the ancient language is retained in Modern Greek. Nouns may be singular or plural—the dual is lost—and all dialects distinguish a nominative (subject) case and accusative (object) case. A noun modifying a second noun is expressed by the genitive case except in the north, where a prepositional phrase usually replaces this. The indirect object is also expressed by the genitive case (or by the preposition *se* "to," which governs the accusative, as do all prepositions). Thus:

o yatrós	*ípe tin istoría*	*s ton adherfó tiz dhaskálas*
"The doctor	told the story	to the brother of the teacher"
(nominative)	(accusative)	(genitive)

The ancient categorization of nouns into masculine, feminine, and neuter survives intact, and adjectives agree in gender, number, and case with their nouns, as do the articles (*o* "the," *enas* "a"). In general, pronouns exhibit the same categories as nouns, but the relative pronoun *pu* is invariant, its relation to its own clause being expressed when necessary by a personal pronoun in the appropriate case: *i yinéka pu tin ídhe to korítsi* "the woman *pu* her saw the girl" (*i.e.*, "the woman whom the girl saw").

The verb is inflected for mood (indicative, subjunctive, imperative), aspect (perfective, imperfective), voice (active, passive), tense (present, past), and person (1st, 2nd, 3rd, singular and plural). The future is expressed by a particle *tha* (from earlier *thé[o] na* "[I] want to") followed by the subjunctive. There are also two participles, an indeclinable present active one in *-ondas*, which is confined to certain individual usages (*tróghondas érkhete i óreksi* "in eating comes the appetite"), and a past passive one in *-ménos* (*kurazménos* "tired"). Formally, the finite forms of the verb (those with personal endings) consist of a stem + (optionally) the perfective aspect maker (*-s-* in active, *-th-* in passive) + personal ending (indicating person, tense, mood, voice). Past forms are prefixed by *e-* (the "augment"), although this is usually lost in mainland dialects when unstressed. In the active, the present endings are *-o, -is, -i, -ume, -ete, -un*(e) (*-usi* in southeast dialects), and the past endings are *-a, -es, -e, -ame, -ate* (Peloponnesian, standard, elsewhere *-ete*), *-an*(*e*). In both active and passive paradigms only six tenses are distinguishable in pronunciation. The active forms of "you (singular) write," for example, are:

	Present	Past	Imperative
Imperfective	(1) *ghráfis*	(3) *éghrafes*	(5) *ghráfe*
Perfective	(2) *ghrápsis*	(4) *éghrapses*	(6) *ghrápse*

Ghráfis "you write" represents both the present indicative and imperfective subjunctive; *ghrápsis* "you (may) write" is the perfective subjunctive, and *éghrafes* and *éghrapses* are the imperfect indicative "you were writing" and the preterite "you wrote," respectively.

Aspect in Modern Greek

Aspectual differences play a crucial role. Roughly, the perfective marker indicates completed, momentary action; its absence signifies an action viewed as incomplete, continuous, or repeated. Thus the imperfective imperative *ghráphe* might mean "start writing!" or "write regularly!" while *ghrápse* means rather "write down!" (on a particular occasion). Compare also *tha ghrápho* "I'll be writing" but *tha ghrápso* "I'll write" (once). The difference is sometimes represented lexically in English: *ákuye* "he listened" and *ákuse* "he heard." The passive forms are largely confined to certain verbs active in meaning like *érkhume* "I come," *fováme* "I am afraid," and reciprocal usages (*filyóndusan* "they were kissing"). There are also phrasal constructions representing completed action: *ékho ghrápsi* "I have written" (standard), *ékho ghramméno* (in most dialects). These are, however, much rarer than the corresponding English perfect forms. There is no infinitive; ancient constructions involving it are usually replaced by *na* (from ancient *hína* "so that") + subjunctive. Thus *thélo na ghrápso* "I want to write," *borí na ghrápsi* "he can write." Indirect statement is introduced by *oti* or *pos* (*léi oti théli* "he says that he wants").

Vocabulary. The vast majority of demotic words are inherited from Ancient Greek, although quite often with changed meaning; *e.g.*, *filó* "I kiss" (originally "love"), *trógho* "I eat" (from "nibble"), *kóri* "daughter" (from "girl"). Many others represent unattested combinations of ancient roots and affixes; others enter demotic via Katharevusa: *musío* "museum," *stikhío* "element" (but inherited *stikhyó* "ghost"), *ekteló* "I execute." In addition, there are over 2,000 words in common use drawn from Italian and Turkish (accounting for about a third each), and from Latin, French, and, increasingly, English. The Latin, Italian, and Turkish elements (mostly nouns) acquire Greek inflections (from Italian *síghuros* "sure," *servitóros* "servant," from Turkish *zóri* "force," *khasápis* "butcher"), while more recent loans from French and English remain unintegrated (*spór* "sport," *bár* "bar," *asansér* "elevator," *futból* "football").

Greek Law

Any survey of ancient "Greek law" has to begin with a caution: there never was a "Greek law" in the sense of a system of institutions recognized and observed by the nation as a whole as its legal order. There were, however, a number of basic approaches to legal problems, certain methods used in producing legal effects, and a legal terminology, all shared to varying degrees by the numerous independent states constituting the Hellenic world. To the extent that concepts, institutions, and techniques may be attributed to common heritage or otherwise considered as typical expressions of Greek ways of thinking, the postulate of the existence of a "Greek law" appears to be legitimate—though it remains controversial. It should not be forgotten, however, that such common foundations as there were gave rise to a great variety of individual legal systems differing as to their completeness and elaboration and reflecting the tribal (*i.e.* Dorian, Ionian, etc.) and historical backgrounds as

well as the changing social, economic, political, and intellectual conditions of their respective societies.

Disconnected details are known from many of these systems, and knowledge of them will most probably increase as legal research into the Greek inscriptions proceeds. But only two systems of the pre-Hellenistic period are sufficiently documented to admit of real insight into their nature. A famous inscription containing the 5th-century-BC legislation of the Cretan city of Gortyn detailed many institutions of that city. Even more important is the Athenian law of the later 5th and 4th centuries BC. It is not only the best documented and most thoroughly explored system but also seems to have been the most highly developed and therefore perhaps the most truly representative of the legal culture of Classical Greece. This article will be based primarily on the Athenian evidence, but with glances at the other systems, in so far as these feature characteristic deviations.

THE SOURCES

The best sources of information are speeches written by Athenian orators of the 5th and 4th centuries for the purpose of being delivered at trials. Isaeus and Demosthenes were pre-eminent figures but others, such as Antiphon, Lysias, Isocrates, and Hyperides, as well as some anonymous rhetoricians included in the *Corpus Demosthenicum,* also contributed important material still extant. It should be noted that forensic oratory was what came closest in Greek literature to professional writing on legal matters. Such works as Aristotle's treatises on constitutions (*Athenian Constitution, Politics*) or Theophrastus' treatment of private law topics in his "On the Laws" (only a brief fragment of which has been preserved) were mainly confined to mere description or philosophical analysis and criticism or both. Within these limits they do, of course, throw much light on the institutional framework, though not on the practical workings, of contemporary systems.

Sources of knowledge

Information on positive law that can be gathered from other philosophical writings and from general literature is more limited. Plato's *Laws* and Aristotle's *Nicomachean Ethics* and *Rhetoric* suggest some conclusions as to institutions and practices forming the background of the authors' theories. Beyond that, however, legal history profits little from them. Modern research has established that Plato's suggestions concerning legal policy and Aristotle's philosophical analysis of justice exerted no significant influence on court practice in either Classical or Hellenistic times, while the impact that they may have had on legislators of the latest Classical period (*e.g.*, in Athens, Demetrius of Phaleron) and of Hellenistic times is difficult to ascertain. Sporadic, though often valuable, bits of knowledge, however, can be gleaned from poetic and historical literature. Among the former, the epic, the chief source for the Archaic period, and Attic Comedy, especially Menander, deserve mention.

A nonliterary but rich body of sources are inscriptions, coming from every part of the Greek world and covering every period of history beginning before 600 BC. Recording, or referring to, enactments and other juridical acts, such as treaties, as well as private agreements, wills, manumissions, court decisions, etc., these have provided hundreds of texts that offer a most varied picture of the actual life of the law. Their particular value lies in the information they contain on non-Attic laws, for which these inscriptions are often the only evidence available. Save for a few exceptions, such as the law code of Gortyn, juridical research in inscriptions is still in its beginning stage.

A third group of sources, namely, the thousands of papyrus documents discovered in Egypt and, to a much lesser degree, in Mesopotamia and Palestine, is confined to the Hellenistic and Roman periods and will be considered elsewhere (see HELLENISTIC LAW).

GENERAL CHARACTER OF GREEK LAW

Greek legal life of the 5th and 4th centuries was determined by three dominant factors. One, already referred to, was the existence of a multiplicity of city-states (*poleis*), each of which possessed and administered its own set of laws. The second element was the fact that in many, if not most, of the *poleis* (one certain exception was Sparta) the laws were laid down in written statutes, some of them elaborate and more or less complete codes setting forth procedural methods and substantive rules for the administration of justice. This was the result of a great movement for codification that from the 7th century had swept the Greek world. Solon of Athens (594 BC), who had been preceded in 621 by Draco, is the best known of a number of famous lawgivers, other outstanding ones being Zaleucus of Locri Epizephyrii (south Italy) and Charondas of Cantana; Lycurgus of Sparta is considered legendary. A number of enactments rightly or wrongly attributed to Solon still are known from literary quotations rendering them in a modified form that reflects a legislative reform of 403–402 BC. One of the Draconian laws has been preserved in an Attic inscription giving it in a revised version dating from 409 to 408 BC. The law code of Gortyn, which is itself the revised version of an older code, is the only one that comes close to being fully preserved.

The third determining factor for Greek law was the absence of a body of jurisprudence comparable to that of the Romans. Even the Attic orators, for all their practical familiarity with the laws of the city, were mainly interested in presenting arguments suited to persuade the mass juries before whom they had to argue, not in analyzing the legal system with the object of obtaining a deeper insight into its implications. Nor, for that matter, did the philosophers care for the law as it was, their aim being the discovery of abstract standards of justice.

The three factors above had important effects on the general character of Greek law. The first two resulted in a rather stiff positivism. Contrary to views held by scholars until recently, new research has shown that the Athenian dicasts who sat in judgment did not feel free to base their verdicts on vague notions of equity, but adhered, at least in theory, to the literal meaning of the written statutes (*nomoi*), which they were bound by a solemn oath to observe. This somewhat narrow clinging to literal interpretation, combined with the absence of any attempt to deal with statutes or legal situations in an analytical manner, led to the result that Greek law never attained anything comparable to the doctrinal refinement of Roman law, notwithstanding the remarkable technical flexibility that characterized it in Hellenistic times.

INSTITUTIONS OF PRIVATE LAW

Persons, family, succession. *Status.* In the classical Greek *polis* only the grown-up male citizen was in unrestricted possession of public and private rights. Each city-state laid down its own requirements for citizenship; democratic Athens, for example, insisted, as a matter of principle, on legitimate descent from citizens on both sides, although naturalization was allowed occasionally. Resident aliens who were officially admitted, such as the Athenian metics (*metoikoi*), enjoyed full protection of their freedom and property, but might be subject to some discrimination in addition to being deprived of political rights; in Athens they could not live in legitimate wedlock with a citizen or own real property. The exigencies of its maritime trade induced 4th-century Athens to allow nonresident foreign merchants to sue and be sued before special courts sitting for this purpose in Piraeus. Normally, however, nonresident aliens had no access to the courts of the city and depended on a friendly citizen (*proxenos*) to act on their behalf.

Status of women

The status of women varied from city to city. Athens, in accordance with its closely knit family system, subjected them to the head of the house who as their *kyrios* ("master") had power over their share in the family estate and was entitled to give them in marriage. Under a family law less rigidly patriarchal, women might own property and be without a *kyrios;* such was the case in Gortyn and some other non-Attic states.

Slavery existed everywhere. It ranged from unlimited

chattel slavery, making the slave the full property of his master (Athens), to various degrees of serfdom (*e.g.*, Spartan helotry or the status of the villein, *voikeus,* in Gortyn) that curtailed the freedom of the serf and usually subjected him and his family to a personal master, without, however, reducing him to a mere chattel. This, of course, concerned only his legal condition and did not necessarily involve a more tolerable social status. Manumission, apparently permitted everywhere, bestowed personal freedom, in many places by putting the freedman under divine protection, but did not result in his obtaining citizenship. Special obligations were often imposed on freedmen by their manumissors or even by the law itself.

The concept of *oikos*

Family. The family law of the classical *polis* was based on the concept of *oikos.* In its original meaning of "house" the term signified the individual citizen's family, forming a collectivity that rested on special religious ties and duties following from common descent as well as on a common patrimony in which the several members had actual or potential shares. When secularism grew in 4th-century Athens, the term took on its second and more materialistic meaning of "estate." After a citizen's death his *oikos* was carried on by his direct successors, upon whom the estate and the responsibility for the religious duties of the family devolved.

The prerequisites of membership in the *oikos* were not uniform in all the *poleis.* In the democratic period of Athens, it was confined to legitimate sons (*gnēsioi*) and further descendants of the head of the house in the male line, or, male offspring lacking, to the sons of an *epiklēros* (a brotherless daughter). A man without sons was allowed to adopt a son. Elsewhere the rigid restriction of membership to legitimate offspring did not prevail. In the absence of *gnēsioi,* some states granted succession to *nothoi,* who were the sons of concubines, this having also been the rule in predemocratic Athens. In Gortyn, adoption was permitted despite the presence of *gnēsioi,* but the adoptee acquired only the somewhat reduced status of a daughter.

Diversities such as these are indicative of the existence of several types of collective family organization reflecting differences in the basic character of their respective societies. Another confirmation of this inference, which is also suggested by the discrepancies regarding the status of women pointed out above, is found in the rules governing the management of the patrimony in different places. In Athens, where order was founded on the strict principle of paternal power, the father alone as *kyrios* was entitled to dispose of property belonging to the house. Even grown-up sons, though enjoying control of their own possessions, in a marked contrast to their status under the Roman *jus civile,* were denied any influence on the management of the family estate during their father's lifetime. A principle quite opposite to this Athenian concentration of authority emerges, to cite only one example, from numerous inscriptions found at Delphi, where title to the estate was apparently vested in the group as a whole, including the women. Each of its members, alone or conjointly with others, seems to have been in a position to alienate common property, unless checked by the veto of another member possessing equal rights.

Marriage and divorce. The legal principles governing marriage derived from its function of producing legitimate offspring for the perpetuation of the *oikos. Epigamia* (*i.e.*, the ability of the spouses to live in lawful matrimony) was an indispensable prerequisite of a valid marital union. It was sometimes withheld for political reasons; thus democratic Athens, while liberal regarding marriages of kinsfolk and even condoning cohabitation with a half-sister, excluded all noncitizens from *epigamia.* The establishment of a marital union was a concern of the families rather than the spouses themselves. Athens, therefore, regularly required a solemn "giving in marriage" (*engyē*) of the bride by her father or closest male relative acting as her *kyrios,* to be followed by her actual "delivery" (*ekdosis*) to the groom. Monogamy was the norm, although all *poleis* did not go to the same extreme as democratic Athens, which peremptorily excluded from the *oikos* the children of concubines (though possibly allowing a citizen to maintain more than one *oikos*).

In Athens, and other states where the status of women was similarly reduced, the husband became the *kyrios* of his wife and her property, including her dowry (*proix*), the latter consisting of a share in the estate of the bride's *kyrios,* customarily, though not in fulfillment of a legal claim, conveyed by him to the groom. If the marriage was terminated by the death of the wife, title to the *proix* passed to her sons, although the widower might keep it until he died. In all other cases, the husband or his heir was liable for the return of the dowry to the wife's family (*dikē proikos*).

Divorce was permitted to either spouse and might be effected simply by expelling or abandoning the other, no justifying reason being required. A divorced woman returned to her own family, the head of which became again her *kyrios.*

Guardianship. The estate of a fatherless minor (in Athens to 18 years of age) was administered by a guardian (*epitropos*) who was his closest agnate (*i.e.*, relation through male descent), unless the father had appointed a guardian *inter vivos* or by will. The *epitropos* became the temporary *kyrios* of the ward's estate and had to support him. In Athens his management was supervised by the *archōn* (chief magistrate), and every citizen might file a complaint against a negligent guardian. His office having expired, the guardian was liable to the ward for the return of the estate (*dikē epitropēs*). In view of a widespread confusion of concepts, it is necessary to stress that at Athens, though less so in Hellenistic Egypt, there was a marked difference in function and terminology separating guardianship from the domestic power (*kyrieia*) over women.

Succession. The sacral and political importance of the *oikos* and the resulting necessity of securing its perpetuation, as far as possible, was also decisive for the law of succession. In Athens legitimate sons, both natural and adopted, excluded all other persons from intestate (where there is no will) and testate succession. The evidence is vague as to what happened when an Athenian whose father was still alive died intestate and without leaving children, but what is known suggests that the father was entitled to seize the son's property as belonging to the family's *klēros* ("estate"). If the father, too, was dead, the title of *klēronomos* ("possessor of the estate") would pass to the *anchisteis* (agnates) in a legally prescribed order. Women could not inherit under Athenian law. A brotherless daughter (*epiklēros*), however, though not herself entitled to her father's *klēros,* transmitted the right of succession to her sons. The danger of the patrimony thereby passing into the hands of outsiders was averted by the right of the closest *anchisteus* to claim her as his wife, together with the *klēros;* the fact that she might be married to another man was apparently notwithstanding. Analogous regulations existed in Gortyn, Sparta, and probably other places.

Testamentary succession played no large part in Classical Greece. Some *poleis,* such as Gortyn, did not recognize it at all, and everywhere it was excluded by the presence of legitimate sons. An Athenian law attributed to Solon allowed a citizen who had no son to appoint an heir by executing an adoption to take effect after his death. An early custom of dividing an estate among several future heirs widened in Classical times into the practice of drawing up a written will (*diathēkē*) ordering individual bequests to various persons.

Property. Individual ownership was known in the Greek world from at least epic times. Important exceptions in the Classical period were the control over the helots of Sparta, which was vested in the state as a whole, and, apparently, in some city-states other than Athens, certain forms of collective ownership of land and other real property, such as the inalienable ancestral city house of the Gortynian family.

Title to property

Regarding the theoretical construction and the judicial protection of property rights, Greek law remained primitive. Title signified no more than a general relation to the object. Its extent and quality varied in accordance with the purpose for which the relation had been established, ranging from full and permanent ownership through control of a ward's estate or a wife's dowry, and through mortgage to temporary tenancy. Within the limits set by the purpose, title involved the rights to hold or establish actual dominion (*kratēsis*) and to sell or otherwise dispose of the object (*kyrieia*). The holder of a title might under certain circumstances forcibly seize its object. Beyond this he was given only indirect protection, inasmuch as unwarranted resistance to his seizure or wrongful violation of his position gave rise to tort actions.

Modes of original acquisition of title were succession, the gathering of crops, and the taking of war booty. Derivative acquisition required a valid transfer by the rightful holder of the title, who within his own power of disposal might determine the quality of the title to be conveyed. The validity of a title acquired by purchase was, in addition, contingent on the payment of the price ("principle of surrogation"), while, contrary to Roman law, conveyance of the actual possession was neither sufficient nor requisite. A distinctive characteristic of Greek legal methods as compared with those of other ancient nations lay in the fact that in many *poleis* the full effect of a transfer of title to real property depended on varying forms of publicity, such as previous announcement by heralds, a formal statement of the transfer in the presence of private or official witnesses, or a recording of the transaction in a public register, the contents of which were sometimes kept permanently available by inscribing them on stone.

Obligation. *Contract.* As might be expected, contracts played an important part in the economic life of the classical *poleis*, many of which engaged in extensive commerce. Contractual liability, however, resulted only indirectly. Contrary to widely accepted views, recent research has established that Greek law did not attribute a binding effect to agreements entered upon by mere consent. Every contract (*synthēkē*) needed a "real" foundation consisting in a consideration for the loss of which the debtor could be held responsible if by failing to perform his obligation he frustrated the creditor's purpose. Because of this structure, the contractual obligation was necessarily one-sided, and the creditor had no claim to specific performance but only a right to resort to a *praxis* (enforcement proceeding) that the debtor could not avert, unless he paid a ransom usually amounting to double the damages. Historically, this system seems to have evolved from the delict (or tort), which the Greeks called *blabē*. Since, however, parties were at liberty to lay down the prerequisites of liability according to their own wishes and to fix the amount of the damage beforehand, in the epoch of the orators liability for nonfulfillment of a contractual obligation had ceased to be considered as one arising from tort. One of the important factors in this change was the principle that whatever a man voluntarily acknowledged ("homologated") should be *kyrion; i.e.*, "irrefutable" (literally "determining"). In Athens, this was confirmed by express legislation.

The development of a highly diversified stock of standard contracts was probably an achievement of professional draftsmen of the Hellenistic period, but the foundations were laid in Classical times. One of the oldest transactions was *misthōsis* (lease), its earliest and always most important object being agricultural land. Another method known already to the Archaic period, and possibly modelled after a Semitic pattern that may have been Phoenician, was to submit to liability through the acceptance of an *arrha*. Its chief area of application was sale. The *arrha* was a down payment, a multiple of which the seller had to refund as a penalty if he failed to fulfill his part of the bargain. It functioned as an indirect means of obtaining delivery that the buyer could not enforce directly, since sale was held to be strictly a cash transaction that created no obligation apart from a warranty (*bebaiōsis*) of the title conveyed. Basically, *arrha* was, of course, one form of the general contract of credit. Following the simple pattern of the loan (*daneion*) and bearing interest if agreed upon, this was the predominant type of transaction; on account of its flexibility it was, in fact, excellently suited to the needs of business. It was used to finance the extended sea trade in the particular form of the maritime loan, *i.e.*, a sum of money secured by ship or cargo or both and to be repaid on condition of safe completion of the voyage, thus also serving in a primitive fashion the economic function of insurance.

Greek law did not tie the validity of a contract to any particular form. An oral understanding arrived at in the presence of witnesses was sufficient. From the 4th century on, however, written agreements were preferred, and maritime loans were always embodied in a document (*syngraphē*).

Security. Security was known under Greek law in both personal and real forms. In the personal form, the surety (*engyos*) vouched for a defendant's appearance in court or for the fulfillment of a debtor's promise and could be held liable for the same penalty as the latter. The prevalent type of real security in Classical times was the lien (*hypothēkē*), usually drawn up as an "equity of redemption" (*prasis epi lysei*). The debtor might for the time being remain in possession of the pledge, but the creditor had a right to seize it as a forfeit after default. It was, however, possible to mortgage the same object to several creditors, each of whom would be entitled to lay hands on it but who had to satisfy in full any preceding creditors. Agreements permitting creditors to seek satisfaction by selling the lien did not come into use before the Hellenistic period.

Torts. Under Athenian law the most important private tort was *blabē*, the causing of damage, not necessarily confined to physical destruction, to another person's property. The penalty for willful infliction was twice the amount of the detriment. Other torts, basically related to but technically distinguished from *blabē*, were illegal breaking into another's domain by the use of force (*bia*) and hindrance of a rightful seizure (*exoulē*, literally "ejectment"). *Hybris* (overbearing conduct), in addition to being a public crime, gave rise in Athens to two private tort actions: one, *dikē aikeias*, could be brought for physical injury, the other, *dikē kakēgorias*, for some specified types of libel. The penalty was a fine to be determined individually from case to case. Even murder, punishable by death or exile, was basically a private tort —a relic of an archaic custom of taking private revenge —inasmuch as the prosecution of the murderer was restricted to and incumbent on the victim's relatives.

CRIMINAL LAW

Offenses under Greek law

The strongly collectivistic spirit of the classical *polis* explains the character of its public criminal law. In the democratic period of Athens, criminal conduct was a common concern of all the citizens, each of whom was entitled to bring a prosecution. Punishment was confined to conduct classified as criminal by positive legislation, but the list of offenses was long. It ranged from deeds immediately detrimental to the state and its religion, such as treason, cowardice, posing as a citizen, or acts of impiety (*asebeia*), through those jeopardizing the democratic order (*e.g.*, introducing legislation conflicting with the existing legal order) to acts disturbing the domestic peace, such as theft. Even acts revealing an uncivil attitude, such as *hybris* or undue treatment (*kakōsis*) of parents, women, or orphans, were classified as criminal. The penalties exacted were death, exile, sale into slavery, and fines.

COURTS AND PROCEDURES

At the present stage of research, the only system sufficiently known to warrant description is that of 4th-century Athens. It is important to note that its structure was peculiar to Athens, although the basic concept of *dikē* (originally, an act of seizure) was common to all the Greeks.

The Athenian judiciary. In the democratic period justice was administered by magistrates, popular courts (*dikastēria*), and the Areopagus. The functionaries received the actions and arranged the trials that took place before the courts, with each functionary having a specific jurisdiction: the archon over matters pertaining to family and succession, the "king" (*archōn basileus*) over religious matters (including murder), the *thesmothetai* ("determiners of customs") and others over the rest. A special jurisdiction was that of the *polemarchos* (literally, "general") over the metics. The trial competence of the dicasteries rested on the principle, first introduced within certain limits by Solon and made universal after the establishment of full democracy, that the citizenry in its totality should judge the affairs of its members. The dicasts were selected by lot, every citizen over 30 years old being eligible. In rare cases of great political importance, the whole *hēliaia* (*i.e.*, the popular assembly organized as a court of 6,001 men) was convened. Normally sections of the *hēliaia* (specifically called *dikastēria*), composed of 1,501, 1,001, or 501 men in criminal cases and 201 men in civil cases, were charged with the decision.

Murder cases were argued before the Areopagus, a body composed of former archons. Probably transformed from an original council of the nobility, it was a relic of the predemocratic period.

Procedure. In the Greek view, the trial served to determine the justification of a claim to seize the defendant's person or belongings or both by way of an enforcement proceeding (*praxis*). The claim (*dikē*) might be raised by the plaintiff in pursuance of a private right or as a "public" (*dēmosia*) *dikē* for the purpose of obtaining the defendant's punishment. The filing of a public *dikē* (technically called a *graphē*) was open to every citizen. Apart from this, the differences between private and criminal procedures were slight.

Both private *dikai* and *graphai* had to be initiated by summoning the defendant (who might be under arrest) to the magistrate having jurisdiction in the matter and by filing a written complaint with the latter, who would subject it to a preliminary examination (*anakrisis*). Parties to a civil suit concerning pecuniary affairs were then sent to a public arbitrator (*diaitētēs*). If one of them refused to accept the award or if the matter was not subject to compulsory arbitration, the case was referred to a discastery presided over by the magistrate. The dicasts, after listening to the arguments and evidence submitted by the parties, found their decision, which could only be a choice between the two proposals made by the parties, by secret ballot without debate. Their judgment was final between the parties, but the loser might bring a private tort action (*dikē pseudomartyriōn*) against a witness whose false deposition had influenced the verdict. A victorious plaintiff in a private lawsuit had to enforce the judgment himself by attaching property of the defendant.

HISTORICAL IMPORTANCE OF THE GREEK LAW

In distinct contrast with the Greek philosophy of justice, the positive law of ancient Greece had little influence on later developments. Its concepts and methods did, of course, widely determine the legislation and practice of Hellenistic monarchies, and a few institutions of Greek origin, such as the "Rhodian" maritime law of jettison or certain methods of documentation (mostly Hellenistic, to be sure), were adopted by the Romans. Contrary to views held some decades ago, however, the late Roman law, and with it west European legal doctrine, did not undergo any notable degree of Hellenization. Only in the customs of isolated places in Greece itself do some ancient traditions seem to survive; their extent is still a problem for legal historians.

BIBLIOGRAPHY. P. VINOGRADOFF, *The Jurisprudence of the Greek City*, vol. 2 of his *Outlines of Historical Jurisprudence* (1922), is largely obsolete but still deserves mention among the books written on Greek law in the English language. Comprehensive presentations of more recent date include J.W. JONES, *The Law and Legal Theory of the Greeks* (1956); and A.R.W. HARRISON, *The Law of Athens*, vol. 1, *The Family and Property* (1968). An extensive discussion of procedural matters, unfortunately not fully satisfactory from a legal point of view, is found in the philological work by R.J. BONNER and G. SMITH, *The Administration of Justice from Homer to Aristotle*, 2 vol. (1930–38, reprinted 1968). A small but also valuable work is G.M. CALHOUN, *Introduction to Greek Legal Science* (1944), dealing with the intellectual background of Greek law. Detailed bibliographical data may be found in all these works.

Greek Mythology

The body of stories concerning the gods, heroes, and rituals of the ancient Greeks is the subject matter of Greek mythology. That myths contained a considerable element of fiction the more critical Greeks, such as the philosopher Plato in the 5th–4th centuries BC, recognized; in general, however, the myths were viewed in the popular piety of the Greeks as true accounts. Greek mythology has subsequently had extensive influence on the arts and literature of Western civilization, which fell heir to much of Greek culture.

Nature and significance. Although men of all countries, eras, and stages of civilization have developed myths that explain the existence and workings of natural phenomena, recount the deeds of gods or heroes, or seek to justify social or political institutions, the myths of the Greeks have remained unrivalled in the Western world as sources of imaginative and appealing ideas. Poets and artists from ancient times to the present have derived inspiration from Greek mythology and have discovered contemporary significance and relevance in classical mythological themes.

Importance of Greek mythology in the Western world

Myths helped to illuminate and make Greek religion intelligible to worshippers by providing a wealth of religious background detail conceived in simple and picturesque terms. The Romans identified their own functionally perceived deities with their more fully anthropomorphized Greek counterparts, which resulted in a wholesale, though mainly literary, adoption of Greek mythology.

During the Renaissance, the view of myth was reinterpreted in terms of allegory (a symbolic story form), and, in the course of its reinterpretation, Greek mythology enriched literature from the Renaissance period onward with classical allusions. In the modern world, not only art and literature have benefitted from Greek mythology but scientists also have retained the ancient practice of naming new stars and planets (and later, even rockets) after Greek gods and heroes. Indeed, the names of Greek mythological figures have survived in innumerable contexts—from advertising to the cinema—in modern times.

The conquests of Alexander the Great in the 4th century BC and, later, those of the Romans helped to spread Greek mythology throughout the ancient Mediterranean world, profoundly influencing Mediterranean culture. Even the myths of the Egyptians and Babylonians were retold in typical Greek style. The Roman poets, particularly Virgil and Ovid, were most influential in bequeathing Greek mythology to Western posterity. Without the rich heritage of Greek mythology, the literature and art of the Renaissance and modern world would have been infinitely poorer. English and German literature and, above all, French are especially indebted to Greek myth. Psychoanalysts such as Sigmund Freud as well as dramatists (*e.g.*, Jean-Paul Sartre in France and Eugene O'Neill in the United States) have reinterpreted classical myths in the light of modern contemporary experience. Greek mythology has also provided artists with an unparalleled variety of exciting motifs.

Sources of myths: literary and archaeological. *The Homeric poems: the Iliad and the Odyssey.* Homer, who lived probably in the 9th or 8th century BC, is the oldest known literary source of Greek myth and legend: both of his great epics, the *Iliad* and the *Odyssey*, belong to a tradition reaching back into Mycenaean times (*c.* 1400–1100 BC). In them, Homer collected the many myths of the gods, arranged them in a coherent whole, assembled

the gods on Mt. Olympus, and related in detail their activities, loves, and hates. Unlike Hesiod, another great poet, who flourished *c.* 800 BC, Homer was not primarily concerned with cosmogony (origin of the world), and he thus refers only incidentally to Oceanus and his wife Tethys as the authors of creation and to the Titans (offspring of Uranus and Gaea) as imprisoned within the ground. The aim of an epic poet was to entertain; thus, much of what Homer says about the gods is not intended to be taken seriously, and even more about them he assumed. The myth that the god Apollo spread plague by discharging his arrows is a type of religious myth. But others, like the goddess Hera's punishments, are more akin to folktales. Homer remains a primary source of legends connected with the city of Troy in Asia Minor, as well as of older sagas, such as those of the heroes Heracles (in Roman mythology Hercules), Meleager, and Jason.

Cosmogonic and etiological interests

The works of Hesiod: Theogony and Works and Days. The fullest and most important source of myths about the origin of the gods is the *Theogony* ("Divine Genealogy") by Homer's near contemporary, the Boeotian poet Hesiod. The grim tale of mutilation, revolt, and struggles against older gods and monsters bears some relation to Near Eastern cosmogonical myths. Much else is a bare catalog of matings and births of gods, rivers, planets, winds, and more abstract phenomena. The story of Prometheus' tricking of Zeus, the leading god of Olympus, in giving him bones rather than meat is an etiological (explanatory) myth pertaining to the customs of Greek sacrifice. On the other hand, the myth of Pandora (the first woman, who opened an urn, thus releasing various evils upon mankind) is clearly based on folktale. Both myths reappear in the *Works and Days* (a farmer's calendar, in epic form, of somewhat later date) as well as the myth of the Four Ages of the world, further genealogies, and other myths.

Other literary works. Fragmentary post-Homeric epics, of varying date and authorship, filled the gaps in the accounts of the Trojan War recorded in the *Iliad* and *Odyssey;* the so-called Homeric Hymns (shorter surviving poems) are the source of several important religious myths. Many of the lyric poets preserved various myths, but the odes of Pindar of Thebes (flourished 6th–5th centuries BC) are particularly rich in myth and legend. The works of the three tragedians—Aeschylus, Sophocles, and Euripides, all of the 5th century BC—are remarkable for the variety of the traditions they preserve. In Hellenistic times (323–30 BC) Callimachus, a 3rd-century-BC poet and scholar in Alexandria, recorded many obscure myths; and Euhemerus, a novelist of the 3rd century BC, suggested that the gods were originally human, thus giving his name to this view, known as Euhemerism. Apollonius of Rhodes, another scholar of the 3rd century BC, preserved the fullest account of the Argonauts in search of the Golden Fleece. In the period of the Roman Empire, the *Library* of the pseudo-Apollodorus (attributed to a 2nd-century-AD scholar), the antiquarian writings of the Greek biographer Plutarch, and the works of Pausanias, a 2nd-century-AD geographer, as well as the *Genealogies* of Hyginus, a 2nd-century-AD mythographer, have provided valuable sources in Latin of later Greek mythology.

Significance of Mycenaean and Minoan archaeological discoveries

Archaeological discoveries. The discovery of the Mycenaean civilization by Heinrich Schliemann, a 19th-century German amateur archaeologist, and the discovery of the Minoan civilization in Crete (from which the Mycenaean ultimately derived) by Sir Arthur Evans, a 20th-century English archaeologist, helped to explain many of the questions raised by scholars about Homer's epics and provided archaeological proofs of many of the mythological details about gods and heroes. Unfortunately, the evidence about myth and ritual at Mycenaean and Minoan sites is entirely monumental, because the Linear B script (an ancient form of Greek found in both Crete and Greece) was mainly used to record inventories, though the names of gods and heroes have been doubtfully revealed.

Geometric designs on pottery of the 8th century BC depict scenes from the Trojan cycle, as well as the adventures of Heracles. The extreme formality of the style, however, renders much of the identification difficult, and there is no inscriptional evidence accompanying the designs to assist scholars in identification and interpretation. In the succeeding Archaic (*c.* 750–*c.* 500 BC), Classical (*c.* 480–323 BC), and Hellenistic periods, Homeric and various other mythological scenes appear to supplement the existing literary evidence.

Forms of myth in Greek culture. *Religious myths.* Greek religious myths are concerned with gods or heroes in their more serious aspects or are connected with ritual. They include cosmogonical tales of the genesis of the gods and the world out of Chaos, the successions of divine rulers, and the internecine struggles that culminated in the supremacy of Zeus, the ruling god of Olympus. They also include the long tale of Zeus's amours with goddesses and mortal women, which usually resulted in the births of younger deities and heroes. The goddess Athena's unique status is implicit in the story of her motherless birth (she was born directly from Zeus); and the myths of Apollo explain that god's sacral associations, describe his remarkable victories over monsters and giants, and stress his jealousy and the dangers inherent in immortal alliances. Myths of Dionysus (a wine god whose cult involved orgiastic rites), on the other hand, demonstrate the hostility aroused by a novel faith. Some myths are closely associated with rituals, such as the account of the drowning of the infant Zeus's cries by the Curetes, attendants of Zeus, clashing their weapons, or Hera's (the queen goddess of Olympus) annual restoration of her virginity by bathing in the spring Canathus. Some myths about heroes and heroines also had a religious basis. The tale of man's creation and moral decline forms part of the myth of the Four Ages (see below). His subsequent destruction by flood and regeneration from stones is partly based on folktale.

Themes of legends and folktales

Legends. Myths were viewed as embodying divine or timeless truths, whereas legends (or sagas) were quasi-historical. Hence, famous events in epics, such as the Trojan War, were generally regarded as having really happened, and heroes and heroines were believed to have actually lived. Earlier sagas, such as the voyage of the Argonauts, were accepted in a similar fashion. Most Greek legends were embellished with folktales and fiction, but some certainly contain a historical substratum. Such are the tales of more than one sack of Troy, which are supported by archaeological evidence, and the labours of Heracles, which suggest Mycenaean feudalism. Again, the legend of the Minotaur (a being part human, part bull) could have arisen from exaggerated accounts of bull leaping in ancient Crete.

In another class of legends, heinous offenses, such as attempting to make love to a goddess against her will, deceiving the gods grossly by inculpating them in crime, or assuming their prerogatives, were punished by everlasting torture in the underworld. The consequences of social crimes, such as murder or incest, were also described in legend (*e.g.*, the story of Oedipus, who killed his father

Heracles fighting with the Amazons, detail from a volute crater attributed to Euphronius, *c.* 500 BC. In the Museo Archeologico, Arezzo, Italy.
Alinari

and married his mother). Legends were also sometimes employed to justify existing political systems or to bolster territorial claims.

Folktales. Folktales, consisting of popular recurring themes and told for amusement, inevitably found their way into Greek myth. Such is the theme of lost persons —whether husband, wife, or child (*e.g.*, Odysseus, Helen of Troy, Paris of Troy)—found or recovered after long and exciting adventures. Journeys to the land of the dead were made by Orpheus (a hero who went to Hades to restore his dead wife Eurydice to the realm of the living), Heracles, Odysseus, and Theseus (the slayer of the Minotaur). The victory of the little man by means of cunning against impossible odds, the exploits of the superman (*e.g.*, Heracles), or the long-delayed victory over enemies are still as popular with modern writers as they were with the Greeks. The successful countering of the machinations of cruel sires and stepmothers, rescues of princesses (who are often witches) from monsters, or temporary forgetfulness at a crucial moment are also familiar themes in Greek myth. Recognition by tokens, such as Odysseus' scar or peculiarities of dress, is another common folktale motif. The babes-in-the-wood theme of the exposure of children and their subsequent recovery (though usually as the result of a dream or an oracle) is also found in Greek myth. Wishful thinking was responsible for the theme of victory over death, the related visit to the land of ghosts, and, of course, the happy ending, as noted, for example, in the Argonaut saga.

Types of myths in Greek culture. *Myths of origin.* Myths of origin represent an attempt to render the universe comprehensible in human terms. Greek creation myths (cosmogonies) and views of the universe (cosmologies) were more systematic and specific than those of other ancient peoples. Yet their very artistry serves as an impediment to interpretation because true myth is usually embellished with folktale and fiction told for its own sake. Thus, though the aim of Hesiod's *Theogony* is to describe the ascendancy of Zeus (and, incidentally, the rise of the other gods), the inclusion of such familiar themes as the hostility between the generations, the enigma of woman (Pandora), the exploits of the friendly trickster (Prometheus), or exciting struggles against powerful beings or monsters like the Titans (and, in later tradition, the Giants) merely enhances the interest of an epic account.

According to Hesiod, four primary divine beings first came into existence: Chaos (Space), Gaea (Earth), Tartarus (the Abyss), and Eros (Love). The creative process began with the forcible separation of Gaea from her doting consort Uranus (Heaven) in order to allow her progeny to be born. The means of separation employed, viz., the cutting off of Uranus' genitals by his son Cronus, bears a certain resemblance to a similar story recorded in Babylonian epic. The crudity is relieved, however, in characteristic Greek fashion by the friendly collaboration of Uranus and Gaea, after their divorce, in a plan to save Zeus from the same Cronus, his cannibalistic sire.

According to Greek cosmological concepts, the Earth was viewed as a flat disk afloat on the river of Ocean. The Sun (Helios) traversed the heavens like a charioteer and sailed around the Earth in a golden bowl at night. Natural fissures were popularly regarded as entrances to the subterranean house of Hades, home of the dead.

Myths of the ages of the world. Egyptians and Sumerians knew of a paradise free from death and suffering reserved for the gods. Hesiod, on the other hand, in the *Works and Days*, came near to propounding a philosophy of history in explaining man's decline by the myth of the Four Ages. The gods created the men of the Golden Age during the reign of Cronus. They never grew old, were free from toil, and passed their time in jollity and feasting. When they died, they became guardian spirits on Earth.

The decline of man

Why the Golden Age came to an end Hesiod failed to explain, but it was succeeded by the Silver Age. After an inordinately prolonged childhood, the men of the Silver Age began to act presumptuously and neglected the gods. Consequently, Zeus hid them in the Earth, where they became spirits among the dead.

Zeus next created the men of the Bronze Age, men of violence who perished by mutual destruction. At this point the poet somewhat illogically intercalates the Race of Heroes, of whom the more favoured (who were related to the gods) reverted to a kind of restored Golden Age existence under the rule of Cronus (forced into honorable exile by his son Zeus) in the Isles of the Blessed.

The final age, the antithesis of the Golden Age, was the Iron Age, during which the poet himself had the misfortune to live. But even that was not the worst, for he believed that a time would come when infants would be born old, and there would be no recourse left against the universal moral decline. The presence of evil was explained by Pandora's rash action in opening the fatal urn.

Myths of the gods. Myths about the gods described their births, victories over monsters or rivals, love affairs, special powers, or connections with a cultic site or ritual. As these powers tended to be wide, the myths of many gods were correspondingly complex. Thus, the Homeric Hymns to Demeter, a goddess of agriculture, and to the Delian and Pythian Apollo describe how these deities came to be associated with sites at Eleusis, Delos, and Delphi, respectively. Similarly, myths about Athena, the patroness of Athens, tend to emphasize the goddess' love

of war and her affection for heroes and the city of Athens; and those concerning Hermes (the messenger of the gods), Aphrodite (goddess of love), or Dionysus describe Hermes' proclivities as a god of thieves, Aphrodite's lovemaking, and Dionysus' association with wine, frenzy, miracles, and even ritual death. Poseidon (god of the sea) was unusually atavistic, in that his union with Earth and his equine adventures appear to hark back to his pre-marine status as a horse or earthquake god. Many myths, on the other hand, are trivial and lighthearted. Typical of such are the amusing descriptions of conjugal friction between Zeus and Hera in the *Iliad*, which, though conceivably reflecting religious hostility between Zeus worshippers and Hera worshippers in prehistoric times, were mainly the products of fiction and folktale. Similarly, the beauty contest described in the famous Judgment of Paris (son of the king of Troy) appears to be little more than a fairytale in essence.

Combinations of myths, legends, and folktales

As time went on, an accretion of minor myths continued to supplement the older and more authentic ones. Thus, the loves of Apollo, virtually ignored by Homer and Hesiod, explained why the bay (or laurel) became Apollo's sacred tree and how he came to father Asclepius, a healing god. Similarly, the presence of the cuckoo on Hera's sceptre at Hermione or the invention of the panpipe were explained by fables. Such etiological myths proliferated during the Hellenistic era, though in the earlier periods genuine examples are harder to detect.

Of folk deities, the Nymphs (nature goddesses) personified nature or the life in water or trees and were said to punish unfaithful lovers. Water nymphs (Naiads) were reputed to drown those with whom they fell in love, such as Hylas, a companion of Heracles. Even the gentle Muses (goddesses of the arts and sciences) blinded their human rivals, such as the bard Thamyris. Satyrs (youthful folk deities with bestial features) and Silens (old and drunken folk deities) were the Nymphs' male counterparts. Like sea deities, Silens possessed secret knowledge that they would reveal only under duress. Charon, the grisly ferryman of the dead, was also a popular figure of folktale.

Myths of heroes. Hero myths included elements from tradition, folktale, and fiction. The saga of the Argonauts, for example, is highly complex and includes elements from folktale and fiction, but the information that the fleet mustered at Colchis may be regarded as genuine legend. Episodes in the Trojan cycle, such as the departure of the Greek fleet from Aulis or Theseus' Cretan expedition and death on Scyros, may belong to traditions dating from the Minoan–Mycenaean world. On the other hand, events described in the *Iliad* probably owe far more to Homer's creative ability than to genuine tradition. Even heroes like Achilles, Hector, or Diomedes are largely fictional, though doubtlessly based on legendary prototypes. The *Odyssey* is the prime example of the wholesale importation of folktales into epic. All the best known Greek hero myths, such as the labours of Heracles and the adventures of Perseus, Cadmus, Pelops, or Oedipus, depend more for their interest on folktales than legend. Certain heroes—Heracles, the Dioscuri (the twins Castor and Pollux), Amphiaraus (one of the Argonauts), or Hyacinthus (a youth loved by Apollo and accidentally killed)—may be regarded as partly legend and partly religious myth. Thus, whereas Heracles, a man of Tiryns, may originally have been a historical character, the myth of his demise on Oeta and subsequent elevation to full divinity is closely linked with a cult. In time, Heracles' popularity was responsible for connecting his story with the Argonauts, an earlier attack on Troy, and with Theban myth. Similarly, the exploits of the Dioscuri are those of typical heroes: fighting, carrying off women, and cattle rustling. After their death they passed six months alternately beneath the Earth and in the world above, which suggests that their worship, like that of Persephone (the daughter of Zeus and Demeter), was connected with fertility or seasonal change.

Myths of seasonal renewal. Certain myths, in which goddesses or heroes were temporarily incarcerated in the underworld, were allegories of seasonal renewal. Perhaps the best known myth of this type is the one telling how Hades (Latin Pluto), the god of the underworld, carried Persephone off to be his consort, causing her mother Demeter, the corn goddess, to allow the earth to grow barren out of grief. Because of her mother's grief, Zeus permitted Persephone to spend six months above and six months below ground. The meaning is patent. During the torrid Greek summer the earth lies bare and unproductive. When rain falls in autumn and the fields are ploughed, the land begins to bloom once more. This simple myth seems to have inspired the Eleusinian Mysteries (an agricultural and salvatory religion), whose annual celebration helped men to find a compromise with death.

The mysterious myth of the concealment of the infant Zeus in Crete has, as already mentioned, ritual associations. In other words, the child, born of Rhea, one form of the earth mother, was in origin a fertility spirit. His counterparts were Adonis and Attis. Adonis, son of Myrrha (the balsam tree), was loved by Aphrodite and killed by a boar. Zeus therefore arranged that Adonis should spend a third of his life above ground, a third below, and a third where he wished. Hence, female devotees ritually lamented the season of his passing. Attis similarly was born of the almond tree and the beloved of Cybele. When Attis died as a result of a frenzy in which he emasculated himself, Cybele persuaded Zeus to preserve his body and keep one finger (a phallic symbol) alive.

A well-known Attic myth describes how Cecrops' daughters, significantly styled Agraulos (Shining), Herse (Dew), and Pandrosos (All Dew), were given the snake monster Erichthonius, the product of the fire god Hephaestus' attempt to rape her, to keep in a chest for Athena. Snakes are phallic symbols and are associated with the earth, thus suggesting a fertility motif.

Myths involving theriolatry. Many Greek myths involve animal transformations, though there is no proof that theriolatry (animal worship) was ever practiced by the Greeks. Gods sometimes assumed the form of beasts in order to deceive goddesses or women. Zeus, for example, assumed the form of a bull when he carried off Europa, a Phoenician princess, and appeared in the guise of a swan in order to attract Leda, wife of a king of Sparta; Hera, in another incident, transformed Io, a maiden loved by Zeus, into a heifer. Poseidon took the shape of a stallion to beget the wonder horses Arion and Pegasus, as did Boreas (the North Wind) to mate with mares.

Deities appearing in nonhuman form

Though such animals are involved in significant mythical events, they are not necessarily the objects of theriolatry, as noted above. They usually served other purposes in the story, such as being agents of change, symbols of strength and passion, objects to test the courage of heroes, agents of escape, or forms of punishment. Snakes licked the ears of the seer Melampus, thus enabling him to understand the language of birds. Tiresias, a Theban seer, changed his sex after killing a female serpent in the act of mating and was thus able to settle the argument that had arisen between Zeus and Hera as to whether man or woman gained more pleasure from love. Bulls represented unbridled strength and passion and were not especially associated with any particular deity. Poseidon was responsible for the bull that captivated Pasiphae, wife of King Minos of Crete, and begot the Minotaur (half human, half bull). The same beast was reputed to have been brought by Heracles from Crete and to have been captured by Theseus, who sacrificed it to Apollo at Marathon. Mythical land or sea monsters, as well as lions and boars, served to test the heroes' courage. Notable were the famous Calydonian boar hunt, in which many heroes took part, and Heracles' capture of the Erymanthian beast. Other animal transformations are also known. Leto, the mother of Apollo and Artemis, assumed the form of a wolf in order to escape Hera. Lycaon, king of Arcadia, was changed into a wolf by Zeus for practicing human sacrifice. The huntsman Actaeon was changed into a stag by Artemis for surprising her in the act of bathing.

Other types. Other types of myth exemplified the belief that the gods sometimes appeared on Earth disguised

Deities appearing in human form

as men and women and rewarded any help or hospitality offered them. Baucis, an old Phrygian woman, and Philemon, her husband, for example, were saved from the flood by offering hospitality to Zeus and Hermes, both of whom were in human form. The punishment of men's presumption in claiming to be the gods' superiors, whether in musical skill or even the number of their children, is described in several myths. The gods' jealousy of their musical talents appears in the beating and flaying of the flute-playing Satyr, Marsyas, by Athena and Apollo, as well as in the attaching of ass's ears to King Midas for failing to appreciate the superiority of Apollo's music to that of the god Pan. Jealousy was the motive for the slaying of Niobe's many children, because of Niobe's flaunting her fecundity to the goddess Leto, who had only two offspring. Similar to such stories are the moral tales about the fate of Icarus, who flew too high on homemade wings, or the myth about Phaethon, the son of Helios, who failed to perform a task too great for him (controlling the horses of the Sun).

Transformation into flowers or trees, whether to escape a god's embraces (such as Daphne, a nymph transformed into a laurel tree), as the result of an accident (such as Hyacinthus, a friend of Apollo, who was changed into a flower), or because of pride (*e.g.*, the beautiful youth Narcissus who fell in love with his own reflection and was changed into a flower), were familiar themes in Greek myth.

Also popular were myths of fairylands, such as the Garden of the Hesperides (in the far west) or the land of the Hyperboreans (in the far north), or encounters with monstrous or outlandish people, such as the Centaurs or Amazons.

Greek mythological characters and motifs in art and literature. The earliest visual representations of mythological characters and motifs occur in late Mycenaean and sub-Mycenaean art. Though identification is controversial, Centaurs, a Siren, and even Zeus's lover Europa have been recognized. Mythological and epic themes are also found in Geometric art of the 8th century BC, but not until the 7th century did such themes become popular both in ceramic and sculptured works. During the Classical and subsequent periods, they became commonplace. The birth of Athena was the subject of the east pediment of the Parthenon in Athens, and the legend of Pelops and the labours of Heracles was the subject of the corresponding pediment and the metopes (a space on a Doric frieze) of the Temple of Zeus at Olympia. The battles of gods with Giants and of Lapiths (a wild race in northern Greece) with Centaurs were also favourite motifs. Pompeian frescoes reveal realistic representations of Theseus and Ariadne, Perseus, the fall of Icarus, and the death of Pyramus.

Resurgence of Greek mythological motifs

The great Renaissance masters added a new dimension to Greek mythology. Among the best known subjects of Italian artists are Botticelli's "Birth of Venus," the Ledas of Leonardo da Vinci and Michelangelo, and Raphael's "Galatea."

Greek mythology formed the staple of most Greek poetry and epic, as well as of dramatic works. It also influenced the thoughts of philosophers and historians to a marked degree. Homer mingled myth with legend, and Hesiod attempted to give a consistent account of mythology in general or employed it for didactic or social ends. Pindar, unlike the other lyric poets, took an independent line and toned down the more unsavoury features. The tragedians manipulated myths in the interests of drama or to suit their inner vision, and Aristophanes exploited mythological parody. During the Hellenistic Age, poets such as Apollonius, Callimachus, and others in the *Palatine Anthology* passed on a wealth of Greek myth to the Romans.

Through the medium of Latin and, above all, the works of Ovid, Greek myth influenced medieval poets such as Petrarch and Boccaccio in Italy and Chaucer in England; Dante in Italy during the Renaissance; and, later, the English Elizabethans and John Milton. Racine in France and Goethe in Germany revived Greek drama, and nearly all the major English poets from Shakespeare to Robert Bridges turned for inspiration to Greek mythology. More recently, classical themes have been reinterpreted by such major dramatists as Jean Anouilh, Jean Cocteau, and Jean Giraudoux in France, Eugene O'Neill in America, and T.S. Eliot in England and by great novelists such as James Joyce (Irish) and André Gide (French). The German composer Christoph Gluck (18th century), the German-French composer Jacques Offenbach (19th century), and many others have set Greek mythological themes to music.

Conclusion. The importance of Greek mythology in the intellectual, artistic, and emotional history of Western man can hardly be overestimated. To deny its value and significance would be tantamount to denying the achievements of Western culture itself and the genius of the great writers and artists who have been inspired by it. The origins of myth are still obscure, but most scholars would agree that it provides an unerring guide to the thought and psychology of a people. The directness, clarity, and transcendent humanity of the Greeks permeate all their works, and the imaginative appeal of their mythology, rather than any real or fancied symbolism, has stimulated creative effort. Men of all eras have been moved and baffled by the deceptive simplicity of Greek mythmaking, whether in word or stone.

Greek Religion

Greek religion is concerned with the beliefs of the ancient Hellenes about gods, conceived in human terms, and the way they worshipped them. It is not the same as Greek mythology, which is concerned with traditional tales, though the two are closely interlinked. Curiously, for a people so religiously minded, the Greeks had no word for religion itself—the nearest term being *eusebeia* (piety).

Greek religion, in its developed form, lasted for more than a thousand years, from the time of Homer (probably 9th or 8th century BC) to the reign of the emperor Julian (4th century AD), though its origins may be traced to the remotest eras. During that period its influence spread as far west as Spain, east to the Indus, and throughout the Mediterranean world. Its effect was most marked on the Romans, who identified their deities with the Greek. Under Christianity, Greek heroes and even deities survived as saints, while the rival madonnas of southern European communities reflected the independence of local cults. The rediscovery of Greek literature during the Renaissance and, above all, the novel perfection of classical sculpture produced a revolution in taste that had far-reaching effects on Christian religious art. The most striking characteristic of Greek religion was the belief in a multiplicity of anthropomorphic deities, coupled with a minimum of dogmatism. Though pious and parochial in their attitude toward local cults, the Greeks welcomed such foreign deities as the Thracian Bendis

and Cotys (Cotytto), the Phrygian Cybele and Sabazius, and the Egyptian Isis and Sarapis.

The Greeks' reticent attitude toward their own religious beliefs constitutes in itself an obstacle to knowledge. Firsthand information about the details of ritual, such as the precise working of the Delphic oracle, is lacking; and of some important religious events, like the mysteries at Eleusis, little is known, since the initiates were bound to secrecy; and late Christian accounts are naturally biassed. Also, the early history of the Dionysiac cult is relatively obscure, apart from covert references in Homer, fanciful vase paintings, and the dramatic description given in Euripides' *Bacchae*. The main sources of knowledge are inevitably literary, for although archaeology has thrown much light on the externals of religion, it has not and cannot hope to reveal the feelings and attitudes of worshippers. The best sources are historical and antiquarian (the evidence of Pausanias in the 2nd century AD is uniquely valuable), though poetry and philosophy contribute a great deal. Inscriptions, too, are of vital importance in revealing the identities of buildings, cults, calendars, and sacred writings and are often the sole source of information.

HISTORY

The roots of Greek religion. Greek religion evolved during Neolithic times in the original home of the Greeks in Central Europe, where the Indo-European sky god, variously known as Zeus, Jupiter, and Dyaus, was believed to control the weather. As waves of Greek-speaking peoples moved south into the peninsula during the 2nd millennium BC, they absorbed Pelasgian (pre-Greek) cults such as those of the primitive oracle at Dodona, the river and wind gods, and horse-headed Demeter. Whether Greek deities were ever visualized in animal form is uncertain, though each possessed its familiar beast or bird. Some, like Hestia, the hearth goddess, in whose honour a perpetual fire was kept burning in public buildings, were only vaguely personified; while others, like Apollo, Hermes, and Dionysus, were sometimes represented as shaped stones, columns, stocks, or posts.

Indo-European nature deities

In southern Greece the newcomers developed a powerful suzerainty, centred at Mycenae, and came into contact with the Minoan nature religion. As a result, Zeus himself acquired a Cretan origin as well as a consort in the powerful Argive goddess Hera. Athena, the palace guardian, became Zeus's daughter, while Artemis, the "mistress of wild beasts," was said to be Apollo's twin. The period and direction of Apollo's advent are still unresolved, but the Dorians who destroyed the Mycenaean civilization about 1100 BC apparently assisted in popularizing his worship. The Dark Ages that followed the Dorian invasion ended in the 8th century BC, though the traditions of previous eras were doubtless preserved by bards. Kings were succeeded by feudal aristocracies. The gods of Homer's *Iliad* and *Odyssey* appear to mirror the society for which he composed: wealthy, urbane, and easy living. Hesiod (fl. *c.* 800 BC), on the other hand, in his *Works and Days*, preached piety and ritualism and regarded Zeus as the principle of justice in an unjust world.

The Archaic period. Sometime before Homer composed his epics, the orgiastic cult of the nature divinity Dionysus reached Greece from Thrace and Phrygia. Because the god's name is Greek and has been recognized in a Mycenaean tablet, it has been suggested that his worship represented not so much a novelty as a reversion to Minoan religion. His devotees, armed with *thyrsoi* (wands tipped with pinecones) and known as Maenads ("mad ones") or Bacchants, were reputed to wander in *thiasori* (revel bands) about mountain slopes, such as Cithaeron or Parnassus, right down into Roman imperial times. They were also supposed, in their ecstasy, to practice the *sparagmos*, the tearing of living victims to pieces and feasting on their raw flesh (*ōmophagia*). This orgiastic cult of Dionysus, however, was subsequently civilized and tamed. Tragedy developed from the choral song of Dionysus.

Dionysus and the Eleusinian mysteries

Since the nobles owned the land they naturally tended to control the agrarian cults, and this practice continued until comparatively late times. Besides, they were also clan chieftains; and long after the political reorganization of Athens in the late 6th century BC, the worship of clan deities, such as Athena Phratria (Protectress of the Clan) and Zeus Phratrios (Protector of the Clan), remained popular. The 7th and 6th centuries BC were characterized by the revolt of the underprivileged against the nobles. Popular leaders, known as tyrants, seized power in the city-states; and some, like the Peisistratids at Athens, enhanced their glory by building temples and reviving religious festivals. Political unrest was reflected in spiritual unrest. Initiation into the mysteries of Demeter and Kore at Eleusis fulfilled a deep religious need, while oracles, with their claim to reveal the future, were eagerly consulted by individuals and states. Delphi became the cultic centre not only of Greece but of Lydia also. In addition to the official cults, credence was placed in soothsayers and the ability of adepts to evade death and undertake psychic journeys.

The Classical period. During the 6th century BC the rationalist thinking of Ionian philosophers had offered a serious challenge to traditional religion. At the beginning of the 5th century, Heracleitus of Ephesus and Xenophanes of Colophon heaped scorn on cult and gods alike. The Sophists, with their cynical probing of accepted values, continued the process, as did the dramatists Euripides and Aristophanes. Despite these attacks, the civic cults at Athens and elsewhere attained their apogee. The old Peisistratid temples destroyed during the Persian sack of 480 BC were gradually replaced by larger and more imposing edifices, culminating in the Parthenon of Pericles.

Festivals were expressive of religion's social aspect and attracted large gatherings (*panēgyreis*). Being mainly agrarian in origin, they were seasonal in character, held often at full moon and on the 7th of the month in the case of Apollo, and always with a sacrifice in view. Many were older than the deity they honoured, like the Hyacinthia and Carneia in Laconia, which were transferred from local heroes to Apollo. The games were a special kind of festival, sometimes forming part of other religious events.

Popular religion flourished alongside the civic cults.

Gad Borel—Boissonnas

Painting showing a dead man (right) receiving an offering of a votive ship and two calves, and the priestess (left) pouring a libation. From a terra-cotta sarcophagus from the necropolis of Ayia Triádha, Crete, *c.* 1400 BC. In the Archaeological Museum, Crete.

Peasants worshipped the omnipresent deities of the countryside, such as the Arcadian goat-god Pan, who prospered the flocks, and the Nymphs (like Eileithyia, they aided women in childbirth) who inhabited caves, springs (Naiads), trees (Dryads and Hamadryads), and the sea (Nereids). They also believed in nature spirits such as satyrs and sileni, who were mimed in drama, and equine centaurs. Among the more popular festivals were the rural Dionysia, which included a phallus pole; the Anthesteria, when new wine was broached and offerings were made to the dead; the Thalysia, a harvest celebration; the Thargelia, when a scapegoat (*pharmakos*) assumed the communal guilt; and the Pyanepsia, a bean feast in which boys collected offerings to hang on the *eiresiōne* ("wool pole"). Women celebrated the Thesmophoria in honour of Demeter, and commemorated the passing of Adonis with laments and miniature gardens, while images were swung from trees at the Aiora to get rid of an ancient hanging curse. Magic was widespread. Spells were inscribed on lead tablets. Statues of Hecate, goddess of witchcraft, stood outside dwellings, while Pan's image was beaten with herbs in time of meat shortage.

The Hellenistic period. Though the city-states were vanquished by Alexander the Great, loyalty to the old deities remained remarkably tenacious, and colonists spread their worship abroad. Apollo (and the Sibyl) reached Italy during the 8th century; other cults followed, and the process of identification with native counterparts began. It was always more marked in mythology than cult, and some native deities (*e.g.*, Quirinus) were little affected. Cybele was introduced from Phrygia in 204 BC, but the lodges of Bacchus were suppressed in 186 BC.

The Hellenistic era was characterized by the popularity of mystery religions. The Cabeiri, or Great Gods, of Samothrace were patronized both by the Ptolemies (the Macedonian dynasty ruling Egypt) and the Romans, while the Egyptian cults of Isis and Sarapis, though already Hellenized, quickly spread over the classical world. Syncretism—*i.e.*, the blending of deities' functions and identification with foreign gods—was a feature of the post-Alexandrian world. Astrology was studied seriously by astronomers and philosophers, but on a lower plane it descended into quackery. Christianity then arose at a time of political and religious crisis. Papan views of the afterlife remained unsatisfactory, whereas the new creed that recognized neither national nor class barriers brought the hope of personal salvation to all.

BELIEFS

The gods. The Greeks regarded the gods as the immortal controllers of natural forces, which were suitably departmentalized. Zeus, as weather god, was known by such cult titles as Maemactes (Stormy) and Cataebates (Striker), and in times of drought his mountain shrines were visited. Poseidon was god of the sea, Hades (or Pluto) of the underworld; Demeter was goddess of the harvest, Hera of marriage, and Athena of courage, craft (Ergane), and victory (Nike). Apollo visited men with plagues or alternatively sanctioned purifications, Ares personified war, Themis justice, and Aphrodite and Eros roused sexual passion. The individual spheres were nonetheless elastic, so that Zeus also protected guests under the title of Xenios, guarded the house as Herkeios or Ktesios and, more sinisterly, was associated with lycanthrophy (human assumption of the wolf form) and cannibalism as Lycaeus. Apollo was a god of herdsmen (Nomios) and prophecy (Pythios) and Poseidon was a god of horses (Hippios) as well as a causer of earthquakes. Other powerful deities were Nemesis at Rhamnous; Athena, surnamed Alea, at Tegea; Aphaea in Aegina; Artemis Orthia at Sparta; and Despoina (the Mistress) in Arcadia.

The gods in Homer and Hesiod

Homer assembled the major deities, who gave unity to Greek beliefs, on Olympus for his own epic purposes. As portrayed by him the gods are fair of form and move, for all their suprahuman size, with the lightness of birds. Freed, for the most part, from the trammels of cult, they have leisure to indulge their whims. Often they appear to give visible expression to human emotions or, like the Muses (who had cults in Pieria and on Helicon), personified inspiration. Of these cynical and arrogant gods, who were yet terrible on occasion, only Zeus is nobly drawn.

Hesiod composed a detailed genealogy of the gods in his *Theogony*, which appears to depend upon Oriental prototypes. The treatment is entirely mythical, and the gods are derived ultimately from Gaea (Earth) and Uranus (Heaven).

Superior to the gods was *moira* (fate). Even Zeus was unable to interfere with its workings. Moira and Ker (doom) come close in meaning, and the heroes' fates were literally in the balance when Zeus hung out his scales. Sometimes Zeus was the instrument of *moira*, but he never controlled it in the final outcome. When they could not be more specific, the Greeks referred to a *daimōn* (power) as being responsible for some event. According to Hesiod, *daimōnes* were the guardian spirits of those who perished during the Golden Age, but in later Greek religion they were regarded as beings intermediate between men and gods.

Hero cults

Offerings were made to dead Mycenaean kings, but the cult of heroes was a post-Homeric phenomenon. Heroes were regarded as inferior to gods, although some, such as Heracles, the Dioscuri (the heavenly twins), and Asclepius (the healer), were not far removed from divinity. Major heroes included Ajax of Salamis, who was worshipped in an ancestral capacity; Theseus, king of Athens, and Pelops of Olympia, whose shrines were places of asylum and pilgrimage; and Triptolemus at Eleusis. In addition, personalized powers were also revered: Cyamites (Bean-Man), Amynos (Protector), or Echetlaeus (Plow-Handle), who was said to have fought at Marathon. Hero cults were managed by elected officials known as *orgeōnes*. Cults of heroines, such as Helen, were also known.

Cosmogony. Hesiod stated that Chaos was the primal condition of the universe. Then came Earth, visualized as a flat disk, girdled by the stream of Ocean, Tartarus (Hell), and Eros (Love), the active element. From these were born Erebus (the dark void) and Night. Earth bore Heaven and by him became the mother of the Titans, Pontus (Sea), and the river of Ocean, as well as other beings. The Orphics modified Hesiod's system by introducing the novelty of the cosmic egg. From the egg sprang Phanes, the primal deity, who married Night and begat Heaven and Earth.

Man. For the Greeks the universe was man centred. Man consisted of a body (*sōma*) and a soul (*psychē*). The *psychē* was the death rattle, the last exhalation of breath, visualized as a pale replica of the living person; it flew away gibbering to the house of Hades, attracted, according to Plutarch, by the music of the Sirens, whose monstrous forms crowned tombs. The beliefs of certain ascetics—known as followers of Orpheus, the legendary minstrel—that the body was the prison of the soul and that everyone ultimately shared in the divine gave rise to the dualism familiar in Plato and Christianity.

Man's relation to the gods had two aspects: formal and personal. As a member of the community, he shared in the sacrifices proffered for the fortune of the state; he also shared in the god's displeasure if there was any deviation from the accepted ritual or hint of physical pollution. The manslaughter of suppliants was regarded as especially heinous and could endanger the general weal. Private sacrifices were also made and offerings of various kinds, including vases, statuettes, or even large statues that were dedicated in the sacred precincts (temene).

In addition to the Olympians, the Greeks worshipped chthonian (underworld) deities such as Zeus Meilichios (the Gracious, a euphemistic title), who rid Athens of pollution. Like Erichthonius, the ancient Attic hero, and certain domestic deities, he was sometimes represented in snake form. Domestic cults included the formal acceptance of a newborn child into the family by parading it round the hearth (Amphidromia) in the presence of the

Moirai (Fates), which are still honoured by women in modern Greece. Libations were made to the gods, including the Agathos Daimon (Good Spirit), who protected the household, while the Dioscuri were sometimes invited to share a feast (Theoxenia). Outside each dwelling stood the tutelary pillar of Apollo Agyieus (of the highway) or a "herm" (stock embellished with the head and genitals of Hermes), which was set up in the streets of Athens and elsewhere to bring good luck.

Immortality and death

Eschatology. In Homer only the gods were immortal, but Elysium was reserved for their favoured sons-in-law, who were also exempt from death. Heracles alone gained a place on Olympus by his own efforts. The ordinary hero hated death, for the dead were regarded as strengthless doubles who had to be revived with draughts of blood, mead, wine, and water in order to enable them to speak. They were conducted, it was believed, to the realm of Hades by Hermes; but the way was barred, according to popular accounts, by the marshy river Styx. Across this, Charon ferried all who had received at least token burial, and coins were placed in the mouths of corpses to pay the fare. Originally only great sinners like Ixion, Sisyphus, and Tityus, who had offended the gods personally, were punished in Tartarus. But the doctrines of the Orphics influenced Pindar, Empedocles and, above all, Plato. According to the latter, the dead were judged in a meadow by Aeacus, Minos, and Rhadamanthus and were consigned either to Tartarus or to the Isles of the Blest. Long periods of purgation were required before the wicked could regain their celestial state, while some were condemned forever. The dead were permitted to choose lots for their next incarnation, but usually their choice was unwise. Subsequently they drank from the stream of Lethe, the river of oblivion, and forgot all.

WORSHIP, PRACTICES, AND INSTITUTIONS

Sacred writings. Greek religion was not based on a written creed or body of dogma. Nevertheless, certain sacred writings survive in the form of hymns, oracles, inscriptions, and instructions to the dead. Most elaborate are the Homeric Hymns, some of which may have been composed for religious festivals, though their subject matter is almost entirely mythological. Delphic inscriptions include hymns to Apollo but, like the Epidaurian hymn by Isyllus to Asclepius, they are not concerned with liturgy. Delphic oracles are quoted from literary sources but appear, on the whole, to be retrospective concoctions, like the Hebraic–Hellenistic collection of Sibylline prophecies. Questions scratched on folded lead tablets have been found at Dodona, and detailed instructions to the dead, inscribed on gold leaf and possibly of Orphic inspiration, have been found in Greek graves in southern Italy. More recently papyrus fragments of similar character have been recovered from graves in Macedonia and Thessaly.

Shrines and temples. In the earliest times deities were worshipped in awesome places such as groves, caves, or mountain tops. Mycenaean deities had no temples of their own but shared the king's palace. Fundamental was the precinct (temenos) allotted to the deity, containing the altar, temple (if any), and other sacral or natural features, such as the sacred olive in the temenos of Pandrosos on the Athenian Acropolis. *Naoi* (temples—literally "dwellings"—that housed the god's image) were already known in Homeric times and, to judge from models discovered at Perachora, were of wood and simple design. Poros and marble replaced wood by the end of the 7th century BC when temples became large and were constructed with rows of columns on all sides. The image, crude and wooden at first, was placed in the central chamber (cella), which was open at the eastern end. No ritual was associated with the image itself, though it was sometimes paraded. Hero shrines were far less elaborate than temples and were provided with pits for offerings. Miniature shrines also were known.

Oracles and divination

Most oracular shrines included a subterranean chamber, but no trace of such has been found at Delphi, though the Pythia was always said to "descend." At the oracle of Trophonius, discovered in 1967 at Levádhia, incubation was practiced in a hole. The most famous centre of incubation was that of Asclepius at Epidaurus. His temple was furnished with a hall where the sick were advised by the demigod in dreams. Divination was also widely practiced in Greece. Augurs interpreted the flight of birds, while dreams, and even sneezes, were regarded as ominous. Seers also divined from the shape of altar smoke and the conformation of victims' entrails.

Priesthood. Even in the state cults, priesthoods were frequently ancestral prerogatives. Eteobutads organized the cult of the hero-king Erechtheus at Athens; Praxiergids superintended the washing of Athena's robes at the Plynteria; Clytiads and Iamids officiated at the altar of Zeus at Olympia. Although there was no official clergy, since the religious and secular spheres were not sharply divided (*e.g.*, the wife of the *archōn basileus* was ritually wed to Dionysus at the Anthesteria), professional assistance was available at sacrifices. There was no necessary correspondence between the sex of deities and that of priests. Hera and Athena favoured priestesses, but Isis and Cybele favoured priests. Apollo again inspired the Pythia (priestess) at Delphi but a priest at Ptoon. The mysteries at Eleusis were stage-managed by the Eumolpids and Kerykes. The latter assembled the *mystai* (initiates), while the former provided the Hierophant, who revealed the mysteries in the torchlit Anaktoron (king's shrine) within the great Telesterion, or entrance hall.

Festivals. The precise details of many festivals are obscure. Among the more elaborate was the Panathenaea, which was celebrated at high summer, and every fourth year (the Great Panathenaea) on a more splendid scale. Its purpose, besides offering sacrifice, was to provide the ancient wooden image of Athena, housed in the "Old Temple," with a new robe woven by the wives of Athenian citizens. The Great Panathenaea included—in addition to a procession—a torch race, athletic contests, mock fights, and bardic recitations. Next in importance was the Great Dionysia, celebrated at Athens in spring. At the end of the ritual the god's image was escorted to the theatre of Dionysus, where it presided over the dramatic contests. It, like its rural counterpart, included phallic features.

Olympic Games

The Olympic Games formed part of the great festival of Zeus held every fourth summer in the god's sacred precinct—the Altis beside the river Alpheius in the western Peloponnese. A truce was proclaimed in order to permit any warring Greeks to compete, and the celebrations lasted five days. Sacrifice and libation were made at the altar of Zeus, where omens were taken and oracles proclaimed, and at the tomb of Pelops and the altar of Hestia. Competitors and judges took the oath to observe the rules, processions were held, bards recited, and winners were honoured at state banquets. The richer and more famous were immortalized by lyric poets, such as Semonides, Bacchylides, and Pindar. Though women were banned, girls competed at the festival of Hera. The games held in honour of Zeus at Nemea, Apollo at Delphi, and Poseidon at the Isthmus followed the Olympian pattern.

Rites. Sacrifice was offered to the Olympian deities at dawn at the altar in the temenos, which normally stood east of the temple. Representing as it did a gift to the gods, sacrifice constituted the principal proof of piety. The gods were content with the burnt portion of the offering, while the priests and worshippers shared the remainder of the meat. Different animals were sacred to different deities—*e.g.*, heifers to Athena, cows to Hera, pigs to Demeter, bulls to Zeus and Dionysus, dogs to Hecate, game and heifers to Artemis, horses to Poseidon, and asses to Priapus—though the distinctions were not rigorously observed. The practices of ritual washing before sacrifice, sprinkling barley grains, and making token offerings of hair are described by Homer. Victims were required to be free of blemish, or they were likely to offend the deity. Sacrifice also was made to chthonian powers in the evening. Black victims were offered, placed in pits, and the meat was entirely consumed. Sacrifice preceded battles, treaties, or similar events. Human sacri-

fice, though legendary and even historical instances were reported, appears, if it was practiced at all, to have been the exception. Bloodless sacrifices were made to some deities and heroes.

Prayers and processions

Prayers normally began with compliments to the deity, followed by discreet references to the petitioner's piety, and ended with his special plea. If made to an Olympian, the suppliant stood with his arms raised palm upward. Processions formed part of most *panēgyreis* (gatherings) and festivals. The Panathenaic procession set out from the Pompeion (sacred storehouse) at dawn, headed by *kanēphoroi* (maiden basket bearers), who carried the sacred panoply. Elders bore boughs (*thallophoroi*) while youths (*ephēboi*) conducted the victims for sacrifice, and cavalry brought up the rear. The robe was spread on the mast of a wheeled ship.

The procession to Eleusis to restore the sacred objects, brought by the *ephēboi* to the Eleusinium some time previously, followed the wooden image of Iacchus (a personification of the ritual cry), which was escorted by its own priest, the *iacchagogos*, and officials. The *mystai* wore myrtle crowns and carried corn sheaves. Whatever the nature of the mysteries, those initiated returned in a mood of exaltation. Adepts (*epoptai*) were later admitted to more solemn rites (to see an ear of wheat, scoffers said).

Painted Greek vase showing a Dionysiac feast, 450–425 BC. In the Louvre, Paris.
Andre Held—Ziolo

Religious art and iconography. Art illuminates Greek religion, though the scenes represented are often obscure and sometimes completely baffling. On a well-known sarcophagus from Ayía Triádha in Crete, a priestess dressed in a skin skirt assists at a sacrifice, flanked by wreathed axes on which squat birds. The significance of the scene has been much discussed. The birds have been regarded as epiphanies of deities, giving sacral meaning to the transformations in Homer. Again, since goddesses appear to preponderate in Minoan–Mycenaean art, while male deities are represented on an inferior scale, this has been thought to reflect the general superiority of goddesses in many parts of Greece. In the earliest period, terra-cotta statuettes of deities were small and crude, while the old cult images were made of wood and commonly attributed to Daedalus. When artists turned to bronze and marble, deities were fashioned with increasing realism. Gods were shown naked and often bearded, while goddesses were robed until the 4th century BC. Since religious architecture was dominant in ancient Greece, it attracted the leading artists. Phidias was commissioned to construct the colossal chryselephantine statue of Athena for the Parthenon. He also made the image of Zeus for the temple at Olympia, as well as the bronze Athena on the Acropolis. Though the cult statue has disappeared, the masterly rendering of the Panathenaic procession on the Parthenon frieze reflects the dignity of contemporary religious feeling. A famous mural by Phidias' contemporary Polygnotus on the hall of the Cnidians at Delphi depicted scenes in the underworld with gruesome realism, according to Pausanias' description.

The sublimity of 5th-century religious art was rarely maintained in succeeding eras. The grave majesty of the Demeter of Cnidus is a notable exception, as indeed is the Aphrodite from Melos; but for all the liveliness of Scopas' sculpture from the temple of Athena Alea at Tegea and the moving perfection of Praxiteles' Hermes, their work patently heralds a religious decline.

Apart from cult statues and dedications like the Acropolis *korai* ("maidens"), the gods frequently were represented on the pediments, metopes, and friezes of temples, usually in mythological scenes. For the details of ritual, vase painting has proved a fruitful source of information. Dionysiac subjects are common, though usually imaginary, but cult scenes and fertility customs also appear.

The evolution of Greek religion

The history of Greek religion, including beliefs, forms of worship, and visible expression in art, has been traced from the earliest times to its final absorption in Christianity. It falls naturally into stages because, unlike more authoritarian and rigid faiths, men's view of the gods and of the nature of piety and virtue were always changing. Though its essence was stable, Greek religion was never static but was always evolving. It was a polytheism that, paradoxically, contained within it the seeds of a monotheism that was already latent in Homer and Hesiod. Homer's gods form a hierarchy under Zeus, who in Hesiod is the guarantor of right and justice. Aeschylus, the tragedian, also saw in Zeus something like Providence. Poets and philosophers often referred to God, without further specification, as the ultimate arbiter of the universe. Nevertheless, polytheism never wholly perished. Festivals and processions still form an important part of Christian pageantry, while the healing shrine at Epidaurus finds a counterpart in Lourdes. Mysticism is derived in great measure from the mysteries, and the doctrine of free will is at least Greek in spirit. By insisting always on the primacy of man, the Greeks left him at liberty to worship God as he pleased.

(J.R.T.P.)

Greenland

Greenland (Danish Grønland), the largest island in the world and, since 1953, an integral part of the Kingdom of Denmark, lies in the Northern Hemisphere, on a northeastern extension of the structural shelf fringing the continent of North America. Its icy, inhospitable environment, lying mostly within the Arctic Circle and extending to within less than 500 miles (805 kilometres) of the North Pole, makes the territory appear to be of little importance to man. Yet it possesses considerable potential, as attested by the flow of investment following the abolition, in 1951, of the governmental commercial monopoly. Indeed, on close examination it can be characterized as one of the few northern parallels to the developing regions of the Southern Hemisphere.

Physical dimensions

Greenland forms a wedge-shaped mass of about 840,000 square miles (2,175,600 square kilometres), of which over 700,000 square miles (1,800,000 square kilometres) are ice covered. Its maximum north–south extension is 1,650 miles (2,650 kilometres), and it is over 750 miles (1,200 kilometres) across at its widest point, at about 70° N. The length of its indented coastline has been calculated at 24,430 miles (39,310 kilometres)—almost exactly equal to that of the circumference of the earth at its Equator. Its southernmost tip is Cape Farewell (Kap Farvel), 59°45′ N, while Cape Morris Jesup, at 83°39′ N, was, until a 1969 recalculation of the position of Kaffeklubben Island, some 20 nautical miles to the east, considered as the nearest land to the North Pole. The westernmost point, Cape Alexander, at 73°05′ W, is farther west than the American city of Boston, while its easternmost point, Nordost Rundingen, at 12°09′ W, is almost as far east as Ireland. At the narrowest point, Greenland is only 16 miles (26 kilometres) from Ellesmere Island in the Canadian north. A submarine ridge, no deeper than 600 feet (183 metres), connects the island physically with North America, from which it is separated, from north to south, by the Nares Strait, the Robeson Channel, the Kennedy Channel, the Kane Basin, Smith Sound, Baffin Bay, Davis Strait, and the Labrador Sea. To the north lies Lincoln Sea and the ice masses of the Arctic Ocean, while on the east and south lie the Greenland Sea, Denmark Strait, and the Atlantic Ocean. At a depth of about 2,000 feet (610 metres) another submarine ridge (the Yermak Plateau) connects Greenland with Spitsbergen, while at the same depth the Faeroe-Iceland Ridge snakes across the ocean floor to Scotland and the European continent.

THE LANDSCAPE

Structurally, Greenland is an extension of the Laurentian Shield, the vast, rough plateau dominating the Canadian north and made up of hard Precambrian gneiss and granite rocks, among the most ancient of the earth's surface. In addition, the northern shoulders of Greenland, notably the mountains of Peary Land and their westward extension to Ellesmere Island, are structurally linked, via Spitsbergen, to the Caledonian orogeny of Europe.

From the dawn of geological time, the vast mass of Greenland, now largely obscured by ice, has been molded by a series of earth movements and related processes. At the earliest period, volcanic activity took place along the eastern edge. Later, sand and clay were washed out from ancient mountains into a long structural trough along the east coast. This became filled with layers of sandstone, limestone, and shale many thousands of feet thick, which were then uplifted to form the fold mountains of east Greenland. In more recent times, sandstones were laid down on both the east and west coasts, and coal of the Cretaceous Period, about 100,000,000 years ago, is found in the coastal areas of Disko Island and the Nûgssuaq Peninsula. Later still, some 50,000,000 years ago, further volcanic activity formed horizontal layers of hardened lava streams, which can still be seen as black bands interlacing exposed rock faces. Basaltic survivals of this period are at the Scoresbysund hot springs area in the east, at Julianehåb in the south, and on Disko Island, and Nûgssuaq and Svartenhuk peninsulas in the west. The many fossils in the Cretaceous sandstones and coal deposits testify that a temperate climate then existed.

The onset of the ice age, a million or so years ago, totally changed the Greenland environment. Vast accumulations of ice slid from the interior to the coasts, scouring away the rock masses beneath through debris frozen to the base of the slowly moving ice. Lakes formed on the coastal periphery, and plains also developed from sediments washed out from under the advancing ice; it was these sand and clay surfaces that were used for military airfields during World War II. Today, the indented, island-strewn coast forms, in part, a narrow, ice-free fringing strip. Long, deep fjords—drowned former valleys—reach far into both the east and west coasts in complex systems, offering magnificent, if desolate, scenery. The Scoresbysund network on the east coast is the largest, with a length of about 185 miles (300 kilometres) and a breadth of 125 miles (200 kilometres). A range of mountains 7,000 feet (2,130 metres) high also runs along the east coast, with Mt. Gunnbjorn, 12,139 feet (3,700 metres), marking the highest point in Greenland. Among many parts of the coast, the ice sheet fronts directly on the sea, with large chunks breaking off the tongueing glaciers and sliding into the waters as icebergs.

The ice sheet

The ice sheet itself, the major feature of the Greenland landscape, is the largest ice mass outside of Antarctica. It is contained by coastal mountains on the east and, to a lesser extent, on the west, although the rock floor far beneath its surface is at, or slightly beneath, current sea level. The average depth of the ice is 5,000 feet (1,500 metres), with a maximum of 10,000 feet (3,000 metres). Layers of snow falling on its barren, windswept surface become compressed into ice layers, which constantly move outward to the peripheral glaciers—the Jakobshavn Glacier, often moving 100 feet (30 metres) a day, is among the world's fastest. Nunataks—lofty, isolated peaks—emerge occasionally around the rim of the ice sheet, whose total area is 708,100 square miles (1,833,900 square kilometres).

Climate. The climate of Greenland is bleak and Arctic, modified only by the slight influence of the Gulf Stream in the southwest. Rapid changes, from dazzling sunshine to impenetrable blizzards, are common and result from the eastward progression of low-pressure air masses over a permanent layer of cold air above the ice. January average temperatures at Ivigtut are 18° F (−7.8° C) with July readings of 49.5° F (9.7° C), while at Thule, the American military base in the north, the corresponding figures are −7.5° F (−21.9° C) and 41° F (5° C). Precipitation decreases from 40 inches (1,000 millimetres) per year in the south to eight inches (200 millimetres) per year in the north, with summer rainfall concentrated in the southwest; snow can, and does, fall in any month. Although summers can be quite pleasant on the southwest coast, the inland ice is uniformly cold, with a July average of 10° F (−12.2° C) and a February mean of −53° F (−47.2° C). In 1966 American scientists drilled a 4,500-foot (1,310-metre) ice core near Thule, detailing climatic fluctuations up to 100,000 years ago and enabling correlations with the fossil "raised beaches" of the coasts, which indicate relative changes in sea and land levels. The climate became noticeably warmer during the early part of the 20th century, with a 1930 maximum, associated with northward

Recent climate changes

seal movements and an increase in the cod population. By the late 1960s and early 1970s, sea temperature was dropping again, causing a serious decrease in cod fishing.

Vegetation. The vegetation of Greenland is represented mainly by tundra types, with heather, birch, willow, and alder scrub together with sedge, cotton grass, and lichen. The Greenland summer is rich in plant life. Of the 400 or more species, 300 are of North American origin, 50 or so were imported by the earliest Norse inhabitants, and the rest, on the isolated nunataks, have survived the ice ages. In southernmost Greenland, winter hay is grown for sheep, and along the western coast such vegetables as radishes, cabbage, and lettuce are raised, with potatoes in the extreme south.

Animal life. The rich animal life of the surrounding seas is the basis of existence for Greenlanders. The sea mammals—seals and whales—were formerly the main sources of nourishment, with ring- and black-sided seals predominating. Land mammals are represented by seven species—polar bears, musk-oxen, reindeer, arctic foxes, snow hares, ermines, and lemmings. Half of the breeding birds are native, and most of the remainder are from North America. The most important sea birds are eiders, guillemots, auks, wild geese, ducks, and gulls, while land birds include ptarmigans, ravens, white-tailed eagles, gyrfalcons, peregrine falcons, snowy owls, snow buntings, and longspurs. Among insects, mosquitoes appear, surprisingly enough, in summer. Salmon and trout are found in the rivers, while cod, salmon, flounders, halibuts, and *angmagssat* (capelin) are important saltwater fish.

THE PEOPLE

Ancient and modern influences had, by the 1970s, created a uniquely blended society in Greenland. The strongest element stems from Eskimo culture, whose representatives, many with admixtures of European blood, are known as Greenlanders. By 1970 they numbered over 38,000 out of a total population of 47,000. The pure Eskimo are now found only in the far north, near Thule, and in east Greenland. In terms of origin, the Eskimo are believed to have crossed from North America to northwest Greenland, using the islands of the Canadian Arctic as stepping stones in a series of migrations that stretched from 4000 BC to AD 1000. Each wave of migration was represented by different cultures, beginning with Independence cultures (named after a nearby fjord), which followed the musk-ox and reindeer north to Peary Land. About the same time, the Sarqaq culture spread along the west coast and even reached east Greenland, although the lack of hunting grounds impeded movement around the northern rim of the island. Later migrations brought the Dorset, Dundas (Thule), and Inugsuk cultures.

The Eskimo contribution

Greenlanders today retain a clear linguistic and cultural identity (the Eskimo refer to themselves collectively as simply *inuit*, "people"). The Eskimo dialects, taken together, form a language group differing from all others. A Greenlander grammar (1851) and a dictionary (1871) built up an Eskimo literary language, and Eskimo is the predominant spoken language of Greenland. The material culture, especially in the north, includes such beautifully constructed practical hunting equipment as the kayak, often considered the most elegant boat in the world. The Eskimo, with his snow igloo, his dog team, and his hunting instruments, survives effectively in one of the most inhospitable places in the world.

The second element in Greenland society is represented by European, specifically Danish, influence. Apart from the early Norse settlers—whose colonies became extinct by the early 15th century as a result of climatic deterioration and who left only an archaeological legacy—the Eskimo remained the sole inhabitants of the island until 1721, when a Danish missionary initiated new settlement. Greenland was a closed society until 1951, and

Danish immigration was small, consisting largely of administrators. Faeroese and Danish settlement increased during the 1950s and 1960s. The modernization of Greenland society was given great impetus by developments in air communications and global strategy during and following World War II. Lying between the great superpowers of the Northern Hemisphere, Greenland became of prime importance in radar and air communications and in weather observations. One result was the construction of the giant United States base at Thule in 1951, although American personnel had little direct contact with, or influence on, the indigenous population.

Permanent settlement is extremely dispersed and entirely confined to the coastal fringe. Greenland entered the 1970s with 154 inhabited places, made up of 19 towns, 117 villages, and 18 weather stations and airports. Over the decade of the 1960s, urban population increased by some 14 percent, to a total of nearly 70 percent; this resulted from the superior fishing facilities of the towns and an associated decline in the village-based seal hunting. Population has grown in recent decades: in 1805 (the first census) it was 6,046; in 1925, 13,600; in 1950, 23,642; in 1960, 33,140; and in 1970, 45,600, of whom 7,200 were Danes. The capital, Godthåb, has a population (1969) of 7,200. A half dozen or so other towns have populations of 1,500 to 2,000. Half of the population is below 15 years of age. The population growth has been aided by improved medical facilities, resulting in a declining overall death rate (8.3 per 1,000 population in the early 1970s, contrasting with 25.5 per 1,000 during the period 1945–49), coupled with an unchanged high birth rate of around 40.0 per 1,000.

The contemporary population

THE ECONOMY

Seal hunting, once the mainstay of the Greenland economy, declined drastically in the early part of the 20th century, partly as a result of overintensive hunting and partly due to climatic amelioration. By the early 1970s, sealing was still the occupation of some 5,000 people, a fifth of whom were actually hunters, based mainly in Ûmának, Upernavik, Thule, and east Greenland. Catch value exceeded 3,600,000 kroner (7.518 kroner = $1 U.S.; 18.043 kroner = £1 sterling, December 1, 1970) with an export value approaching 5,400,000 kroner.

Hunting and fishing

Fishing, which flourished in the warmer waters, replaced seal hunting at the most important economic activity, and cod fishing, canning, and freezing have played major roles in modernizing Greenland economy and sustaining population growth. Some 10,000 people made a living from fishing in the early 1970s, with about 3,000 fishermen directly engaged in catching, using a fishing fleet of over 1,000 motorboats. The state owns 60 fishing plants, eight of which are of major importance, and there are also nine private plants. The decline in the cod catch consequent upon the lowering seawater temperature occasioned some concern in the late 1960s: the total catch dropped from 45,000 tons in 1967 to 34,000 tons in 1968, for example, causing a fall in export value from 76,000,000 kroner to 70,000,000 kroner. Shrimp and salmon are also a valuable export, and they, too, suffered drops in annual value of up to 20,000,000 kroner in the later 1960s.

Animal husbandry is marginally possible in the milder southwestern portion of Greenland, where two-thirds of a total of 20,000 sheep perished in the severe winter of 1966–67 through a combination of hostile environment and insufficient fodder. Reindeer, first introduced from Norway in 1953, numbered about 8,000 by 1970.

Mining

Mining operations have been erratic: deposits may be rich, but extraction and transportation costs have often been high. The Ivigtut cryolite mine, opened in 1864, closed down its production in 1963, when it proved no longer economically feasible to operate what had been the world's largest natural deposit of this mineral. The similarly unprofitable coal-mining operations on Disko Island also became increasingly marginal by the 1970s. The zinc and lead mines at Mesters Vig, opened 1956, were exhausted by 1962. On the other hand, extensive explorations by international companies, utilizing the state licenses available in the 1950s and '60s, have discovered considerable potential in terms of uranium, molybdenum, zinc, lead, and other important deposits, and—given the possibility of improved extractive technology—the mineral prospects of Greenland remained to the economic forefront at the start of the 1970s.

Greenland trade has continued to fall largely into government hands, in spite of the ending of the official state trading monopoly in 1951. The Royal Greenland Trade Department (Den Kongelige Grønlandske Handel; KGH) continues to supply the country with necessary consumer and other goods, helping to overcome excessive transport costs. By the 1970s total sales amounted to well over 200,000,000 kroner, a substantial portion of total imports. Industrial expansion and economic development have caused a great excess of imports over exports (see Table 2). Nearly half of the local economic enterprises are conducted through the Greenland Technical Organization (Grønlands Tekniske Organisation; GTO), which hands its small factories, workshops, and other enterprises over to local, private ownership after setting them up. A good proportion are now in Greenlander, as opposed to Danish, ownership.

Table 2: Trade, 1960 and 1970
(000,000 kroner)

Total	108	396*	Total	58	105

*Figures do not add to total given because of rounding.

TRANSPORTATION

By the early 1970s, the transportation system of Greenland, both internal and external, had undergone a complete transformation linked with the development of a market economy and with technological improvements, notably in air communications. Freight continues to be largely shipped by sea, while passenger traffic is usually airborne. The Denmark–Greenland connection is open all the year round, both by ship and by plane. Shipping connects freight fish products from, and oil, coal, and salt to, Greenland, while passenger vessels ply the west coast. The airport at Søndre Strømfjord, in addition to its function as a stopover on transpolar flights to North America and Asia, is the focus of flights into Greenland from Europe. Mail and passengers are then transported to their subsidiary destinations by the use of helicopters, although in the wilder areas of the northwest coast and east Greenland, dog-drawn sledges are of fundamental importance, with about 10,000 dogs still in use. At the start of the 1970s, over 13,000 passengers were transported between Denmark and Greenland, 12,000 of whom went by air. Along the west coast, 33,000 passengers were carried annually by ship and about 23,000 by air. Mail is carried by the governmental postal service, while the vast size of the island has led to the establishment of an ultramodern telephone, telegram, Telex, and radiotelephone network, with more than 90 separate stations, quite apart from the sophisticated military network associated with NATO and the North American defense system.

ADMINISTRATION AND SOCIAL CONDITIONS

Links with Denmark

Greenland, whose inhabitants enjoy equal political rights with Danish citizens, is administered from the Greenland ministry in Copenhagen, represented by a governor (*landshøvdingen*). There are three administrative subdivisions. Overall planning is the responsibility of the Greenland Provincial Council (Grønlandsrådet), made up of members of the National Council (Landsrådet) and the Danish Parliament, which makes recommendations

to the Minister for Greenland. The National Council administers public finances, which include about 50,000,000 kroner annually from alcohol and tobacco duties. Bills with reference to Greenland must be submitted to the council before their introduction in Parliament. The president of the council is now elected from its members, a significant move toward local autonomy made in 1966; before that date the post was held by the governor.

Greenland elects two members of the Danish Parliament, the electorate consisting of all Danish subjects (*i.e.*, Greenlanders and Danes) over the age of 21 who are resident in Greenland. The 16 members of the National Council each represent separate districts and voting for these posts, as in the case of the smaller local community councils, is restricted to those who have voted in parliamentary elections. With the growth of population, separate political parties are beginning to emerge.

Justice. The High Court (Landsret) consists of a judge, a graduate of the faculty of law of the University of Copenhagen, and two lay judges. The 16 district courts are headed by lay judges, from whom appeal can be made to the High Court, and, ultimately, to the Supreme Court in Copenhagen. There are 14 police districts headed by a chief constable. Although the changing patterns of social life have introduced a rising crime rate, with alcoholism a problem, there were no actual prisons, apart from temporary detention facilities, in Greenland by the early 1970s. Fishing inspection vessels are based at Grønnedal.

Education. The educational system consists basically of seven-year elementary schools, with provision for kindergarten classes. In addition, there are some high school facilities. The system is headed by the governor, the head of the church (most Greenlanders are Evangelical Lutherans), two National Council members, and a professional director. There are 17 school districts. The number of pupils in the Danish-financed, but largely Greenlander-staffed, system doubled over the decade of the 1960s, and the pressure of a growing and youthful population necessitated travel to Denmark for advanced studies. A state technical college was opened in 1970.

Health and welfare. The health service is state supported and without charge, utilizing Danish-trained staff in 17 districts, each with a doctor and a small hospital. The central hospital is located in Godthåb. Tuberculosis, responsible for 31 percent of all deaths in 1953, caused only three deaths 15 years later, at the end of an intensive campaign to eliminate the disease. The welfare service, which provides a wide range of assistance, was expanded in 1968, with the state underwriting 30 percent of welfare expenses and the National Council the remaining 70 percent. Social services expenses achieved the high rate of 1,000 kroner per person in the early 1970s. Although the developing market economy has stimulated expansion, tripling the standard of living in the period from 1950 to 1970, the standard of living remains at half of Denmark's. An increasing tax burden has appeared.

CULTURAL LIFE AND INSTITUTIONS

The cultural heritage of the Greenlanders finds most prominent expression in the Eskimo material culture: kayaks, umiaks (large boats paddled by women), sledges, harpoons, and soapstone lamps, all of which have a close relationship to the environment. Cultural values, in the wider sense, arose from the design concepts developed during the construction of these artifacts and found expression in sculptures (some made for the commercial market) in the mediums of ivory, wood, and soapstone.

Crisis in cultural identity

In Eskimo legends of today a relationship to the past and to other Eskimo groups around the Arctic is maintained. Modern poetry attempts to revive old traditions but points to a break between Greenlandic and Danish culture, with the Greenlander feeling the danger of losing his cultural identity in the developing market economy and modern European values. A folk high school, opened in 1963, attempts to support Greenlandic traditions.

Press and broadcasting. The press of Greenland dates back to the 1860s, when the newspaper *Atuagagdliutit* (literally "Something to Read") made an appearance in Godthåb. It is still published, in Greenlandic and Danish, as a fortnightly publication, contrasting with its erratic appearances of a century ago. There is also an embryonic local press, a product of the recent movement to the towns. Broadcasting, which started in World War II, expanded considerably with the building of a new station in 1958. This provides a wide range of programming, under Greenlandic management. In the early 1970s, the introduction of television was under consideration.

Problems and prospects. Although visits between Greenlanders and Canadian Eskimo have increased in recent decades, there is, as yet, no evidence of a pan-Eskimo movement linked to the resurgence of ethnic consciousness among North American Indians. The industrialization of fishing activities, started in the 1950s, has produced radical changes in Greenlandic society and a large population growth. The huge investments made in this program were threatened, in the late 1960s, by the departure of cod for warmer waters following a slight drop in seawater temperature. A return of seal hunting might be expected, and hopes for a developing tourist industry—perhaps linked to a conservational theme—could cushion potential blows to the local economy. It appeared, at least in the early 1970s, that long-term mineral development offered the only path for sustained economic growth. If that should fail, a large-scale migration to Europe might develop, a trend already seen in the exodus of part of a very youthful population. If this should occur, educational preparation for the transition to Danish culture and society would appear an unsatisfactory, but necessary, development.

BIBLIOGRAPHY. DANISH COMMISSION FOR THE DIRECTION OF THE GEOLOGICAL AND GEOGRAPHICAL INVESTIGATIONS IN GREENLAND, *Meddelelser om Grønland*, 189 vol., containing many papers in English, German, Danish, French, and Greenland Eskimo (1879–), is the largest existing work about Greenland, written by prominent specialists, and mostly covering geological, geographical, and ethnographic subjects. *Greenland*, 3 vol. (1928), although quite old, remains a useful source of information, notably in matters concerning the physical environment and ethnography; KAJ BIRKET-SMITH, *The Eskimos*, 2nd ed. (Eng. trans. 1959), the most authoritative work on the Eskimos and their culture; PETER FREUCHEN, *Book of Eskimos* (Eng. trans. 1961), a good, entertaining account by a famous Danish explorer; VILHJALMUR STEFANSSON, *Greenland* (1942), a readable work on Eskimo culture by a famous American explorer, now mainly of historic interest; SVEND KLITGAARD, *Greenland* (Eng. trans. 1970), an up-to-date extensive volume covering all aspects of Greenland life. Current information may be found in the *Danish Foreign Office Journal*, and in publications of the Danish Ministry of Foreign Affairs.

(M.Ga.)

Greenland Sea

A major outlying sea of the Arctic Basin, the Greenland Sea lies to the east of Greenland, between latitude 66° and 80° north. It covers 465,000 square miles (1,205,000 square kilometres)—an area almost as large as Tibet—and is of considerable scientific interest, although its inhospitable environment has severely limited its utilization by man. A line linking northeast Iceland; the isolated island of Jan Mayen; and Bjørnøya (Bear Island), lying halfway between the northern tip of Scandinavia and the great archipelago of Svalbard forms the conventional borders between the Arctic Greenland Sea and the more moderate environment of the Norwegian Sea to the southeast. The line so drawn also serves to mark off the course of significant underwater ridges and also to indicate the average edge of Arctic ice. The Greenland Sea is also linked to the North Atlantic via Denmark Strait (between Greenland and Iceland); with the Arctic Basin via the strait between the northern extremities of Greenland and Spitsbergen; and with the Barents Sea through the strait between Bjørnøya and Spitsbergen. Average depth in the sea is 4,750 feet (1,450 metres), with the deepest recorded point at 16,000 feet (4,800 metres).

The first scientific investigations of the region were carried out from the Norwegian vessel "Vøringen" in 1876–78. Norwegian, Icelandic, and Soviet vessels, among others, have since carried scientific expeditions into the area. In 1909 Fridtjof Nansen, the famous ex-

Scientific importance

plorer, had a hand in detailing the complex current system of the region, and his scheme has been brought up to date by a number of Soviet studies. Publications by scholars of a number of nations now make it possible to obtain a reasonably clear scientific picture of the Greenland Sea (for related information see ARCTIC OCEAN; ATLANTIC OCEAN; GREENLAND).

Physical characteristics. The bed of the Greenland Sea deepens irregularly northward and is divided by the submarine Mohns Ridge into the Greenland Basin (Hollow) and, to the south, the North Icelandic Deep. Ridge structures greatly influence major current directions. Bottom sediments, dispersed by currents and ice, are of nonorganic terrestial origin. Silts fill the submarine hollows and gorges; silty sands, gravel, boulders, and other products of erosion coat the shelves and ridges.

The sub-Arctic climate of the region causes a considerable accumulation of ice, and bitter north and northeast winds prevail throughout the year, cooling the sea surface and driving the cold waters southward. Absolute minimum air temperatures reach as low as −57° F (−49° C) off Spitsbergen, while the absolute maximum temperatures reach 77° F (25° C) off Greenland. Averages, however, are 14° F (−10° C) in the south and −15° F (−26° C) in the north, for February, the coldest month; August, the warmest month, experiences averages of 41° F (5° C) in the south and 32° F (0° C) in the north. The number of frosty days rises northward from 225 to 334. Precipitation totals 10 inches (250 millimetres) annually in the north and double this amount in the south. Surface water temperatures range from 30° F (−1° C) in the north, in February, to 43° F (6° C) in the south, in August. Fogs are frequent.

The hydrological system of the region is determined by the East Greenland Current, which brings ice down from the north and birfurcates when it approaches the central ridge. Branches of warm Atlantic currents, notably the West Spitsbergen branch of the Norway Current, also have some effect, resulting in a northward retreat of floating ice and in the formation of a "whale bay" in the ice cover beyond the sea's northern limit. The ice season lasts from October to the following August, and the ice includes Arctic pack ice (several yards thick), sea ice (about a yard thick), and freshwater ice in the form of towering icebergs. In June, as the bay ice breaks up along the coasts, icebergs that have split off from coastal glaciers are released to float out into the Atlantic via Denmark Strait. Tides in the Greenland Sea increase in amplitude near the coast and, in combination with the complex current system, break up the ice sheet and cause a mixing of the various water layers.

Biological characteristics. Because of the rather large amount of dissolved nutrient salts in its waters, the Greenland Sea is quite densely inhabited by lower life forms, which serve as the base of the food chain. Large invertebrates, fishes, birds, and mammals all feed on the smaller invertebrates and small organisms. Fish include cod, herring, redfish, halibut, and plaice; and mammals include seals, whales, and dolphins. Mosses, lichens, and scanty bushes are found around the coasts: they support the few deer and bull musks. Coastal waters are richer in fauna, including many types of gulls and ducks.

The role of nutrient salts

Fishing is weakly developed: with the exception of narrow zones off Iceland and Spitsbergen, which are fished by a number of European nations, the fish supplies of the Greenland Sea are only utilized by the local population.

Gregory I, Saint and Pope

Considered by many to be the architect of the medieval papacy, Gregory I the Great was known in his own time as a people's pope who was canonized (proclaimed a saint) by popular acclaim. His administrative, social, liturgical, and moral reforms became examples for those who followed him as bishop of Rome and pope of the medieval Roman Catholic Church.

Early life and career. Born in Rome about 540, Gregory was the son of a Gordianus and Silvia, who may have belonged to the eminent patrician family of the gens Anicia. His great-grandfather was Pope Felix III (483–492), and Pope Agapetus I (535–536) also may have been related to him. During his early years in Rome, the Lombards threatened and then invaded Italy (568). In about 572 Gregory, at the age of 32, became *praefectus urbis* (urban prefect; *i.e.*, the administrative president of Rome). Political and social conditions apparently caused him to relinquish this highest civilian office only two years later. Having a great interest in monasticism, Gregory converted the palace at Caelian Hill, which he had inherited as part of a large paternal fortune, into St. Andrew's Monastery, but he did not become its abbot. He then utilized his entire estate for the establishment of six additional monasteries on his other holdings in Sicily. Pope Benedict I (reigned 575–579) assigned him a diaconate in Rome, and in 579 Pope Pelagius II (reigned 579–590) sent him to Constantinople (the capital of the Byzantine Empire) as a papal nuncio, or representative, the curia's (papal administrative office) only foreign post. Gregory probably served there under Emperor Tiberius II (reigned 578–582) and Emperor Maurice (reigned 582–602) until 584, on the whole without much success in securing aid for Rome against the Lombards, who were also in a state of war in Italy with Byzantium.

Interest in monasticism

Election to the papacy. After sincere efforts to evade his election to the papacy Gregory was elected in 590 to that highest ecclesiastical position in the West. He complained in letters that he had been forced to assume the office. He determined to be a pope for the people, and he immediately devoted himself to alleviating the misery of the populace and of the refugees, including 3,000 nuns alone who had fled from the Lombards. Gregory I had grain sent from Sicily and used the revenues from church property to aid those who were starving and living in severe poverty.

He centralized the entire papal administration and vigorously opposed the graft and negligence of those in positions of responsibility, who, according to his view, administered the property of the poor and therefore were obligated to live up to the norms of absolute justice. The corrupt Byzantine officials had to be kept in check with gifts. Gregory became the first pope especially known for his devotion to social concerns, a devotion succinctly stated in one of his letters (Epistle I:44): "We do not want the treasury of the church defiled by disreputable gain." Gregory increased his diversified assistance, aides, and economic advisors in view of the devastation and barbarism of the Lombards.

Centralization of the papacy

The Pope attempted to reform and save the church in Italy, which was endangered spiritually as well as materially. He began his attempt by slowly catholicizing, in spite of their external Arianism (a heresy that denied the essential unity of God the Father and God the Son), the uncivilized Lombards. He did not want to see them destroyed but rather won for the kingdom of God, without breaking with Byzantium. He protested against the oppressive fiscal policies of the Byzantine exchequer, which so harshly taxed the people that they sometimes had to sell their children or emigrate into areas controlled by the Lombards. The Lombards, in turn, so extorted the Pope on their behalf that he called himself the "paymaster of the city."

Romanus, the Byzantine governor of Ravenna, who wanted war instead of the proposed peace of the Pope, ignored the Lombard King Agilulf's (reigned 590–616) stipulations for peace. He acted more badly toward Greg-

ory than toward the Lombards and agitated against him before the emperor Maurice. The letters of Gregory during the Lombard danger, citing the intrigues of Romanus and the accusations of the Emperor, provide a vivid and illuminating interpretation of the history of the time as well as an insight into the character of the Pope. Not until 598 did a temporary peace result in Italy.

Relations with Byzantium. In 602 Phocas, a Thracian centurian in the imperial army, during a period of disorder, managed to get himself elected emperor. He had Emperor Maurice, Empress Constance, the couple's five sons—the oldest was the godson of the Pope—and three daughters all executed. Knowing how to make use of the existing conditions of social and political disorder, Phocas, later known as a hated tyrant, also knew how to manipulate people. He made the Pope sympathetic toward both himself and his Lombard policy. Gregory's greeting and approval of one of the most hated tyrants of that century remains a blemish on his otherwise saintly character. Phocas, who was thus able to act with increasing terror, sought support from Gregory, whose blessing was tantamount to absolution for all offences. This action on the part of the head of the highest moral court of Europe established a precedent that was followed by many popes. The Byzantine Phocas, however, made peace with the Lombards, and thus peace for Italy in its relations with the Lombards was not secured by Gregory. The realization that a peace purchased at the price of agreement with Phocas also would incur negative consequences had not occurred to Gregory.

Phocas recognized the papal primacy of jurisdiction in the church and gave Gregory the impression of subordination. The Roman papacy had always valued such an attitude and in doing so overlooked other matters, including even the character or those with whom it came to terms. Gregory was deceived by Phocas, who conferred on him, rather than on John IV (the Faster), the patriarch of Constantinople, the disputed title of "ecumenical patriarch." The deposed and executed emperor Maurice, a devout humane ruler, had not previously granted the sought after title to the patriarch of Constantinople. The patriarch John, therefore, conferred this title on himself, as had other patriarchs before him, a practice that Pope Pelagius II had previously disputed. Gregory in 595 protested against this designation out of his conviction regarding the primacy of the pope. Instead, Gregory conferred on himself the title "servant of God's servants," a title borrowed from St. Augustine, which in its far too great humility meant, in effect, the opposite.

A reign of anarchy under Phocas spelled the end of the late Roman era. Gregory, with foresight, clearly recognized the approaching importance of the migrating peoples of the West, who were hardly or not at all christianized, and that the future of the church of the West lay with them. The visionary ideals of his conception in practice, however, would be to bring the barbarian powers of the West under the political sovereignty of Byzantium in the sense of a united Christian world under the ecclesiastical authority of Rome. He intensified his influential connections with Theodolinda, the Catholic Bavarian wife of the Lombard king Agilulf, whose son Adaloald only became Catholic in 615, and with Brunhilda, the powerful queen of Merovingian with whom he dealt just as submissively as he had with Phocas.

Missions. In 596, under the protection of Brunhilda, he initiated one of the greatest acts of his pontificate, the establishment of missions in England. His decision to do so may have emanated from his apprehension that the highly spiritual Irish–Scottish monasticism, which was strongly influenced by the Eastern Church and had not joined Rome, might finally take possession of the mission to England. He appointed Augustine (later St. Augustine of Canterbury) abbot of his St. Andrew's Monastery and later the first archbishop of Canterbury—as well as 40 monks—to begin the work in England. In contrast to other regions, Gregory had much regard for the pagan mentalities and customs in England, to which Augustine seldom adhered. The later English missionary monks St. Willibrord (658–739) and St. Boniface (*c.* 672/673–754) were able to conduct their missionary campaigns on the European continent because of the efforts of Gregory in regard to England.

Gregory, however, thought about missions in terms that were not always consistent with the monastic ideal of conversion by peaceful persuasion. He sometimes advocated a war of aggression against heathens in order to christianize them. His letter to Gennadius, the Byzantine governor from Africa, with the demand "to wage numerous wars"—in complete opposition to his peace efforts in Italy—in order to convert the subjugated to Christianity, can be viewed as the earliest conception of a crusade, a "holy war" differing from the spiritual battles of missionary activities. Gregory became, according to some misrepresentations, the model for the warring Pope Gregory VII (*c.* 1025–1085) as well as for Anselm of Lucca (Pope Alexander II) and Bonizone of Sutri, the well-known war theorists and contemporaries of Gregory VII. The earliest war benediction orginated with Gregory; he has become, along with St. Augustine (354–430), a precedent setter for the ecclesiastical war ideology of the Middle Ages. He admonished Brunhilda to prevent pagan sacrifices by means of armed forces.

Relations with the Jews

In regard to the Jews, to whom he offered seemingly economic advantages at conversion, the Pope was essentially tolerant. Had forced conversions been successful, however—such a policy was practiced in Spain by King Recared (died 601), who shortly beforehand (587) had become Catholic, and by the great church leader and adversary of the Jews St. Isidore of Seville (*c.* 560–636)—it is probable that Gregory would have agreed to such a policy.

Other concerns. Gregory did not take any definite action against the slave trade. He bought and sold slaves but would also free them; and sometimes he threatened others with severe punishments for their mistreatment.

He advocated rigid asceticism, and—perhaps because of this—he suffered from a stomach disorder and then from arthritis, which caused him to become almost totally lame in one of the last two years of his life.

He was an organizer, missionary, and manager, but not a politician. With the consolidation of the patrimony of Peter (lands controlled by the papacy), Gregory, without realizing it himself, became the founder of the later Papal States and of the temporal papal authority. According to his view, the patrimony of Peter ought to be at the immediate disposal of the church and of the poor. The view that this state would at one time serve the authoritative demands of the popes and would result in wars conducted by popes for augmentation of their imperialistic policies was inconsistent with his concept of the papacy's role in temporal affairs. He understood his period of rule as one of irrevocable service, as charity over the authority. His epitaph bears his policy's most suitable distinguishing mark: God's Consul.

Gregory did not comprehend that rulers and nations were incapable of following his conception of a *societas reipublicae Christianae* (a society of a Christian republic), which was formalized later in the Middle Ages. He was completely dependent upon the teaching (especially the concept of *The City of God*) of St. Augustine but not, however, predestined to speculative theology. The Pope —in whose views and actions are found the first attempts to subjugate secular authority to ecclesiastic authority and to elevate the priest to an extremely high status—exhibited a strange mixture of withdrawal from the world and energy, idealism and realism, melancholy and trust in God, and otherworldliness and the desire for power.

As a monk, which he always remained, he naturally had the expansion of monasticism especially at heart. Through him the Benedictine monastic principle attained broader support and results. Because of his concern for people, he tried to make their faith more intelligible to themselves by popularizing miracles and the concept of purgatory, as well as by encouraging a reform of the mass—from which came the Gregorian chant. His numerous writings—including his letters—possess little originality, but his *Regulae pastoralis liber*

("Book of Rules for Pastors") became a spiritual and practical guide to medieval bishops. The *Moralia in Job*, a textbook on moral theology and biblical interpretation, also exerted much influence in succeeding centuries. His ecclesiastical training was not extensive; he rejected culture and art as characteristic values; he treated the pre-Christian spiritual life with hostility. Estimations of his character oscillate in history; and he has undergone highly contrary evaluation, ranging all the way from ecclesiastical adulation to sharp criticism.

Gregory died in 604; his body lies buried in St. Peter's basilica in Rome. He had forbidden veneration of his corpse under penalty of excommunication. Since the 8th century he has been honoured as a doctor (teacher) of the church. His festivals of commemoration are March 12 (the date of his death) and September 3.

Gregory VII, Saint and Pope

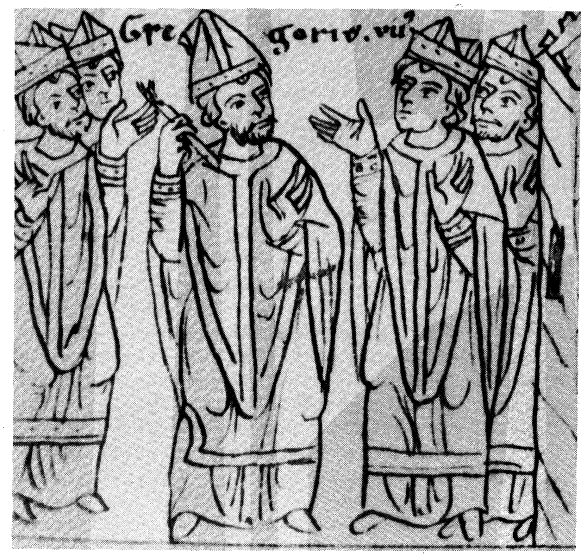
Pope Gregory VII, though now known primarily for his role in church–state relations because of the Investiture Controversy (see below), was first and foremost, in his own correct estimation, a pope devoted to ecclesiastical and spiritual reforms. He was, indeed, one of the greatest and most successful reform popes of the Middle Ages.

Early career

Known as Hildebrand before he became pope, Gregory VII was born near Soana in Tuscany (Italy) about 1020 of a workingman's family. He went to Rome at an early age and began his education at the Monastery of St. Mary on the Aventine Hill, where his uncle was abbot. He apparently became a monk but continued his education at the Schola Cantorum (School of Musicians) in the Lateran Palace. This was a school for clergy and, perhaps, for laymen also, since Gregory mentions that two Roman nobles were educated with him. One of his teachers there, John Gratian, later became Pope Gregory VI (reigned 1045–46). Gregory took Hildebrand into his service and when he was deposed by Emperor Henry III (1017–56) at the Council of Sutri in 1046, Hildebrand went with his fallen patron into exile in Germany.

In Germany Hildebrand found favour with Emperor Henry III and was called back to Rome by Pope Leo IX (reigned 1049–54). He formed one of the groups of reformers that Leo IX was assembling, a group that was to exert a profound influence on the 11th-century church. Hildebrand became the "man behind the throne" during the pontificate of his immediate predecessor, Pope Alexander II (1061–73), having already been an important member of the Roman reform group. He became a cardinal and archdeacon of Rome and was able to satisfy his monastic inclinations by reforming the famous Monastery of St. Paul. He demonstrated his love of people by curbing the activities of the petty nobles who had caused excessive disorder in Rome and the neighbourhood. He also served on several important papal legations. Perhaps the most important of these was his legation to the Synod of Tours at which Berengar professed his faith in the Real Presence of Jesus in the Eucharist.

Elected by acclamation (April 22, 1073) to succeed Alexander II, Hildebrand took the name of Gregory VII. He was consecrated in St. Peter's basilica on June 30, 1073.



Gregory VII, after his expulsion from Rome, lays a ban of excommunication on the clergy "together with the raging king"; drawing from the chronicle of Otto von Freising (*c.* 1111–58). In the library of the University of Jena, Germany.

Election as pope

The keynote of Gregory's pontificate was reform and renewal of the church. To understand Gregory's personality and influence it is necessary to realize how deeply he was committed to the spiritual values of his age. From the beginning of his career he was not successful as a politician or a statesman; his specialty was spiritual leadership.

Gregory tried to restrain the marauding Normans of France in their conquest of south Italy (*c.* 1030–71) and to defend the Papal States, but found it difficult to subdue these hard fighting and acquisitive Frenchmen. Deeply interested in healing the still-young schism that had occurred between the Western and Eastern churches in 1054, he tried to encourage the European states to embark on a crusade to help Constantinople and the Eastern Christians, but in this he failed.

As a spiritual leader he was more successful even though he faced a task of awesome proportions. The efforts aimed at ecclesiastical reform by his predecessors, the attempts of the monks based at the Benedictine monastery at Cluny (France) to reform the church spiritually, and the preaching of reformers such as Peter Damian (1007–72) and Cardinal Humbert (*c.* 1000–61) were only partially successful. Gregory promptly began an attack on the chief problems of the church: simony (selling or purchasing ecclesiastical offices) and nicolaitism (clerical marriage or concubinage). He held a synod at Rome every Lent that decreed strong measures against the buyers and sellers of sacred offices and married clergy. He attempted to associate the bishops and the lay rulers with him in his effort to eliminate these problems. Since many bishops had purchased their positions and many also held very loose views of clerical celibacy, Gregory had his work cut out.

Because he found it difficult to work through the bishops, he tended to centralize authority. He used papal legates (representatives) freely and insisted on their precedence over local bishops. He sought uniformity in the Western Church and he discouraged the use of the Mozarabic liturgy (pre-Islāmic and Byzantine influenced rite) in Spain and the use of Slavonic language in the liturgy in Bohemia.

Investiture Controversy

Gregory is chiefly known for his contest with the German emperor Henry IV (1050–1106) over lay investiture (the right of lay rulers to grant ecclesiastical officials the symbols of their authority), a contest that he helped to

precipitate. Gregory's first concern was for reform, and he believed that secular rulers should support church authority in bringing it about. He had seen the beneficent results of the reform-minded emperor Henry III's (1017–56) interference, and he tried hard to work with young Henry IV. It was only when he lost confidence in Henry that Gregory began his attack on lay investiture.

The Pope's Roman Synod of 1075 struck hard at lay investiture and began the long conflict that was to go beyond Gregory's lifetime. At that synod Gregory excommunicated five of Henry's advisers. In late 1075 the situation deteriorated. Henry's defeat of the rebellious Saxons had increased his power and reduced his distractions. In Milan Erlembald, the leader of the Patarines, a lay reform group, was killed and the anti-reform party got the upper hand. Henry now openly showed his hand, gave support to the anti-reform party in Milan, and placed a new bishop in the position of the legitimate bishop, Atto (flourished 1085). He also appointed bishops to Spoleto and Fermo.

In 1075, while Gregory was saying Christmas mass in St. Mary Major, he was attacked, slightly wounded, and carried off by Cencius, a Roman noble. The Romans, who had much admiration for Gregory, rallied to his defense, attacked Cencius' stronghold and forced him to release the Pope, who went back to St. Mary Major to continue his mass. Gregory spared the life of Cencius.

Although Gregory had written to Henry in December 1075, holding out the possibility of negotiations on the issue of lay investiture, Henry gave no satisfaction to the legates that the Pope had sent to Germany. Indeed, he openly defied Gregory and with his bishops renounced obedience to Gregory and bade him step down from the papal throne. Supported by north Italian bishops, Henry sent the Roman Synod of 1076 a letter beginning: "Henry, King not by usurpation, but by the pious ordination of God to Hildebrand now not Pope but false monk."

Excommunication of Henry IV

The reading of such a document aroused indignation in the synod, and Gregory struck back hard. He and the synod excommunicated Henry, and the Pope declared him deposed. Gregory defended his actions against Henry in two letters to Bishop Hermann of Metz: the emperor is in the church and therefore he may be called to account by the pope. Gregory defended this position by arguments from Scripture, the Fathers, and history.

The excommunication had its effect. The number of Henry's partisans dwindled and the restless Saxons once more rose in arms. Plans were set on foot by the magnates to depose Henry and elect another king. Apparently, at the persuasion of Gregory's legates, a more moderate position was taken, though the terms drawn up by the magnates were severe enough. Henry was to leave the decision of his case to the Pope, who was to come to a meeting of the magnates at Augsburg on February 2, 1077. He was expected to repudiate his rebellion against the Pope and to urge his advisers who had been excommunicated to seek absolution. Thus was the stage set for a famous action at Canossa.

Early in 1077 Gregory went north to cross the Alps but found, instead of the guards the Germans had promised, the news that Henry was hastening to Italy. Alarmed, the Pope withdrew to the castle of Canossa, a stronghold of his faithful friend and supporter, Matilda (*c.* 1046–1115), countess of Tuscany. Henry, however, was coming not as a foe but as a suppliant. For three cold January days he stood outside the castle pleading for absolution while Matilda and St. Hugh, abbot of Cluny, added their pleas to his. Gregory was in a quandary. The nobles and bishops of Germany were awaiting his presence at Augsburg to discuss Henry's fate, and here was Henry in the cold begging piteously for absolution. The priest in Gregory prevailed over the politician, and the Pope absolved Henry from excommunication. It is to the Pope's credit as a spiritual leader that he absolved Henry, even though the action was disastrous to his own cause.

Henry promptly regarded himself as legitimate king again, and Gregory had to write somewhat apologetically to the German magnates explaining his action. The Germans cancelled the Augsburg meeting and called for another gathering at Forchheim on March 13. Gregory desired to attend this meeting, but apparently neither Henry nor the leader of the opposition, Rudolf of Swabia (died 1080), really desired the Pope's presence. Gregory, however, sent legates who pleaded with the assembled nobles and bishops not to proceed with an election until the Pope could be present. The magnates went ahead, however, and elected Rudolf of Swabia, thus precipitating a bloody civil war. Gregory tried to mediate between Henry and Rudolf. He recalled his legates, and when Henry imprisoned one of them, the other excommunicated Henry. To prevent the Pope from confirming this excommunication the King sent ambassadors to plead with the Pope. They succeeded and the Pope contented himself with calling for a great meeting to settle the quarrel. For two years, 1078–80, Gregory maintained a mediatior's position and was abused by both sides.

Later reign

By 1080 the Pope was convinced that Henry was intransigent and once more excommunicated him and declared him deposed. This meant war. Henry had the support of his faction in Germany and that of the Lombard (north Italian) anti-reform party. Gregory sought the aid of the formidable Robert Guiscard, duke of Apulia and Calabria (*c.* 1015–85). Henry's German bishops met at Brixen (Italy) and declared Gregory deposed. To replace him they chose Guibert, archbishop of Ravenna, who took the name Clement III (1080, 1084–1100).

The tide began to flow strongly in favour of Henry when Rudolf of Swabia was killed at the Battle of the Elster (1080). Henry, freed from pressure in Germany, came over the Alps, defeated the forces of Countess Matilda, and besieged Rome. Gregory renewed his excommunication of the King. He tried to stir up opposition to Henry in Germany by urging Welf I of Bavaria (died 1101) and the princes to hold an election to replace Rudolf, but this did not deter Henry from besieging Rome in 1081, 1082, and 1083. Still firm, Gregory held a synod at the Lateran in November 1083 to attempt a settlement, but Henry prevented some bishops from attending.

The fathers of the synod, very much aware of the menacing presence of Henry's soldiers across the Tiber, pleaded with Gregory not to renew his excommunication of Henry at this time, whereupon the Pope contented himself with a general excommunication of all who prevented attendance of the synod. All attempts at peace failed, and on March 21, 1084, Henry's troops took the city. Gregory sought refuge in the castle of St. Angelo and suffered the chagrin of seeing Guibert of Ravenna (now Clement III) crowned in St. Peter's. Guibert in turn crowned Henry emperor. Help, however, was on the way. Robert Guiscard, back from an unsuccessful attempt on the Byzantine Empire, marched on Rome and rescued the Pope. Gregory's safety was dearly bought, for in a fight between the Normans and the Romans a large part of the city was burned down. Gregory, now unpopular with the embittered Romans, left with Guiscard. He died at Salerno on May 25, 1085. A biographer placed on his dying lips the words, "I have loved justice and hated iniquity, therefore I die in exile."

In 1584 Gregory XIII beatified him. He was canonized by Paul V in 1606, and Benedict XIII extended his feast to the whole church in 1728. Gregory's feast is kept on May 25.

BIBLIOGRAPHY. A primary source is the correspondence of Gregory. His *registrum* and other letters may be found in ERICH CASPAR, *Das Register Gregors VII* (1955); J.P. MIGNE, *Patrologia Latina*, vol. 148 (1888); and selections from the *registrum* in EPHRAIM EMERTON, *The Correspondence of Pope Gregory VII* (1932). AUGUSTIN FLICHE, *La Réforme Grégorienne*, vol. 2 (1924), is devoted entirely to Gregory and has an excellent critical study of the sources. BRIAN TIERNEY, *The Crisis of Church and State, 1050–1300* (1964), is a perceptive account containing some of the key documents. See also WALTER ULLMAN, *The Growth of Papal Government in the Middle Ages* (1955); and SCHAFER WILLIAMS, *The Gregorian Epoch* (1964), an interesting and provocative selection of extracts from historians who disagree on Gregory.

(J.S.Br.)

Gregory IX, Pope

Canon lawyer, theologian, founder of the papal Inquisition, defender of papal prerogative, the irascible Gregory IX (reigned 1227–41) stands as one of the most vigorous popes of the 13th century—the century in which the power of the church reached its zenith.

Alinari

Gregory, a nephew of Pope Innocent III, was born prior to 1170 of the family of the counts of Segni and was baptized Ugo or Ugolino. He studied theology at the University of Paris, but his early ecclesiastical career marked him as a diplomat. Shortly after his creation as a cardinal-deacon by his uncle in 1198, he was involved in peace negotiations with Markwald of Anweiler in southern Italy. Twice before 1210 he served Innocent as a papal legate in Germany. In 1206 Innocent promoted him to the cardinal bishopric of Ostia, the port city of Rome. During the pontificate of Pope Honorius III (1216–27), Ugo continued to play a leading role. He enjoyed not only the support of the Pope but also that of the youthful emperor-elect, Frederick II of Hohenstaufen, king of Sicily, whose cause he had supported during the reign of Innocent III. Ugo was a deeply religious man, closely attuned to the great spiritual movements of his time. He was friend to both St. Dominic and St. Francis of Assisi, founders of the first mendicant orders. He served as cardinal-protector of the Franciscans and adviser to St. Clare of Assisi, the founder of the Poor Clares. Like his predecessors, Ugo firmly supported the crusading movement, and it was from his hands that Frederick II took the cross as a symbol of his intention to lead a crusade. Ugo was an austere man of decisive mind and somewhat harsh personality. Even those he loved and admired most sometimes felt the strength of his convictions and the force of his will. But there can be no doubt about his moral integrity and dedication to the church. Still, it was his quickness to anger and his impatience with opposition that marked the character of his pontificate.

When Ugo ascended the papal throne as successor to Honorius III on March 19, 1227, he had already lost patience with the moderate policies of his predecessor. In particular, he had grown increasingly disenchanted with Emperor Frederick II. Frederick's delays in embarking on his promised crusade and his efforts to hold both the imperial throne and the crown of Sicily aroused opposition to him in the Roman Curia. The rupture broke into the open shortly after Gregory's election, when Frederick, who had finally launched his crusade, was forced to return to Brindisi because of an outbreak of plague. Already suspicious of Frederick's sincerity, the Pope excommunicated him on September 29, 1227, and issued a pained and angry encyclical to justify his action. Frederick responded by an attack on the excommunication as unjustified and a denunciation of the Roman Curia.

Excommunication of Frederick II

Nevertheless, Frederick embarked for the East, where he conquered Cyprus and negotiated with the sultan of Egypt for Jerusalem. Gregory was incensed at Frederick's presumption in leading a crusade while under ban of excommunication. Claiming provocation by Frederick's vicar in the Kingdom of Sicily, Gregory raised an army and launched an attack on the kingdom. This war marked the end of the policy of negotiation. Though Frederick's return witnessed the defeat of the papal forces, the deep fears aroused by his policies remained unsettled by the Treaty of San Germano (1230). In 1231 Gregory sharply protested Frederick's issuance of the *Liber Augustalis*, or Constitutions of Melfi, a code of laws for the Kingdom of Sicily. Though there was little in these laws that was actually objectionable, their thrust in the direction of a strong monarchy contained a threat to the church.

During the early 1230s Gregory took advantage of the respite in his struggle with the Emperor to turn his attention more to the internal and spiritual problems of the church. He ordered the canonist Raymond of Peñafort to compile the *Decretals*, a code of canon law based both on conciliar decisions and on papal letters, which he promulgated in 1234. This collection, arranged topically in five books, remained as the fundamental source of ecclesiastical law for the Catholic Church until after World War I. He also entered into negotiations with the Greek Orthodox Church that resulted in a series of conferences at Nicaea in January 1234 but proved abortive. Gregory continued the policies of his predecessors against heresy in southern France and northern Italy. He strengthened the Inquisition and entrusted its operations to the Dominicans. One of these inquisitors, Bernardo Gui, wrote the principal contemporary biography of Gregory IX.

Church reforms

The truce between Gregory and Frederick II was severely strained in 1235 by imperial accusations that the Pope had been working with the Lombards of northern Italy to undermine imperial influence. While Gregory denied the charge, the work of the Dominicans among heretics in northern Italy, many of whom were leagued with Frederick's supporters, did provide a foundation for imperial fears. Frederick's invasion of Sardinia, a papal fief, on behalf of the candidacy of his son Enzio for the Sardinian crown, led to a renewal of the excommunication on March 20, 1239, and caused Gregory to seek supporters in northern Italy. The propaganda war that accompanied the renewed hostilities is noted more for vitriolic than for reasoned argumentation. Gregory accused Frederick of crimes against the church in the Kingdom of Sicily and labelled him a blasphemer. The effort to find a settlement between the secular and the spiritual powers of medieval society received a decisive blow in this struggle. No definitions of separate spheres of authority would ever again overcome the reality of the fears that dominated both the papal Curia and secular powers.

With Frederick's army invading the Papal States, Gregory summoned a general council of the church, which met in Rome on Easter Sunday 1241. The capture of a large number of prelates on their way to the council by Frederick's Pisan allies put an end to this project, at least during Gregory's pontificate. Gregory IX died soon after, on August 22, 1241, his work unfinished. He had attempted to carry on the work of Innocent III and was successful in many of his efforts. Historians have judged him harshly because of his conflict with Frederick II, but too often their judgments have turned on the defects of his personality rather than the objectives of his policy.

BIBLIOGRAPHY. The most valuable account is contained in A. FLICHE and V. MARTIN (eds.), *Histoire de l'église depuis les origines jusqu'à nos jours*, vol. 10, pp. 217–426 (1950), which should be supplemented by ERNST BREM, *Papst Gregor IX bis zum Beginn seines Pontifikats* (1911). As yet there is no standard biography except that of P. BALAN, *Storia di Gregori IX e dei suoi tempi*, 2 vol. in 1 (1872–73), H.K. MANN, *History of the Popes in the Early Middle Ages*, 2nd ed., vol. 13 (1925), is long out of date. Brief discussions of Gregory's con-

troversies with Frederick II may be found in J.M. POWELL, "Frederick II and the Church: A Revisionist View," *Catholic Historical Review*, 48:485–497 (1963); and (trans. and ed.), *The Liber Augustalis* (1971).

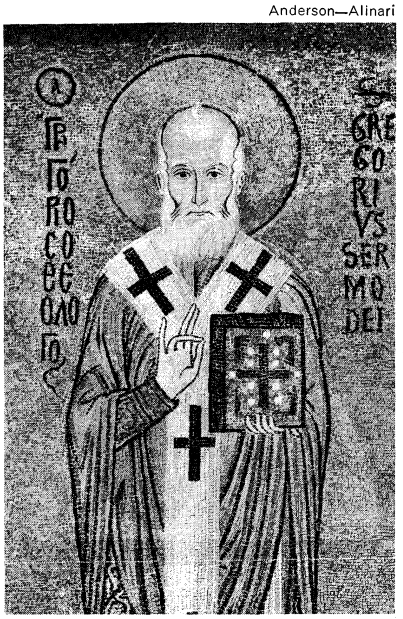
Gregory of Nazianzus, Saint

Among the Fathers of the Church, Gregory of Nazianzus is distinguished by the clear and vigorous exposition of the trinitarian theology (relating to God the Father, Son, and Holy Spirit) that he and his fellow Cappadocians, Basil the Great (*c.* 329–379) and Gregory of Nyssa (*c.* 335–*c.* 394), formulated; the three are called the Cappadocian Fathers. The dramatic episodes of Gregory's career in church and state give his life a certain romantic interest, of which he himself was not unaware.

Anderson—Alinari



St. Gregory of Nazianzus, detail of a mosaic in the Palatine Chapel, Palermo, Italy, 12th century.

Gregory's father, also named Gregory, was converted to the Christian faith from the monotheistic sect known as the Hypsistarii (Worshippers of the Most High) under the influence of his Christian wife. He was soon afterward consecrated bishop of his native city, Nazianzus (the exact location of which is not known; Cappadocia was in eastern Anatolia), by bishops on their way to the Council of Nicaea in 325. Born some years later (*c.* 330), the younger Gregory thus grew up in a Christian and clerical family. Nevertheless, he received a classical as well as religious education, studying first at Caesarea, the provincial capital; at least briefly at Alexandria; and finally at Athens (*c.* 351–356). He was a close friend of Basil, his fellow student and later bishop of Caesarea, and in his panegyric at Basil's death in 379 he gave a vivid picture of student life of the period. Among Gregory's other contemporaries as a student at Athens was the future emperor Julian, who in his brief two-year reign attempted to revive paganism. Soon after returning to Cappadocia, Gregory joined the monastic community that Basil had founded at Annesi in Pontus. During this time, in order to preserve the thought of the great Alexandrian theologian Origen, many of whose speculative views were under attack, the two friends collaborated in editing the *Philocalia,* an anthology of theological and devotional selections from the works of Origen.

Education

In 362 Gregory accepted ordination to the priesthood to assist his father, though he went to Annesi for further preparation and remained there until the following Easter. For the next 10 years he worked at Nazianzus supporting Basil—who was first presbyter and from 370 to 379 bishop of Caesarea—in his struggles with personal rivals, with Arians (who denied the divinity of Christ and were semi-Origenists), and with the Arian emperor Valens. Basil was attempting to retain control of the church in at least part of the new province of Cappadocia Secunda, which had been created by Valens to diminish orthodox authority. Gregory, under pressure from Basil to assist him in this conflict, reluctantly accepted consecration (372) to the episcopate for the village of Sasima. He never took possession of the bishopric, however, and withdrew with a sense of grievance against Basil for having presumed on their friendship. He briefly administered the church of Nazianzus again after his father's death in 374, but when a successor was installed in that bishopric he retired to a monastery in Isauria, in south central Anatolia.

The death of Valens in 378 at the Battle of Adrianople ended the imperial patronage of Arianism, and after Basil died on the following January 1, Gregory became the outstanding spokesman in Asia Minor of the Nicene party that accepted the decrees of the Council of Nicaea of 325. He was invited to take charge of the Nicene congregation at Constantinople, a city torn by sectarian strife. His Chapel of the Resurrection (Greek Anastasia) became the scene of the birth of Byzantine (from Byzantium, the earlier name of Constantinople) Orthodoxy —*i.e.,* the post-Nicene theology and practice of the majority of Eastern Christianity. Among the sermons he preached there, the *Five Theological Orations* are a striking presentation of trinitarian doctrine, and his memorial addresses and others on special occasions are important historical sources. Though Gregory wrote no commentaries, he was famous for his deep knowledge of Scripture; among his hearers at Constantinople was the biblical scholar Jerome, who gained a greater understanding of the Greek scriptures from Gregory. A religious adventurer, Maximus the Cynic, however, was set up as a rival to Gregory by bishops from Egypt, who broke into the Anastasia at night for a clandestine consecration.

Leading exponent of Nicene theology

When the new emperor, Theodosius, came east in 380, the Arian bishop of Constantinople, Demophilus, was expelled, and Gregory was able to lead his congregation to the Great Church (probably the earlier basilica on the site of the present-day Hagia Sophia). The council (later recognized as the second ecumenical council) that met at Constantinople in 381 was prepared to acknowledge Gregory as bishop of Constantinople; but on the arrival of Bishop Timothy of Alexandria, his position was challenged on technical grounds. Weary of disputes and intrigues, Gregory withdrew after an eloquent farewell discourse. The council, however, supported his policy, condemning old and new heresies, denying all validity to the consecration of Maximus, and forbidding bishops to interfere outside their own areas of authority (a step toward the system of patriarchates). It endorsed the trinitarian doctrine of three equal persons (Father, Son, and Holy Spirit) as taught by Gregory and expressed in the "creed commonly called the Nicene," which is still regarded as authoritative in East and West alike, including most leading Protestant churches.

For the rest of his life Gregory lived quietly on the family property at Arianzus near Nazianzus, except for a brief period as administrator of the church of Nazianzus during a vacancy. He continued his interest in church affairs through correspondence, even during one year when he took a vow of silence for Lent. He wrote to his successor, the amiable but ineffective Nectarius, and others against the heresy of Apollinaris, who denied the existence of a human soul in Christ. His writings of the period include a long autobiographical poem (commonly referred to as *Carmen de se ipso,* "Song Concerning Oneself") and many short poems, mostly on religious subjects. His preserved works include a number of sermons, not improperly called orations, and a large collection of letters. His death is dated about 389, according to a statement of Jerome.

Poetry

BIBLIOGRAPHY. The Benedictine edition of Gregory's works, vol. 1 (1778), and vol. 2 (1840; delay in publication caused by the French Revolution), is reprinted in J.P. MIGNE (ed.), *Patrologia Graeca,* vol. 35–38 (1857–62). *Five Theological Orations* were edited with a valuable commentary by A.J.

MASON (1899). Selected orations and letters were translated by C.G. BROWNE and J.E. SWALLOW in *Nicene and Post-Nicene Fathers*, ser. 2, vol. 7, pp. 185–498 (1894); the theological orations and letters on Apollinarianism are reprinted in *Library of Christian Classics*, vol. 3 (1954), with an introduction by E.R. HARDY. Book 8 of the *Greek Anthology* comprises 254 of Gregory's Epigrams, in *Loeb Classical Library*, ed. and trans. by W.R. PATON, vol. 2, pp. 400–505 (1917).

For biographical information, see CARL ULLMANN, *Gregorius von Nazianz* (1825, 2nd ed. 1867; Eng. trans. by G.V. COX, 1851), still valuable; and ROSEMARY RUETHER, *Gregory of Nazianzus: Rhetor and Philosopher* (1969). There are useful sketches by J.H. NEWMAN, who felt a strong kinship with Gregory, in *The Church of the Fathers* (1840), reprinted in *Essays and Sketches*, vol. 3 (1948); and DOROTHY BROOKE, *Pilgrims Were They All*, ch. 4 (1944). On Gregory's thought, see J.N.D. KELLY, *Early Christian Doctrines*, 3rd ed. (1965); and on the Council of 381 and the Creed, J.N.D. KELLY, *Early Christian Creeds*, 2nd ed., ch. 10, pp. 296–321 (1960).

Gregory of Nyssa, Saint

As a philosophical theologian and mystic, Gregory of Nyssa completed the contributions to Christian thought of the other two Cappadocian Fathers, his brother Basil of Caesarea and their friend Gregory of Nazianzus. His ecclesiastical career was less successful than theirs, but Gregory's work as scholar and writer was creative, and in the 20th century it is being rescued from undeserved neglect.

Alinari

St. Gregory of Nyssa, detail of a 12th-century mosaic. In the Palatine Chapel, Palermo, Italy.

Early ecclesiastical career

A younger son of a distinguished family of Caesarea in Cappadocia, Gregory was born about 335 and educated in his native province but was more deeply influenced by his philosophical training than Basil and Gregory of Nazianzus. He began his adult life as a teacher of rhetoric and may have been married—although several references that suggest this are capable of a different interpretation, and the strictures on marriage in his treatise *On Virginity* seem to imply the contrary. In the 360s he turned to religious studies and Christian devotion, perhaps even to the monastic life, under Basil's inspiration and guidance. As part of Basil's struggle with Bishop Anthimus of Tyana—whose city became the metropolis (civil and therefore ecclesiastical capital) of western Cappadocia in 372—Gregory was consecrated as bishop of Nyssa, a small city in the new province of Cappadocia Secunda, which Basil wished to retain in his ecclesiastical jurisdiction. In 375, however, Gregory was accused of maladministration by the provincial governor as part of the Arianizing campaign of the Emperor Valens (an attempt to force the church to accept the views of the heretic Arius, who denied the divinity of Christ). He was deposed in 376 by a synod of bishops and banished. But on Valens' death in 378 his congregation welcomed him back enthusiastically.

Though Basil had considered Gregory unsuited for ecclesiastical diplomacy, after his return to his diocese he was active in the settlement of church affairs in the years that followed. In 379 he attended a council at Antioch and was sent on a special mission to the churches of Arabia (*i.e.*, Transjordan); his visit to Jerusalem on this occasion left him with a dislike for the increasingly fashionable pilgrimages, an opinion he expressed vigorously in one of his letters. In 381 he took part in the General (second ecumenical) Council at Constantinople and was recognized by the emperor Theodosius as one of the leaders of the orthodox communion in Cappadocia, along with Basil's successor at Caesarea. He declined election to the important bishopric of Sebaste, but the care of his small diocese left him free to preach at Constantinople on such special occasions as the funerals of Theodosius' wife and daughter. Under the unlearned Nectarius, the successor of Gregory of Nazianzus at Constantinople, Gregory of Nyssa was the leading orthodox theologian of the church in Asia Minor in the struggle against the Arians.

Contribution as a scholar

Gregory was primarily a scholar, whose chief contribution lay in his writings. Besides controversial replies to heretics, particularly the Arians—in which he formulated the doctrine of the Trinity (Father, Son, and Holy Spirit) that emerged as a clear and cogent answer to Arian questioning—he completed Basil's *Hexaëmeron* ("Six Days"), sermons on the days of the Creation, with *The Creation of Man*, and he produced a classic outline of orthodox theology in his *Great Catechesis* (or *Address on Religious Instruction*). The latter work is especially notable for developing systematically the place of the sacraments in the Christian view of restoration of the image of God in human nature—lost through sin in the fall of Adam. His brief treatise *On Not Three Gods* relates the Cappadocian Fathers' theology of three Persons in the Godhead (*i.e.*, the Trinity) to Plato's teachings of the One and the Many. As a Christian Platonist, Gregory followed the great Alexandrian theologian Origen (*c.* 185–*c.* 254), though not slavishly; most notably, he shared Origen's conviction that man's material nature is a result of the fall and also Origen's hope for ultimate universal salvation. In imitation of Plato's *Phaedo*, Gregory presented his teaching on resurrection in the form of a deathbed conversation with his sister, the Abbess Macrina.

Platonic and Christian inspiration combine in Gregory's ascetic and mystical writings, which have been influential in the devotional traditions of the Eastern Orthodox Church and (indirectly) of the Western Church. His *Life of Macrina* blends biography with instruction in the monastic life. *On Virginity* and other treatises on the ascetic life are crowned by the mystical *Life of Moses*, which treats the 13th-century BC journey of the Hebrews from Egypt to Mt. Sinai as a pattern of the progress of the soul through the temptations of the world to a vision of God. A notable emphasis of Gregory's teaching is the principle that the spiritual life is not one of static perfection but of constant progress. His greatest achievement is his remarkably balanced synthesis of Hellenic (Greek) and Christian traditions, in an age when both were represented by vigorous and acute minds.

Gregory did not, however, neglect his practical and pastoral duties, as is attested by his preserved letters and sermons. Many of the latter were written in praise of the saints venerated in Cappadocia or to celebrate the great days of the church year. Others, such as Gregory's attacks on usury and on the postponement of Baptism, deal with ethical problems of the church in his time. His more intimate discourses on the Lord's Prayer and the Beatitudes (Matt. 5:3–12) combine ethical and devotional interests, as does his commentary on the Song of Solomon. Gregory disliked attending gatherings of bishops but was periodically invited to preach at such occasions. His last public appearance was at a council at Constantinople in 394, and he probably died soon afterward.

BIBLIOGRAPHY. The unsatisfactory 17th-century edition of Gregory's works reprinted in J.P. MIGNE (ed.), *Patrologia Graeca*, vol. 44–46 (1858–62), is being replaced magnificently by W. JAEGER *et al.*, *Gregorii Nysseni Opera* (1952–). The *Life of Moses* has been edited by J. DANIELOU in *Sources Chrétiennes*, 3rd ed., vol. 1 (1968), with French translation; the *Catechetical Oration*, edited with commentary by J.H. SRAWLEY (1903). Treatises and letters were translated by W. MOORE and H.A. WILSON in *Nicene and Post-Nicene Fathers*, ser. 2, vol. 5 (1893); the *Address on Religious Instruction* and *On Not Three Gods* by C.C. RICHARDSON in *Library of Christian Classics*, vol. 3 (1954), with introduction and bibliography; the *Life of Macrina* by W.K.L. CLARKE (1916); *Sermons on the Lord's Prayer and the Beatitudes* by H.C. GRAEF in *Ancient Christian Writers*, vol. 18 (1954).

There is a good sketch and bibliography by J. QUASTEN, "Gregory of Nyssa," in *Patrology*, vol. 3, pp. 254–296 (1960). On Gregory's theology, see J.N.D. KELLY, *Early Christian Doctrines*, 3rd ed. (1965); on his philosophy and mysticism, J. DANIELOU, *Platonisme et théologie mystique: Essai sur la doctrine spirituelle de Saint Grégoire de Nysse*, 2nd ed. (1954), a basic work; selections from his mystical writings chosen by Danielou are in *From Glory to Glory*, trans. by H. MUSURILLO (1961). W. JAEGER, *Early Christianity and Greek Paideia*, pp. 75–102 (1962), is a valuable discussion of Gregory's place in cultural history.

(E.R.Ha.)

Gregory of Tours, Saint

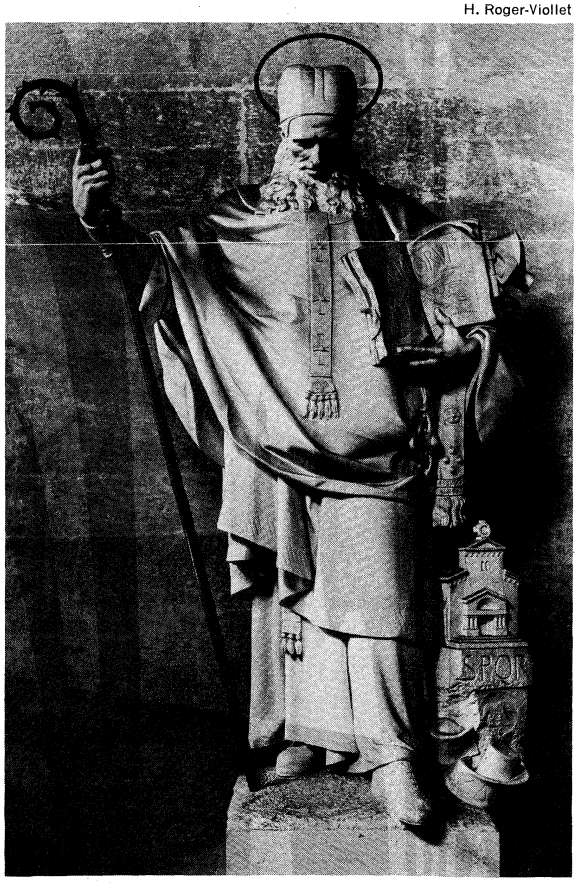
Gregory of Tours, bishop, historian, and saint, provided the major source for knowledge of the 6th-century Franco-Roman kingdom in his *History of the Franks* and himself played a notable part in some of the events he recorded.

Gregory was born at Augustonetum (now Clermont-Ferrand, France) on November 30, 538/539, to an aristocratic family. On both sides his family supplied several of the chief bishops of what today is central France. He was educated at Arvernia in the bishop's household. In 573 he succeeded his cousin as bishop of Tours.

At that moment the Frankish kingdom (which included present Rhineland Germany) was divided into three kingdoms under the three surviving grandsons of the great Clovis, the founder of the Merovingian dynasty in western Europe: Guntram, ruling Burgundy and Provence; Chilperic, ruling Neustria, the western kingdom; and Sigebert, ruling Austrasia, the eastern kingdom, but with appendages at Tours and in the south. Just as Gregory became bishop, one of the fratricidal wars endemic among the family of Clovis broke out; Sigebert was murdered (575), and Chilperic seized Tours. Gregory was bishop for ten years under the capricious and tyrannical Chilperic. Outside the city of Tours was the sanctuary of St. Martin, the revered 4th-century bishop of Tours, where famous criminals or persecuted persons sought shelter. Chilperic's own son Merovech sought shelter there from his father; and, in consequence of trying to protect Merovech and the right of sanctuary, Bishop Gregory became embroiled with his king and especially the queen, Fredegund. He was alternately threatened and cajoled with offers of bribes and had to defend himself formally, at the Council of Berny in 580, against the charge of spreading scandal that the Queen had committed adultery with the Bishop of Bordeaux. The council accepted Gregory's denial on oath and acquitted him. Gregory stood up to Chilperic to protect a fellow bishop and to resist the King's unorthodox opinions on the Trinity. "It would be no sensible man but a lunatic that would adopt views like yours," he told the man whom he once described as the Nero and Herod of his time. In 584 Chilperic was murdered, and Tours came under King Guntram of Burgundy. With Guntram, who possessed a certain degree of political ability, his relations were far happier. In 587 the Treaty of Andelot between Guntram and Sigebert's son Childebert II restored Tours to Austrasia, and Gregory came under Childebert. As bishop he restored the great church of St. Martin at Tours, dedicated a number of churches, protested successfully against excessive taxation in his diocese, and arbitrated in Frankish vendettas. His last years were disturbed by a riot that he had to quell in the nunnery of St. Radegunda at Poitiers. He died in 594 or 595 at Tours.

Gregory as bishop

H. Roger-Viollet



St. Gregory of Tours, statue by Emmanuel Frémiet, 19th century. In the Panthéon, Paris.

Gregory wrote several groups of lives of saints, called the "Lives of the Fathers," and seven books of miracles. These afford unique evidence of the piety and social life of Merovingian France. In addition, he wrote a commentary on the Psalms (of which only fragments survive) and a treatise on church offices. But his fame rests on his *History of the Franks* (which he called simply the *History;* its complete title is not the original). It was written in three separate sections: the first (books 1–4) covered the period to the death of Sigebert in 575 and was written soon afterward; the second (books 5–6) was composed about 581–584; the third (books 7–10) was written about 590–591. The manuscripts show two texts, a longer one and a shorter one, and perhaps Gregory himself personally edited the additions or subtractions. In an age of dry annalists his history has only one Latin competitor, namely, the work of Bede, the Anglo-Saxon historian. In his pages France of the 6th century comes alive as nowhere else. Gregory's chronicle is an unforgettable portrait of the western kingdoms just after the breakup of the western Roman Empire.

Writings of Gregory

Though he was a compulsive writer, he lamented his confusion over grammar, especially genders and prepositions, and thought that he wrote like a country bumpkin. He once asked his mother about the matter: she said that if he wrote in everyday language, everyone would understand. He tended, nevertheless, to drag in classical quotations when he could. He arranged his presentation by years but was never dull like the contemporary monastic chroniclers. Yet the story is at times disordered and confused. His genius as a writer was for graphic, fast-moving, blunt narrative, understated rather than rhetorical. He had no interest in personal details or the habits of society, and none of his characters (except himself) comes alive. His strength lay primarily in describing dramatic situations.

His philosophy of history (in so far as someone so unphilosophical could have one) saw the world as groaning and the church as fighting the battle to save humanity

from its bonds. He stated his aim thus: "to record the wars of kings with their enemies, of the martyrs with the heathen, and of the churches with the heretics." He looked for villainy to find its just punishment, and virtue its just reward, in this life as well as in the next. He thought an orthodox faith to be important and judged kings partly by whether or not they professed it. Gregory made no effort to paint the church of his day in rosy colours, describing warrior bishops or adulterous and drunken priests with equal impartiality. He generally used his authorities well, though he did not transcribe them well. In describing events of his own time (in books 4–10) he was most successful as a chronicler.

Gregory enjoyed the world, shared deeply in the superstitions of the age, travelled constantly and knew France as well as any man of his time, was affectionate to little children, and gave in his writings the unconscious impression of a likable, down-to-earth, courageous, not very spiritual, but Christian and humane, man.

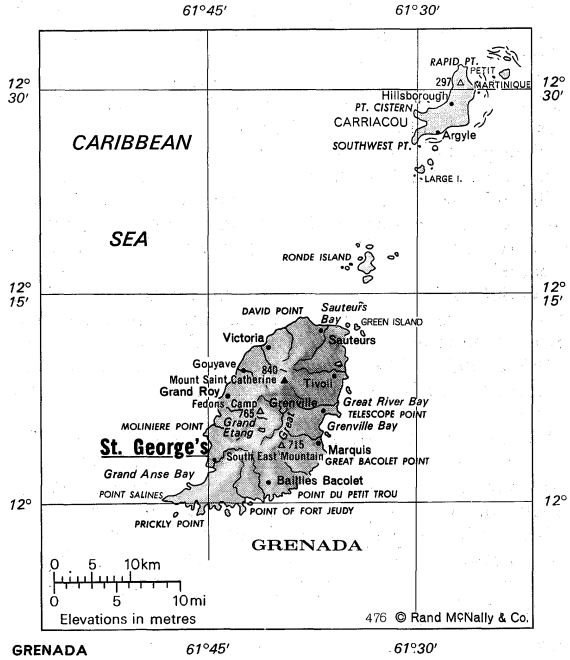
BIBLIOGRAPHY. Editions of Gregory's works may be found in the *Patrologiae cursus completus . . .*, vol. 71, and in B. KRUSCH and W. LEVISON, *Scriptores Rerum Merovingicarum*, vol. 1; rev. ed. by R. BUCHNER, 2 vol. (1955). An English translation of the histories, with a valuable introduction by O.M. DALTON, is *The History of the Franks, by Gregory of Tours*, 2 vol. (1927). For background information, see H.G.J. BECK, *The Pastoral Care of Souls in South-East France During the Sixth Century* (1950); S. DILL, *Roman Society in Gaul in the Merovingian Age* (1926); and J.M. WALLACE-HADRILL, "Gregory of Tours and Bede: Their Views on the Personal Qualities of Kings," in *Frühmittelalterliche Studien*, 2:31–44 (1968).

(W.O.C.)

Grenada

The island of Grenada, also known as the Isle of Spice, is the southernmost of the Windward Islands in the eastern Caribbean Sea about 100 miles (160 kilometres) north of the coast of Venezuela. In 1974 it attained complete independence within the Commonwealth of Nations and membership in the United Nations, the first of the six West Indies Associated States to do so.

Oval in shape, the island is approximately 21 miles (34



kilometres) long and 12 miles (19 kilometres) wide with an area of 120 square miles (311 square kilometres). The southern Grenadines—the largest of which is Carriacou, about 20 miles (32 kilometres) north-northwest, with an area of 13 square miles (34 square kilometres)—are a dependency.

In 1970 the population of Grenada and its dependency was 93,000, and by 1975 it was estimated at 100,000. The capital, St. George's, is on the southwest coast and has a population of about 6,300. It is also the main port, having a fine natural harbour as well as picturesque pastel-coloured houses that rise up the hillsides from the waterfront. The waterfront itself is known as the Carenage because island schooners were once careened (beached for cleaning or repair) there. St. George's is the yachting and charter-boat centre of the eastern Caribbean. The capital

The natural environment. *Relief.* Grenada is volcanic in origin, with a ridge of mountains running north and south—the steeper slopes to the west and a more gradual incline to the east and southeast. The highest point is Mt. St. Catherine (2,756 feet [840 metres]) in the northern part of the interior. The landscape is attractive, with fairly deep, steep-sided valleys, about 10,000 acres (4,000 hectares) of forest, and many plantations of bananas, cocoa, nutmegs, and sugarcane.

There are several short, swiftly flowing streams that supply all towns and most villages with piped clean water. A further source of water supply is Grand Etang, a circular lake covering 36 acres (15 hectares) in the crater of an extinct volcano at 1,740 feet (530 metres) altitude.

Climate. The climate is of the tropical maritime type, with equable temperatures varying with altitude and averaging 82° F (28° C) in the low country. Rainfall is adequate, except in the Point Salines area in the southwest; it varies from an average of 60 inches (1,524 millimetres) in coastal districts to 164 inches (4,166 millimetres) at Grand Etang. The rainy season lasts from June to December. November is the wettest month, but showers occur frequently during the other months. Grenada lies south of the usual track of hurricanes and is seldom visited by high winds.

Vegetation. The island is verdant, with a year-round growing season and a wide variety of tropical fruits, flowering shrubs, and ferns. There are also forests of teak, mahogany, saman (known as the rain tree), and blue mahoe (a strong-fibred tree) in the interior. In addition to bananas, cocoa, nutmegs, and sugarcane, commercial crops include limes, coconuts, coffee, and vegetables. Lesser quantities of spices—pepper, cloves, cinnamon, ginger, and vanilla—are also grown. Sea Island cotton is grown on Carriacou. Fruit crops

Animal life. The animal life is varied and includes domestic livestock and such wild animals as the mona monkey (a small, long-tailed, West African species introduced by slaves from Africa), the manicou (a species of opossum), the agouti (a rabbit-sized rodent, brown or grizzled in colour), the iguana, and a variety of turtles and land crabs. Birds, whose numbers were much reduced by the hurricane of 1955, are again plentiful.

History. Grenada was discovered by Christopher Columbus on August 15, 1498, when he sailed past the island without landing and gave it the name of Concepción. The origin of the name Grenada remains obscure. After its discovery by Columbus, Grenada was dominated for the next 150 years by the warlike Carib Indians, who had earlier killed off the more peaceful Arawaks. In 1609 a company of British merchants attempted to form a settlement but were forced by the Caribs to leave the island. The French governor of Martinique, du Parquet, purchased Grenada from a French company in 1650 and established a settlement at St. George's.

In 1674 Grenada became subject to the French crown, remaining so until 1762, when it capitulated to a British force. The island was formally ceded to Britain in 1763 by the Treaty of Paris. Sixteen years later, in 1779, it was recaptured by the French, only to be restored to Britain by the Treaty of Versailles in 1783.

In the late 18th century the British imported large numbers of slaves from Africa to work the sugar plantations. During 1795 and 1796, when French policy favoured the abolition of slavery, a rebellion against British rule occurred, led by a French planter and supported by the French in Martinique. The rebels massacred a number of the British, including the lieutenant governor, but the uprising was quelled.

The emancipation of the slaves finally took effect in

1833 and was accompanied by less economic and social upheaval than elsewhere because of the rapid growth of peasant proprietorship.

Grenada was the headquarters of the government of the British Windward Islands from 1885 until 1958, when Grenada joined the Federation of the West Indies at its formation. The federation was dissolved in 1962, after which Grenada attempted to federate with the remaining territories in the Windward Islands, as well as with Barbados and the Leeward Islands. On March 3, 1967, however, the island became a self-governing state in association with the United Kingdom.

In the general election of August 1967, the Grenada United Labour Party defeated the Grenada National Party and took office under the premiership of Eric M. Gairy, a trade unionist. The party was re-elected in February 1972.

Grenada became an independent nation on February 7, 1974. The transition was marked by violence, strikes, and political controversy centring upon Gairy, who was named prime minister.

The people. About 95 percent of the population is of African and mixed descent. There are also a few thousand East Indians, descendants of indentured labourers brought to replace the freed slaves; a few hundred descendants of the old French and British settlers; and a handful of more recent immigrants from North America and Europe. The century of French rule left its mark on the island; a form of patois is still spoken by older people in the villages, and many place-names, although now pronounced in an English fashion, are French. English is the accepted language, however, and the literacy rate is 93 percent. A majority of the population, predominantly of French descent, is Roman Catholic; other Christian denominations represented include Anglicans and Methodists.

Economy. Grenada's economy is partially dependent on financial help from Britain, its principal trading partner. About 40 percent of all exports (especially bananas) go to the United Kingdom, and about a quarter of all imports (mainly manufactured goods, motor vehicles, and foodstuffs) come from the United Kingdom. The balance of trade is adverse, with imports generally exceeding exports in value.

Agriculture and tourism are the main sources of the island's income. Agriculture is the mainstay of the economy, and about 37 percent of the labour force lives off the land. To a greater extent than in any other West Indian island, Grenada's arable land is divided into small holdings on which peasant proprietors cultivate diversified crops. Less than 1 percent of the farm holdings exceed 100 acres; indeed, 87 percent of all farms are of five acres or less. Because of these small holdings and the generally hilly terrain, mechanical tilling is rare. The three major export crops, bananas, cocoa, and nutmegs, in the past were controlled by cooperative associations, but there is now greater governmental control. Banana exports, until 1969 greater in value than those of cocoa and nutmegs, depend upon preferential terms given by the United Kingdom and are affected by the European Common Market. Exports of lime juice also provide substantial earnings. Copra, and, increasingly, other products processed from the coconut, are also exported; they have surpassed bananas as export earners. A wide variety of tropical fruits are also grown—mangoes, passionfruit, guavas, tamarind, and citrus fruits. The government is encouraging increased production of vegetables, such as peas, tomatoes, sweet potatoes, pumpkins, and maize (corn).

Land holdings

Tourism, a growing factor in the island's economy, is encouraged by the government, and there are a dozen hotels, chiefly near the Grand Anse Beach south of St. George's. During the winter season, from October to March, as many as 100 cruise ships call at Grenada.

Tourism

Other sources of employment are such secondary industries as the milling of sugar, brewing, the distilling of rum (a strong white rum is made for local consumption), the processing of copra, and soapmaking. There is a cotton ginnery on Carriacou. Fishing, a traditional occupation, is limited by outmoded vessels and methods.

Customs and excise duties are the principal base for the country's budget, but taxes are also levied on incomes and professions. Expenditures are primarily for the civil service, education, roadbuilding, and waterworks. In most years there is an appreciable excess of expenditure over revenue.

Canadian, British, and U.S. banks are in operation, as well as the Grenada National Bank and Trust Company, founded in 1969 as a joint enterprise of the government and a group of U.S. investors. The unit of currency is the East Caribbean dollar (ECar$2.33 = U.S. $1; ECar$4.82 = £1 sterling in October 1975).

Transport and communications. Grenada has a network of more than 600 miles (1,000 kilometres) of roads. Bus service is available between the larger towns and villages, and there are several thousand private vehicles. Pearls Airport—providing daily air connections to nearby islands with connecting flights to South America, London, and New York—is located on the northeast coast. Plans are underway to expand air service by enlarging Pearls Airport and establishing a subsidiary airstrip at Point Salines on the southern tip of the island. There is a small airstrip on Carriacou.

The harbour at St. George's has berths for two ocean-going vessels, as well as a yacht basin and service facilities. Several shipping lines maintain regular passenger and cargo services to North America, the United Kingdom, Europe, and neighbouring West Indian islands.

Grenada was the centre for the Windward Islands Broadcasting Service, but its station became independent as Radio Grenada. Two newspapers are published in St. George's.

Administration. A member of the Commonwealth of Nations, Grenada is an independent state and a member of the United Nations, the World Bank, and other international bodies. The governor general of the island is appointed by the British crown on the advice of the prime minister of Grenada.

Prospects for the future. Grenada is faced with the problems of overpopulation and underemployment that are common to the West Indian islands. As emigration to South and Central America, Trinidad, and the United Kingdom has become more difficult, the pressure of people on resources is greater. Birth control, however, is not popular because some 60 percent of the people are Roman Catholics.

Grey, Charles Grey, 2nd Earl

English politician and leader of the Whig party, Lord Grey assumed power in 1830 at the age of 66 with less experience of office than any British prime minister of the 19th century. Yet his achievement in securing the passage of the Reform Act of 1832, which extended the franchise to the middle classes and favoured larger communities in the distribution of seats, has secured him an unchallenged place among English statesmen.

Grey, painting attributed to T. Phillips, c. 1820.
In the National Portrait Gallery, London.

His father, the younger son of an old Northumberland family, was a distinguished army general who was raised to the peerage in 1801. Charles, the future second earl, was born on March 13, 1764, at Falloden, Northumberland, and received a conventional aristocratic education at Eton and Cambridge. When only 22 he was elected member of Parliament for Northumberland. Entering the London world in 1786, he gravitated immediately to the fashionable but rakish circle of the leader of the liberal Whig party, Charles James Fox; the politician-playwright Richard Sheridan; and the Prince of Wales. Handsome, witty, and attractive, Grey soon became prominent among the aristocratic Whig set that provided the political opposition to the conservative government of William Pitt (1759–1806). When the French Revolution in 1789 revived the political agitation caused by the American Revolution, Grey was one of the young Whig aristocrats who formed the Society of the Friends of the People (1792) to encourage lower and middle class demands for parliamentary reform. These activities—which at the time were considered radical—followed by the outbreak of war with revolutionary France in 1793, split the Whig party. The emotions generated by the conflict with France, the repressive, though popular, measures taken by the government, and the extreme and often absurd lengths to which Fox carried his pro-French sympathies turned his following into an impotent and discredited minority. Grey's parliamentary reform bill of 1797 was heavily defeated, and for some years afterward Fox's faction of the Whigs virtually withdrew from parliamentary life.

Entry into politics

Grey's marriage in 1794 to Mary Elizabeth Ponsonby, the daughter of a leading Irish liberal family, strengthened his sympathies with the cause of Catholic emancipation; however, it weakened his zeal for politics. A devoted husband with a growing family (numbering 15 children by 1819), Grey found contentment in a close and affectionate home life. In 1801 his bachelor uncle Sir Henry allowed him to use Howick, a country house on the Northumberland coast, as his permanent residence. Howick was four days travel from London, and Grey's dilatoriness in coming south for the parliamentary sessions frequently evoked Fox's good-humoured reproaches. Some of Grey's political extremism had also waned. His criticisms of the government for resuming the war with France in 1803 were noticeably milder than those of his chief. When on Pitt's death in 1806 Lord Grenville formed the so-called government of All the Talents that included the Fox group, Grey (now Lord Howick) became first lord of the Admiralty. When Fox died the same year, Grey took his place as foreign secretary and leader of the Foxite Whigs. The dismissal of the ministry the following year, because of a disagreement with the King over relieving Catholic disabilities, left Grey with an ingrained distaste for office without freedom of action or pledges without certainty of performance. The loss of his seat for Northumberland as a result of his Catholic sympathies, followed by his removal in 1807 to the House of Lords, increased his political detachment. In the political negotiations of 1810–12, which were initiated by the Prince of Wales when he became regent, Grey and Grenville frigidly declined to accept anything less than complete power. The end of the war came with the Pittite Cabinet of Robert Banks Jenkinson, 2nd earl of Liverpool, firmly established in office.

Foreign secretary

Between 1815 and 1830 Grey was patron, rather than leader, of the quarrelsome and divided Whig opposition. While holding that Catholic Emancipation was a condition of any genuine Whig government, he accepted the fact that parliamentary reform must wait until there was solid support for it in the country. He thought the political stability of Britain was endangered both by the reactionary postwar policy of the administration of Lord Liverpool and by the demands for democratic reform put forward by doctrinaire agitators. His private conclusion was that the task of a Whig ministry, if one could ever be formed, would be to produce a measure of reform large enough to satisfy respectable opinion and yet conservative enough to preserve the basic principles of the aristocratic constitution.

In 1830 Grey's opportunity came at last. The grant of Catholic emancipation in 1829 had destroyed the last cohesion of the conservative Liverpool party. The collapse of the Duke of Wellington's ministry in 1830 brought Grey into office on his own terms and with popular backing for a reform of the antiquated parliamentary representative system. But the extent of the changes proposed in his bill of 1831 staggered even his own supporters, and it needed a fresh general election and the coercion of the House of Lords before the bill ultimately passed into law. Grey had misjudged the temper of both houses and involved himself in a painful conflict with the new king William IV when he had reluctantly to ask for enough new peers to be created to carry the bill. He had not, however, misjudged the temper of the country. A wave of popular enthusiasm sustained him during the long battle for reform in 1831–32 and returned a vast liberal majority to the House of Commons in 1833. The epoch-making Reform Act of 1832 was the crowning achievement of the old Whig party to which Grey belonged, and he had shown courage and imagination in forcing it through to the statute book. But the measure that he envisaged as a conservative and healing act of statesmanship was regarded by many of his new supporters as a springboard for further extensive changes in church and state. The strains of the new era produced quarrels and resignations in his cabinet, and Grey retired from politics two years later. He died at Howick on July 17, 1845.

Griffith, D.W.

More than any other individual, the pioneer American director D.W. Griffith developed the techniques through which motion pictures became an art form—an instrument able to express emotions and ideas. A genius in the art of the film, who never worked with a script, he innovated continually in the use of the camera angles and movement, in lighting, and, especially, in editing and tempo, and his influence throughout the world on the most creative directors of the next generation, such as Erich von Stroheim and Sergey Eisenstein, is inestimable. With the premier of his greatest success, *The Birth of a Nation*, in 1915, the previously little-known Griffith became the best known motion-picture director in the industry and, with some publicity assistance, became known as the Shakespeare of the screen.

Griffith.

Early life and influences

David Wark Griffith, the son of Jacob Griffith, a former Confederate colonel, was born on January 22, 1875, in Floydsfork, Kentucky, a tiny hamlet, later called Crestwood, not far from Louisville. He received his early education in one-room schools, largely under the tutelage of his older sister, and was subject to the strong influence of his father's imaginative stories of the Mexican and Civil wars and family readings of the works of Dickens, Shakespeare, and Sir Walter Scott. The Griffith family was impoverished upon the death of Jacob Griffith, when David was seven years old. After a brief stay with relatives, the family moved to Louisville. Griffith's formal education was terminated in secondary school by the necessity of contributing to the family's financial needs. He became, successively, an elevator operator in a dry-goods store and a clerk in a bookstore. During the latter clerkship, Griffith was exposed to the literati of Louisville and to the actors and actresses who played at Louisville's Temple Theatre.

Griffith began an acting career with several amateur theatre groups and made his professional debut in small roles with a stock company at the Temple Theatre. A barnstorming career with various touring companies followed, concluding with a Boston engagement in the spring of 1906. Following this engagement, Griffith completed a play, *A Fool and a Girl*, based on his personal experiences in the California hop fields, which was produced in Washington, D.C., in the fall of 1907. The play was a failure, despite the presence of Fannie Ward in the leading role. After the closing of the play, Griffith wrote a second play, *War*, which was based on events that occurred in the American Revolution. This later play remains unproduced.

On the advice of a former acting colleague, Griffith sold some scenarios for one-reel films, first to Edwin Porter, the director of the Edison Film Company, and then to the Biograph Company, both located in New York City. Griffith appeared as an actor in one film for the Edison Company, *Rescued from an Eagle's Nest*, under Porter's direction, and in several films for the Biograph Company. When an opening for a director developed at Biograph, Griffith was hired. During the next five years, from 1908 to 1913, Griffith made over 400 films for Biograph, the majority in the one-reel format, lasting approximately 12 minutes. His first film was *The Adventures of Dollie* (1908), about a baby stolen by and recovered from Gypsies. During the latter part of his employment, he experimented with longer films; his last Biograph film, *Judith of Bethulia* (1913), a biblical story of Judith and Holofernes, based loosely on a play of the same title by Thomas Bailey Aldrich, comprised four reels.

Career at the Biograph

During his Biograph period D.W. Griffith introduced or refined the techniques of motion-picture exposition, including the close-up, a film shot in which a single object or face filled the screen; the scenic long shot, showing an entire panoramic view; and cross-cutting, a technique of editing scenes at various locations together and intermixing them to give the impression to the viewer that the separate actions were happening simultaneously. With the assistance of his brilliant cinematographer, G.W. "Billy" Bitzer, Griffith made effective use of the fade-out and fade-in, a technique in which the screen darkens gradually to black or lightens from black to a full image, to indicate the end or the beginning of the story or of an episode, and the framing of film images through the use of special masks to produce a picture in other than the standard rectangular image. Griffith introduced to the screen young actors and actresses who were to become the motion-picture personages of the future. Included among these were Mary Pickford, Lillian and Dorothy Gish, Mack Sennett, Mae Marsh, Lionel Barrymore, and Harry Carey.

In 1913 Griffith left Biograph and entered into an agreement with Mutual Films for the direction and supervision of motion pictures. From this association, among other films, came *The Birth of a Nation*. With the official opening of the film under the title, *The Clansman*, at Clune's Auditorium in Los Angeles on February 8, 1915, the infant art of the motion picture was revolutionized. The film was subsequently lionized for its radical technique and condemned for its "racist" philosophy. Filmed at a cost of $110,000, it returned millions of dollars in profits, making it, perhaps, the most profitable film of all time, although a full accounting has never been made.

As a result of public opposition to its alleged racist message, however, *The Birth of a Nation* was censored in many cities, including New York, and Griffith became an ardent opponent of censorship of the motion picture. His next important film, *Intolerance* (1916), was, in part, an answer to his critics.

Censorship of *Birth of a Nation*

Intolerance, a film of epic proportions, combined four separate stories: the fall of ancient Babylon to the hordes of Cyrus, the St. Bartholomew's Day Massacre of the Huguenots in 16th-century France, the crucifixion of Jesus, and a contemporary story dealing with a wrongfully condemned man. The giant settings, especially the one representing ancient Babylon, have remained a benchmark for motion-picture spectacle, and the opulent settings for 16th-century Paris were almost equally impressive. Griffith interwove the four stories in an increasingly complex manner until all were brought to resolution in a controlled torrent of images that still leaves the viewer breathless. Only the contemporary story was given a happy ending. The film ends with an allegorical plea for the end of war through divine intervention, indicated through superimpositions of heavenly hosts above a flower-strewn battlefield. The film was an artistic success on its presentation in New York on September 5, 1916, but proved to be a financial failure. Nevertheless, tribute has been paid to its seminal influence on the work done by many film directors. Almost unanimously, critics have hailed *Intolerance* as the finest achievement of the silent film.

Success and failure of *Intolerance*

Most of Griffith's profits from *The Birth of a Nation* were used and lost in the making of *Intolerance*, but he was able to secure the financing for the building of his own studio in Mamaroneck, New York. His films were to be released through United Artists, a motion-picture distributor of which he was a founding partner, with Mary Pickford, Charles Chaplin, and Douglas Fairbanks. Despite making such distinguished films as *Broken Blossoms* (1919) and *Orphans of the Storm* (1921), and an extremely profitable film, *Way Down East* (1920), his studio foundered on the failure of lesser films and the business recession of the first half of the 1920s.

Director at Paramount Pictures

Griffith was subsequently employed as a director by Paramount Pictures and as contract director by United Artists. His view of the American Revolution was realized in *America* (1924), and his next-to-last film, *Abraham Lincoln* (1930), was another view of the American Civil War in a somewhat ponderous biographical style. Despite his past success and the general acknowledgement of his vital contributions to the syntax of the motion picture, Griffith was unable to find permanent employment after *Abraham Lincoln*. His last film, *The Struggle* (1931), a grim study of the degeneration of an alcoholic husband, was an abject failure, withdrawn by United Artists after a brief run. Griffith had produced *The Struggle* independently and, although not destitute, was never again able to finance another film or to find regular employment in the motion-picture industry. He died on July 23, 1948, in Hollywood.

Griffith married twice. His first wife, Linda Arvidson, was an actress. They were married in 1906 and separated in 1911. Griffith won a divorce in 1936 and then married Evelyn Marjorie Baldwin. This second marriage also ended in divorce. There were no children from either marriage.

MAJOR WORKS

The Adventures of Dollie; The Taming of the Shrew; (both 1908). *Edgar Allan Poe; The Curtain Pole; The Voice of the Violin; The Drunkard's Reformation; Resurrection; The Cricket on the Hearth; The Lonely Villa; The Mended Lute; 1776: or, The Hessian Renegades; Pippa Passes; In the Watches of the Night; Through the Breakers; Lines of White on a Sullen Sea; The Red Man's View; A Corner in Wheat* (all 1909). *In Old California; The Unchanging Sea; Ramona; The Usurer; The Message of the Violin;* (all 1910). *His Trust; His Trust Fulfilled; Fisher Folks; The Lonedale Operator; Enoch Arden; Fighting Blood; The Last Drop of Water; The Battle; The Miser's Heart;* (all 1911). *The Mender of Nets; The Goddess of Sagebrush Gulch; A Girl and Her Trust; Old Lena and the Geese; Man's Genesis; The Sands of Dee; A Pueblo Legend; An Unseen Enemy; The Musketeers of Pig Alley; The Massacre; The New York Hat;* (all 1912). *The Battle at Elderbush Gulch; Judith of Bethulia* (all 1913); *The Battle of the Sexes; The Escape; Home Sweet Home; The Avenging Conscience;* (all 1914). *The Birth of a Nation* (1915); *Intolerance* (1916); *Hearts of the World; The Great Love; The Greatest Thing in Life* (all 1918). *A Romance of Happy Valley; The Girl Who Stayed at Home; Broken Blossoms; True Heart Susie; The Mother and the Law; Scarlet Days; The Greatest Question* (all 1919). *The Idol Dancer; The Love Flower; Way Down East* (all 1920). *Dream Street* (1921); *Orphans of the Storm* and *One Exciting Night* (both 1922); *The White Rose* (1923); *America* (1924); *Sally of the Sawdust; Isn't Life Wonderful?; That Royle Girl* (all 1925); *Sorrows of Satan* (1927); *Drums of Love* and *The Battle of the Sexes* (both 1928); *Lady of the Pavements* (1929); *Abraham Lincoln* (1930); *The Struggle* (1931).

BIBLIOGRAPHY. ROBERT M. HENDERSON, *D.W. Griffith: His Life and Times* (1972), is the only full-length biography; the same author's *D.W. Griffith: The Years at Biograph* (1970), is a detailed study of Griffith's apprentice years as a film director for the Biograph Film Company from 1908 to 1913. The latter book contains an extensive bibliography. IRIS BARRY and EILEEN BOWSER, *D.W. Griffith, American Film Master*, rev. ed. (1965), is a perceptive monograph that gives a brief summary of Griffith's career, credits for the major films, and a critique of the major films after the Biograph period. The following books devote chapters to Griffith and his career in the context of the history of the motion picture: ALBERT R. FULTON, *Motion Pictures: The Development of an Art from Silent Films to the Age of Television* (1960); BENJAMIN B. HAMPTON, *A History of the Movies* (1931, reprinted 1970); LEWIS JACOBS, *The Rise of the American Film* (1939); ARTHUR KNIGHT, *The Liveliest Art* (1957).

(R.M.He.)

Grimm Brothers

The fairy tales of the famed German scholars Jacob and Wilhelm Grimm collectively became a classic of world literature, gave new direction to writing for children, and drew attention to the long-neglected riches of oral traditions. The Grimms' work on their *Kinder- und Hausmärchen* and their comparative studies of the folk literature of many nations led to the birth of the science of folklore. Through his grammar book Jacob became one of the founders of historical linguistics and the science of Germanic philology. His collection of ancient law practices and his *Deutsche Mythologie* were of far-reaching influence everywhere. The *Deutsches Wörterbuch*, begun by the two, set an international example for the historical dictionary of language.

Jacob (right) and Wilhelm Grimm, oil portrait by Elisabeth Jerichau-Baumann, 1855. In the National-Galerie, Berlin.

Beginnings and Kassel period. Jacob Ludwig Carl Grimm was born on January 4, 1785, and Wilhelm Carl Grimm on February 24, 1786, in Hanau, near Frankfurt am Main, in Hessen-Kassel. They were the oldest in a family of five brothers and one sister. Their father, Philipp Wilhelm, a lawyer, was town clerk in Hanau and later justiciary in Steinau, another small Hessian town, where his father and grandfather had been ministers of the Calvinistic Reformed Church. The father's death in 1796 brought social hardships to the family; the death of the mother in 1808 left 23-year-old Jacob with the responsibility of four brothers and one sister. Jacob, a scholarly type, was small and slender with sharply cut features, while Wilhelm was taller, had a softer face, and was sociable and fond of all the arts. After attending the high school in Kassel, the brothers followed their father's footsteps and studied law at the University of Marburg (1802–06) with the intention of entering civil service. At Marburg they came under the influence of Clemens Brentano, who awakened in both a love of folk poetry, and Friedrich Karl von Savigny, cofounder of the historical school of jurisprudence, who taught them a method of antiquarian investigation that formed the real basis of all their later work. Others, too, strongly influenced the Grimms, particularly the philosopher Johann Gottfried Herder (1744–1803), with his ideas on folk poetry. Essentially, they remained individuals, creating their work according to their own principles. In 1805 Jacob accompanied Savigny to Paris to do research on legal manu-

Influence of Savigny and Brentano

scripts of the Middle Ages; the following year he became secretary to the war office in Kassel. Because of his health, Wilhelm remained without regular employment until 1814. After the French entered in 1806, Jacob became private librarian to King Jérôme of Westphalia in 1808 and a year later *auditeur* of the Conseil d 'État but returned to Hessian service in 1813 after Napoleon's defeat. As secretary to the legation, he went twice to Paris (1814–15), to recover precious books and paintings taken by the French from Hesse and Prussia. He also took part in the Congress of Vienna (September 1814–June 1815). Meantime, Wilhelm had become secretary at the Elector's library in Kassel (1814), and Jacob joined him there in 1816. By that time the brothers had definitely given up thoughts of a legal career in favour of purely literary research. In the years to follow they lived frugally and worked steadily, laying the foundations for their lifelong interests. Their whole thinking was rooted in the social and political changes of their time and the challenge these changes held. Jacob and Wilhelm had nothing in common with the fashionable "Gothic" Romanticism of the 18th and 19th centuries, a state of mind that made them more realists than romantics. They investigated the distant past and saw in antiquity the foundation of all social institutions of their days. But their efforts to preserve these foundations did not mean that they wanted to return to the past. From the beginning, the Grimms sought to include material from beyond their own frontiers—from the literary traditions of Scandinavia, Spain, The Netherlands, Ireland, Scotland, England, Serbia, and Finland.

They first collected folk songs and tales for their friends Achim von Arnim and Clemens Brentano, who had collaborated on an influential collection of folk lyrics in 1805, and the brothers examined in some critical essays the essential difference between folk literature and other writing. To them, folk poetry was the only true poetry, expressing the eternal joys and sorrows, the hopes and fears of mankind.

Publication of the fairy tales

Encouraged by Arnim, they published their collected tales as the *Kinder- und Hausmärchen*, implying in the title that the stories were meant for adults and children alike. In contrast to the extravagant fantasy of the Romantic school's poetical fairy tales, the 200 stories of this collection (mostly taken from verbal sources, though a few were from printed sources) aimed at conveying the soul, imagination, and beliefs of people through the centuries—or at a genuine reproduction of the teller's words and ways. The great merit of Wilhelm Grimm is that he gave the fairy tales a readable form without changing their folkloric character. The results were threefold: the collection enjoyed wide distribution in Germany and eventually in all parts of the globe (there are now translations in 70 languages); it became and remains a model for the collecting of folktales everywhere; and the Grimms' notes to the tales, along with other investigations, formed the basis for the science of the folk narrative and even of folklore. To this day the tales remain the earliest "scientific" collection of folktales. The *Kinder- und Hausmärchen* was followed by a collection of historical and local legends of Germany, *Deutsche Sagen* (1816–18), which never gained wide popular appeal, though it influenced both literature and the study of the folk narrative. The brothers then published (in 1826) a translation of Thomas Crofton Croker's *Fairy Legends and Traditions of the South of Ireland*, prefacing the edition with a lengthy introduction of their own on fairy lore. At the same time, the Grimms gave their attention to the written documents of early literature, bringing out new editions of ancient texts, from both the Germanic and other languages. Wilhelm's outstanding contribution was *Die deutsche Heldensage* ("The German Heroic Saga"), a collection of themes and names from heroic legends mentioned in literature and art from the 6th to the 16th centuries, together with essays on the art of the saga.

While collaborating on these subjects for two decades (1806–26), Jacob also turned to the study of linguistics with an extensive work on grammar, the *Deutsche Grammatik* (1819–37). The word *deutsch* in the title does not mean strictly "German," but it rather refers to the etymological meaning of "common," thus being used to apply to all of the Germanic languages, the historical development of which is traced for the first time. He represented the natural laws of sound change (both vowels and consonants) in various languages and thus created bases for a method of scientific etymology; *i.e.*, research into relationships between languages and development of meaning. In what was to become known as Grimm's law, Jacob demonstrated the principle of the regularity of correspondence among consonants in genetically related languages, a principle previously observed by the Dane Rasmus Rask. Jacob's work on grammar exercised an enormous influence on the contemporary study of linguistics, Germanic, Romance, and Slavic, and it remains of value and in use even now. In 1824 Jacob Grimm translated a Serbian grammar by his friend Vuk Stefanović Karadžić, writing an erudite introduction on Slavic languages and literature.

Grimm's law

He extended his investigations into the Germanic folkculture with a study of ancient law practices and beliefs, *Deutsche Rechtsaltertümer* (1828), providing systematic source material but excluding actual laws. The work stimulated other publications in France, The Netherlands, Russia, and the southern Slavic countries and has not yet been superseded.

The Göttingen years. The quiet contentment of the years at Kassel ended in 1829, when the brothers suffered a snub—perhaps motivated politically—from the Elector of Hessen-Kassel: they were not given advancement following the death of a senior colleague. Consequently, they moved to the nearby University of Göttingen, where they were appointed librarians and professors. Jacob Grimm's *Deutsche Mythologie*, written during this period, was to be of far-reaching influence. From poetry, fairy tales, and folkloristic elements, he traced the pre-Christian faith and superstitions of the Germanic people, contrasting the beliefs to those of classical mythology and Christianity. The *Mythologie* had many successors all over Europe, but often disciples were not as careful in their judgments as Jacob had been. Wilhelm published here his outstanding edition of Freidank's epigrams. But again fate overtook them. When Ernest Augustus, duke of Cumberland, became king of Hanover, he high-handedly repealed the constitution of 1833, which he considered too liberal. Two weeks after the King's declaration, the Grimms, together with five other professors (the "Göttingen Seven"), sent a protest to the King, explaining that they felt themselves bound by oath to the old constitution. As a result they were dismissed, and three professors, including Jacob, were ordered to leave the kingdom of Hanover at once. Through their part in this protest directed against despotic authority, they clearly demonstrated the academic's sense of civil responsibilities, manifesting their own liberal convictions at the same time. During three years of exile in Kassel, institutions in Germany and beyond (Hamburg, Marburg, Rostock, Weimar, Belgium, France, The Netherlands, and Switzerland) tried to obtain the brothers' services.

The "Göttingen Seven"

The Berlin period. In 1840 they accepted an invitation from the king of Prussia, Frederick William IV, to go to Berlin, where as members of the Royal Academy of Sciences they lectured at the university. There they began their most ambitious enterprise, the *Deutsches Wörterbuch*, a large German dictionary intended as a guide for the user of the written and spoken word as well as a scholarly reference work. In the dictionary, all German words found in the literature of the three centuries "from Luther to Goethe" were given with their historical variants, their etymology, and their semantic development; their usage in specialized and everyday language was illustrated by quoting idioms and proverbs. Begun as a source of income in 1838 for the brothers after their dismissal from Göttingen, the work required generations of successors to bring the gigantic task to an end in our day. Jacob lived to see the work proceed to the letter *F*, while Wilhelm only finished the letter *D*. The dictionary became an example for similar publications in other

countries: Britain, France, The Netherlands, Sweden, and Switzerland. Jacob's philological research later led to a history of the German language, *Geschichte der deutschen Sprache*, in which he attempted to combine the historical study of language with the study of early history. Research into names and dialects was stimulated by Jacob Grimm's work, as were ways of writing and spelling—for example, he used roman type and advocated spelling German nouns without capital letters.

For some 20 years they worked in Prussia's capital, respected and free from financial worries. Much of importance can be found in the brothers' lectures and essays, the prefaces and reviews (*Kleinere Schriften*) they wrote in this period. In Berlin they witnessed the Revolution of 1848 and took an active part in the political strife of the succeeding years. In spite of close and even emotional ties to their homeland, the Grimms were not nationalists in the narrow sense. They maintained genuine —even political—friendships with colleagues at home and abroad, among them the jurists Savigny and Eichhorn; the historians F.C. Dahlmann, G.G. Gervinus, and Jules Michelet; and the philologists Karl Lachmann, John Mitchell Kemble, Jan Frans Willems, Vuk Karadžić, Pavel Josef Šafařik. Nearly all academies in Europe were proud to count Jacob and Wilhelm among their members. The more robust Jacob undertook many journeys for scientific investigations, visiting France, The Netherlands, Belgium, Switzerland, Austria, Italy, Denmark, and Sweden. Jacob remained a bachelor; Wilhelm married Dorothea Wild from Kassel, with whom he had three children: Herman (literary and art historian, 1828–1901), Rudolf (jurist, 1830–89), and Auguste (1832–1919). Wilhelm Grimm died on December 16, 1859, and Jacob on September 20, 1863. Their graves are in the Matthäikirchhof in West Berlin.

MAJOR WORKS

JOINT WORKS: *Kinder- und Hausmärchen* (2 vol. 1812–15; 3 vol. 1819–22), of which there are many translations into English, generally as *Grimm's Fairy Tales*, complete edition based on trans. by Margaret Hunt (1944), by Joseph Campbell (1944), by Francis P. Magoun, Jr. and Alexander H. Krappe as *The Grimms' German Folk Tales* (1960; also published in 1963 and 1965); *Altdeutsche Wälder*, 3 vol. (1813–16); *Deutsche Sagen*, 2 vol. (1816–18); *Deutsches Wörterbuch* (1852–1960; new ed. 1965 ff.).

BY JACOB: *Über den altdeutschen Meistergesang* (1811); *Deutsche Grammatik*, 4 vol. (1819–37); *Deutsche Rechtsaltertümer* (1828); *Reinhart Fuchs* (1834); *Deutsche Mythologie* (1835); *Geschichte der deutschen Sprache*, 2 vol. (1848); *Kleinere Schriften*, 8 vol. (1864–90, reprinted 1965).

BY WILHELM: *Altdänische Heldenlieder, Balladen und Märchen* (1811); *Über deutsche Runen* (1821); *Grâve Ruodolf* (1828); *Die deutsche Heldensage* (1829); *Vrîdankes Bescheidenheit* (1834); *Kleinere Schriften*, 4 vol. (1881–87).

BIBLIOGRAPHY. L. DENECKE, *Jacob Grimm und sein Bruder Wilhelm* (1971); and K. SCHULTE KEMMINGHAUSEN and L. DENECKE, *Die Brüder Grimm in Bildern ihrer Zeit* (1963), standard modern biographies; earlier studies include: *Die Selbstbiographien von Jacob und Wilhelm Grimm* (1830; ed. by I. SCHNACK, 1958); W. SCHERER, *Jacob Grimm* (1865, 1885, new ed. 1921), antiquated but not dispensable; K. ZUCKMAYER, *Die Brüder Grimm. Ein deutscher Beitrag zur Humanität* (1948, 1972); H. GERSTNER (ed.), *Die Brüder Grimm: Ihr Leben und Werk in Selbstzeugnissen, Briefen und Aufzeichnungen* (1952), collected documents; W. SCHOOF, *Jacob Grimm* (1961) and *Wilhelm Grimm* (1960), collected essays with documents; G. GINSCHEL, *Der junge Jacob Grimm, 1805–1819* (1967), an outstanding work. English language works: RUTH MICHAELIS-JENA, *The Brothers Grimm* (1970), detailed and fully illustrated; MURIEL E. HAMMOND, *Jacob and Wilhelm Grimm* (1968), a pleasant introductory work; MURRAY B. PEPPARD, *Paths Through the Forest: A Biography of the Brothers Grimm* (1971), learned and readable.

Festschrift publications: *Brüder Grimm Gedenken 1963*, ed. by L. DENECKE and I.M. GREVERUS with G. HEILFURTH (1963), contains 27 contributions from 15 countries, East and West; *Jacob Grimm zur 100. Wiederkehr seines Todestages*, ed. by W. FRAENGER and W. STEINITZ (1963), 12 contributions from 6 East-European countries.

Letters: For a complete list of edited correspondence, see L. DENECKE (above); for a choice of important editions, RUTH MICHAELIS-JENA (above).

Special subjects: R. STEIG, *Goethe und die Brüder Grimm* (1892, reprinted 1972), contains surprising aspects of this relationship; H. KUECK, *Die Göttinger Sieben* (1934), with political tracts and documents; W. EBEL, *Jacob Grimm und die deutsche Rechtswissenschaft* (1963), a concise study.

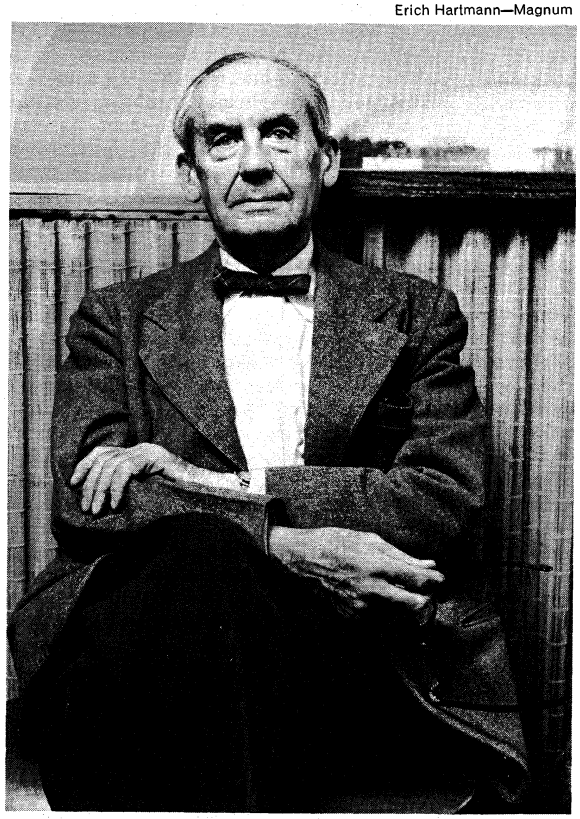
(L.De.)

Gropius, Walter

Walter Gropius, German-born architect and educator, was an enthusiastic and influential proponent of modern design who furthered his ideas through the Bauhaus school of design (which he founded in Germany in 1919), through his own architectural works, and through his long years of teaching at Harvard University. Among his most important ideas was his belief that all design—whether of a chair, a building, or a city—should be approached in essentially the same way: through a systematic study of needs and problems, taking into account modern construction materials and techniques, without reference to previous forms or styles.

Erich Hartmann—Magnum



Walter Gropius, photographed by Erich Hartmann.

Youth and early training. Walter Adolph Gropius was born in Berlin on May 18, 1883, of an architect father, Walter, and Manon (Scharnweber) Gropius. He studied architecture at the technical institutes in Munich (1903–04) and in Berlin–Charlottenburg (1905–07). He worked briefly in an architectural office in Berlin (1904) and saw military service (1904–05). Before completing school he built his first buildings, farm labourers' cottages in Pomerania (1906). He travelled for a year in Italy, Spain, and England and, in 1907, joined the office of the architect Peter Behrens in Berlin.

Work with Peter Behrens

Gropius acknowledged that his work with Behrens and the design problems he undertook for a German electricity company did much to shape his lifelong interest in progressive architecture and the interrelationship of the arts. From the time he left Behrens in 1910 until 1914, Gropius developed a clear commitment and talent for organization and for promoting his ideas on the arts. In 1911 he became a member of the Deutscher Werkbund (German Work Union), which had been founded in 1907 to ally creative designers with machine production. Gropius argued for such building techniques as prefabrication of parts and assembly on the site. However much he accepted the inevitability and restrictions of mechanization, he felt it was up to the artistically trained designer to "breathe a soul into the dead product of the machine." He was against imitation, snobbery, and dogma in the arts and cautioned against such oversimplification as the notion that the function of a product should determine its appearance.

Gropius' growing intellectual leadership was complemented by his design of two significant buildings, both done in collaboration with Adolph Meyer: the Fagus Works at Alfeld-an-der-Leine (1911) and the model office and factory buildings in Cologne (1914) done for the Werkbund Exposition. The Fagus Works, bolder than any of Behrens' works, is marked by large areas of glass wall broken by visible steel supports, the whole done with little affectation. The Cologne buildings were more formal, some say influenced by the U.S. architect Frank Lloyd Wright. Together these two buildings testify to Gropius' design maturity prior to World War I.

Military service and marriage

During that war Gropius served as a cavalry officer on the western front, was wounded, and received the Iron Cross for bravery. In 1915 he married a widow, Alma (Schindler) Mahler, whom he had met in 1910 when she was still married to the Austrian composer Gustav Mahler. Their wartime marriage, dependent on furloughs, was complicated by her affair with the German author Franz Werfel, and they were divorced in 1919. Their only child, Alma Manon, died in 1935.

Bauhaus period. Even before the end of the war, the city of Weimar approached Gropius for his ideas on art education. In April 1919 he became director of the Grand Ducal Saxon School of Arts and Crafts, the Grand Ducal Saxon Academy of Arts, and the Grand Ducal Saxon School of Arts, which were immediately united as Staatliches Bauhaus Weimar. Acceptance of this appointment was the most decisive step in his career. With his temperament for the practical world of art, politics, and administration, Gropius succeeded in establishing a viable new approach to design education, one that became an international prototype and eventually supplanted the 200-year-old supremacy of the French École des Beaux-Arts.

Gropius' Bauhaus program

A key tenet of Gropius' Bauhaus teaching was the requirement that architect and designer undergo a practical crafts training to acquaint himself with materials and processes. Although the program was to have been a comprehensive one, budget limitations permitted only a portion of the crafts shops to open. No formal study of architecture was offered at Weimar. Despite the early Werkbund principle of joining art with industry, much activity centred around handicrafts, such as ceramics, weaving, and stained-glass design. Many painters and sculptors joined the staff: Paul Klee, Lyonel Feininger, Wassily Kandinsky, Gerhard Marcks, and, later, László Moholy-Nagy and Josef Albers—altogether an astonishing roster of artists.

Somehow it did not seem incongruous for artists to be teaching applied design. As an introduction to design principles, a beginning course, *Vorkurs*, was developed by the Swiss painter and sculptor Johannes Itten, which itself became the most widely copied aspect of the Bauhaus curriculum. Students explored two- and three-dimensional design using a variety of simple materials, such as wire, wood, and paper. The psychological effects of form, colour, and texture were studied as well. Although his instructors were gifted, it was Gropius' own persistence that made this educational experiment work.

Historians disagree on the character of the early Bauhaus years. Certainly in 1919–22 Bauhaus students were allowed to express subjective feelings in their art; individuality and expressionism were not uncommon. The prewar Gropius belief that art must conform to and express the economic character and rational order of modern society seemed to be submerged in a new belief that the greatness of art stood above utilitarian considerations. A reverse shift came in 1922, not without controversy; Itten left, and a more rational and objective approach returned. The individually made products were intended as prototypes for machine production, and some designs were produced commercially. They emphasized geometrical forms, smooth surfaces, regular outlines, primary colours, and modern materials—all of which, to many eyes, epitomized impersonality in art. It is this last phase of Bauhaus output that is publicly accepted as characteristic of Bauhaus "style," although Gropius himself disdained the use of the word concept.

Gropius saw architecture and design as ever changing, always related to the contemporary world. He spoke of the architect's duty to encompass the total visual environment. He himself designed furniture, a railroad car, and an automobile. He emphasized housing and city planning, the usefulness of sociology, and the necessity of using teams of specialists.

Move to Dessau

In 1925 the Bauhaus moved to Dessau with the promise of better financial support and to escape the growing antagonism of the Weimar community. In Dessau, Gropius built the school building and faculty housing (1925–26). The school itself is a key monument of modern architecture and Gropius' best-known building. Its dynamic composition, asymmetrical plan, smooth white walls set with horizontal windows, and flat roof are features associated with the so-called International Style of the 1920s. Gropius resigned as director in 1928 to return to private practice in Berlin. During 1929–30 he designed a portion of a housing colony in Berlin–Siemensstadt. Gropius' regular facades of enormous length, together with a rigid orientation, illustrate an excessively intellectual solution with a "curse of uniformity," which Gropius himself decried in later years.

Harvard years. Unsympathetic to the Nazi regime, he and his second wife, Ise Frank, whom he had married in 1923, left Germany secretly via Italy for exile in England in 1934. Hitler's government closed the Bauhaus in 1933. Gropius' brief time in England was marked by collaboration with the architect Maxwell Fry that resulted in their important work, Village College at Impington, Cambridgeshire (1936).

In February 1937 Gropius arrived in Cambridge, Massachusetts, to become professor of architecture at Harvard University. The following year he was made chairman of the department, a post he held until his retirement in 1952. He became a naturalized U.S. citizen in 1944. At Harvard he introduced the Bauhaus philosophy of design into the curriculum, although he was unable to implement workshop training. He was also unsuccessful in abolishing the history of architecture as a course. His crusade for modern design, however, was immediately popular among the students. His innovations at Harvard soon provoked similar educational reform in other architectural schools in the United States and marked the beginning of the end of a historically imitative architecture.

In addition to his teaching, Gropius collaborated with Marcel Breuer, a former Bauhaus pupil and later fellow teacher, from 1937 until 1940. Among their designs was Gropius' own house in Lincoln, Massachusetts, which, with its use of white-painted wood and fieldstone, restated New England traditionalism in modern terms. This house and others designed by them were controversial, but the architects lived to see acceptance of their ideas. In 1942 Gropius renewed his interest in the production of architecture by industry when he became the vice president of General Panel Corporation, a company that made prefabricated housing. He retired in 1952.

The Architects Collaborative

In 1946, with six of his former Harvard pupils as partners, Gropius formed The Architects Collaborative (TAC), based in Cambridge. Among its varied U.S. and interna-

tional commissions, TAC received one to do the Harvard University Graduate Center (1949–50), a grouping of dormitory buildings and dining commons. The design is reminiscent of but less forceful than the Dessau Bauhaus buildings. Other TAC designs include the United States Embassy in Athens (1960) and the University of Baghdad, Iraq (design accepted 1960, still under construction). Gropius remained an active member of TAC until he died at the age of 86. In accord with his request made in 1933 that his funeral not be a mournful affair but marked in a festive manner, 70 friends in Cambridge drank champagne in his remembrance two days after his death in Boston on July 5, 1969. He was survived by his wife and adopted daughter, Beate, who was Ise Gropius' niece.

Assessment. Most assessments of Gropius' career centre upon his achievements as educator and author rather than as architect. Dedicated to the reform of art and to administration, as a man of visionary zeal and practical ambition, Gropius can be said to have fully achieved his goal. In his own assignments he turned away from personal and subjective aspects in favour of reaching for intellectual solutions of larger and socially urgent problems. His architecture does not have the aesthetic fascination of Wright's or Le Corbusier's but reflects a sober and programmatic concern that marked his whole life. Yet always, in conversation and criticism, he reminded his pupils of the vitality of the individual spirit, of the spontaneity of life itself. His habit of wearing a beret with a business suit was perhaps symbolic of the two worlds he hoped to bridge, "the gap between the rigid mentality of the businessman and technologist and the imagination of the creative artist."

MAJOR WORKS

Fagus Works, Alfeld-an-der-Leine, Germany (1911); with A. Meyer, Pavilion for Deutz Machinery Factory, Werkbund Exhibition, Cologne (1914); Bauhaus, Dessau, Germany (1925–26); Toerten Housing Development, Dessau (1926–28); Municipal Employment Office, Dessau (1927–28); Siemensstadt Housing Estate, Berlin (1929–30); Gropius House, Lincoln, Massachusetts (1937); Housing Development, New Kensington, Pennsylvania (1938–41); Harvard University Graduate Center, Cambridge, Massachusetts (1949–50); U.S. Embassy, Athens (commissioned 1960).

FITCH, *Walter Gropius* (1960), a brief, well-illustrated, general account.

(H.F.K.)

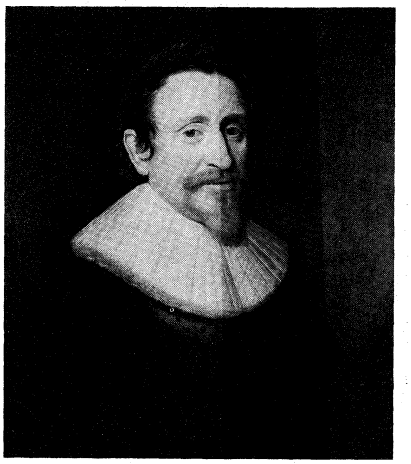
Grotius, Hugo

Hugo Grotius (Huigh or Hugeianus de Groot) was a Dutch statesman, jurist, philologist, theologian, and Humanist whose juridical works are of fundamental importance in international law.

Childhood and education

He was born at Delft on April 10, 1583. His father, a learned man, had been burgomaster of Delft and curator of Leiden University. After initial schooling in Delft, his father entrusted him to the Hague preacher and theologian Johannes Uyttenbogaert, who was to play a leading role in a crisis over Arminianism in 1618–19 that resulted in years of imprisonment for Grotius. An extremely gifted child, Grotius wrote Latin elegies at the age of eight and became a student in the faculty of letters at Leiden University at the age of 11. Very soon Grotius was the best pupil of the famed Latinist Joseph Scaliger, who undoubtedly contributed greatly to his development as a poet.

When at the age of 15 he accompanied the leading statesman Johan van Oldenbarnevelt on an embassy to Henry IV of France, he was received there with great honour and decided to remain to study law at Orléans. That same year his *Pontifex Romanus* appeared, six monologues offering a synthesis of the political situation



Grotius, portrait by M.J. van Mierevelt (1567–1641). In the Rijksmuseum, Amsterdam.
By courtesy of the Rijksmuseum, Amsterdam

in 1598. In later years he was to regret having chosen a career in law rather than letters. In 1599 he returned to Holland and settled as an advocate in The Hague, lodging for a time with his former teacher Uyttenbogaert. In 1600 his "Mirabilia" appeared, a poem about what had taken place on land and sea in the first half of that year. In 1601 the states of Holland appointed the able young lawyer their official Latin historiographer and specifically requested from him a description of the Dutch republic's revolt against Spain. Always interested in the history of his native country, Grotius began the same year, entitling his work *Annales et Historiae de Rebus Belgicis* in the manner of the Roman historian Tacitus. It consists of two parts: the "Annales," covering the period from 1559 to 1588, and the "Historiae" beginning in 1588 and concluding with the Twelve Years' Truce (1609–21).

Grotius was also very prolific in philology and poetry. He edited, with a commentary, Martianus Capella's handbook of the seven liberal arts (1598) and at about the same time the "Phaenomena," an astronomical poem by the Greek Aratus of Soli; he also published, in collaboration with the Humanist Daniel Heinsius, a Latin translation of the Greek bucolic poet Theocritus. In 1601 his *Sacra*, a volume of Latin poetry, appeared, made up of sacred poems, together with the drama *Adamus Exul* ("Adam in Exile"). The latter work, widely read and imitated, was greatly admired by the English poet John Milton. In 1614 he again edited a Roman author, Lucanus.

Involvement in politics. Increasingly, however, he became involved in Dutch politics. Although the republic was then at peace with the united kingdom of Spain and Portugal, the latter claimed a monopoly of trade with the East Indies. When a Dutch admiral seized the Portuguese vessel "Santa Catarina," the Dutch East India Company asked Grotius in 1604 to write a juridical treatise, "De Jure Praedae" ("On the Law of Prize and Booty"), defending the action on the ground that Spain–Portugal had deprived the Dutch of their trading rights. In 1609 one chapter of it, in which Grotius defends free access to the ocean for all nations, appeared under the title "Mare Liberum." The work circulated widely and was often reprinted.

Argument for freedom of the seas

In 1607 Grotius was appointed *advocaat fiscaal* (attorney general) of the province of Holland. In 1608 he married Maria van Reigersberch, the daughter of the burgomaster of Veere, an intelligent and courageous woman who stood by him unwaveringly in difficult years. They had seven children. In the same year he published *Christus Patiens*, a drama that was to be widely imitated.

In 1613 Grotius led an embassy to James I of England. Its official purpose was the settlement of trade differences, but he took advantage of the opportunity to discuss religious matters with the King as well, especially the reunion of all Christian churches, a problem that

concerned him deeply. The same year he became deeply involved in the religious and political controversy that was dividing the republic. Originally this had been a theological argument about predestination between two Leiden professors, Jacobus Arminius and Franciscus Gomarus; it developed into a dispute between the province of Holland and the orthodox Calvinist majority of the States General of the Netherlands under the leadership of Prince Maurice. Grotius, though a gentle and moderate man who always strove for peace and unity among Christians, was profoundly influenced by Oldenbarnevelt and the provinces. Under orders from the estates (assembly) of Holland he published in 1613 the *Ordinum Hollandiae et Westfrisae Pietas*, an ardent plea for the ecclesiastical policy of the estates.

Imprisonment and exile

In 1618 Prince Maurice ordered the arrest of the leaders of the opposition, including Grotius and the statesman Johan van Oldenbarnevelt. The latter was executed for high treason; Grotius was sentenced to life imprisonment and incarcerated in the castle of Loevestein. His wife and children were permitted to join him there. In prison he wrote a poem in behalf of Dutch sailors, whom he saw as peaceful propagators of the Christian faith, "Bewijs van den waren Godsdienst." He later translated it into Latin prose as "De Veritate Religionis Christianae" (1627). It established Grotius' fame and was translated into 13 languages, including Arabic and Urdu. He also began an introduction to the jurisprudence of Holland, *Inleydinghe tot de Hollandsche Rechts-geleerdheyt*, a very important work published in 1631. In the Republic of South Africa, the *Inleydinghe* was law from 1859 to 1901.

Hidden in a chest of books, he made a celebrated escape from the castle of Loevestein on March 22, 1621. He fled to Antwerp and to Paris, where he was received with great honour by Louis XIII and numerous statesmen and scholars. His wife and children were permitted to join him in Paris. There the family lived precariously on what Grotius was able to earn with his pen. Although Louis granted him a pension, it was paid rather irregularly; as a Calvinist he was unable to obtain a professorship.

Life in Paris. In 1625, still in exile, he published his legal masterpiece *De Jure Belli ac Pacis* (*On the Law of War and Peace*), in which he laid the foundations of international law. He defended the position taken by Holland and himself in the religious conflict in *Apologeticus eorum qui Hollandiae Westfrisiaeque et vicinis quibusdam nationibus ex legibus praefuerunt*. He also worked on a Latin translation of Euripides' *Phoenissae* (1630) and on a commentary on the Bible, *Annotationes in Libros Evangeliorum*.

In 1625 Prince Maurice died, and in 1631 Grotius returned to Holland. After hot debate in the assembly and despite the intervention of Prince Frederick Henry of Orange, he was again threatened with arrest. In 1632 he went to Hamburg, then the centre of Franco-Swedish diplomatic relations. So great was his international prestige that the Swedish chancellor, Count A.G. Oxenstierna, offered him in 1634 the important position of Swedish ambassador in Paris. Grotius accepted; he wrote in his benefactor's honour a drama, *Sophompaneas* (1635), in which he relates the fortunes of the biblical Joseph as minister at the Egyptian court, which to him was a reflection of his own situation. The great Dutch poet Joost van den Vondel translated this drama as *Joseph in 't Hof* ("Joseph at the Court"). Grotius settled again in Paris but soon realized that he lacked the talents of a diplomat.

During the years 1636–37 he worked on the *Historia Gotthorum, Vandalorum et Langobardorum* ("History of the Goths, Vandals, and Lombards"), written in honour of Sweden. He also edited the works of Tacitus (1640). In 1644, when Queen Christina invited him to Sweden, he was received with great honour but nevertheless relieved of his post of ambassador. Although he was offered membership in the Swedish Council of State, he refused to settle in Sweden. On his way back to Paris he was shipwrecked on the coast of Pomerania and died of exhaustion at Rostock two days later, on August 28, 1645.

Appraisal of his work

Grotius' enormous gifts were those of a scholar rather than of an original thinker or creative genius. His best poetry was written in Latin; it was complex in both structure and content. His Dutch poetry, of which he wrote a great deal, was didactic in nature. As an historian he worked in the style of Tacitus; his *Annales et Historiae* is a masterpiece of Humanistic historiography. As a theologian his ideal was the early Christian community, and Grotius was not only in close contact with Protestant theologians but also counted Catholic priests among his many friends. A considerable body of his correspondence with eminent contemporaries has survived.

His enduring fame stems from his *De Jure Praedae* and *De Jure Belli ac Pacis*, which form the basis of modern international law. Their principal merit lay in their synthesis of the ideas of older writers and thinkers. His chief innovation was his insistence that nations are bound by natural law, which he considered to be independent of God and based on man's own nature.

BIBLIOGRAPHY. For a bibliography of the works of Grotius, see J. TER MEULEN and P.J.J. DIERMANSE, *Bibliographie des écrits imprimés de Hugo Grotius* (1950) and *Bibliographie des écrits sur Hugo Grotius, imprimés au XVIIe siècle* (1961). A recent collection of Grotius' correspondence is *Briefwisseling van Hugo Grotius*, 6 vol., ed. by P.C. MOLHUIJSEN, vol. 1–2 (1928–36) and by B.L. MEULENBROEK, vol. 3–6 (1961–67). An English translation of Grotius' *Adamus Exul* is in W. KIRKCONNELL, *The Celestial Cycle* (1952).

Editions of Grotius' works on jurisprudence include: R. FRUIN (ed.), *De iure praedae commentarius* (1868). This appeared in an English translation as: *De jure praedae commentarius. Commentary on the Law of Prize and Booty*, 2 vol. (1950). For the *De iure*, see P.C. MOLHUIJSEN (ed.), *Hugonis Grotii de Jure Belli ac Pacis libri tres* (1919). This was translated into English and appeared in "The Classics of International Law" with an introduction by J.B. SCOTT (1925). See also: C. VAN VOLLENHOVEN, *Verspreide geschriften*, pp. 349–602 (1934), and *The Framework of Grotius' Book De Jure Belli ac Pacis, 1625* (1931); G.N. CLARK and W.J.M. VAN EYSINGA (eds.), *The Colonial Conferences Between England and the Netherlands in 1613 and 1615*, 2 vol. (1940–51); and SIR HERSCH LAUTERPACHT, "The Grotian Tradition in International Law," *British Yearbook of International Law*, 23:1–53 (1946).

A major work of scholarship on Grotius is the edition of his Latin poems, *De Dichtwerken van H.G.* (1970–), which includes the Latin text, a Dutch translation, and a thorough commentary.

Biographies of Grotius are: W.S.M. KNIGHT, *The Life and Works of Hugo Grotius* (1925); and A. LYSEN (ed.), *Hugo Grotius: Essays on His Life and Works*, 2 vol. (1925).

Groundwater

Vertical distribution and definitions

Groundwater is the water that occurs below the surface of the Earth, where it occupies all or part of the void spaces in a geological layer or layers. It is also called subsurface water to distinguish it from surface water, which flows overland and in rivers. Both surface and subsurface water are related through the hydrologic cycle, which is the path taken by the water on Earth: from oceans to atmosphere by evaporation, from atmosphere to the ground by precipitation, and ultimately back to the sea by runoff or streamflow.

The subsurface occurrence of groundwater classically has been divided into a zone of saturation, in which all interstices are filled with water, and a zone of aeration, in which the interstices are occupied partially by water and partially by air. The nomenclature associated with the vertical distribution of groundwater is shown in Figure 1.

The saturated zone often is separated from overlying soil water by an intermediate zone. The water in the intermediate and soil zones is known as suspended, or vadose, water. In arid regions the intermediate zone may be more than 300 metres (1,000 feet) thick, whereas in moist regions it may be absent. The intermediate zone terminates at its base in a capillary fringe, which may best be described as water in many minute, hairlike channels. In coarse-grained sediments the transition from the intermediate zone to the capillary fringe is abrupt,

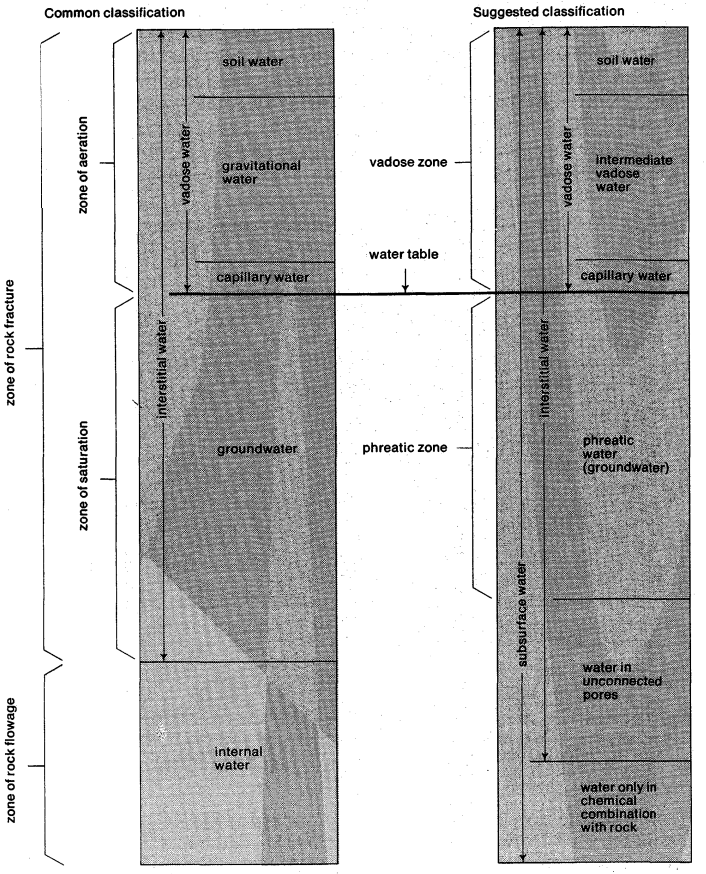

Figure 1: Classifications of subsurface water.
From S.N. Davis and R.J.M. DeWiest, *Hydrogeology* (Copyright 1966); used by permission of John Wiley & Sons, Inc.

but in silts and clays it is gradual. There may be very little difference in moisture content between the intermediate zone and the capillary fringe when recharge (percolation through the ground to the zone of saturation) occurs in fine-grained soils. The irregular surface of the capillary fringe constantly changes its position depending on change in water level and amount of recharge. Water movement in the upper part of the capillary fringe is slowed because of the presence of numerous pockets of air. In the lower part of the fringe, however, the soil is fully saturated, as it is below the water table—the theoretical surface approximated by the water levels in wells that penetrate the saturated zone. The water table separates the zone of groundwater, or phreatic water, from the capillary fringe. If groundwater flow is horizontal, water levels in wells will correspond closely to the water table. The groundwater zone merges at some depth into a zone of dense rock. Water is contained in the pores of such rock, but the pores are not connected and water will not migrate. The depth at which these zones will merge varies with the geological environment. In areas of crystalline intrusive and metamorphic rocks, which are essentially impermeable, the depth of the zone may start at 3,000 metres (10,000 feet), whereas in sedimentary basins the depth may be nearly 15,000 metres (50,000 feet). Temperature and pressure may become so great at depths of more than 30,000 metres (100,000 feet) that the pores are closed and the water will be present only in chemical combination with other material.

HISTORIC AND MODERN USE OF GROUNDWATER

The early development of wells and infiltration galleries in Asia arose because of the scarcity of water in dry regions, locally dense populations, and a dominance of agriculture. Mention of well water and well construction occurs in ancient literature and biblical accounts.

Man and animal power, aided by hoists and primitive hand tools, were the basis for well construction in the Near East. Despite great difficulties, these people built a number of large-diameter wells, some of which could accommodate donkey paths, although they rarely exceeded a depth of 50 metres (165 feet). Little evidence exists of technological advance in well drilling during historic times, although Egyptians perfected core drilling in stone quarries as early as 3000 BC. The ancient Chinese developed a churn drill for water wells that, although made of wood and powered by human hands, in principle was almost identical to modern machines. Wells of amazing depths were produced by using a slow drilling rate sustained for years and even decades. Depths as great as 1,500 metres (5,000 feet) have been reported. Brine and gas, rather than potable water, were obtained from the deepest wells. A slight modification of these methods is still used in rural areas of Laos, Cambodia, Thailand, Burma, and China.

Drilling for water in ancient times

The construction of long infiltration galleries, or *qanāt*s, was the greatest ancient achievement in groundwater utilization. *Qanāt*s collected water from alluvial fans; *i.e.*, sedimentary deposits laid down by streams at the bases of mountains and highlands. These fan-shaped structures, commonly several kilometres long (one kilometre equals 0.6 miles), collected water for agricultural and domestic purposes. The use of *qanāt*s, probably began about 2,500 years ago in Iran, from which the techniques of construction spread eastward to Afghanistan and westward to Egypt. It has been reported that one extensive *qanāt* system irrigated large tracts of fertile land west of the Nile in about 500 BC. Many *qanāt*s are currently used in Iran and Afghanistan, the best known of which are located on the alluvial fans of the Elburz Mountains in Iran (see further ALLUVIAL FANS).

A lack of early cultural contact between western Europe and China caused modern percussion methods of well drilling to develop independently in western Europe. Development stemmed from the discovery of flowing wells in Flanders in about AD 1100 and a few decades later in eastern England and northern Italy. In AD 1126 Carthusian monks from a convent near the village of Lillers, France, dug one of the first wells. In Gonnehem, Flanders, near Béthune, a water mill was driven by four wells cased (provided with interior piping or lining) 3.5 metres (11⅓ feet) above ground level and drilled several hundred feet deep to tap water under pressure from a fractured chalk bed that cropped out in the higher plateaus of the province of Artois. Wells from the region of Artois became so famous that all flowing wells are called artesian wells after them.

Many improvements have been made in the methods of drilling for water in the last 100 years because of understanding borrowed from oil- and gas-drilling experience. The development of hydraulic rotary methods has had the greatest significance in the advance of drilling techniques. Early rotary drilling was accomplished with the aid of an outer casing, which was dispensed with in about 1890 when thick mud was found to be sufficient for holding up the walls of the hole.

In the years between 1910 and 1930 well drilling was further advanced by the perfection of the deep-well turbine pump. Previously, deep wells had to be fitted with low-capacity piston pumps of poor efficiency. The new turbine pumps made irrigation by wells possible in areas previously underdeveloped for agriculture. As a result of the large production of these wells, bigger and more permanent wells are now in demand from the well-drilling industry.

Streams and lakes supply about four-fifths of the water used for all purposes in the United States (exclusive of hydroelectric power and navigation). Nonetheless, subsurface water plays an important economic role as well. Groundwater is more desirable than surface water for at least seven reasons: (1) it is commonly free of pathogenic organisms, and purification for domestic or industrial use is not necessary; (2) its temperature is nearly constant, which is advantageous if the water is used for heat exchange; (3) it is generally free of turbidity and colour; (4) its chemical composition usually is constant; (5) groundwater supplies are not seriously affected by short

Advantages and disadvantages of groundwater use

droughts; (6) most of it has not been affected by radiochemical and biological contamination; (7) it is available in many areas that do not have dependable surface water supplies because the groundwater has been stored by nature through many years of recharge.

Groundwater development is discouraged in some areas for at least three reasons: (1) many regions are underlain by rocks with insufficient porosity or permeability to yield much water to wells; (2) the content of dissolved solids is generally higher in groundwater than surface water in the same region; (3) well development is usually more costly than stream development, especially in regions of moderate to high precipitation.

SPECIAL IMPORTANCE OF GROUNDWATER IN ARID AREAS

Groundwater plays a vital role in the development of arid and semi-arid zones. Withdrawal eventually will deplete even large groundwater basins, but it is of great economic and social value if agriculture and industry thrive even for several decades. In some favourably situated areas within arid and semi-arid zones, groundwater and imported surface water already supply agricultural and domestic needs, although in vast areas further development in groundwater use is desirable.

Aquifers (water-bearing layers of rock) that antedate the formation of deserts will remain generally unaffected by an increase in aridity with the passage of time. In deserts the high temperature and general absence of organic matter suggest that small amounts of infiltrating water will not dissolve much carbon dioxide. In humid temperate regions the reverse is true and much carbon dioxide is dissolved, thus enhancing the chemical weathering (breakdown) of rocks. For this reason, and because of a general lack of moisture in deserts, chemical weathering will be slow, and the formation of solution openings in carbonate and other rocks will be retarded. The existence in some deserts of extensive carbonate aquifers may be attributed to former climates, considerably more moist than those presently prevailing. Other aquifers, such as those of the south flanks of the Atlas Mountains, may originate from the action of large amounts of water infiltrating into intake areas in well-watered uplands adjacent to the deserts.

Desert sedimentation and aquifers

The type of desert sedimentation is greatly influenced by desert conditions and in turn controls the type of aquifers found in unconsolidated (not yet cemented and transformed to rock) Cenozoic deposits (those formed in the last 65,000,000 years). Volcanic or tectonic obstructions will often alter stream courses and result in closed basins that fill with fine lake deposits mixed with saline residues in their central parts. Along the margins of such basins, or in deeper aquifers not affected by present arid conditions, are found the only freshwater or useful aquifers. The most important desert aquifers are formed from stream channel deposits. Desert channels carry such large amounts of material in suspension and traction that flows may become viscous mixtures of mud and debris, which is not true of streams in humid regions. Resulting deposits are usually poorly sorted and of low permeability. Permeable zones develop where streamflow persists long enough to sort the coarser debris and usually occurs during the declining stages of streamflow, when the stream is confined to narrow parts of the channel bottom. Consequently, permeable zones represent only a fraction of the alluvial deposits and are not easy to locate by drilling.

Most of the important desert aquifers of the southwestern United States, northwestern Mexico, northern Chile, and parts of Central Asia are composed of nonindurated Cenozoic deposits formed by volcanism and block faulting (vertical movements along fractures that bound block-shaped mountains). In most other desert regions, however, erosion has been the dominant feature. As a result, bedrock is near the surface, and nonindurated aquifers occur only in shallow deposits along ephemeral streams (those flowing only occasionally), basal parts of very large sand dune tracts, and wind-eroded basins. Extensive consolidated and semiconsolidated aquifers are found in some desert basins that lack thick alluvial deposits. Two examples of this are the Mesozoic sandstones (ranging from 65,000,000 to 225,000,000 years in age) of the Great Artesian Basin of Australia and the Nubian sandstone of Egypt and parts of adjoining countries (Figure 2). Water contained in these systems ranges

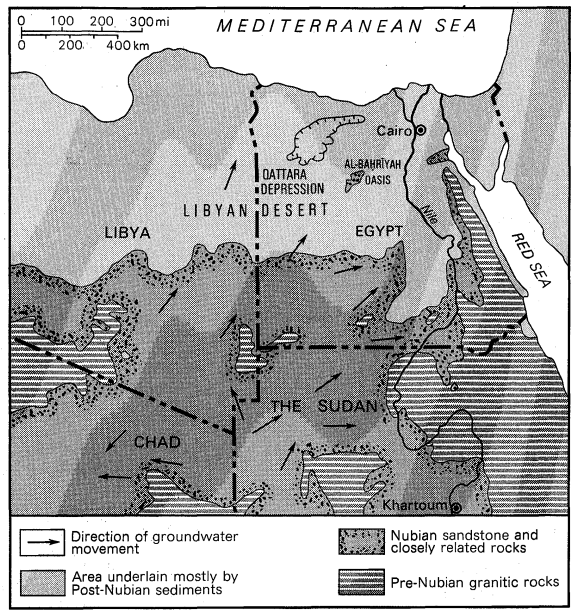

Figure 2: Outcrop area and general direction of groundwater movement in sandstones, northeastern Africa.

from potable, in parts within a few hundred miles of recharge areas, to brackish, in the deeper buried parts of the aquifers. Oases from the Nubian aquifers have existed for countless centuries at Wāḥāt ad-Dākhilah, Wāḥat al-Farafirah, and al-Wāhāt al-Baḥrīyah. Despite the fact that modern wells have increased water discharge and thus caused some reduction of the hydraulic head (due to pressures that result from the height of water in a well), the total amount of water available from the Nubian aquifers is so great that an increase in the number of wells may be justified if the water can be utilized profitably.

Soil moisture, infiltration, and recharge

The quantity and quality of available groundwater in arid regions affect the types of hydrogeologic features that are found. When rainfall is less than 125 to 250 millimetres (five to ten inches), passage of recharge water will be blocked by most soils, depending on the permeability of the soil, its retention of water, and the distribution of rainfall in relation to the temperature. During the summer heat, a loss of soil moisture to a depth of two feet in soils with a specific retention of 15 percent will require nine centimetres (3.6 inches) of rain merely to compensate for the soil moisture deficiency. More than nine centimetres will be needed for recharge if the rain occurs at several different times during the year, causing loss of water from the intervening periods of dry weather. On the other hand, if the sand in a sand dune has a specific retention of less than 5 percent, rainfall of five centimetres will penetrate more than three feet. In this case, penetration probably will go beyond the zone of seasonal drying in some parts of the dune.

Recent work in the western part of the Central Valley of California has proved (at least in this semiarid region) that rainfall does not infiltrate as a saturated line or front. The original porosity of the clay-rich and mudflow deposits found in a number of small alluvial fans in this region is so high that the sediment is unstable under the slightest overburden load. Experiments with flooded test plots and studies of the moisture content of numerous cores have shown that saturation of the porous deposits has not occurred since burial. The dry state extends to more than 30 metres (100 feet) below the surface in some places. Even if the rate of deposition was fairly rapid, thousands of years were required to deposit

these sediments. The subsurface zones of these small alluvial fans, therefore, have not been infiltrated by rain during this time span. The mean annual rainfall in this region today is about seven inches, which is greater than the rainfall in extremely arid regions. It may be concluded, therefore, that in desert soils with an appreciable amount of clay, considerable infiltration does not occur.

Typical barren rock or hard clay surfaces in deserts will shed rains of only a few tenths of an inch. Large amounts of soil and surface debris usually are eroded by runoff, and the eroded material varies from very turbid water to a viscous mudflow. In rare instances, the runoff may be relatively free of suspended material. If turbidity is low and permeability of the channel bottom is deep enough, water will flow into the gravel and sands of the channel bottom. Evaporation will restore much of this water to the atmosphere. Vigorous infiltration may recharge underlying aquifers, predominantly in constricted portions of the channel rather than in portions in which the flow covers large sections of the desert floor. This is caused by the greater concentration of permeable material at the constrictions, which are also most likely to receive the last part of the flood flow; the latter is made up of water draining from the earlier deposited saturated floor debris and is relatively free from suspended sediments.

The great depths to water in upland areas and the exceptionally flat hydraulic gradients (pressure changes with distance and direction) that usually are found in deserts reflect the small amounts of recharge that take place. When the subsurface layers are undisturbed after deposition, the gradients may be so small that it is not possible to distinguish between the important hydrogeologic barriers. The amount of water moving through the subsurface increases, and all gradients are steepened by groundwater development, which accentuates the zones of lower permeability.

Dealt with in this article are the factors that influence the origin, occurrence, and distribution of groundwater, the fluctuation of groundwater levels and abundance, and its movement in the subsurface. For further information on the role of groundwater in the hydrologic cycle, see HYDROLOGIC CYCLE. See also CLIMATE; CLIMATIC CHANGE; RIVERS AND RIVER SYSTEMS; ESTUARIES; CAVES AND CAVE SYSTEMS for information on the relations between these topics and groundwater.

ORIGIN AND OCCURRENCE OF GROUNDWATER

Hydrologic conditions and their influence. Groundwater and surface water are related through the hydrologic cycle, the path traveled by the waters of the Earth, of which they are interdependent components. Water evaporates from the oceans and forms clouds, which move inland, condense, dropping the water to the Earth as precipitation. From the land, through river channels and underground, the water runs off to the oceans. There is no evidence that water decreases in quantity at a global level; it is neither destroyed nor generated.

Evaporation, precipitation, and runoff

A large amount of the water that falls upon the Earth is returned to the atmosphere as vapour through the combined actions of evaporation, transpiration (evaporation via plant life), and sublimation (change of state from solid to vapour). On a global basis the total amount of precipitation on the continents P_c and on the oceans P_o is equal to the total amount of evapotranspiration from the continents E_c and from the oceans E_o. On a continental basis the total precipitation P_c is equal to the evapotranspiration from the continents E_c and the runoff R, a relationship that may be expressed: $P_c = E_c + R$. For all continents the average values are 674 millimetres precipitation = 420 millimetres evapotranspiration + 254 millimetres runoff.

The term runoff is usually taken to be synonymous with streamflow and is the sum of surface runoff and groundwater flow that reaches stream channels. Because groundwater contributes the base flow, or dry-weather flow of rivers, groundwater studies must be related to the runoff cycle. A study of the interrelationship between surface water and groundwater is always indicated, and in many projects, measurements of surface discharge provide the only indications of amounts of groundwater available. Surface runoff equals precipitation minus surface retention and infiltration. Infiltration is the passage or movement of water through the surface of the soil and is to be distinguished from groundwater flow.

Factors influencing surface runoff include precipitation intensity, permeability of the ground surface, duration of precipitation, type of vegetation, area of drainage basin, distribution of precipitation, stream-channel geometry, depth to water table, and the slope of the land surface. Surface runoff is commonly represented in the form of a hydrograph, which is a time record of stream-surface elevation or stream discharge at a particular channel cross section. In general, a hydrograph is a plot of the discharge from a hydraulic or hydrologic unit or system, such as a river or drainage basin, versus time, or it may depict the time variation of the runoff component of a storm. In the case of perennial streams, in periods of drought when no direct overland flow reaches the river, the hydrograph is a line that slopes gently down. The streamflow at this time is provided entirely by groundwater flow.

Infiltration and its effects

When a storm begins, much precipitation is caught and stored by trees and vegetation as interception, but because water stored in this way is usually exposed to wind and open to evaporation, storms of light intensity and short duration may be entirely depleted by interception and by the small amount of water that infiltrates through the surface and fills puddles and surface depressions. For water to infiltrate, a proper soil surface is necessary. Overland flow starts when the available interception and depression storage is exhausted and when the rainfall intensity of the storm at the soil surface exceeds the infiltration capacity. A thin sheet of water, known as the surface detention, then covers the soil surface. When the overland flow reaches a stream channel, it is called surface runoff.

Part of the water that infiltrates the soil will reach the stream channel by continuing a lateral flow (interflow) at shallow depths because of the presence of impervious horizons just below the soil surface. Another part will percolate downward to the water table and provide the base flow of the stream when it reaches the stream channel. The last part will remain above the water table in the zone of unsaturated flow.

When a large storm occurs in the drainage basin of a perennial stream and conditions are such that the rainfall intensity exceeds the rate of infiltration and the volume of infiltrated water exceeds the soil-moisture deficiency, then the hydrograph of the river discharge becomes quite peaked. There is above-normal streamflow because of the contributions from channel precipitation, surface runoff, interflow, and groundwater flow. The contribution from groundwater flow may be negative, however, when continued high runoff causes the river to become influent—surface water flowing from the channel down gradient, to contribute to the groundwater.

It is very difficult to separate the base flow from surface runoff because streamflow measurements do not reveal the times when a stream becomes influent; that is, contributes water to the adjacent aquifers. It is possible to make an approximate separation that is acceptable for most purposes, however. This is based on a horizontal line drawn through the point where the rising limb of the hydrograph starts and its intersection point with the recession curve. The groundwater-flow (base-flow) component is the volume of water given by the area below the horizontal line.

Geological factors. Geological factors, principally the porosity (relative void space) and permeability (a measure of the ease of flow) of water-bearing rock layers, are of great importance in determining groundwater occurrences.

The porous rock and soil media, in which water is collected by water-bearing strata and through which it flows under the influence of various forces, have a solid matrix or skeleton that is an assemblage of solid mineral

grains separated and surrounded by voids, pores, or interstices. These may be filled with water, gases, or organic matter. The term rock commonly applies to a cemented or consolidated porous medium, such as a sandstone or limestone, whereas soil or sediment refers to unconsolidated, uncemented material, such as sand, gravel, or clay.

Porosity is defined as the ratio of the volume of voids to the total volume of the material under consideration. Porosity of unconsolidated materials is determined by the packing of the grains, their shape, arrangement, and size distribution; porosity of consolidated materials is determined by the degree of cementation, the state of solution, and fracturing of the rock. Openings left between grains will be filled by smaller grains, and thus the porosity associated with nonuniform size distribution is smaller than with well-sorted grains.

Porosity is a measure of the water-bearing capacity of a formation and is also a factor in the ability of a formation to transmit water. This ability is known as the hydraulic conductivity of a formation. The relationship between porosity and hydraulic conductivity is complex, and other factors are also involved. For example, large rounded or angular sand grains may have a smaller porosity than small platelike clay particles. This is because of the larger specific surface of the plate shape, which causes high molecular forces of attraction between the clay and water particles.

Porosity is the sum of effective porosity and specific retention. The specific retention is that percentage of porosity that is occupied by water that cannot be drained by gravity from the rock. The hydraulic conductivity K of an aquifer is equal to the permeability of the medium times the unit weight of the water divided by its dynamic viscosity. This may be represented: $K = k\frac{\gamma}{\mu}$, in which γ is the specific weight of water, μ the dynamic viscosity of water, and k the intrinsic permeability of the medium. The intrinsic permeability is characteristic of the solid matrix (*e.g.*, the material that binds together the particles in a sandstone) of the medium alone. It has the dimensions of a surface (that formed by the interstices between particles) and takes into account effects of stratification, packing, arrangement of grains, size distribution, and porosity.

The hydraulic conductivity is expressed as a velocity of flow. In the metric system it may be expressed in centimetres per second; in English units it may be expressed in feet per second or in gallons per day per square foot of surface.

The so-called darcy unit, which is used in petroleum engineering as well as in hydrogeology, is used as a measure of the intrinsic permeability k. It equals 0.987 $\times 10^{-8}$ square centimetres (1.062×10^{-11} square feet).

Aquifers, aquicludes, and aquitards

Geological rock formations of relevance in groundwater studies are defined according to their water-bearing and water-transmitting properties. Thus, an aquifer is a geological formation containing, or capable of containing, water in its voids or pores that may be removed economically and used as a source of water supply. Unconsolidated alluvial deposits of sand and gravel and porous sandstones are examples of water-bearing formations.

A geological formation so impervious that for all practical purposes it completely obstructs the flow of groundwater (although it may be saturated with water itself) and completely confines other strata with which it alternates in deposition is an aquiclude. A shale is an example.

If a geological formation is impervious and semiconfining and transmits water at a very slow rate compared with the aquifer, it is called an aquitard. Over a large area of contact, however, such a formation may permit the passage of large amounts of water between adjacent aquifers, which it separates from each other. Clay lenses interbedded with sands, if thin enough, may form aquitards. If a rock formation neither transmits nor stores water, it is called an aquifuge.

When the surface of the saturated groundwater zone is in direct contact with the atmosphere through open spaces in permeable material, it is called free, and the groundwater is unconfined. Aquifers containing water in these conditions are called unconfined *sensu lato*. Confined water is separated from the atmosphere by impermeable material. Aquifers containing such water are called confined *sensu lato*. The division between confined and unconfined water is entirely a matter of gradation, and the term semiconfined is used for intermediate conditions.

Confined water is also called artesian water; this term, however, was first applied to water under sufficient pressure to produce flowing wells. In recent years artesian has been used more or less as a synonym for confined water.

World distribution of groundwater. A vast amount of groundwater is distributed throughout the world, and a large number of groundwater reservoirs are still underdeveloped or uninvestigated. In September 1968 the Water Resources Section of the United Nations invited a group of experts to study groundwater storage at the global level. The panel of experts, together with the technical advisers of the UN Resources and Transport Division, drafted a manual on groundwater storage and presented 70 case studies, constituting a sampling of occurrence and world distribution of groundwater. This sampling does not reflect the overall world situation, however, because the cases presented apply principally to areas that have been carefully investigated in response to a shortage of water resources or to a high demand for water. The number of cases cited do suffice to give some general impression of the distribution of groundwater according to climate, physiography, and geology (see Table 1).

Table 1: Distribution of Groundwater

	number of cases
Climatic distribution	
Type of climate	
Arid or semi-arid	16
Tropical humid	9
Cold or temperate, humid	7
Desertic	5
Temperate (oceanic, Mediterranean, etc.)	25
Continental	8
Physiographic distribution	
Physiographic characteristics	
Alluvial valleys	19
Coastal plains	18
Deltas	2
Islands	3
Inland plains (fluvoglacial and morainic)	5
Other types of inland plains and deserts	14
Plateaus	4
Mountains (mainly carbonate karstic rock)	5
Geographic distribution	
Country or continent	
Americas and Caribbean	9
Africa and Madagascar	12
Europe	21
Middle East and Central Asia	13
Asia, Far East, and the Pacific	15
Geological distribution	
Type of rock	
Unconsolidated sand and gravel	51
Carbonate (dolomite, limestone)	26
Sandstone	14
Volcanic	4

The most frequently investigated or exploited groundwater reservoirs are of the unconsolidated clastic (mainly sand and gravel) or carbonate hard-rock type of alluvial valleys and coastal plains under temperate or arid conditions.

FLUCTUATION OF GROUNDWATER LEVELS

Phreatophytes and daily fluctuations. Phreatophytes are desert plants that grow along streams and in areas with relatively shallow water tables. They have deeply penetrating roots that reach the groundwater and thus permit plant survival. Some phreatophytes are valuable guides to the presence of potable water in arid and semiarid regions because they have a low tolerance for salt. The ash, alder, willow, cottonwood, and aspen have been useful in this way and generally grow where the water table is less than ten metres (30 feet) deep.

Water consumption by phreatophytes

Most of the phreatophytes have little or no economic value and waste a large quantity of water in arid regions. Alfalfa, *Medicago sativa*, which is a widespread phreatophyte of great economic value, is an exception to most other phreatophytes. In the western United States alone, amounts of about 30,000,000,000 cubic metres (about 25,000,000 acre-feet) of water are wasted by phreatophytes each year. The loss of water via phreatophytes in the arid and semiarid regions of the world is many times this quantity.

Various factors influence the amount of water used by phreatophytes, such as plant species, density of growth, climate, and hydrology. Sunlight, temperature, and humidity are the most important climatic factors. If there is no sunlight or if the temperature drops below about 4° C (40° F), transpiration in some plants will almost stop. In other plants, transpiration will be slight during the night but will stop when the mean temperature drops below 18° C (65° F). Plants will tend to transpire less if the relative humidity is high.

The most important factors are depth to water and water quality. For many phreatophytes, water consumption and depth to the water table are inversely related. Thus, if the water table would rise from a depth of 40 centimetres (16 inches) to a depth of 70 centimetres (28 inches), water use might be doubled. The effect of water quality varies in different plants. Most plants such as salt grass will have an optimum growth with water that has dissolved-solids concentration of several thousand parts per million.

Water-level fluctuations in shallow wells are related to plant transpiration. The nightly rises in water levels signify recovery of water at times of no transpiration. In view of the fact that the water fluctuations are small compared with the total energy moving the water and the thickness of the saturated material, the maximum velocity of water rise in the hydrograph is a close approximation to the velocity of water moving continuously into the area of water withdrawal. Water use, therefore, is approximately equal to this maximum velocity, multiplied by the total area of open space within the saturated material.

Water use by dense plant growth ranges from less than one foot per year in subarctic environments to more than 2.3 metres (7.5 feet) per year in hot, dry environments. Salt cedar, *Tamarix gallica*, which is native to Europe and Asia, uses the highest quantities of water. Tests conducted in Arizona showed that this plant consumed 270 centimetres (110 inches) of water from a water table at a depth of 123 centimetres (48 inches). Representative transpiration values for various phreatophytes are given in Table 2.

Table 2: Water Use by Dense Growths of Phreatophytes

common name	scientific name	climate	depth to water		annual water consumption	
			cm	in.	cm	in.
Salt cedar	*Tamarix gallica*	hot, dry	123	48	270	110
		hot, dry	213	84	224	88
Greasewood	*Sacrobatus vermiculatus*	cool, dry	50	20	66	26
Willow	*Salix*	hot, dry	61	24	134	53
Cottonwood	*Populus*	hot, dry	220	87	238	94
Alfalfa	*Medicago sativa*	cool, dry	91	36	80	31
		hot, dry	138	54	113	44
Alder	*Alnus*	hot, dry	...	...	162	64

Current wastage of groundwater by useless vegetation can be avoided by various means. When the water is very shallow, the water table can be lowered by drainage wells, which will kill most grasses and small shrubs that are phreatophytes. The water that is drained can then be used for other practical purposes. Weed killers, burning, or mechanical cleaning will remove other useless phreatophytes, and the area can be planted with useful phreatophytes, such as alfalfa. Removal can be quite difficult, however, because of the great growth rate of some of the noxious plants. One example is the salt cedar, which can produce more than 500,000 seeds per plant per year, many of which will germinate rapidly and produce a jungle-like growth in less than five years.

Climatic variations. Short-term climatic variations of groundwater levels are those extending over periods of several years or more. Alternating series of wet and dry years, in which the rainfall is above or below the mean value, will produce long-period fluctuations of levels. The long periods of rainfall and groundwater levels in San Bernardino Valley, California, shown in Figure 3, illustrate this point. Rainfall is not an accurate indicator of groundwater level changes. Correlation of the monthly precipitation on two small drainage basins, Trent River and Swift Creek in North Carolina, with monthly discharge of these rivers was undertaken for the 15-year period 1952–66. In this application of the interrelationship between surface water and groundwater, measurements of surface-water discharge were made to indicate the quantity of available groundwater. It is assumed that all base flow of a river is contributed by its groundwater basin and that this water, released from the basin, can be replenished by recharge through rainfall. If there were not enough recharge, the base flow would decrease over a number of years, and this would be reflected in the annual trend of the streamflow records. If no such trend can be observed, it may be assumed that the base flow is replaced by recharge.

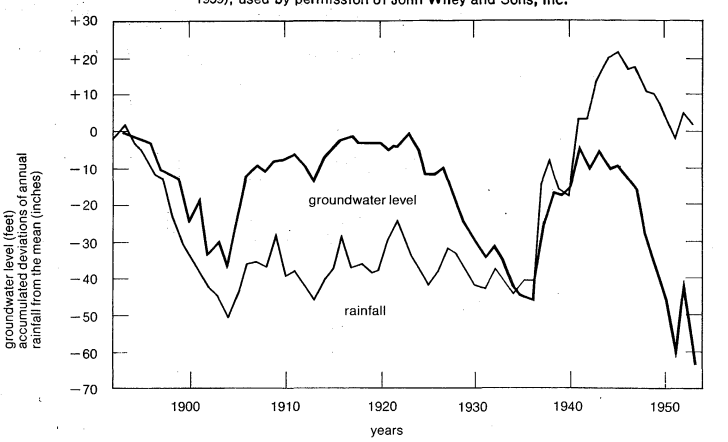

Figure 3: Variation of annual groundwater level and annual rainfall in San Bernardino Valley, California.

In the case of the Trent River, base flow rose from about 14 percent of the average precipitation for a five-year period to 20 percent of the average precipitation for a ten-year period, when the average precipitation increased 7 percent from one period to the other. In the case of Swift Creek, base flow increased from 10 to 19 percent of the average precipitation when the precipitation increased by 6 percent. Thus, groundwater levels reflect short-term climatic variations.

MOVEMENT OF GROUNDWATER

Darcy's law. Groundwater moves from levels of higher energy to levels of lower energy, and its energy is essentially the result of elevation and pressure. Groundwater flow is amenable to a classical mathematical treatment only if the flow is laminar (nonturbulent), as in unconsolidated sediments and in some sedi-

mentary rocks. For water movement in karstic terrain (limestone media, with caves and sinks), in which the flow is often turbulent, only approximative mathematical formulations or empirical expressions based upon hydraulic experiments are currently available. For a mathematical expression of groundwater motion in the subsurface, the interested reader should consult the literature cited in the bibliography of this article.

In laminar flow, kinetic energy of groundwater is neglected because groundwater velocities are very small. During flow, groundwater experiences a frictional loss in energy caused by contact with the walls of the granular medium along its seepage path. The water lost per unit length of distance travelled, called the hydraulic gradient, is proportional to the velocity of groundwater for laminar flow in sandy aquifers or seepage through earth embankments. The proportionality of hydraulic gradient and groundwater can be expressed by a linear law of flow called Darcy's law.

Similarity to flow in pipes

The similarity between groundwater flow and laminar pipe flow was recognized in 1856 by Henri Darcy, a French engineer, who conducted an experiment on a vertical cross-sectional area A filled with sand under conditions simulated by Figure 4. Darcy concluded from

From M.K. Hubbert, *Journal of Geology* (copyright 1940); University of Chicago Press

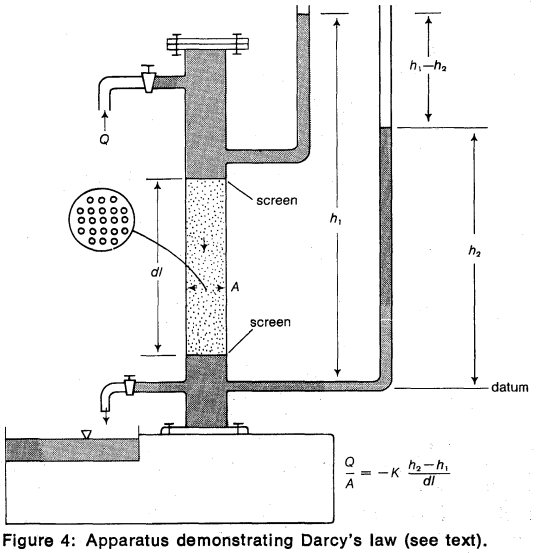

Figure 4: Apparatus demonstrating Darcy's law (see text).

his study of the flow through horizontally stratified beds of sand that the flow rate Q was directly proportional to the energy loss, inversely proportional to the length of the flow path, and proportional to a coefficient K that depends on the type of sand. The coefficient K is also subject to the properties of the fluid, however. Darcy's law may be expressed as $Q = -KA(dh/dl)$, in which dh/dl = head lost over a length of porous medium dl, and $K = k(\gamma/\mu)$, in which K is the hydraulic conductivity as before; γ is the specific weight of the fluid, μ is the dynamic viscosity of the fluid, and k is the intrinsic permeability of the medium. If the granular skeleton of the porous medium were a simple geometrical assembly of prismatic, unconnected tubes, groundwater flow could be dealt with microscopically by the laws of hydrodynamics. In fact, however, the seepage path is a tortuous one, branching into a multitude of tributaries. With the introduction of a twofold averaging macroscopic concept, Darcy's law avoids the insurmountable difficulties of the hydrodynamic microscopic picture.

The law is based on consideration of a fictitious flow velocity, the Darcy velocity or specific discharge, through a determined cross section of a porous medium rather than the true velocity between the grains. It also considers average hydraulic values rather than local values of this velocity. These concepts were simplified because of the nature of Darcy's experiment, which permitted the measurement of only average hydraulic values in the sand-filled cylindrical pipe. Because Darcy's law reflects average conditions, it is essentially a statistical result.

Flow nets. A widely used graphical method consists of fitting a flow net to the boundary conditions that define a given groundwater problem. A flow net is a two-dimensional graph consisting of two families of curves of a distinctive nature: flow lines or streamlines that show how water travels, and equipotential lines that connect points of the same potential. Use of the graph is thus limited to the investigation of two-dimensional cross sections that represent the main flow and to the analysis of three-dimensional problems with either axial or radial symmetry.

Streamlines are everywhere at right angles to equipotential lines, and flow nets are particularly useful when observations of static water levels are made in closely spaced wells. If the heads of water in the wells are equal to the elevation of the water level in the wells, it is possible to construct groundwater contours from an observation of these water levels. This permits estimation of the direction of groundwater flow, which is orthogonal (at right angles) to the family of constructed contour lines.

Oil and gas associations. The anticlinal theory was the first attempt to establish laws of oil and gas accumulation in subterranean media in the early days after the discovery of oil at Titusville, Pennsylvania, in 1859. It conceived of a static system of gas, oil, and water with horizontal interfaces, resting on the crests of anticlines. This theory was generally accepted in the first half of the 20th century, except for some sporadic thinking about the requirements of fluid dynamics in the 1920s and 1930s, which made the flow of water an essential requirement for oil and gas movement. In 1953 there was renewed emphasis on the hydrodynamic aspect of the problem, which is basically the correct approach. The most prominent features in this approach are the concepts that force potentials act on the fluids in question and that the fluids involved are immiscible. This leads to the occurrence of distinct fluid–fluid interfaces, along which surface-tension effects are important.

A water-saturated environment is the normal site for petroleum and gas, formed by the decomposition of organic matter deposited in sedimentary rocks. For convenience because of this, the potential energy of these fluids is expressed in terms of that of the surrounding groundwater. In the study of oil and gas movement in porous rocks, a distinction is made between primary migration from the source rocks, in which the fluids originate in a dispersed state, to the reservoir rocks and the movement that occurs in them.

The force potential per unit mass for liquid petroleum at a given point includes the work done against gravity and pressure and that involving the energy between petroleum, water, and rock, whereas these substances meet to form an interface or surface (Figure 5). In general, considering oil and water, rocks are preferentially wet by water, and the pressure inside the oil exceeds the pressure inside the water. This is important in the primary migration of oil from source rocks to reservoir rocks, which is related to the geometry of the porous medium (overall configuration of the rock body) and the pressure gradient across the boundary of the different rocks. Discontinuities in permeability are the paramount driving force in migration.

The force acting on the liquid petroleum is oriented along the direction in which the grain size of the rock increases most rapidly. This force is inversely proportional to the grain size of the rock. Because this increase in grain size normally occurs perpendicularly to the planes of sedimentary deposition, the oil globules have a tendency to move in that direction under the influence of capillarity. Once a globule reaches the boundary between rocks of different texture, part of its mass is subjected to a capillary force. It follows that an oil globule, in a liquid or gaseous state in a water-saturated environment, can pass only from fine- to coarse-textured rocks and not in the opposite direction. Capillary action would not be present if oil were not surrounded by water; hence, the importance of groundwater in oil and gas migration.

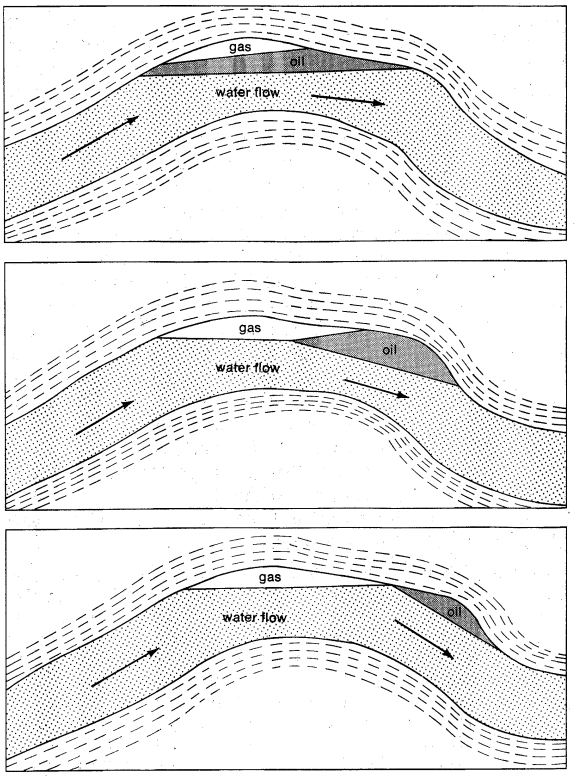

Figure 5: Hydrodynamic oil and gas accumulation in gently folded thick sand, showing changes in oil–gas–water interfaces with water flow through time (top is earliest).
From M.K. Hubbert, *Journal of Geology* (copyright 1940); University of Chicago Press

Movement in reservoir rocks

In the flow of oil within reservoir rocks, the role of capillary forces may be neglected because of the large grain size. The capillary pressure of oil in sandstone is only of the order of tenths of an atmosphere (one atmosphere is atmospheric pressure at sea level, or 14.70 pounds per square inch). The impelling force for a particular flow of the ambient (surrounding) water is the variation in density of the hydrocarbons present. Density variation also is responsible for the direction of the total force and for the separation of liquid petroleum and gas under particular geological conditions. Depending upon the angle of dip or inclination of the reservoir strata, gas may be deflected upward along the inclined strata, whereas liquid petroleum will move downward. A change in the magnitude of the impelling or driving force could change this situation and cause both fluids to migrate in the same direction. It is clear that elements of petroleum generally will move from regions of higher energy to regions of lower energy and will come to rest when the energy of their surroundings is higher than their own energy or when they are trapped between regions of higher energy and impermeable barriers. Oil and gas accumulations in such traps will form a static horizontal interface; the oil–water interface will be sloping if water is flowing underneath the oil.

Saline water in coastal areas. Saltwater encroachment or intrusion is the shoreward movement of sea or ocean water into confined or unconfined coastal aquifers and results in the displacement of freshwater from these aquifers. If freshwater and salt water are considered as two immiscible fluids, then they are separated by a sharp interface with a slope somewhat like that of an oil–water interface. Because the interface slopes, the front of the salt water can be compared to a tongue, progressing into the land as a result of overdraft of the overlying freshwater and pushed back seaward when precipitation replenishes the amount of freshwater. Actually, freshwater and seawater mix to form a region of dispersed water, and saltwater dispersion should be taken into account in order to obtain a more accurate concept of the nature of groundwater flow in a coastal aquifer. When the water supply of islands and coastal regions depends upon groundwater, the study of saltwater encroachment, which may reach several thousand feet inland, is of great interest and importance (Figure 6). Wells that become contaminated with salt water may either be abandoned or

From M.K. Hubbert, *Journal of Geology* (copyright 1940); University of Chicago Press

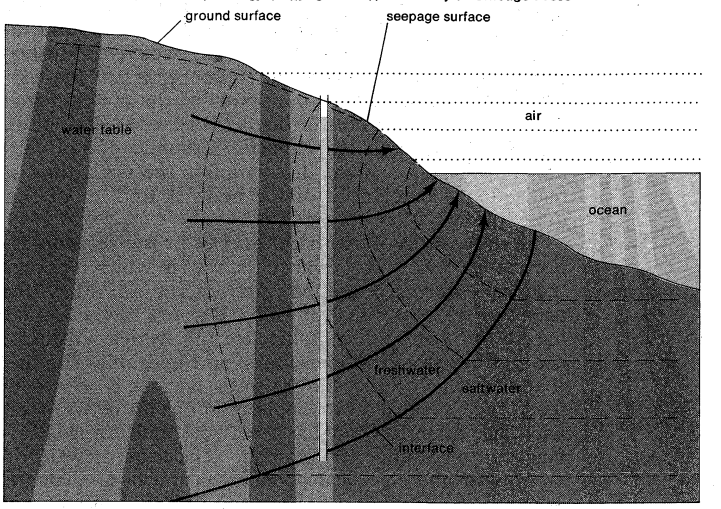

Figure 6: Saltwater encroachment (dashed seepage surfaces) and freshwater flows (arrows) as related to wells in coastal regions.

have to be injected with freshwater to stop the inland movement of the salt water and to establish a freshwater barrier. An idea of the freshwater losses to the ocean through discharge under sea level might be obtained by a study of the location of an idealized interface.

Physical analogue models

Analogue models of groundwater systems. One of the physical analogues currently used in groundwater studies is the sandbox. It represents a true model because an aquifer and the model both involve flow through porous media. A sand model is a scale model of an aquifer with the boundaries scaled down and the permeability modified. Unconfined aquifers can be modelled with the water table naturally reproducing the upper boundary; confined aquifers are reproduced by providing an impervious layer so that pressure can be applied. The effect of capillary rise is greatly exaggerated in this kind of analogue, however, and it lacks versatility. For this reason, other models, such as the viscous-flow analogue and the electric analogue, are favoured. The sandbox is still in use in soil mechanics and agricultural laboratories.

In 1899 it was shown that pressure and gravity forces can cause a viscous liquid to flow between closely spaced parallel plates. The first apparatus used to demonstrate this flow was designed in 1897, and since then the analogue has been used extensively to simulate the two-dimensional laminar flow of water through porous soil. Theoretically, such a viscous-flow analogue is a perfect model because it conforms to the equations of flow that describe groundwater movement. One requirement, however, is that the density of the fluid remain constant, and this is difficult to satisfy because of the problem of keeping the temperature of the fluid constant and because the viscosity of most oils and glycerine is very much temperature dependent. Analogues utilizing such fluids are usually in temperature-controlled rooms, and, if the fluid is pumped on some occasions it is necessary to cool the fluid after it leaves the pump.

The versatility of the parallel-plate, viscous-flow analogue as a tool for the investigation of groundwater flow lies in the easy simulation of different values of the hydraulic conductivity of the soil through variation of the spacing of the plates and the fluid properties. Regional variations of hydraulic conductivity may be accounted for by the insertion of thin strips to reduce the spacing in the desired region.

The model also has been used with the plates oriented horizontally to study the effects on the groundwater table of artificial replenishment in the well fields of the water works company of Zealand Flanders. For the analogue to

be suitable for the study of unconfined aquifers, it must be assumed that groundwater-level fluctuations are relatively small compared with the thickness of the aquifer.

Electric analogue models

Electrical models involve an R–C (resistor–capacitor) analogue network in which solutions to the equations describing groundwater flow may be obtained by varying current and voltage; the solutions can be visualized directly on an oscilloscope. The use of electric-circuit elements to simulate the distributed properties of the subsurface strata is only for the points of the medium that correspond to the points of the network, consisting of an assembly of resistors and capacitors. Application of voltage and current sources that simulate the excitations is made to the boundaries of the network and at interior nodes (points) when required.

The dissipation of electrical energy in the resistor–capacitance network is similar to the way in which a porous medium consumes groundwater energy to allow the travel of water through its voids. Because of the similar nature of electrical conductance, in which electrical charges are stored in capacitors, and hydraulic conductivity, in which water storage in an aquifer is related to its storage coefficient, a simple relationship between capacitance of an R–C analogue network and storage coefficient of an aquifer can be made. The head of water in an aquifer and electrical potential in the R–C analogue network are analogous. Hence, the elevation of water in a well can be obtained by application of Ohm's law (current equals voltage divided by resistance); consequently, electrical R–C analogue models are of great utility, and their use in studies of current or future groundwater conditions is widespread.

Other electrical analogues also have been used. The electrical resistance network, employing a solid sheet made of a conductive material in a tank filled with an electrolyte (conducting fluid solution), has been a favourite tool of agricultural engineers and soil physicists in studies of drainage and infiltration. The voltage distributions in the sheet and in the electrolyte simulate the conditions of groundwater flow.

The electrolytic tank is usually a watertight container of a nonconductive material filled to a shallow depth with a few centimetres of electrolyte. The following model conditions must prevail: the conducting liquid should have no electrical reactance, its resistivity must be uniform, there must be a linear relation between voltage and current, chemical reactions between liquid and electrodes must not occur, and the rate of evaporation of the liquid must be slow to prevent change of the resistivity in time.

The principle governing the conductive-sheet analogue and the one underlying the electrolytic tank are the same. Sheets of electrically conducting material of uniform properties in all directions and high resistance are suitable. This material may consist of filter paper soaked in a suspension of colloidal graphite, of woven grids of metal wire and silk thread, of conductive rubber, or of metallized paper, among other things.

From D.K. Todd and J. Bear, *River Seepage Investigation*, University of California. Berkeley

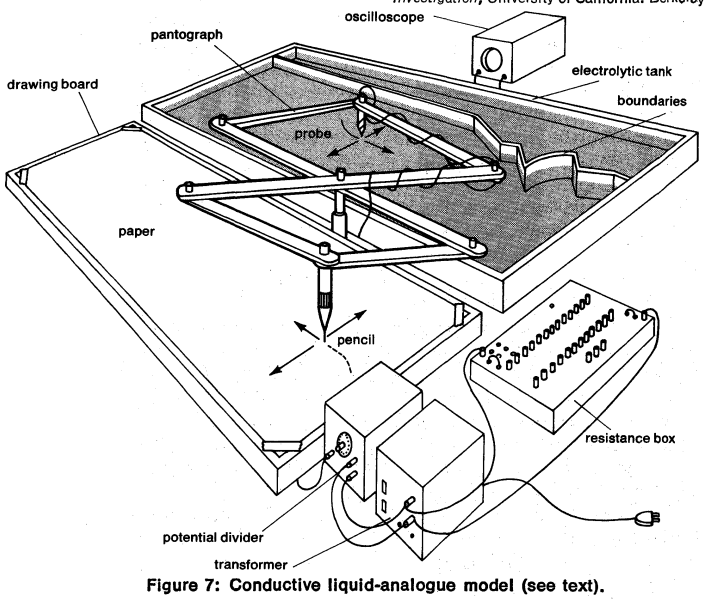

Figure 7: Conductive liquid-analogue model (see text).

Shown in Figure 7 is a typical liquid-analogue model consisting of the electrolytic tank, the electrical equipment, and the drawing board with pantograph. Voltage is reduced, as in the case of the resistance-network analogue, to avoid electrocution and heating of the electrolyte. The voltage is divided into a large number of subdivisions by a potential divider. The identification of the potential at the probe position is made with the help of an oscilloscope through which no current flows when the probe is of the desired potential and the pencil of the pantograph is depressed to leave a mark on the drawing paper. By connecting points of the same potential, equipotential lines are sketched. The application of the theory of the electrolytic tank, which has been known for a long time, to groundwater flow is based on the similarity between the differential equations that describe groundwater flow and those that govern electrical current flow through conducting materials.

BIBLIOGRAPHY. The following books provide an overview of the several aspects of groundwater covered in this article: D.K. TODD, *Ground Water Hydrology* (1959); and R.K. LINSLEY, M.A. KOHLER, and J.L.H. PAULHUS, *Applied Hydrology* (1949). More modern treatments of the subject, including the mathematical equations that describe groundwater motion, well hydraulics, and similar topics, are presented in: R.J.M. DE WIEST, *Geohydrology* (1965); S.N. DAVIS and R.J.M. DE WIEST, *Hydrogeology* (1966); and P.S. EAGLESON, *Dynamic Hydrology* (1970). The basis for much of the modern theory of groundwater flow is contained in the classic paper: M.K. HUBBERT, "The Theory of Groundwater Motion," *J. Geol.*, 48:785–944 (1940). See also R.J.M. DE WIEST (ed.), *Flow Through Porous Media* (1969).

Growth

Although the essence of growth is increase, it is useful to distinguish between growth of living things and that of inanimate objects. The growth of inanimate objects, such as occurs during the formation of crystals, is limited. The crystals can increase in size but are unable to reproduce themselves; living things, on the other hand, not only increase in size but also reproduce themselves. Growth of living things always occurs by an increase in the number or size of the basic units of organisms, cells, and always eventually includes reproduction. To appreciate fully how living things grow and how this growth is regulated requires a consideration of the way in which cells increase in size and number.

The increases in cell size and number that take place during the life history of an organism are seldom random; rather, they occur according to a plan that eventually determines the size and shape of the individual. Growth may be restricted to special regions of the organism, such as the layers of cells that divide and increase in size near the tip of the plant shoot. Or the cells engaged in growth may be widely distributed throughout the body of the organism, as in the human embryo. In the latter case, the rates of cell division and of the increase in cell size differ in different parts. That the pattern of growth is predetermined and regular in plants and animals can be seen in the forms of adults. In some organisms, however, notably the slime molds, no regular pattern of growth occurs, and a formless cytoplasmic mass is the result.

The rate of growth of various components of an organism may have important consequences in its ability to adapt to the environment and hence may play a role in evolution. For instance, an increase in the rate of growth of fleshy parts of the fish fin would provide an opportunity for the fish to adapt more easily to terrestrial locomotory life than could a fish without this modified fin. Without disproportionate growth of the fin—ultimately resulting from random changes in the genetic material (mutations)—the evolution of limbs through natural selection might have been impossible.

Growth is often used synonymously with development, and, indeed, increase in size is a striking feature of development. But development also includes changes in the types of cell specialization (differentiation) and extensive movements of cells. Movements of cells and tissues during embryonic development are partially responsible for the form of the body and various organs.

The discussion below focusses on the types of growth and how growth rates may be regulated by factors in the external environment and from within the organism (see DEVELOPMENT, ANIMAL; DEVELOPMENT, PLANT for detailed discussions of development).

TYPES OF GROWTH

In cells. The increase in size and changes in shape of a developing organism depend on the increase in the number and size of cells that make up the individual. Increase in cell number occurs by a precise cellular reproductive mechanism called mitosis. During mitosis the chromosomes bearing the genetic material are reproduced in the nucleus, and then the doubled chromosomes are precisely distributed to the two daughter cells, one of each chromosomal type going to each daughter cell. Each end of the dividing cell receives a complete set of chromosomes before the ends separate. In animal cells this is a pinching off (cytokinesis) of the cell membrane; in plant cells a new cellulose wall forms between the new cells.

During the period of cell life preceding the actual distribution of chromosomes, the mother cell often grows to twice its original size. Hence, a cycle consisting of cell growth and cell division is established. Cell growth—an increase in cytoplasmic mass, chromosome number, and cell surface—is followed by cell division, in which the cytoplasmic mass and chromosomes are distributed to the daughter cells. An increase in cytoplasmic mass does not always occur during cell-division cycles, however. During the early development of an embryo, for example, the original egg cell, usually a very large cell, undergoes repeated series of cell divisions without any intervening growth periods; as a result, the original egg cell divides into thousands of small cells. Only after the embryo can obtain food from its environment does the usual pattern of growth and mitosis occur.

In plants. The fact that most plant cells undergo extensive size increase unaccompanied by cell division is an important distinction between growth in plants and in animals. Daughter cells arising from cell division behind the tip of the plant root or shoot may undergo great increases in volume. This is accomplished through uptake of water by the cells; the water is stored in a central cavity called a vacuole. The intake of water produces a pressure that, in combination with other factors, pushes on the cellulose walls of the plant cells and is responsible for the increase in length and girth of the cells and of the plant. In plants, much of the size increase occurs after cell division and results primarily from an increase in water content of the cells without much increase in dry weight.

The role of water in plant-cell growth

The very young developing plant embryo has many cells distributed throughout its mass that undergo the cycle of growth and cell division. As soon as the positions of the root tip, shoot tip, and embryonic leaves become established, however, the potential for cell division becomes restricted to cells in certain regions called meristems. One meristematic centre lies just below the surface of the growing root; all increases in the number of cells of the primary root occur at this point. Some of the daughter cells remain at the elongating tip and continue to divide. Other daughter cells, which are left behind in the root, undergo the increase in length that enables the new root to push deeper into the soil. The same general plan is evident in the growing shoot of higher plants, in which a restricted meristematic region at the tip is responsible for the formation of the cells of the leaves and stem; cell elongation occurs behind this meristematic centre. The young seedling secondarily develops cells associated with the vascular strands of phloem and xylem—tissues that carry water to the leaves from the soil and sugar from the leaves to the rest of the plant. These cells can divide again, providing new cell material for development of a woody covering and for more elaborate vascular strands. Hence, the growth of higher plants —*i.e.*, those aspects involving both the pattern of stems, leaves, and roots and the increase in bulk—results primarily from cell division at the meristem followed by a secondary increase in size because of water uptake. These activities occur throughout the period of plant growth.

In animals. *General features.* The growth of animals is more restricted in time than is that of plants, but cell division is more generally distributed throughout the body of the organism. Although the rate of cell division differs in different regions, the capacity for cell division is widely distributed in the developing embryo. Increase in size is rapid during the embryonic period, continues at a reduced rate in juveniles, and thereafter is absent. Cell division and size increase continue, however, even after increase in total body size no longer occurs. Because these events are balanced by cell death, post-juvenile increase in cell number is primarily a replacement phenomenon. Height increase in mammals is limited by cessation of cell division and bone deposition in the long bones. The long juvenile period of growth in humans is unusual, most higher animals attaining mature size soon after the end of embryonic development. Some organ systems undergo little cell division and growth after birth; for instance, all of the germ cells (precursors of egg cells) of the female are formed by the time of birth. Similarly, all of the nerve cells of the brain are formed by the end of the embryonic period. Further increase in the size of the nervous system occurs by outgrowth of nerve fibres and deposition of a fatty insulation material along them. Although the greatest increase in size of nerve cells occurs, as in plant cells, after the cessation of cell division, the nerve fibre outgrowth in animals represents a true increase in the amount of cytoplasm and cell surface and not just an uptake of water.

Some organs retain the potential for growth and cell division throughout the life-span of the animal. The liver, for example, continues to form new cells to replace senescent and dying ones. Although cell division and growth occur throughout the liver, other organs have a special population of cells, called stem cells, that retain the capacity for cell division. The cells that produce the circulating red cells of mammalian blood are found only in the marrow of the long bones. They form a permanent population of dividing cells, replacing the red cells that continuously die and disappear from the circulation.

The rates of both growth and cell division can vary widely in different body parts. This differential increase in size is a prime factor in defining the shape of an organism.

Tumours. When growth is not properly regulated, anomalies and tumours may result. If the increase in the number of liver cells is abnormal, for example, tumours of the liver, or hepatomas, may result. In fact, one feature of malignant tumours, or cancers, is the absence of the usual growth patterns and rates. The cells of malignant tumours, in addition to having abnormal growth rates, have altered adhesive properties, which enable them to detach easily from the tumour; in this way the cells may spread to other parts of the body (metastasize) and grow in unusual locations. It is the growth of tumours in places other than the organ of origin that usually causes the death of an organism. Tumours may vary widely in their growth rates. The accompanying Table presents a sample of some rates of cell division in tumour tissues. Tumours may grow very rapidly or so slowly that the rate approaches that of normal cell division in adult tissues. Tumours are not only characterized by an increase in the rate of cell division but also by abnormal patterns of growth. The new cells formed in the tumour are not organized and incorporated into the structure of the organ and may form large nodules. These abnormal growths may present no medical problems (*e.g.*, moles) or may cause disastrous effects, as is the case of the pressure on the brain caused by a tumourous mass of the meningeal covering of the brain.

Features associated with tumour growth

Regeneration. Not all abnormal growths are tumours. If a tree is partially burned, cells below the bark produce

Rates of Growth of Selected Tumours

tumour type	host animal	time required for tumour to double in size
L 1210 leukemia	mouse	13 hours
Ehrlich ascites	mouse	8 hours
Human leukemia	man	60 hours
Human leukemia	tissue culture	18 hours
Lewis lung tumour	mouse	19 hours
Breast tumour	mouse	33 days
Human breast tumour	man	43 days
Burkitt's lymphoma	man	1.5 days
Stomach cancer	man	6.8 days
Cancer of the colon	man	14.2 days

Source: H.E. Skipper, "The Cell Cycle and the Chemotherapy of Cancer," *The Cell Cycle and Cancer*, R. Baserga (edit.), 1971.

a new covering for the exposed vascular strands. Growth may not be normal, and an obvious scar or growth of the new bark is apparent. Similarly, if the skin of a mammal is severely injured, the repair, although abnormal and imperfect, causes the organism no physiological difficulty. Many organisms possess the ability to regrow, or regenerate, with varying degrees of perfection, parts of the body that are lost or injured. Salamanders possess remarkable powers of regeneration, being able to form new eyes or a new limb if the original is lost. Lizards can regenerate a new tail; even humans can regenerate parts of the liver. The reasons for the differences in regenerative powers in different animals remains a fascinating mystery of great practical importance. When regeneration does occur, some specialized cells usually lose their specialized characteristics and enter a period of an increased rate of cell division; subsequently, the new cells respecialize into the tissues of the original body part. Plants whose tops are lost as in pruning can also sometimes form new meristematic centres from dormant tissues and produce new shoots (see also REGENERATION, BIOLOGICAL).

Compensatory growth. Many organs of animals occur in pairs, and if one is lost the remaining member increases in size, as if responding to the demands of increased use. If one of the two kidneys of a human is removed, for example, the other increases in size. This is called a compensatory reaction and may occur either by some increase in cell size (hypertrophy), by an increase in the rate of cell division (hyperplasia), or both. Although an increase in cell number is primarily responsible for the compensatory reaction of the kidney, the number of individual filtration units (glomeruli) does not increase. Hence, cell division increases the size of glomeruli but not the total number. Some of the most striking examples of increases in cell size in animals take place during stimulation of endocrine organs, which secrete regulatory substances called hormones; when the thyroid gland is stimulated, for example, the individual cells of the gland may increase dramatically in size.

Compensatory growth in the kidney

FACTORS THAT REGULATE GROWTH

The environment. *Temperature.* The environment in which an organism lives plays an important role in modifying the rate and extent of growth. Environmental factors may be either physical (*e.g.*, temperature, radiant energy, and atmospheric pressure) or chemical. Organisms and the cells of which they are composed are extremely sensitive to temperature changes; as the temperature decreases, the biochemical reactions necessary for life occur more slowly. A lowering of the temperature by 10° C (18° F) slows metabolism at least twofold and often more.

The width of trees increases partly by cell division and enlargement of secondary meristematic tissue below the bark. During the cold of winter, cell division and enlargement may cease completely; but during the spring renewed growth occurs. This intermittent growth is influenced by temperature, light, and water. The amount of growth may decrease considerably if the spring is cold, if day length is changed by obstructions blocking the sunlight, or if a drought occurs. In fact, the width of the growth rings visible on the surface of the cut tree trunk provides a partial history of climatic conditions, the spacing of the growth rings of different size having been correlated with known periods of drought and cold to provide reliable archaeological dating of various structures, as in the timbers used in Indian pueblos in the southwestern United States.

Temperature also affects both warm- and cold-blooded animals. Many warm-blooded (*e.g.*, bears) and cold-blooded (*e.g.*, frogs) vertebrates cease growing during the cold winter and simply enter an inactive or dormant state, which is characterized by a very low rate of metabolism. In animals that do not become dormant, increased demands for food consumption occur during cold periods to provide energy to maintain body temperature; this utilization of food energy may limit the energy available for size increase if food is in short supply.

Pressure. Because atmospheric pressure is relatively constant except in the mountains, it probably is of little importance in growth regulation. Increases in pressure in the ocean's depths may be significant, however, since it is known that increases in hydrostatic pressure interfere with cell division. Tissues of deep-sea fishes must have become adapted to such pressure effects, which have been little studied thus far. Movements of the terrestrial atmosphere—winds—may affect growth patterns in trees and shrubs, as is evident in the exotic shapes of certain conifers that grow along coastlines exposed to strong prevailing winds (see also PRESSURE AND TEMPERATURE, BIOLOGICAL EFFECTS OF).

Light. Of all the physical factors, light plays the best understood and most dramatic role. Many of the effects of light on plant growth are obvious and direct. Light energy is the driving force for photosynthesis, the series of chemical reactions in green plants in which carbon dioxide and water form carbohydrates and upon which all life ultimately depends. Insufficient light causes death or retardation of growth in green plants. But light also has indirect effects of great importance. Green plants possess small amounts of a pigment called phytochrome that can exist in two forms. One form absorbs red light (660 millimicrons, or mμ; 1mμ = 3.937×10^{-8} inch). When plants containing this pigment absorb red light, the pigment is converted to another form, which absorbs far-red light (730 mμ); the latter form can be converted back again to the original red absorbing form. These conversions have dramatic consequences; for example, red light inhibits stem elongation and lateral root formation but stimulates leaf expansion, chloroplast development, red flower coloration, and spore germination. Cycles of red and far-red light also can affect flower formation.

Indirect effects of light on plants

The effects of light on animals, although less obvious, may be important, as, for example, the effect of light on growth of the reproductive system of some animals. Increase in day length, hence in the amount of light, seems to initiate growth and development of the sex organs (gonads) in some birds during the spring. Curiously, the eyes are not the receptors for the light signal that activates the endocrine system to initiate growth of gonads; rather, cells deep in the brain are sensitive to the small amounts of light that pass directly through the thin skull of the bird.

Most animals show cyclic activity, or rhythms, in various important physical (*e.g.*, movement) and chemical (*e.g.*, respiration) events that are essential to the individual. These rhythms are often regulated by short exposure to light.

Chemical factors. Chemical factors of importance in the environment include the gases in the atmosphere and the water, mineral, and nutritional content of food. Plants require carbon dioxide, water, and sunlight for photosynthesis; drought slows plant growth and may even kill the plant. The effects of atmospheric contaminants—*e.g.*, oxides of nitrogen, hydrocarbons, and carbon monoxide—are known to have deleterious effects on the growth and reproduction of both plants and animals.

Plants and animals require minerals and small amounts of elements such as zinc, magnesium, and boron. Nitrogen and phosphorus are provided to plants as nitrates and

phosphates in the soil. Inadequate quantities of any nutritional factor in the soil result in poor plant growth and poor crop yields. Animals require oxygen, water, and elements from the environment. Because they are unable to synthesize sugars from carbon dioxide, animals must acquire these nutrients through the diet, either directly, by the consumption of plants, or indirectly, by the consumption of other animals that in turn have utilized plants as food. If the quality or quantity of this food is poor, either growth is retarded or death occurs (see NUTRITION; NUTRITION AND DIET, HUMAN; NUTRITIONAL DISEASES AND DISORDERS).

Vitamins, a class of compounds with a variety of chemical structures, are needed by animals in small amounts. Animals cannot synthesize all vitamins they require; those that cannot be synthesized must therefore be acquired in the diet, either from plants or from other animals that can synthesize the vitamin. Because certain vitamins are necessary in certain important metabolic reactions, vitamin deficiency during growth may have a variety of effects—stunting, malformation, disease, or death (see VITAMIN).

Internal factors. The organism is dependent on the environment for the raw materials for growth, but growth is also regulated internally. Because the size and form of plants and animals are under genetic control, events such as the rate and site of cell division and the extent of cell enlargement can be affected by mutations. It is not yet known, however, precisely how these factors, which are the ultimate determinants of growth, are controlled in individual cells.

One very important class of intrinsic growth regulators is that of the hormones. The principle plant hormone, auxin, is produced in the leaves; it moves by precise mechanisms, as yet poorly understood, to the other parts of the plant, controlling such processes as elongation of plant cells. Auxin somehow changes the characteristics of the rigid cell wall of the plant cell so that it becomes more flexible; the internal pressure within the cell then forces it to become larger. Other plant hormones may also play a role in the process; hormones such as cytokinins and gibberellins influence the rate of cell division in the meristems. Some dwarf plants can be stimulated to grow to normal size simply by applying gibberellin.

Hormones also play a decisive role in animal growth. One hormone from the pituitary gland at the base of the brain is called growth hormone because of its extensive and widespread effects on growth. A deficiency of growth hormone in pre-adolescents results in dwarfism, and oversupply of the hormone (often caused by a tumour) results in gigantism. If an excess of growth hormone is produced after the long bones can no longer grow—*i.e.*, post-adolescence—a disease called acromegaly, which is characterized by increases in the size of the hands and feet and broadening of facial features, results. A deficiency of thyroid hormone in children also causes growth retardation.

The sex hormones secreted from the pituitary gland interact in a complex way to regulate the growth of the gonads. The gonads in turn produce estrogen and progesterone in females and testosterone in males; these hormones control the development of human secondary sexual characteristics—body hair, enlargement of mammary glands in females, and growth of the vocal cords in males. Although the growth hormones and sex hormones play a vital role in growth, the exact mechanism by which they function has not been established with certainty (see HORMONE).

In addition to having the ability to synthesize the factors that regulate growth, plants and animals evidently possess exquisite mechanisms for integrating and regulating the production of hormones; *i.e.*, the appropriate amounts of the right hormones are produced at the right time and the right place for normal growth.

Limits of growth

Although many plants, including trees, grow throughout their lives, growth of parts of the organism is not perpetual; *e.g.*, leaves of a given species attain a specific size and can grow no larger. In animals, growth stops entirely, except for replacement, after the juvenile period. The limits for both total body size and organ size are probably established by genetic mechanisms. The factors involved in limiting the growth of an organism are not yet definitely known, but evidence indicates that the liver releases into the bloodstream protein molecules that can limit growth of the organ. Thus, one theoretical view is that an organ may produce substances that serve to limit its own growth, thereby establishing a feedback mechanism. A protein called nerve-growth factor is important for the growth of some parts of the mammalian nervous system. If too much of the nerve-growth factor is present, growth of sympathetic nerve fibres is extensive and aberrant. If the nerve-growth factor is eliminated from the body—by injection of an antibody against the factor—the sympathetic nerves wither and disappear. Other subtle growth regulatory substances specific for various organ systems may eventually be discovered.

THE DYNAMICS OF GROWTH

The growth curve and the measurement of growth. The mathematical analysis of the rate of growth has been a subject of interest for many years. It is based on the rule of cell division: one cell gives rise to two daughter cells. Hence, the theoretical increase in cell number would be a geometric series, in which one cell produces two cells, then four, eight, 16, and so on. In reality, however, the rate of growth is not constant but declines after a period of time, usually because of influences in the environment or because of inherent genetic limitations. Thus the curve showing the growth of cell populations and of organisms is usually S-shaped, or sigmoid, when growth is plotted against time on a graph (see Figure). The increase in cell number resulting from cell division accounts for the rising part of the curve; the rate of cell division decreases at the plateau in the curve. The S-shaped growth curve is generally applicable to the growth of organisms. If growth is plotted against time on a logarithmic scale, the early intense growth (called log growth) in the rising phase of the growth curve falls on a straight line.

Sigmoid growth curves.
(Left) Ideal sigmoid growth curve. (Right) An actual postnatal growth curve of the white rat.

The rate of growth may be defined by the differential equation $v = dW/dt\ (1/W)$, in which v is the growth rate and W is the weight at any given time, t. The solution of this equation provides a value for relative increase—the increase in weight related to the initial mass of the growing substance. The animal that most closely approaches a constant rate of growth is an insect larva. In most animals the rate of growth declines as the organism becomes larger and older.

Although the S-shaped growth curve describes with fair accuracy the growth of populations of single cells, such as bacteria or cells of higher organisms in tissue culture—the growth in a sterile nutrient environment of cells of tissues from organisms—the growth rates of different parts of whole organisms vary. The relationship of the growth of one part of an organism to that in another part is called allometry. An equation expressing the fundamental relationship of allometric growth is $y = b\,x^k$, in which y is the size of one organ; x is the size of another; b is a constant; and k is known as the growth ratio. Although such mathematical tools have allowed a very thorough description of the differential growth of different parts of an organism, they have unfortunately

not provided insight into the physical and chemical control of the growth rate.

The study of growth. Even though the chemical, physical, and genetic bases of growth are elusive, much has been learned about the process by growing tissues in a sterile nutrient environment. Even if the source of the tissue is an organ that has completely stopped growing, such as the nervous system of an animal or the phloem of a plant, the cells will begin to grow again in culture, often at a logarithmic rate of increase. It may therefore be concluded that the organism as a whole places constraints upon the ability of individual cells to reproduce and that, when these constraints are removed, the growth potential of the cells is no longer restrained. Even in tissue culture, however, the rate of cell growth eventually slows, hence the sigmoid-shaped growth curve. During the rapid growth phase of cells in tissue culture, they usually lose the ability to carry out the specialized function characteristic of their organ of origin; for example, if cartilage cells divide rapidly, they no longer synthesize cartilaginous matrix. This phenomenon of apparent despecialization has been a topic of great theoretical interest: are rapid growth and specialization mutually exclusive activities? Evidence shows that some types of specialized cells may be maintained in tissue culture for very long periods of time and still retain the ability to carry out specialized biosyntheses, so that the apparent loss of specialized function in tissue culture cells may not fundamentally result from a mutual exclusivity of growth and differentiation.

Contact inhibition of growth

When the growth of tissue-culture cells begins to slow, one factor responsible is exhaustion of critical components from the medium. But even if the medium is frequently replaced, when the bottom of the culture dish becomes densely packed with a layer of cells, the growth rate drops—a phenomenon called contact inhibition of growth. It is believed that cells so close that they are always touching provide a signal that retards the rate of cell division. Apparently identical cells in tissue culture also show great variation in growth rate. Some cells from the skin, for instance, when placed in culture, may divide every eight hours; other similar cells may divide only every 36 hours. The growth of cells in a controlled environment such as tissue culture offers many possibilities for studying the fundamental mechanisms controlling cell growth and, consequently, the growth of organisms and populations.

Gruiformes

The bird order Gruiformes comprises a rather loose assemblage of 12 families that are generally agreed to be related but that differ widely in many aspects. They are an ancient group with a rich fossil history, but many are now restricted in range and few in number. Members of the order occur on every continent, but the only family with worldwide distribution is the Rallidae (rails, gallinules, and coots), with 132 living species. Cranes (Gruidae) are found on every continent except South America, but many of the 14 species have small populations, some on the verge of extinction. The bustards (Otidae), with 23 species, have a wide distribution, limited to the Old World, but hunting pressures and modern agricultural methods have greatly reduced their numbers. The mesites (Mesitornithidae), however, are confined to Madagascar, and the kagu (*Rhynochetus jubatus*) to the island of New Caledonia. Other small families in the order contain the hemipodes, or button quails (Turnicidae), plains-wanderer (Pedionomidae), limpkin (Aramidae), trumpeters (Psophiidae), finfoots (Heliornithidae), sun bittern (Eurypygidae), and cariamas (Cariamidae).

Although man's impact on them is very great, gruiform birds, because of their scarcity, have a negligible impact on man. With the possible exceptions of the sandhill crane (*Grus canadensis*), which descends on the grainfields of the Canadian prairies during the autumn migration, causing some crop damage, and the brolga, or Australian crane (*Grus rubicundus*), which causes similar damage in Queensland, no gruiform can be considered harmful to man's interests; some of the larger species, in fact, are hunted for food or sport.

GENERAL FEATURES

Size and weight

Gruiform birds range in size from the tiny button quails (*Turnix*) and miniature rails, such as the North American black rail (*Laterallus jamaicensis*) barely 15 centimetres (six inches) long, to the stately sarus crane (*Grus antigone*) of India, standing nearly 1.6 metres (five feet) high. The enormous kori bustard (*Otis kori*) and the Eurasian great bustard (*O. tarda*) may weigh up to 18 kilograms (about 40 pounds) and are the heaviest modern flying birds. Gruiforms vary widely in structure; some are adapted for life in or near water, others for life on land. Some forms fly well; but a number of species are flightless.

As a group, the gruiforms are probably best known for their impressive and graceful courtship displays, the most famous of which, the dances of the cranes, are imitated and adapted by many native peoples. The Ainu of Japan have a crane dance in honour of the Japanese crane (*Grus japonensis*), and many African tribes imitate the dance of the crowned crane (*Balearica pavonina*). Less known, but no less spectacular, are the striking wing display of the sun bittern (*Eurypyga helias*) and the strutting and booming of the larger bustards.

NATURAL HISTORY

Ecology. *Habitat.* Gruiform birds live in a variety of habitats, from water and marshes to arid plains. The most aquatic are the finfoots and coots (*Fulica*). The former live along slow-flowing streams where heavy overhanging vegetation affords them cover, the latter on more open water. Most rails live in saltwater or freshwater marshes. The limpkin (*Aramus guarauna*) is essentially a marsh bird; in Florida it inhabits the sawgrass marshes and cypress swamps of the Everglades. Cranes bridge the gap between marsh and dry-land birds, nesting in marshes but occurring in open plains and cultivated fields on migration and in winter. The sun bittern prefers muddy, wooded riverbanks but also occurs in woods well away from water. Trumpeters, mesites, the kagu, and some rails live in forest and dense brush. The remaining gruiform families inhabit more open country: the cariamas of South America favour grassland or hot, dusty plains with scattered bushes; the Old World bustards, button quails, and the plains wanderer prefer open, grassy plains, although they will accept old pastures and cultivated fields.

Food habits. Corresponding to the wide variety of habitats utilized by the gruiforms is the great diversity of food taken by them. In general, more animal than vegetable food is taken, but as a group the gruiforms are omnivorous. Coots and gallinules consume much aquatic vegetation. Finfoots live largely on mollusks, frogs, and small fish. The limpkin has a more specialized diet, consisting chiefly of certain large snails, which are broken open at certain favourite feeding stations that contain telltale piles of broken shells. The limpkins' near relatives, the cranes, eat almost any animal food, including rats, mice, moles, lemmings, lizards, snakes, frogs, tadpoles, snails, and a variety of insects. On its wintering grounds in Texas, the whooping crane (*Grus americana*) lives largely on crustaceans. The sandhill crane includes

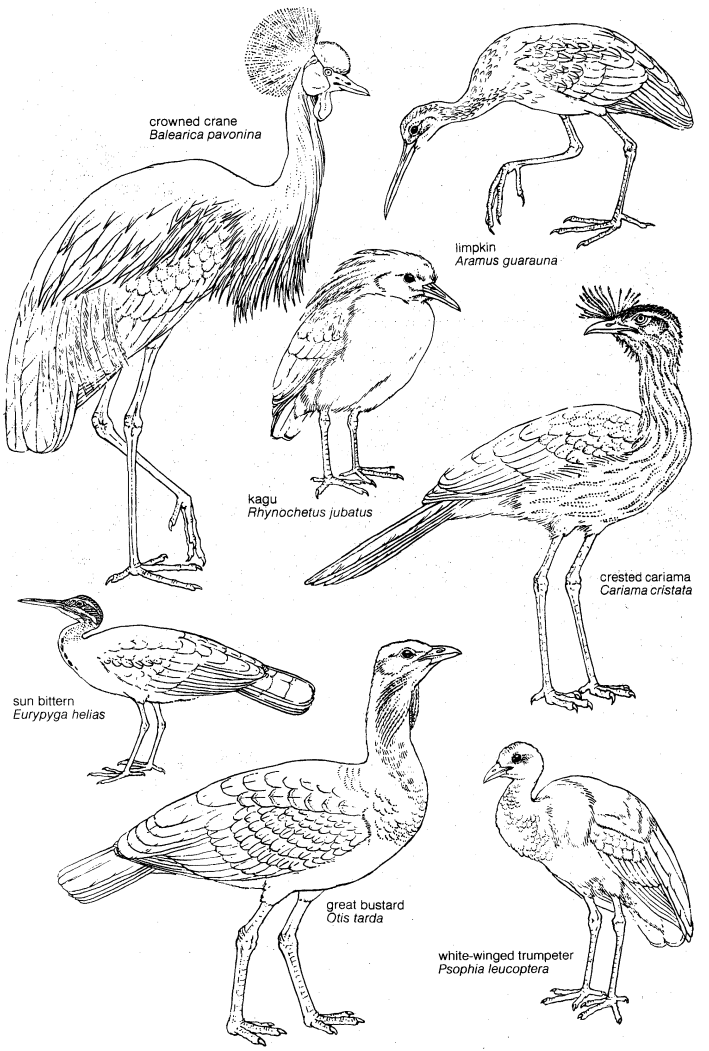

Figure 1: Body plans of some larger gruiforms.
Drawing by R. Keane

berries and grass in its otherwise animal diet on the northern tundra and gleans some plant material from old potato and grain fields on its southern wintering grounds. The Asiatic cranes that winter in Japan (such as the hooded crane, *Grus monacha*, and the white-naped crane, *G. vipio*) glean grain in rice paddies, and Japanese cranes in Hokkaido are fed corn (maize) by the local farmers. Cranes use their powerful bills for digging in the ground to get at bulbs and roots below the surface, and a similar foraging action has been noted for the gray-necked wood rail (*Aramides cajanea*) of tropical America, which probes in ground debris, flicking it aside with the bill. Rails as a group, like cranes, are omnivorous, though the bulk of their diet consists of small marsh animals, such as snails, crustaceans, frogs, and water insects. The purple swamphen (*Porphyrio porphyrio*), a vegetarian, often has a feeding platform on which it stands and pulls up the surrounding water plants; it will also climb up reeds and eat the flower heads.

The other members of the order have a similar mixed animal and vegetable diet, though with the emphasis always on the animal side. Captive cariamas readily eat meat, and a captive kagu feasted on ground steak provided by its owner. Bustards are fond of grasshoppers, and their varied diet also includes dung beetles, termites, centipedes, grass, clover, vegetable crops, and even, in Africa, the gum from the trunks of *Acacia* trees. The sun bittern stalks insects as a heron stalks fish, stealthily approaching its prey with neck drawn in, then grabbing it with a sudden, stabbing thrust of the bill.

Reproductive behaviour. *Courtship.* The breeding cycle of many gruiform birds begins with elaborate courtship rituals and displays. Cranes pair for life, and the strong pair bond necessary to maintain this partnership is initiated and continued by a series of displays that, since they often consist of two birds facing each other and leaping into the air, are generally known as dances.

Dancing by cranes

The ceremony frequently begins as two birds circle each other with a curious, formal step, the legs stiff and the head and neck held high. The next action is bowing or "head bobbing," in which the head is held horizontally, the neck curved down in a U, and in this position the head and neck are bobbed or pumped up and down. One bird may do this while the other bird looks on, or both may do it together. One bird (or both) then turns in a circle on the spot while continuing to bow. The momentum increases until suddenly both birds leap into the air and follow this by dancing. While dancing, the birds often pick up some object from the ground and toss it in the air as they leap. The object is usually something used in nest building, such as a stick, leaf, or tuft of grass, and the action may be related to nest-building drives. Again, while leaping in the air one bird may turn its back on the other. Another beautiful display involving a pair of cranes is the "duet." The birds first circle each other with the same formal step that initiates the dance, but instead of going into the dance they droop their wings, throw back their heads, and call in unison.

Although dancing intensifies at the beginning of the breeding season and is doubtless primarily connected with courtship and pair formation, it can occur at any time of year and may have other functions as well. Dancing often seems to be a method of releasing pent-up energy, as when a bird dances on its own or when a dancing pair sets off dancing in nearby individuals of a flock. So strong is the instinctive urge to dance that a five-day-old chick is recorded as leaping up and down and going through other motions of the dance, even though it had never seen another crane.

Vocalizations of rails

Pair formation in many rails is effected chiefly by voice; males establish territories and defend them vigorously with distinctive songs and calls while at the same time attracting females. Rails produce an amazing variety of noises. In North America, the clapper rail (*Rallus longirostris*) has a loud cackling call, the sora (*Porzana carolina*) an explosive whinny, and the yellow rail (*Coturnicops noveboracensis*) makes a noise like two small stones being clicked together. In Europe, the water rail (*Rallus*

Drawing by R. Keane

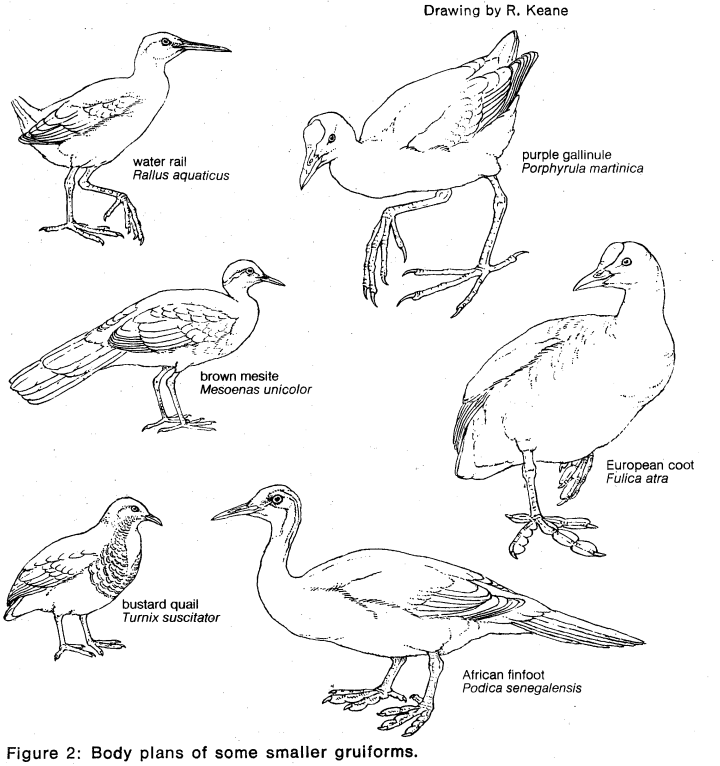

Figure 2: Body plans of some smaller gruiforms.

aquaticus) squeals like a stuck pig, and the corncrake (*Crex crex*) produces a rasp like a heavy comb being drawn over a piece of wood. The gray-necked wood rail greets the dawn with a ringing "Pop-tilly, pop-tilly, pop-tilly, ko-ko-ro-ko-ko," which has given it the local name of "cocaleca" in Panama. In Africa, a large rail, *Himantornis haematopus*, of the Congo forests makes a pumping sound, and the black crake (*Limnocorax flavirostra*) in the papyrus swamps makes a curious gurgling sound. The tiny crakes in the genus *Sarothrura* have a variety of melodious calls, the buff-spotted crake (*S. elegans*) making a low moaning noise like the sound of a tuning fork. More familiar are the plebeian squawks and grunts of the wide-ranging coots and gallinules.

Rails also have courtship displays involving lowering the head, raising the wings, and fanning the tail, often while uttering some special call. Coots and gallinules display their colourful frontal shields and fan their tails to show off the white under tail coverts. Other species circle their partners in various postures. The display often ends with the male chasing the female, and the chase may end in copulation. In button quails the role of the sexes is reversed. The female is the most brightly coloured and courts the male, erecting her tail, puffing out her neck, and running around him while uttering a low crooning note. The male sun bittern selects an open spot, often in a patch of sunlight, where he spreads and raises his tail and wings until they meet in front of his head, exposing elegant patterns of red-brown, olive, gray, and black. In this posture he runs in a circle and may jump up in the air or bob his head.

In its aggressive display, the kagu stands erect, with the long feathers of the crest raised, the wings held out from the body, and the tail drooped. In this posture, it bounces at the adversary. In a playful mood the kagu will toss sticks and stones around with its bill, in a manner reminiscent of cranes. A captive cariama has been seen to run at a tree with lowered head, jerking its tail and giving a short cluck, then striking the tree with both feet. In spring wild birds have a bustard-like display (see below) accompanied by loud yelping calls.

Vocal displays

Trumpeters, named for their loud, resonant cries, have a cranelike dance involving strutting around on the ground and leaping into the air. Males of the larger bustards, the great and kori bustards, for example, develop a special pouch in the neck during the breeding season with which they produce loud, booming calls. The Australian bustard (*Ardeotis australis*) "booms" with closed beak, producing a sound somewhat like the distant roar of a lion. Special display feathers that grow on the head, neck, and breast are molted after the breeding season. A large bustard in full breeding regalia, with all feathers puffed out, is scarcely recognizable; the head is hardly visible, being immersed in an immense ruff, and the wings and tail are raised until they meet over the back, the total effect being that of an enormous feather ball. The ball then struts around in front of a female, who feigns indifference. Smaller bustards have somewhat different displays. The crested bustard (*Lophotis ruficrista*) of Africa has an aerial display flight in which it rises about 100 feet into the air and then planes steeply back to earth.

Nesting. Gruiform birds nest both on the ground and in bushes and trees. Of the ground nesters, button-quails and the plains wanderer nest in a grass-lined hollow, often building a domed roof and side entrance. Cranes raise up a pile of vegetation in open shallow water, and the limpkin builds a concealed nest in dense marsh grasses. Marsh-dwelling rails build simple nests of grass and aquatic plants, often in a thick tuft of grass, the blades of which they pull down over the nest to conceal it. The kagu builds a nest of sticks and leaves in a depression in the ground. Bustards scarcely have a nest at all, the eggs being laid on bare ground, sometimes beneath a bush or clump of grass for concealment. Finfoots and the sun bittern prefer a nest site on a branch of a tree, and finfoot nests generally overhang water. Of the two species of cariamas, one nests on the ground and the other in bushes. Trumpeters are variously reported as nesting on the ground and in holes in trees. Mesites place their simple stick nests a metre or two up in a tree. Being flightless, they must always find a site where a connecting series of branches leads from the ground to the nest, enabling them to hop up to it.

Clutch sizes vary widely within the order, from the single egg of the kagu to over ten in some rails. Exceptional clutches of 15–20, recorded for some coots and gallinules, may be due to more than one female laying in the same nest. The eggs are usually white or buff, sometimes pale gray or pale green, immaculate in a few species, but usually with brown spots or blotches at one end. The incubation period is typically about three weeks, extending to four weeks in the cranes and larger bustards. Both sexes incubate the eggs and care for the young when hatched in all families except bustards, trumpeters, and button quails. Button quails are polyandrous (an individual mating with several members of the opposite sex), and the tasks of incubation and care of the young are performed entirely by the males. In bustards and trumpeters, the female does all of the incubating and caring for the young. Young gruiforms are downy, plain black in rails and dark brown in limpkins, variously patterned in most other groups. They leave the nest immediately or very soon after hatching, except for those of the sun bittern, cariamas, and bustards, which are cared for at the nest for a short time. There is some evidence that in the trumpeters, which habitually travel in flocks in the adult state, several pairs may pool their young and look after them communally.

Incubation of the eggs

Molt. The sequence of molts and plumages is very poorly known except in cranes, the young of which have a brown or gray juvenile plumage, with white-tipped or blackish feathers in some species. The juvenile feathers are gradually replaced at each successive molt with the white or gray feathers of the adult, but the last brown-tipped feathers do not completely disappear until about the third summer, when the bird is a little over two years old. Adult cranes, at least those nesting in northern temperate zones, molt in two stages; many of the wing and tail feathers are molted in early summer, at which time the birds may be flightless for a while; the rest of the plumage is gradually molted between August and October.

Migration and locomotion. Most gruiforms are nonmigratory. Bustards, button quails, and the plains wanderer migrate locally, following the rains to feed and nest. Only the birds nesting in the North Temperate zone

are true migrants; this group includes many cranes, some rails, and the Eurasian bustards. The spectacular migrations of cranes have excited man's interest since earliest times. The peoples of eastern Asia welcome the return of the cranes as symbolic of the coming spring, and in fall the farmers of Japan welcome the birds back to the rice paddies where they spend the winter. In Japan, the cranes return every year to the same traditional wintering grounds, where they are given strict protection. The last remaining whooping cranes in North America are likewise carefully looked after and are counted at the Aransas National Wildlife Refuge in Texas on their return from the north. Most cranes cover great distances on migration. Sandhill cranes travel 4,000 miles from their nesting areas in Alaska and eastern Siberia to southern United States, and common cranes (*Grus grus*) and demoiselle cranes (*Anthropoides virgo*) cover similar distances in the Old World.

When the northern marshes freeze over in winter, rails are forced to head south. Amazingly, these birds that fly so weakly across a marsh, with floppy wings and dangling legs, are able to travel thousands of miles each year on migration. The corncrake, nesting in Scotland, may winter in South Africa, and the sora rail of North America regularly crosses 800 miles of ocean to reach Bermuda.

The Eurasian bustards travel shorter distances, going only far enough to escape bitterly cold weather. Some species form large flocks at migration time. Bustards are great walkers, and local migrations in Africa are for the most part performed slowly on foot.

Travel on foot

Gruiform birds have a predilection for travel on foot. Many only fly when pressed, and some, like the mesites, have become flightless or nearly so. Many oceanic islands have been colonized by rails, which then evolved flightlessness in the absence of predators. The subsequent advent of rats, cats, pigs, or goats on such islands, usually with accidental or intentional assistance from man, has resulted in the extinction of a number of such rails. Rails typically sneak away on foot in thick vegetation, and button quails are equally loath to fly, preferring to walk away with their quick, nervous gait, stopping every so often to raise their heads and look around for danger. Trumpeters run fast and can even swim. Finfoots spend most of their life in water and prefer to hide in thick riverside bushes when disturbed, rather than fly. On the ground, gruiform birds move efficiently and even elegantly. The sun bittern walks gracefully with slow, precise steps, its neck outstretched. Cariamas run swiftly over the plains. Rails have a very characteristic walk in which the tail is flicked up with each step, and both the limpkin and the kagu share this tail-flicking action. Even such fine fliers as the cranes prefer walking, and there is no more elegant sight in the avian world than a tall and stately crane walking with deliberate and dignified gait across the prairie. In flight, cranes and the limpkin have a characteristic wing action—a slow downstroke followed by a quick, flicking upstroke.

FORM AND FUNCTION

Gruiform birds vary greatly in shape and size and exhibit a broad range of morphological characteristics. Their plumage is predominantly brown or gray. Some have brightly coloured soft parts such as the bare, red skin on the head and neck of some cranes, used in displays, and the bright red and yellow bills and frontal (forehead) shields of gallinules. The crowned crane has a curious crest of stiff, golden feathers. The sexes are alike in most groups, except among the button quails, in which the female is more brightly coloured, and the bustards, where the males are more colourful.

The wings are rounded and often long, although in the nearly flightless mesites they are greatly reduced. The length of the tail varies, being proportionately short in button quails, rails, and trumpeters and rather long in mesites, finfoots, and the sun bittern. Cranes have very long inner secondary feathers (those of the inner wing or "forearm"), which extend beyond the end of the tail, giving the impression of a long-tailed bird. The bill is generally long and slender, particularly so in cranes, many rails, and the limpkin, although the cariamas have hooked bills which are doubtless used in tearing up mammalian prey. The legs are rather long, reflecting a preference for walking. The toes vary greatly—in the finfoots and coots they are lobed for swimming, in rails and the limpkin they are long and slender for walking on lily pads and other aquatic vegetation, but bustards and cariamas have short toes for running on hard surfaces. The hind toe, when present, is usually elevated.

Special anatomical features

Some groups have anatomical features peculiar to themselves. The mesites possess five pairs of powder down patches, far more than any other group, and the function of these is uncertain. Cranes, and the adult male limpkin have an extremely long trachea, or windpipe, that is coiled in several convolutions. These convolutions of the trachea probably give added power and resonance to the voice, which can carry for distances of a mile or more. Rails have a laterally compressed body, which gives rise to the expression "thin as a rail," enabling them to sneak between reeds and blades of grass without telltale movements of the vegetation. Most young rails have a claw at the tip of the alula (the "bastard wing" or "thumb") that enables them to clamber around on marsh vegetation. Finfoots have a sharp spur of uncertain function at the bend of the wing. The kagu, like the mesites and some rails, is flightless, a condition that may lead to its extinction by the dogs, cats, pigs, and rats that have been introduced on New Caledonia. Males of great and kori bustards have a gular (throat) pouch during the breeding season that opens into the mouth under the tongue and can be inflated at will. It is used by the birds to produce booming calls during courtship. The Australian bustard has no gular pouch, producing its calls by filling the esophagus with air. The esophagus is similarly used in sound production by the button quails and by rails of the genus *Sarothrura*.

EVOLUTION AND PALEONTOLOGY

Gruiform birds have the best fossil record of any avian order, going back to the Late Cretaceous, nearly 100,000,000 years ago. Fourteen fossil families are known, divided into 86 genera and 146 fossil species. In addition, 39 extant species are also known as fossils.

The oldest gruiform bird is the crane-sized *Laornis* from the Upper Cretaceous of New Jersey, recently shown to be closely related to the rails. *Telmatornis*, from the same epoch, formerly considered a gruiform, is now placed closer to the thick-knees (Burhinidae) in the order Charadriiformes.

Next in age are two families from the Paleocene (about 60,000,000 years ago), the Gastornithidae and the Diatrymidae, the latter containing some fascinating giant species—*Diatryma steini* stood about 7 feet tall and had a massive head and bill—but it is in the Eocene, starting about 54,000,000 years ago, that gruiform birds first became abundant and the first representatives of modern families appeared: rails, cranes, and a bustard. In the Oligocene the limpkins, and the suborder Cariamae had their beginnings. The Cariamae are represented today by only two living species, but their fossil history shows that in earlier epochs they were a more widespread and successful group. They include a number of flightless giants, the best known of which are several species of *Phororhacos* from the lower Miocene of Patagonia. These were powerful birds, the largest in excess of 2.2 metres (seven feet) in height. The best-known form, *P. longissimus*, must have been a formidable predator, having a massive skull 65 centimetres (two feet) long and 25 centimetres (10 inches) high, with a hook at the tip of the beak.

With the exception of the above, and a single *Turnix* from the Pleistocene of China, the smaller modern gruiform families have no fossil records. Nevertheless, the abundance of fossils shows what an amazingly successful group the gruiforms were. They are known from all six continents, and for every fossil species discovered there must have been tens or even hundreds that are unknown. Today, however, the situation is quite different; as a group, gruiform birds are on the decline. Of the twelve gruiform families, fully eight are represented by three

species or less, and four have only a single species. The only one that is at all numerous is that of the rails, with about 130 species. Many gruiform birds appear in the "Red Data Book" of endangered species, published by the International Union for the Conservation of Nature. Five of the fourteen extant cranes are listed as in danger, the best known being the whooping crane. The Red Data Book lists seven rails as in danger and fifteen more that have become extinct since about 1600. Many of the extinct rails lived on small islands and a number had become flightless, making them vulnerable to man and his animals. Nevertheless, the Gruiformes had been declining long before man entered the scene, apparently because the ecological conditions that favoured them in the past are less available to them today.

Endangered species

CLASSIFICATION

Distinguishing taxonomic features. The order Gruiformes is a heterogeneous group bound by taxonomic characters that are largely anatomical, and hence not readily evident on the live bird. Few are common to all members of the group, and no single character serves to separate the Gruiformes from all other orders. Some of the features that have been used in classifying the order are: the condition of the feet and toes; the type of palate, osteologically; the type of pelvic musculature; the number of carotid arteries; the presence (eutaxy) or absence (diastataxy) of the fifth secondary flight feather in the wing; the number of wing and tail feathers; the number of cervical vertebrae; the type of nostrils; the presence or absence of an aftershaft (a small "second feather" attached to the shaft of a body feather); and the behaviour of the young.

Annotated classification. The classification presented here is based on work by the paleontologists Alexander Wetmore, Pierce Brodkorb, and Joel Cracraft. Groups indicated by a dagger (†) are known only as fossils.

ORDER GRUIFORMES

Primarily marsh-dwelling birds of medium to large size. Toes not webbed (lobed in a few genera). Hallux (hind toe) usually elevated, sometimes absent. Two carotid arteries usually present. Aftershaft usually present. Crop lacking. Young usually nidifugous (precocious).

Suborder Mesitornithides

Distinguished from other suborders by reduced clavicles (collarbones) and presence of five powder-down patches.

Family Mesitornithidae (mesites). No fossil record. Superficially dovelike, but with characters of order and suborder. Hallux well-developed and functional. Three species; terrestrial, in forest and dry brush; confined to Madagascar; length 25–27 cm.

Suborder Turnices

Principal difference from other suborders is the possession of a well-developed basipterygoid process (a projection at the base of the skull).

Family Turnicidae (button quails). Pleistocene (one specimen) to present. Small and quaillike; short legs, no hallux; beak short, slightly down-curved. Unique in the order in having only one carotid artery. Female larger and more brightly coloured than male. Eggs roundly oval. Eutaxic. Fifteen species; in grasslands and brush; southern Europe, Asia, Africa, and Australia; body length 11–19 cm.

Family Pedionomidae (plains wanderer). No fossil record. Similar to button quails, but differs as follows: hallux present; two carotid arteries; wing diastataxic; eggs pointed. One species, confined to dry plains of Australia; body length about 16 cm.

†Suborder Gastornithes

Fossil only.

†*Family Gastornithidae.* Upper Paleocene of Europe; five species; large, flightless.

†*Family Diatrymidae.* Upper Paleocene to middle Eocene; North America and Europe; four species; large flightless predators.

Suborder Grues

Adults with down feathers in both pterylae (feather tracts) and apteria (areas between tracts); hallux present and variable; oil gland present and tufted.

Superfamily Gruoidea (cranes, limpkin, and trumpeters)

Only gruiforms with supraorbital furrows (*i.e.*, above the eye); distinguished from others by pelvic muscle formula. Ten to twelve tail feathers.

†*Family Geranoididae.* Fossil only; lower to middle Eocene; North America; seven species known.

†*Family Bathornithidae.* Fossil only; lower Oligocene to lower Miocene; North America; eight species known.

†*Family Eogruidae.* Fossil only; upper Eocene to upper Miocene; eastern Asia; two species known.

Family Gruidae (cranes). Lower Eocene to present. Bill long and straight; neck and legs long; hallux small and elevated. Head usually partly naked in adult. Wing diastataxic. Caudo-femoral muscle present (except in *Balearica*). Twenty-one fossil and 14 Recent species; plains and marshes of the world, except South America; length about 79 to 150 cm.

†*Family Ergilornithidae.* Fossil only; lower Oligocene to lower Pliocene; eastern Europe and Asia; three known species.

Family Aramidae (limpkins). Lower Oligocene to present. Bill long; neck long and slender; head feathered. Hallux large and functional. Caudofemoral muscle absent. Swamps and marshes of New World tropics and subtropics; five fossil and one Recent species; length 58 to 71 cm (in Recent forms).

Family Psophiidae (trumpeters). No fossil record. Bill short. Separated from Gruidae and Aramidae by nostril shape, eutaxic wing, absence of occipital foramina (perforations at the base of the skull). Three species, in lowland forest of South America; length 43 to 53 cm.

Superfamily Ralloidea

Lack occipital foramina and supraoccipital furrows. Hallux well-developed and functional; cervical vertebrae fewer than in Gruoidea.

Family Rallidae (rails, gallinules, and coots). Upper Cretaceous to present. About 56 fossil and 132 Recent species; principally in marshes; worldwide; length about 14 to 51 cm.

†*Family Idiornithidae.* Fossil only. Upper Eocene to lower Oligocene of Europe and North America; eight species known.

Suborder Heliornithes

Distinguishes from all other gruiforms, except coots (*Fulica*), by possession of lobed feet; by pelvic muscle formula, type of flexor tendons, and possession of 18 tail feathers.

Family Heliornithidae (finfoots). No fossil record. Three species; slow-flowing streams in tropical areas of Central and South America, Africa, and India and Southeast Asia; length 30 to 62 cm.

Suborder Rhynocheti

Large aftershaft; powder downs occurring as scattered groups of feathers. Large operculum (covering flap) over nostrils. Young nidoculous (dependent).

Family Rhynochetidae (kagu). No fossil record. One species, confined to forested highlands of New Caledonia; length about 56 cm.

Suborder Eurypygae

One pair of powder-down patches. Oil gland nude. Eighteen cervical vertebrae. Young nidoculous.

Family Eurypygidae (sun bittern). Beak medium length, straight, sharp; neck slender. Tail of medium length. One species; margins of woodland streams in Central and South America; length about 46 cm.

Suborder Cariamae

Distinguishing features in palate structure; talon-like nail on second toe; and type of flexor tendons.

†*Family Cunampaiidae.* Fossil only. Lower Oligocene of Argentina; one known specimen.

†*Family Brontornithidae.* Fossil only. Lower Oligocene to middle Miocene of Argentina and Uruguay; two species known.

†*Family Palaeociconiidae.* Fossil only. Lower Oligocene to middle Pliocene of Argentina; four species known.

†*Family Prophororhacidae.* Fossil only. Lower Pliocene to lower Pleistocene of Argentina; three species known.

†*Family Phororhacidae.* (Phorusrhacidae of some authors). Fossil only. Lower Miocene to lower Pleistocene; ten species, nine from Argentina, one from Florida. Medium to large flightless predators.

†*Family Psilopteridae.* Fossil only. Lower Oligocene to middle Pliocene of Argentina; nine species known.

Family Cariamidae (cariamas or seriemas). No fossil record. Moderate-sized cursorial birds; legs long, feet small; tail long; beak broad, moderately long, slightly decurved. Fore-

head and back of neck crested. Two species; in grassland and brush, respectively, of east-central South America; length 76 to 92 cm.

Suborder Otides

Oil gland absent. Scales on tarsus (lower leg) hexagonal; hallux absent. Sternum with two pairs of notches. Wing with 11 primary flight feathers. Egg white-protein structure (of Otidae) unlike those of other gruiforms.

Family Otidae (bustards). Cursorial, but strong flying birds of open plains of Eurasia, Africa and Australia; three fossil and 23 Recent species; length 37 to 132 cm.

†*Family Gryzajidae.* Fossil only. Lower Pliocene of the Ukranian S.S.R.; one species known.

Critical appraisal. The great diversity in the order Gruiformes is reflected in the uncertainty of taxonomists about gruiform relationships. The most widely accepted classification is that of the American paleontologist Alexander Wetmore, used above, with 12 Recent families in one order. Some authorities place the plains wanderer (*Pedionomus*) in Turnicidae. A German ornithologist, Erwin Stresemann, underlining the differences between the gruiform families, divided them into ten orders, most of them monotypic (*i.e.*, with only a single form). A British anatomist, P.R. Lowe, dismayed by the wide variety of characters in the Gruiformes, eliminated the order altogether, distributing the families among other orders, a decision later repeated by a French worker, R. Verheyen, who divided the families among five orders, some of which are not recognized today. Verheyen's order of Gruiformes contained only the Psophiidae, Aramidae, Gruidae, and Otidae. In an attempt to resolve this confusion, an American biochemist, H.T. Hendrickson, studied the egg-white proteins of 10 of the 12 gruiform families (he had no material for Pedionomidae or Mesitornithidae) and found that a close group was formed by five families—Eurypygidae, Heliornithidae, Rallidae, Turnicidae, and Psophiidae. The Aramidae bridge the gap between this group and the Gruidae, but the remaining families (Rhynochetidae, Cariamidae and Otidae) seemed to be very different, the last so different that they may be of independent origin from the rest of the order.

BIBLIOGRAPHY. A.C. BENT, "Life Histories of North American Marsh Birds," *Bull. U.S. Natn. Mus.* no. 135 (1926), contains long and comprehensive accounts of North American cranes and rails and the limpkin; H.F. WITHERBY *et al.* (eds.), *The Handbook of British Birds*, vol. 4 and 5 (1940–41), provides excellent accounts of European cranes, rails and bustards, with coloured plates; R.P. ALLEN, *The Whooping Crane* (1952), is the classic monograph on this endangered species, with a brief descriptive and distributional treatment of the cranes of the world; L.H. WALKINSHAW, "The Sandhill Cranes," *Bull. Cranbrook Inst. Sci.* no. 29 (1949), contains detailed information on this species; H.E. HOWARD, *A Waterhen's Worlds* (1940), is a monograph of the common gallinule or moorhen, with emphasis on behaviour, one of the early classics in ethology; S. KEITH, C.W. BENSON, and M.P. STUART IRWIN, "The Genus *Sarothrura* (Aves, Rallidae)," *Bull. Am. Mus. Nat. Hist.*, vol. 143, art. 1 (1970), is a study of this genus of African rails, with colour plates of the birds, diagrams of vocalizations, and a general treatment of rail voices; H.T. HENDRICKSON, "A Comparative Study of the Egg White Proteins of Some Species of the Avian Order Gruiformes," *Ibis*, 3:80–91 (1969), contains an exhaustive listing of the taxonomic characters for the order. See also the general works cited in the bibliography for BIRD, many of which have extensive text sections and fine illustrations of gruiforms.

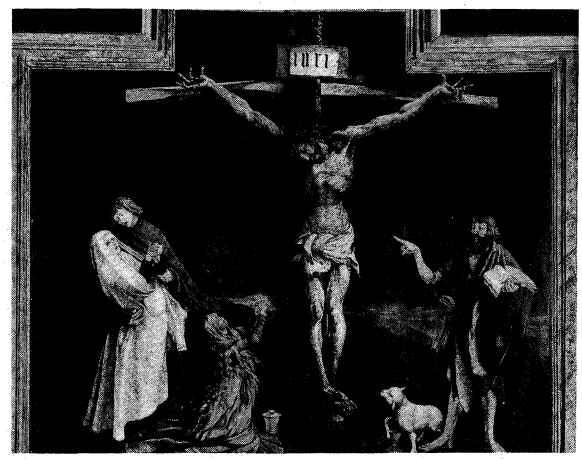
Grünewald, Matthias

One of the most fascinating and, in many ways, enigmatic German artists of the 16th century, Matthias Grünewald was also, perhaps, the greatest painter of his time. Since his death, Grünewald's painterly and expressive achievement remains one of the most striking in the history of art. The name by which the artist is known today is a 17th-century fabrication, but the ten or so paintings (some of which are composed of several panels) and approximately 35 drawings that survive have been jealously guarded and carefully scrutinized in modern times.

Although it is commonly agreed that "Master Mathis" was born in Würzburg, Germany, the date of his birth remains problematic; estimates vary from 1455 to 1480. In all probability he is not identical with another painter, Mathis, active in Aschaffenburg from about 1480 to 1490. His first securely dated work, the "Mocking of Christ," seems to be that of a young man just become a master, not of an older painter more than 50 years of age. Thus, Grünewald, whose real surname was Gothardt, appears first in documents of about 1500 either in the town of Seligenstadt am Main or Aschaffenburg.



"Crucifixion," centre panel (wings closed) of the "Isenheim Altarpiece" by Matthias Grünewald, before 1516. In the Musée d'Unterlinden, Colmar, France. 2.69 m × 3.07 m.
Giraudon

Court painter at Mainz

By about 1509 Grünewald had become court painter and later the leading art official (his title was supervisor or clerk of the works) to the archbishop of Mainz, Uriel von Gemmingen. The archbishop was in residence at Aschaffenburg, just a three-hour walk down the river from Seligenstadt. Grünewald supervised the rebuilding of the cleric's castle at Aschaffenburg, which, among other projects, included an elaborate chimney.

In about 1510 Grünewald received a commission from the Frankfurt merchant Jacob Heller to add two fixed wings to the altarpiece of the "Assumption of the Virgin" recently completed by Albrecht Dürer. These wings depicting four saints (today divided between the Städelsches Kunstinstitut, Frankfurt, and the Staatliche Kunsthalle, Karlsruhe) are painted in grisaille (gray on gray) and already show the artist at the height of his powers. Like Grünewald's drawings, which are done primarily in black chalk with some yellow or white highlighting, the Heller wings convey coloristic effects achieved without the use of colour.

In about 1515 Grünewald was entrusted with the largest and most important commission of his career. Guido Guersi, the Italian preceptor, or knight, who led the religious community of the Antonite monastery at Isenheim (southern Alsace), asked the artist to execute a series of painted wings for the shrine of the high altar that had been carved in about 1505 by Niclaus Hagnower of Strasbourg. It will no doubt always remain a matter of conjecture why the Antonite cleric entrusted such a large and important task to an artist who had never before been active beyond the borders of his native province. No doubt Guersi had some say in the choice and representation of subject matter, but the Isenheim wings also provided Grünewald's genius with one of its fullest expressions, here based, to a large extent, on the text of the popular, mystical *Revelations* of St. Bridget of Sweden (*c.* 1370).

Another important clerical commission came from a canon in Aschaffenburg, Heinrich Reitzmann. As early as 1513 he had asked Grünewald to paint an altar for the Mariaschnee Chapel in the Church of SS. Peter and Alexander in Aschaffenburg. The artist turned to this work in the years 1517–19 (the altar is dismembered and fragmentary today, one panel being in Stuppach, Württemberg, another in Freiburg im Breisgau).

Grünewald apparently married in about 1519, when he would have been almost 50 years old. The marriage does not appear to have brought the artist much happiness (at

least, that is the tradition recorded in the 17th century). His wife did bring with her a son, Andreas, whom Grünewald adopted. After his marriage Grünewald also occasionally added his wife's surname, Neithardt, to his own, thereby accounting for several documentary references to Mathis Neithardt or Mathis Gothardt Neithardt, as well as a monogram intertwining the letters M, G, and N.

In 1514 Uriel von Gemmingen had died, and Albrecht von Brandenburg had become the reigning prince (in 1518 he became a cardinal as well). Although Grünewald may have left the court for several years, his last works show that he was in the prelate's service for about ten years. The costly robes and even jewels of a courtier were listed among the artist's possessions at his death, so that he must have participated, to some extent, in the life of one of the most worldly and cultivated courts of Germany.

For Albrecht, Grünewald did execute one of his most luxurious works, portraying "The SS. Erasmus and Mauritius" (Erasmus is actually a portrait of Albrecht) that is now in the Alte Pinakothek in Munich. Apparently, because of his sympathy with the Peasants' Revolt of 1525, Grünewald left the Cardinal's service in 1526. He spent the last two years of his life visiting in Frankfurt and Halle, cities sympathetic to the newly emerging Protestant cause. In Halle he was involved in supervising the town waterworks. Grünewald died in August 1528; among his effects were discovered several Lutheran pamphlets and documents.

Reputation and influence

Despite his artistic genius, failure and confusion no doubt marked much of Grünewald's life. For instance, the chimney at Aschaffenburg and the fountain at Halle never did work properly. He seems not to have had a real pupil nor, perhaps, even an assistant. His avoidance of the graphic media also limited his influence and renown. In this way Grünewald presents an important contrast to his German contemporary Albrecht Dürer. Grünewald's coloristic effects and dramatic approach to subject matter can perhaps best be observed in his numerous portrayals of the Crucifixion (National Gallery of Art, Washington, D.C.; Kunstmuseum, Basel, Switzerland; "Ishenheim Altarpiece," Musée d'Unterlinden, Colmar, France; Kunsthalle, Karlsruhe, West Germany).

Although Grünewald's works continued to be highly prized, the man himself was almost forgotten by the 17th century. The German painter Joachim von Sandrart, the artist's fervent admirer and first biographer (*Teutsche Akademie*, 1675), was thus responsible for preserving some of the scanty information that we have about the artist, as well as naming him, erroneously and from an obscure source, Grünewald. At the lowest ebb of his popularity, in the mid-19th century, Grünewald was labelled by German scholarship "a competent imitator of Dürer"; however, the late 19th-century and early 20th-century artistic revolt against rationalism and naturalism, typified primarily by the German Expressionists, led to a thorough and, finally, scholarly re-evaluation of the artist's career, and Grünewald's art is today recognized as an often painful and confused but always highly personal and inspired response to the turmoil of his times.

MAJOR WORKS

PAINTINGS: "Lindenhardt Altarpiece" (1503; Parish Church, Lindenhardt, West Germany); "Mocking of Christ" (*c.* 1503; Alte Pinakothek, Munich); "The Crucifixion" (before 1508; Kunstmuseum, Basel, Switzerland); "St. Cyriakus and St. Lawrence" (1511–13; Städelsches Kunstinstitut, Frankfurt); "Isenheim Altarpiece" (before 1516; Musée d'Unterlinden, Colmar, France); "Virgin of Stuppach" (1519; Parish Church, Stuppach, West Germany); "Miracle of the Snow" (1519; Augustinermuseum, Freiburg im Breisgau, West Germany); "The Small Crucifixion" (1519–20; National Gallery of Art, Washington, D.C.); "Crucifixion" and "Christ Bearing the Cross" (part of the "Tauberbischofsheim Altarpiece"; both 1522–23; Staatliche Kunsthalle, Karlsruhe, West Germany); "The SS. Erasmus and Mauritius" (1523; Alte Pinakothek, Munich); "Mourning Over the Body of Christ" (before 1525; Church of SS. Peter and Alexander, Aschaffenburg, West Germany).

DRAWINGS: "Christ on the Cross" (*c.* 1503; Staatliche Kunsthalle, Karlsruhe); Studies for the "Isenheim Altarpiece" including "Study for St. Anthony" (Kupferstichkabinett, Berlin); "Study for St. Anthony" (Kupferstichkabinett, Dresden, East Germany); "Study for St. Sebastian" (2 drawings, Kupferstichkabinetts, Dresden and Berlin); "Kneeling Madonna" (2 versions; Kupferstichkabinett, Berlin); "Woman with Folded Hands" (Sammlung Oskar Reinhart, Winterthur, Switzerland); "Woman with Folded Hands" (2 versions; Freiherr Speck von Sternburg Collection, Lützschena, East Germany); "Study for the Virgin of Stuppach" (Kupferstichkabinett, Berlin); "Man with Folded Hands" (study for St. John of Karlsruhe "Crucifixion"; Kupferstichkabinett, Berlin); "Woman with Folded Hands" (Ashmolean Museum, Oxford); "Kneeling Apostles: SS. James and Peter" (Kupferstichkabinett, Dresden); "Drapery of a Seated Figure" (Smith College Museum of Art, Northampton, Massachusetts); "Kneeling Man Gesticulating" (Kupferstichkabinett, Berlin); "Madonna in the Clouds" (Museum Boymans-van Beuningen, Rotterdam); "St. Dorothy" (Kupferstichkabinett, Berlin); "Weeping Child" and "Screaming Child" (Kupferstichkabinett, Berlin); "Head of a Smiling Woman" (Louvre, Paris); "Self-Portrait(?)" (1529; Universitätsbibliothek, Erlangen, West Germany); "Woman's Head" (Kupferstichkabinett, Berlin); "Kneeling Man and Two Angels" (Kupferstichkabinett, Berlin); "Woman with Two Children" (Kupferstichkabinett, Berlin); "Standing Saint" (Albertina, Vienna); "Nude Man with Trumpet" (formerly Franz Koenigs Collection, Haarlem, The Netherlands); "Three Men's Heads" ("Trias Romana"; Kupferstichkabinett, Berlin); "Profile of a Bearded Man" (Schlossmuseum, Weimar, East Germany).

BIBLIOGRAPHY. H.A. SCHMID, *Die Gemälde und Zeichnungen von Matthias Grünewald* (1911), the first, still basic biography of the artist; H. FEURSTEIN, *Matthias Grünewald* (1930), another standard German monograph, especially important for its emphasis on the literary sources of Grünewald's imagery; ARTHUR BURKHARD, *Matthias Grünewald: Personality and Accomplishment* (1936), the most important monograph in English, but limited; W.K. ZULCH, *Der historische Grünewald: Mathis Gothardt-Neithardt* (1938), an important monograph with many new documentary sources; GUIDO SCHOENBERGER (ed.), *The Drawings of Mathis Gothart Nithart, Called Grünewald* (1948), the first important work on Grünewald's drawings in English; LOTTLISA BEHLING, *Die Hanzeichnungen des Mathis Gothart Nithart, genannt Grünewald* (1955), the most complete, modern scholarly treatment of the drawings; NIKOLAUS PEVSNER and MICHAEL MEIER, *Grünewald* (1958), a well-illustrated study in English; J.K. HUYSMANS and EBERHARD RUHMER, *Grünewald: The Paintings* (1958), another recent, well-illustrated monograph on the paintings; EBERHARD RUHMER, *Grünewald: Drawings* (1970), the most recent scholarly treatment of the drawings in English.

(C.S.Ha.)

Guadalquivir River

The Guadalquivir River (Arabic Wādī al-Kabīr, "Great River") is, as its name implies, the historic major river of southern Spain, with a drainage area of 22,160 square miles (57,390 square kilometres), and a length of 408 miles (657 kilometres). Although, judged by size alone, it is only the second river of Spain and the fourth of the Iberian Peninsula, it has several distinctive characteristics that, taken together, make it of outstanding importance: its natural environment encompasses one of the richest and most varied areas of plant and animal life in Europe, and its irrigative capacity, particularly in its wide and fertile plain, has, in addition to supporting the world-famous vineyards and olive groves of Andalusia, provided a basis for an industrializing region of national and continental importance. The significance of the river over the last two thousand or more years is suggested by the detailed geographical descriptions of it found in the works of Classical and medieval Greek, Roman, Arabic, and Christian writers. This tradition is continued today in the scientific research of Comisión Hidrográfica del Guadalquivir, the Sociedad de Ciencias Naturales "Aranzadi," the Real Sociedad Geográfica, and many other public and private bodies.

The course. The Guadalquivir divides into three regions, illustrating its development from a turbulent mountain stream (its "youth" to geographers), through "maturity," to the wide meanderings of its final floodplain ("old age"). It rises almost 5,250 feet (1,600 metres) above sea level, in Jaén Province of southern Spain, to the north of the Sierra Nevada Mountains fronting the Mediterranean Sea.

Geologic structure of the river's course

After rising, it flows northward for about 30 miles (50 kilometres), running through a narrow valley cut into soils and rocks of the Mesozoic Era of as much as 225,000,000 years ago. After emerging from the man-made lake of El Tranco de Beas, it describes a great arc to the west, following a westerly or southwesterly trend all the way to the Atlantic. Between the cities of Andújar and Montoro, the river leaves the Mesozoic rocks to cut a widening plain in more ancient strata. It flows over Mesozoic rocks again near Marmolejo, and, just before passing the city of Cordoba, the beautiful capital of the medieval Arabian caliphate, runs across the easily eroded rocks and soils of the geologically more recent Tertiary and Quaternary periods (laid down less than 65,000,000 years ago), which it then follows to its mouth. After irrigating the fruitful regions of Posadas and Lora del Río, the Guadalquivir reaches Seville, the capital of Andalusia, and one of the most historic and attractive of Iberian cities. It has been made navigable from Seville to the Atlantic (about 50 miles [80 kilometres]), notably by the construction of the channel of the Corte de Tablada, which will take vessels of up to 30,000 tons. Here the river meanders lazily across a hot coastal plain, traversing the swamps of Las Marismas, the largest in Spain, before entering the Atlantic at Sanlúcar de Barrameda, at the eastern end of the Gulf of Cadiz.

Plant life. The drainage basin of the Guadalquivir encompasses one of the greatest floral resources of Europe, containing representatives of half of the continent's species of plant life, together with virtually all those of the North African subtropical region. The surrounding mountains are crowded by forests of pines and oaks, and by brushwoods. More than a third of the total surface is covered by innumerable olive groves, which annually produce more than 15,000 tons of oil and help to make Spain the leading world producer of this vegetable oil. In addition, cereals (wheat, rye, and barley), cultivated in 30 percent of the basin area, support the regional agriculture, and viticulture produces the great Spanish sherries, such as the amontillados (pale dry sherries), and other wines at a rate of 5,600,000 cubic feet (1,600,000 hectolitres) per year.

Commercial plants

Animal life. Fauna is as varied as the plant life, with animals representing a great variety of European and North African species. In the mountains, wild boar, goat, fallow deer, stag, chamois, partridge, among many others, are found, and the area is one of the great European hunting regions. Fish, notably trout and barbels, are found throughout the Guadalquivir, its artificial lakes, and its more than 800 tributaries.

Regional development. Traditionally, agriculture was the basic way of life of the Guadalquivir Basin, but, by the 1970s, the region was experiencing an accelerating industrialization spurred by government plans for development, one of which has introduced industry to the upper basin at a cost of over 5,000,000,000 pesetas ($70,000,000). As a result of this development, the percentage of the labour force employed in agriculture has declined from 60 percent to 40 percent in recent decades. In addition, there has been a spectacular growth in hydroelectric capacity. By the early 1970s, there were over 80 hydroelectric stations in the region with an installed power of 288,000 kilowatts. The six largest dams, with associated lake areas, were El Tranco de Beas, 6.8 square miles (1,772 hectares); Charco Manzano (Guadalén), 5.2 square miles (1,351 hectares); La Lancha (Jándula), 5.2 square miles (1,350 hectares); Bembézar, 4.1 square miles (1,070 hectares); Torre del Aguila, 4.1 square miles (1,066 hectares); and El Pintado, 4.0 square miles (1,042 hectares). (J.B.Ro.)

Guadeloupe

Guadeloupe (La Guadeloupe), a French overseas *département* (large administrative district), is a group of islands situated in the eastern Caribbean Sea. Most of the islands form a part of the Windward Islands, and all are included in the Lesser Antilles island chain. Guadeloupe is about 4,300 miles away from France and about 370 miles north of the coast of Venezuela. The nearest territorial neighbours of the principal group are the British dependencies of Montserrat to the northwest and Dominica to the south. The largest territory in Guadeloupe consists of the twin islands of Basse-Terre to the west and Grande-Terre to the east, the two being separated by a narrow channel, the Rivière Salée; other islands in the group are Marie-Galante to the southeast, La Désirade to the east, and the Îles des Saintes (Terre de Haut and Terre de Bas) to the south. Two more island dependencies—Saint-Barthélemy and Saint-Martin (the southern third of the latter being under The Netherlands administration)—are situated about 150 miles to the northwest, lying to the northwest of the outer arc of the Lesser Antilles.

The total area of Guadeloupe is 687 square miles (1,780 square kilometres). The population numbered more than 300,000 in 1970. Basse-Terre (population 15,000), on the island of the same name, is the seat of government. The largest town, however, is Pointe-à-Pitre on Grande-Terre, a port with a population of 50,000, which is the economic capital. Guadeloupe lies about 74 miles north of Martinique, the other French overseas *département* in the Windward Islands. (See also MARTINIQUE; for an associated physical feature, see CARIBBEAN SEA.)

Relief and drainage. Basse-Terre, which has an area of 364 square miles, has a chain of mountains running north to south and culminating in Soufrière, a dormant volcano 4,868 feet (1,484 metres) high; it erupted in 1797 and in 1836 and now is a source of hot and sulfur springs. Other summits are Mont Sans Toucher, which is 4,442 feet (1,354 metres) high, and Morne de la Grande Découverte, which is 4,143 feet (1,263 metres) high. The mountain chain forms a watershed from which rivers run down to the sea. The Rivière Rouge (Red River) is so called because iron-bearing sediments give it a rust colour; the place where it falls into the Sablon River is called Matouba, or Matouba's Leap. The principal river on the island is the Goyaves; other rivers are the Grande Plaine, the Petite Plaine, the Moustique, the Lézarde, and the Rose. Basse-Terre has a beautiful coastline, indented with bays and fringed with picturesque beaches.

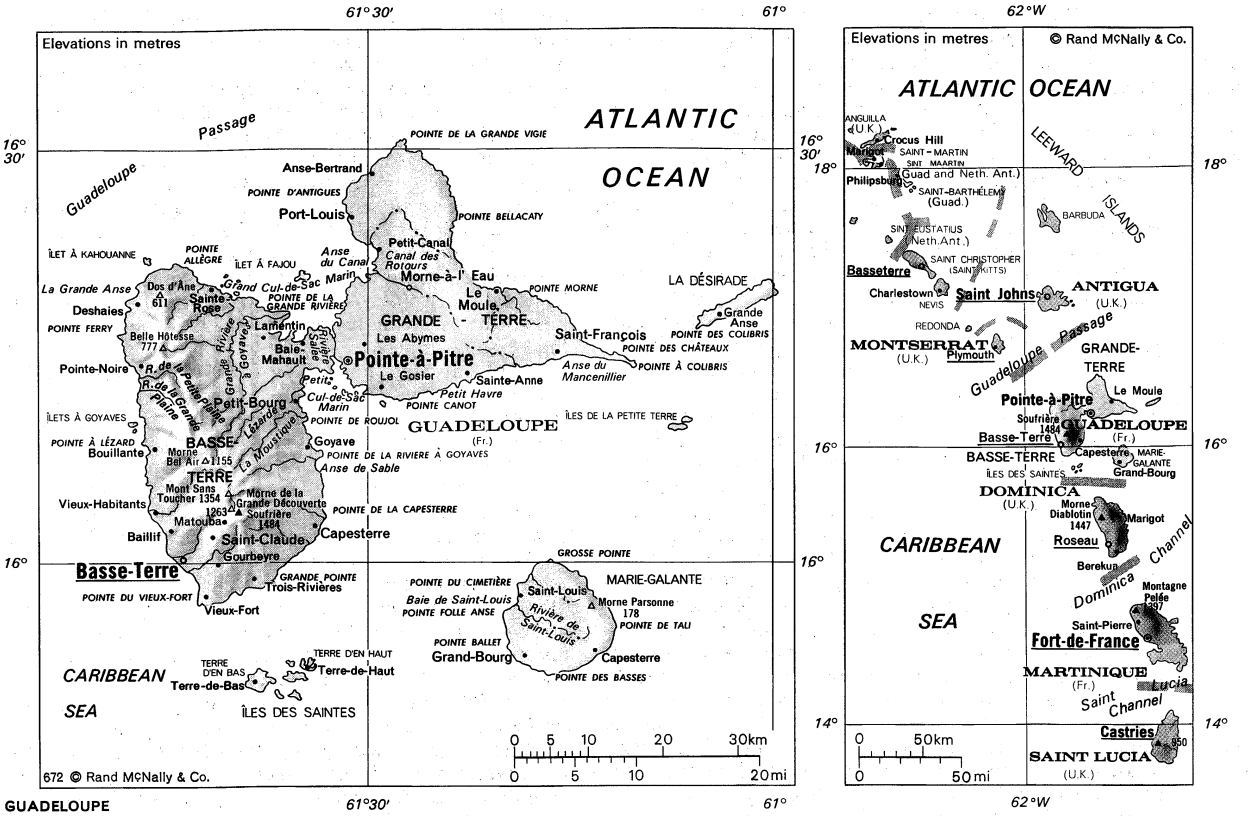
Principal rivers

The island of Grande-Terre has an area of 220 square miles and is generally low lying; it has only a few bluffs that do not exceed 490 feet in height. Saint-Martin and Saint-Barthélemy are rugged and rise to an altitude of 1,391 feet (424 metres) and 921 feet (281 metres), respectively.

Climate. The tropical climate is tempered by the northeast trade winds. The temperature on the coast varies between 77° and 82° F (25° and 28° C), respectively, with extremes reaching 68° and 93° F (20° and 34° C). In the mountains above 1,900 feet, the temperature drops to 61° F (16° C), and at the summit of Soufrière drops to 39° to 41° F (4° to 5° C). There are two distinct seasons—the "Creole Lent," or dry season, which lasts from December to April, and the winter, or rainy season, from July to September–October.

Precipitation varies with altitude and orientation. Grande-Terre receives about 39 inches of rain, for example, while the mountainous parts of Basse-Terre receive more than 100 inches a year. Hurricanes occur occasionally, usually coming from the south.

Vegetation and animal life. The heat, the rainfall, and the fertility of the volcanic soils produce a luxuriant vegetation that is diversified according to altitude. Extensive mangrove swamps occur on the banks of the Rivière Salée near Pointe-à-Pitre. Dense forest occurs in the mountainous regions of Basse-Terre, beginning almost at sea level on the windward slopes and at an altitude of about 750 feet on the leeward side and continuing to altitudes of about 3,000 feet or more. Here, chestnut trees and bracken are found, as well as such hardwoods as mahogany and ironwood. On the highest peaks some flooded basins produce a vegetation of grasses and sedges. Grande-Terre has been cleared of most of its original forests; only a few patches of woodland remain. The smaller islands, such as La Désirade and Saint-Martin, have a different type of vegetation, consisting



GUADELOUPE

primarily of dry forest with groves of latania (a kind of fan palm) and cactus.

Animal life has been modified since the arrival of the Europeans. Raccoons are sought for their fur. The agouti (a short-haired, short-eared, rabbit-like rodent) is still found on the heights of Capesterre, southeast of Basse-Terre. The paucity of game animals is due—apart from excessive hunting—to the presence of mongooses, which abound throughout the islands. In some regions, wild duck, waterfowl, and teal are found.

The warmth of the water around the islands is responsible for a rich variety of fish life, including tarpon, snook (a basslike kind of fish), hogfish, snapper, parrot fish, and many species of ray fish.

History. Discovered on November 4, 1493, by Christopher Columbus, the two main islands, then together known as Karukera (Island of Beautiful Waters), were peopled by Caribs, who had displaced the original Arawak inhabitants. The territory was consecrated to Our Lady of Guadeloupe of Estremadura in Spain, from whom it takes its name.

Early European settlement

Preliminary attempts by the Spanish to establish themselves were repulsed by the Caribs in 1515, 1520, and 1523. In 1626 the Spanish, who had established themselves on the coast, were driven away by Pierre Belain d'Esnambuc, a Frenchman who established a trading company. In 1635 two Frenchmen, Léonard de L'Olive and Jean Duplessis d'Ossonville, landed and established a colony. Until 1640 the colonists fought against the Carib Indians, but thereafter the colony prospered. Made a part of the royal domain of France in 1674, Guadeloupe benefitted from the influence of Jean-Baptiste Labat (1663 to 1738), a strong personality who was the effective founder of the Basse-Terre colony and who, in 1703, armed the black slaves (who had already been brought to the island) in order that they might fight against the English; he also established the first sugar refineries, thereby laying the foundations for the era of prosperity that followed. In 1759 Guadeloupe was occupied by the British for four years but was restored to France in 1763. In 1794 it was again occupied by British troops, allied with French royalists, but was recaptured by Victor Hugues, an official of the French revolutionary government, who proclaimed the abolition of slavery and had several hundred white planters massacred. When slavery was re-established by Napoleon's government in 1802, a revolt of the slaves occurred and culminated in the heroic act of the antislavery forces, who blew themselves up at Matouba when threatened by French forces under the command of Gen. Antoine Richepanse; Richepanse himself had been sent by Napoleon to pacify Guadeloupe, but he died of yellow fever in the same year. The British occupied Guadeloupe in 1810, after which it was—after some temporary changes in status—finally restored to France in 1816.

The abolition of slavery in 1848 was the most significant development of the territory's 19th-century history. Universal suffrage was abolished during the reign of Napoleon III of France, but in 1870 colonial representation in the French Parliament was restored. In 1940 Guadeloupe gave its allegiance to the Vichy government in France, but in 1943 it adhered to Gen. de Gaulle's Free French forces. In 1946 it was given the status of a French *département*.

The contemporary islands. *Population and demography.* The population is composed principally of Creoles (*i.e.*, persons born in the islands), most of whom are black or mulatto, except on Les Saintes where the inhabitants are mainly white. The diminution of the white element during the period of the French Revolution accentuated the African character of the population. The white population on the smaller islands is mostly descended from 17th-century Norman and Breton settlers.

The population numbered 229,000 in 1954 and rose to about 313,000 at the time of the 1967 census, and to 326,000 in 1970, representing a density of 474 persons per square mile. The average rate of increase of the population amounts to about 2 percent a year. About 300,000 people live on the two largest islands, while about 20,000 people live on Marie-Galante, 3,000 on the Îles des Saintes, 1,600 on La Désirade, 2,400 on Saint-Barthélemy, and 5,000 on Saint-Martin.

While French is the official language and is in current use, a local Creole dialect is also widely spoken.

The economy. The economy is marked by a stagnant agricultural sector, an embryonic industrial sector, and a highly developed public-service sector. In effect, the economy is sustained primarily by the salaries of officials

and by French credits, which consist of aid in the form of allocations and grants.

Sugarcane and bananas

Sugarcane and bananas are the two principal cash crops. Sugar exports amount to between 130,000 and 190,000 tons a year. The banana plantations suffered from a series of hurricanes in the 1960s, but the devastation resulted in the replanting of plantations with more productive types of trees. By the late 1960s, banana exports had increased to more than 100,000 tons a year, all of which were sent to France. Rum is also exported.

Industrial development is limited, largely because of the shortage of power. The rivers are too short to permit hydroelectric development. In 1969, however, liquid steam was discovered at a depth of almost 1,000 feet; the steam has a pressure of 104 pounds, a temperature of 482° F (250° C), and a yield of 100 tons an hour. The establishment of a geothermic plant is now considered feasible. Meanwhile, electricity is provided by a semi-public corporation that has four power stations.

There is a severe deficit in the balance of external trade, most of which is with France and the franc zone. Most imports are consumer goods.

Transportation. Guadeloupe maintains regular air and sea links with France and with the North American continent. Traffic at the port of Pointe-à-Pitre is constantly growing; in 1969 alone it was visited by more than 900 ships. The port of Basse-Terre specializes in the banana-export trade. Le Raizet, north of Pointe-à-Pitre, is an international airport used by French, United States, British, and Dutch airlines. On the island of Saint-Martin, the town of Marigot is a free port; there is also an airport at Philipsbourg in the Dutch sector that serves both parts of the island. Local steamers connect Basse-Terre and Grande-Terre with the other island dependencies. The road system on the main islands, which is about 780 miles in length, is kept in excellent condition.

Air services

Administration. The *département* is under the executive authority of a prefect; there is a legislative council consisting of 36 elected members. Guadeloupe is represented in the French National Assembly by three deputies and in the French Senate by two senators.

The territory of Guadeloupe is divided into three *arrondissements* (wards) that are in turn divided into 34 *communes* (the smallest territorial divisions), each administered by an elected municipal council. The judicial system is French. There is a court of appeal at Basse-Terre and a judicial tribunal at Pointe-à-Pitre; justices of the peace are established in each of the 36 cantons (electoral districts).

Social conditions and cultural life. The same social legislation is in effect as in metropolitan France. There is a general hospital at Pointe-à-Pitre, as well as a Pasteur Institute, and other hospitals.

Education

French is the medium of instruction in the schools, and the literacy rate is over 83 percent. In addition to about 300 primary schools, there are two *lycées* (state-supported secondary schools) as well as a teachers' training college and a school of agriculture. A school of humanities and a law school, at Pointe-à-Pitre, constitute in embryonic form what is planned to become the University of the Antilles.

There are about a dozen daily or weekly newspapers. Radio and television programs are broadcast regularly by ORTF (Office de Radiodiffusion Télévision Française) from Pointe-à-Pitre.

Future prospects. Guadeloupe's primary problem is economic and arises from the fact that whereas on the one hand the territory has a rapidly increasing population, on the other its main economic sector is the public service—a situation that results in the *département* consuming more goods than it produces. Tourism is insufficient to bridge the gap, and emigration to France has also proved an insufficient palliative in a situation in which employment opportunities remain limited at a time when the younger generation is becoming increasingly well educated. Problems stemming from these circumstances are expected to grow more acute.

BIBLIOGRAPHY. GUY LASSERRE, *La Guadeloupe: étude géographique*, 2 vol. (1961), is the basic work. See also HENRI BANGOU, *La Guadeloupe, 1492–1848* (1962); and ANTOINE VICTOR JOROND, *La Guadeloupe et ses îles: guide pratique du visiteur* (1965).

(R.Co.)

Guatemala

Guatemala is the third largest of the Central American republics, bordered on the north and west by Mexico, on the east by Honduras and El Salvador, and on the south by the Pacific Ocean. Its northeast border is with British Honduras. The country also has a small coastline on the Caribbean (Gulf of Honduras). Its total area is 42,042 square miles (108,889 square kilometres). The population at the beginning of the 1970s was about 5,600,000. The capital is Guatemala city, the largest city in Central America.

The oldest known inhabitants of Guatemala were a sedentary, agricultural people who made utensils of baked clay. Between the 2nd and 10th centuries AD, these early inhabitants produced the great Mayan civilization, the ruins of which may be seen in the jungles of Petén and the neighbouring Yucatán Peninsula of Mexico. The descendants of the Mayas mixed with other Indian tribes that came to the country after the 10th century and formed small kingdoms, which were later subdued by the Spanish conquerors of the 16th century. (For historical aspects, see CENTRAL AMERICAN STATES, HISTORY OF. For Guatemala's claim to British Honduras, see BRITISH HONDURAS [BELIZE].)

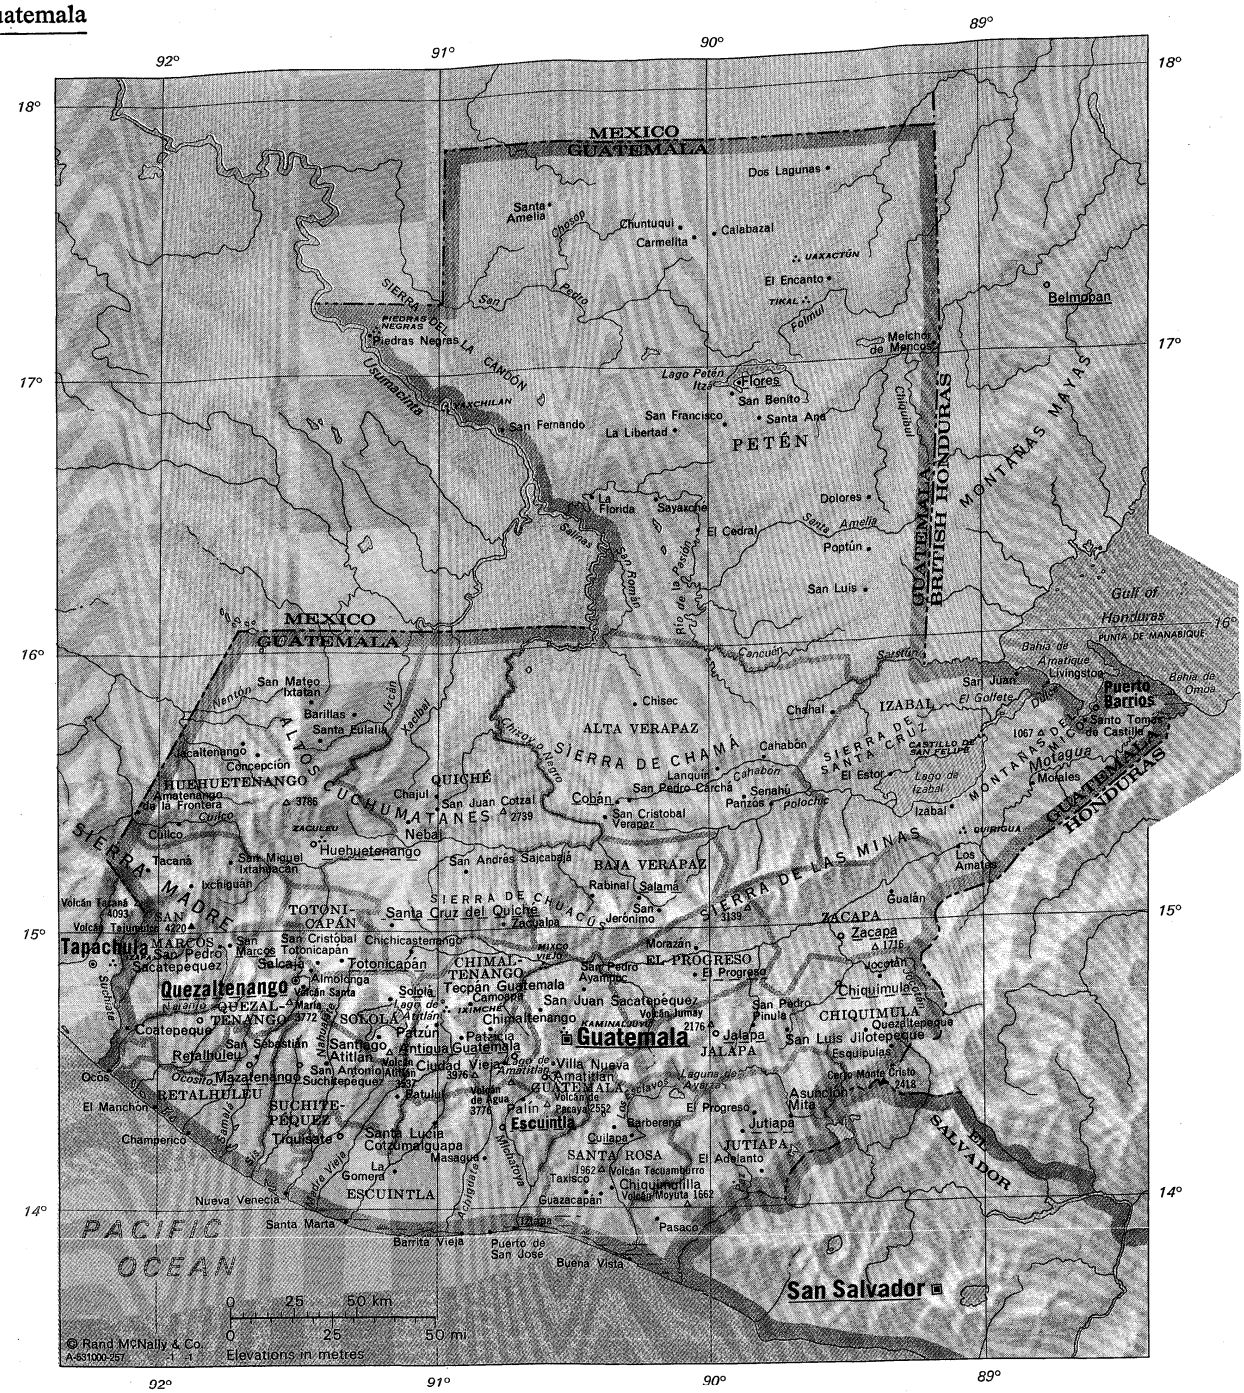
THE LANDSCAPE

Physical geography. The mountain ranges, or cordilleras, of Central America cross Guatemala from west to east, dividing the country into four regions: the Petén, the central highlands, the Atlantic littoral, and the southern coast.

The four regions

The Petén is located between Mexico and British Honduras (Belice) in the northern part of the country and has the same geological characteristics as the rest of the Yucatán Peninsula belonging to Mexico. It is a limestone tableland with altitudes of no more than 650 feet, except in the southern part, extending over about a third of the country. It is relatively unpopulated, covered in large part by jungles and some flat grassland. Petén is dotted with lakes and ponds; there are also many water holes and small ponds that form during the rainy season and drain into underground caverns. Some of the most impressive Mayan ruins (Tikal, Uaxactún, and Piedras Negras) lie sleeping in the jungles of Petén.

The central highlands comprise two branches of the cordilleras (systems of approximately parallel mountain ranges): the Sierra Madre and the Altos Cuchumatanes. The Altos Cuchumatanes, which in the western part of the country reach elevations as high as 9,500 feet, extend northeast (where they are known as the Sierra Chamá, the Sierra de Santa Cruz, the Montañas Mayas, the Sierra de Chuacús, and the Sierra de las Minas), until they drop into the Atlantic Ocean. The Sierra Madre crosses the country from west to east, entering Honduras and El Salvador; it forms the central plateau upon the terraces, valleys, and slopes of which live the greater part of the country's population and where the capital of the republic is located. The southern range of the Sierra Madre is



GUATEMALA

Political subdivisions

Cities and towns

an imposing chain of 33 volcanoes running parallel with the Pacific coast from Mexico to El Salvador. Among them are Tajumulco (13,845 feet [4,220 metres]), Tacaná (13,428 feet [4,093 metres]), Santa María (12,375 feet [3,772 metres]), Atitlán (11,601 feet [3,537 metres]), Acatenango (13,041 feet [3,976 metres]), Agua (12,385 feet [3,776 metres]), Fuego (12,343 feet [3,763 metres]), and Pacaya (8,371 feet [2,552 metres]). Santa María, Fuego, and Pacaya are in permanent activity; the others are either extinct or dormant. Among these volcanoes lie small lakes of great beauty, such as Atitlán and Amatitlán.

The Atlantic littoral is a region of lowlands, containing the country's largest lake, Izabal (with an area of about 228 square miles), and large rivers such as the Motagua, Polochic, Dulce, and Sarstún (Sarstoon). The climate is warm and the rainfall heavy except in a small arid region. The Bahia de Amatique has Guatemala's principal ports. The southern coastal lowland extends 160 miles from Chiapas in Mexico to El Salvador, averaging about 30 miles in width. The soil is of volcanic origin, well-watered by numerous rivers and intense rains.

Geology. The northern part of the country is formed by rocks of the Cretaceous (from 65,000,000 to 136,000,000 years old) and Tertiary (from 2,500,000 to 65,000,000 years old) periods. In the south and east are still more ancient, principally Paleozoic rocks (from 225,000,000 to 570,000,000 years old). Carbonated and calcareous (chalky) deposits predominate; in south Petén, metamorphic (formed by heat and pressure) and igneous (formed by the solidification of molten magma) rocks are found, and ridges representing an ancient rocky mountain system predominate. The central mountainous region is predominantly of volcanic Tertiary rock, covered by recent volcanic layers of lava and ash.

Hydrography. The mountain system determines the hydrographic basins. Rivers emerging on the northern slopes flow into the Gulf of Mexico (Usumacinta and its tributaries) or the Caribbean (Hondo, Belize, Sarstún, Polochic, Motagua). Rivers on the south of the watershed flow into the Pacific (Suchiate, Ocosito, Samalá, Nahualate, Michatoya, Los Esclavos, Paz). The Rió Usumacinta (688 miles long) forms the accepted frontier with Mexico and is the largest of Central America. The Motagua (249 miles) crosses Guatemala from west to east. Both are partially navigable by boats of low draft. The rivers flowing to the Pacific are of shorter length and carry less water; several are almost dry during the dry season but during the rainy season become dangerous torrents.

The river system

Climate. Guatemala is located in the tropic zone, but temperate seas and an irregular terrain provide a diversity of climates. At sea level, mean annual temperatures range between 77° and 86° F (25° and 30° C). In the temperate zones, located at altitudes of 2,000 to 6,000 feet, temperatures range down to 63° F (17° C) in the higher altitudes. At altitudes over 6,000 feet, temperatures may be as low as 55° F (13° C). The coldest months are December and January, but there is little variation in the weather from day to day. There is a rainy season from May to November and a dry season from November to May. On the Atlantic coast, where the winds blow during the whole year from warm Caribbean waters, there is hardly any dry season. In the central region the annual rainfall varies from 80 inches in the high plateaus to less than 40 in the arid section of the eastern part.

Vegetation and animal life. In the north are tropical forests and some flat grasslands. The forests are rich in fine woods, rubber, a variety of palms, and the evergreen chicozapote tree (*Achras zapota*), which produces chicle. Near the southern part of this region, some pine forest may be found. In the low or hot lands, the vegetation is similar. The coastal vegetation also includes mangrove. In higher altitudes the lowland species give way to pines, firs, cypresses, willows, and oaks.

Tropical jungles and evergreen forests

In addition to domesticated cattle, sheep, pigs, and mules, wild animals such as deer, monkeys, and peccaries (nocturnal mammals resembling pigs) are common, especially in the less settled areas. Jaguars, tapirs, and pumas are rarer. Crocodiles are found in the Rió Polochic and manatees (tropical, aquatic, herbivorous mammals) in Lago de Izabal and elsewhere. The bird life of the country is remarkably rich—wild turkeys and ducks, doves, and pheasants abound; one almost extinct bird of magnificent plumage, the quetzal, has been chosen as the national emblem.

THE PEOPLE

Composition. On the basis of cultural traits such as language and dress, the population is divided into two large groups: Indians and Ladinos. The Ladinos are mostly of mixed Hispanic–Indian origin. Indians who

The Indian influence

have adopted Ladino ways are considered Ladinos. The census of 1950 showed 54 percent of the population as Indians and 46 percent as Ladinos. In 1964 the census reported 43 percent Indians and 57 percent Ladinos. The government statistical office does not explore the racial composition of the people, but well over 80 percent of the population is either Indian or of mixed blood. Whites and Negroes are few. Slavery was abolished in 1824, and the black slaves soon mixed with the Indian and Spanish population. Inhabitants of Asian origin are also very few in number. The most traditional Indian groups live in the highland plains, particularly in the west and north. They engage in agriculture, sheep raising, primitive textile industries, and local trade. They also work as labourers and compose the majority of soldiers in the national army.

The official national language is Spanish, but approximately 20 Indian dialects are also spoken. The majority of the latter are of Mayan origin. The most widely spoken Indian languages are Quiché (the language of the *Popol Vuh*, a valuable book written by the Indians during the first half of the 16th century), Cakchiquel, Mam, and Kekchí. Many Indians also speak Spanish.

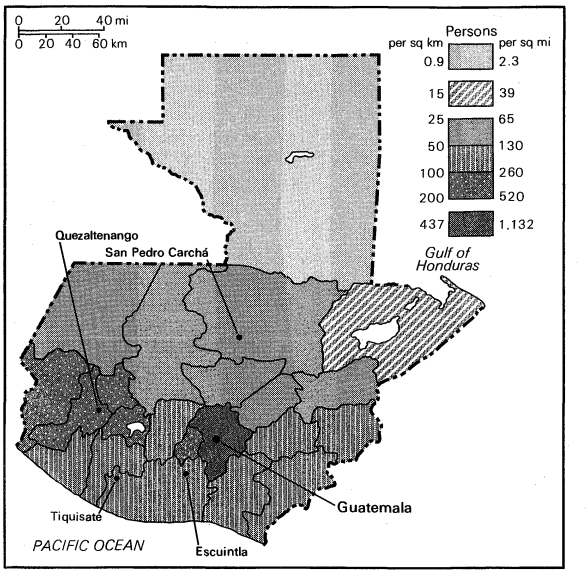
There is no established church, but the prevailing form of religion in Guatemala is Roman Catholic. There are a few Protestants of various denominations and some Jews.

Demography. The total population of Guatemala was estimated in 1972 at 5,600,000. It is believed to be increasing at a rate of 2.4 percent a year. This growth is due almost entirely to the excess of births (about 39 per 1,000) over deaths (15). According to a 1971 estimate 69 percent of the population lived in rural areas and 31 percent in the cities and towns. Some 56 percent were under the age of 19. The most densely populated areas are Guatemala city, and its environs in the highland plain (over 819,000), and the western part of the south coast. The majority of the population live in small villages.

THE ECONOMY

Guatemala is an underdeveloped country, although its natural resources are considerable. Large foreign companies operate in the economy through capital investments made in apparently national companies.

Natural resources. *Mineral resources.* Official surveys of Guatemala's mineral wealth show deposits of coal, gold, silver, antimony, chromium, copper, iron, lead, asbestos, nickel, sulfur, and petroleum. The deposits of nickel are substantial. Mining, however, is little developed. International oil companies have conducted intensive exploration, but in the early 1970s no wells were in operation.



Population density of Guatemala.

Forest resources. Fifty percent of Guatemala is forested. There are over 12,350,000 acres of tropical forest, and coniferous forests abound on the highland plains. They are little exploited because of their inaccessibility.

Hydraulic resources. Conservative estimates indicate that the country has a large electric-power potential in its rivers and mountains; the National Institute of Electrification, a governmental department, is responsible for their development.

Export crops

Sources of national income. *Agriculture, forestry, and fishing.* The national income is drawn principally from agriculture and cattle raising, which occupy two-thirds of the economically active population. Crops raised for domestic consumption include corn (maize), beans, rice, wheat, sorghum, and potatoes. The leading commercial crops are bananas, cardamom, citronella, coffee, cotton, and sugarcane, which are grown principally for export. The 1969 agricultural census counted 1,376,000 cattle, 200,000 horses, 778,000 pigs, and 800,000 sheep. In 1969 the output of the agricultural and livestock sector was estimated at about a quarter of the gross national product. The forestry industry produces lumber and chicle (a gum used in the manufacture of chewing gum) for export. Fish, crustaceans, and mollusks are also exported.

Manufacturing. Industrial activity has increased in recent years, although in 1969 it still accounted for less than 5 percent of the gross national product. The principal industries are cement, sugar, flour, alcoholic beverages and soft drinks, canned food, textiles, tobacco, tires, medicines, chemical products, lumber, and vegetable oils.

Trade and finance. The United States is Guatemala's chief trading partner, for both imports and exports. Significant trade also exists with the other countries of Central America and with Japan, West Germany, the United Kingdom, and Venezuela. The leading imports include machinery, petroleum, paper, metal products, electrical material, medicines, textiles, and books. Major exports include coffee, cotton, sugar, fruits and vegetables, textiles, and chemicals.

The Bank of Guatemala is the note-issuing authority and controls the country's banking system. It also handles the international accounts. Guatemala's monetary unit, the quetzal (1 quetzal = $1 U.S., and 2.4 quetzales = £1 sterling, on December 1, 1970), is maintained at par with the U.S. dollar.

The country's recent industrial development has been assisted by loans from private foreign concerns.

Guatemala has made several agreements with the Cen-

The Central American Common Market

tral American states of El Salvador, Honduras, Nicaragua, and Costa Rica. Together, in 1957 they created the Central American Common Market (Mercomún) for the purpose of fostering free trade among the member countries and establishing a common tariff on products imported from outside the area. The secretariat of the organization is in Guatemala city. It has had considerable success in eliminating or reducing trade barriers among the members. Trade among them, though still not large, increased considerably by the early 1970s.

Management of the economy. The government taxes income, property, bequests and gifts, imports, and sales. Its major revenues are derived from customs duties, sales taxes, and excises on liquor and tobacco. Local taxes are also levied by municipalities.

Through the Consejo Nacional de Planificación Económica (the National Council for Economic Planning) and other specialized agencies, the government has addressed itself to Guatemala's socioeconomic problems: its predominantly rural population; the unequal distribution of property, particularly land; its high rate of illiteracy and other deficiencies in public education; inadequate communications; and a general lack of economic opportunity for the poor. Development plans under way call for substantial investments in roads, public works, electric plants, housing, education, and land reform, financial and administrative reforms, and encouragement of economic development in areas other than Guatemala city, which is now the only industrial centre.

Transportation. There are more than 5,500 miles of paved and surfaced two-lane highways connecting all parts of the country. There are also more than 2,000 miles of dirt roads that can be used during all seasons of the year. The antiquated narrow-gauge railway system has about 600 miles of track, extending from the Pacific ports to Puerto Barrios on the Atlantic and from the Mexican frontier to El Salvador by way of the capital city. It was taken over by the state in 1968.

The ports of Puerto Barrios and Santo Tomás de Castilla on the Atlantic have excellent facilities for loading and unloading. The Pacific ports of Champerico and San José are of lesser significance. Since they are on the open sea, and vessels cannot approach the piers, special barges must be used for loading and unloading.

There is only one international airport, which is in Guatemala city. It is modern and functional and has adequate landing strips for jet service. Various international airlines service it regularly. The government-owned company Aviateca provides the principal domestic service. There are other airports for domestic flights and for private aircraft.

ADMINISTRATION AND SOCIAL CONDITIONS

Constitutional provisions

Government. *Administration.* The constitution defines the country as a sovereign democratic republic. The government has three branches, legislative, executive and judicial. Legislative power is delegated to a Congress of 55 representatives elected every four years by popular, direct suffrage. Executive power is vested in the president and vice president, who are also elected every four years by popular vote. There is a Supreme Court of Justice, which has jurisdiction over all the tribunals of the country. The constitution contains broad guarantees of human, individual, and social rights.

The national territory is divided into 22 departments, each headed by a governor appointed by the president. Governors are usually high-ranking military officers. The departments in turn are divided into autonomous *municipios* (municipalities), which have freedom to dispose of their own revenues. The *municipios* are governed by councils presided over by mayors, elected directly by popular ballot.

Politics. All men and women over the age of 18 are considered citizens and are obliged to register and to participate in all elections. Voting is compulsory for all who are literate and optional for illiterates. (An official 1967 estimate showed that 60 percent of the population over seven years of age was illiterate.)

Broad guarantees are given for the organization and functioning of democratic parties, except the Communist Party and any other that is dedicated to the overthrow of the democratic process. Authorized political parties must show a minimum of 50,000 affiliates, of which at least 20 percent must be literate. Only those parties may nominate candidates for president, vice president, and Congress. Candidates for mayor and other municipal officers do not have to be nominated by political parties. Some of the constitutional guarantees are occasionally suspended.

Instability of governments

Since the liberal reform of 1871, which modified and modernized the political structure of Guatemala, three fundamental constitutions have been promulgated. Each of these was modified more than once to legalize revolutionary coups d'etat (*golpes de estado*). In that period only three presidents have finished their terms (Manuel Lisandro Barillas, in 1892; Juan José Arévalo, in 1951; and Julio César Méndez Montenegro, in 1970). The leaders of coups usually suspend the constitution and govern by provisional measures granting them executive and legislative powers until a new constitution can be drawn up. The constitution now in force was drafted in 1965 by a constitutional assembly convoked by the government that overthrew Gen. Miguel Ydígoras Fuentes (1958–63).

Justice. The Supreme Court of Justice consists of a president and seven magistrates elected by Congress for a period of four years. The constitution provides for free access to justice for all, based on individual rights and guarantees. There are tribunals of various kinds in all the cities and towns. Municipal mayors act as judges in special cases. The death penalty is applicable only in extraordinary cases and may not be applied to women or minors, to those over 70 years of age, or to political prisoners.

The armed forces. There is no official information on the size of the armed forces. The military services include land, air, and sea forces. Most of the troops are Indians. Although constitutionally outside of politics, the army nevertheless represents a powerful element in political struggles.

Social conditions. *Education.* Education is in theory free, secular, and compulsory through the first six years. There are two-year kindergartens, six-year primary schools, and normal high schools (five to six years). The secondary schools train teachers, agricultural experts, industrial technicians, and candidates for universities. There are also private schools. The system is not adequate to cover all the educational needs of the country, and many children go without schooling. Others are unable to finish their primary education, and only a minority reach the secondary level.

Higher education

There are four universities. The state university (Universidad de San Carlos de Guatemala, founded in 1676) is supported from the national budget. None of the recognized professions can be practiced without a diploma from the national university or one of the private universities. Graduates of foreign universities must take board examinations before they are permitted to practice their professions in Guatemala.

Health and social welfare. The Ministry of Public Health and Social Welfare maintains 36 hospitals, which provide free care. There are several private hospitals in the capital and principal cities. Medical and health services are not adequate for the population as a whole, particularly among the poor and in rural areas. In the early 1970s infant mortality rates were still very high, and the numbers of hospital beds, doctors, and dentists were very low. Most physicians live in Guatemala city and the larger provincial capitals. Along with poor sanitation, malnutrition is an important factor contributing to Guatemala's high mortality.

Since 1946 the Guatemalan Social Security Institute has provided medical insurance for public and private employees. The benefits cover accident and common illness, as well as maternity care. The institute also maintains several hospitals.

Housing. The types and quality of housing vary considerably. The rural population lives in huts made from mud, brick, wood, or cane. In the cities and towns, build-

ing follows traditional methods using modern materials and techniques. In the capital city, where the higher income families live, houses have all the modern comforts. Central heating and air conditioning are not considered necessary.

Housing construction has increased considerably since 1945, particularly in the capital and other important cities, where the population has grown rapidly. The government housing agency is committed to the large-scale construction of homes for low-income families, financed with foreign technical aid and state funds. In 1964, of the nation's 840,000 houses, about 275,000 were in towns and the remainder in rural areas.

Living standards

Social classes. Guatemala's upper income group consists of businessmen, plantation owners, merchants, and bankers. There is a middle stratum of industrialists, professionals, and university graduates. The lowest income group consists of rural workers, labourers, artisans, and small merchants. There are no racial barriers among the different social classes.

Incomes vary greatly. The basic salary paid by the government to teachers was 100 quetzales per month in 1971. It was estimated that 40 percent of the population received salaries of less than 50 quetzales per month, that 31 percent were paid from 50 to 100 quetzales, and that only 8 percent earned over 400 quetzales per month. The government-established minimum wage for urban labourers was 1.50 to 1.60 quetzales per day in 1971. Legal working hours cannot exceed eight per day or 48 per week.

Cultural life. Guatemala belongs culturally to the Hispanic–American world, but the presence of the Indian—as already mentioned, at least four-fifths of the population is either Indian or of mixed blood—has given it a distinct accent of its own. Despite the high illiteracy rate, educational opportunities have greatly expanded since World War II in the capital, in cities of the interior, and even in agricultural areas.

Several state institutions promote the arts. The capital city has the Dirección General de Bellas Artes, the National Conservatory of Music, the national orchestra (Orquesta Sinfónica Nacional), the Ballet Guatemala, various museums, and the School of Arts. There is, however, little artistic activity in the provinces. Guatemala has excellent painters and sculptors, many of whom have exhibited and studied abroad. Indian art is a marvel of colour and taste, particularly the handwoven textiles. The Indian pottery, clay, and wood carvings are also of high artistic quality. Traditional dances, music, religious rites, and games have survived in the Indian regions.

Traditional arts

The Universidad de San Carlos de Guatemala is the major intellectual centre. Other scientific and cultural institutions include the Institute of Nutrition of Central America and Panama, the Institute of Anthropology and History, the National Library, the General Archives, and the Society of Geography and History of Guatemala.

The constitution guarantees freedom of press, but this and other guarantees are sometimes suspended. Most of the newspapers are in the capital city. There are 70 radio stations in operation and more than 200,000 receivers. Transistor radios have become very popular, even among rural labourers. There are three television channels.

Prospects for the future. Guatemala faces problems similar to those of many other underdeveloped countries. On the one hand, there is the need to develop the economy, build schools and housing, and improve living conditions. On the other hand, there is the threat to civil peace from the left-wing guerrilla movement that developed in the 1950s in the mountains of the eastern part of the country; the guerrillas have since then appeared in the capital city and other urban centres. Violent deaths, assaults, and kidnappings of high officials have been frequent.

In this continuing crisis, the future of the country is difficult to predict. The government, elected by popular vote, appears to be strong. Nevertheless, while the social evils that foster subversion persist (unjust distribution of the national wealth, illiteracy, inadequate financial resources, lack of confidence on the part of the people in the government), there seems little possibility of a peaceful solution in the near future to the undeclared civil war.

BIBLIOGRAPHY

Geography: Further data is available in the *Diccionario geográfico de Guatemala*, 2 vol. (1961–62, suppl. 1968), published by the INSTITUTO GEOGRAFICO NACIONAL; ALFREDO GUERRA BORGES, *Geografía económica de Guatemala* (1969); G. DENGO, *Estructura geológica, historia tectónica, y morfología de America Central* (1968); and F.W. MCBRYDE, *Cultural and Historical Geography of Southwest Guatemala* (1947). General geographic aspects are covered in M. MONTEFORTE TOLEDO, *Guatemala: Monografía sociologica* (1959); and in N.L. WHETTEN, *Guatemala: The Land and the People* (1961).

Economy and policy: For information on economic development, see the periodical publications of the Banco de Guatemala and of the Dirección General de Estadística; and in the publications of the Secretaría Permenente de Integración Económica Centroamérica (SIECA); the Instituto Centroamericano de Investigación y Tecnología Industrial, Guatemala (ICAITI), and the Consejo Nacional de Planificación Económica. Critical studies on politics and economics may be found in N. AMARO *et al.*, *El reto del desarrollo en Guatemala* (1970); VILLAGRAN-COLON MIJANGOS, *Bases para el desarrollo económico y social de Guatemala* (1966); and K.H. SILVERT, *A Study in Government: Guatemala* (1954).

The social situation: Books on ethnology, anthropology, and demography are abundant, but a basic study may be found in the collection of 29 titles published by the SEMINARIO DE INTEGRACION SOCIAL GUATEMALTECA, such as, RICHARD N. ADAMS *et al.*, *Cultura indígena de Guatemala* (1956); and *Integración social en Guatemala*, 2 vol. (1956–59), collections of articles by several authors. Other social studies are SOL TAX, *Penny Capitalism: A Guatemalan Indian Economy* (1963); R.N. ADAMS, *Encuesta sobre la cultura de los ladinos en Guatemala*, 2nd ed. (1964); and F. TERMER, *Etnología y etnografía de Guatemala* (1957). See also the periodical publications of the Instituto Indigenista Nacional, Guatemala; and *Cuadernos* of the Seminario de Integración Social.

Guerrilla Warfare

Guerrilla warfare is a type of warfare characterized by irregular forces fighting small-scale, limited actions, generally in conjunction with a larger political–military strategy, against orthodox military forces. Guerrillas are usually nondescript in dress, unconventional in weapons and equipment, lack formal supply lines and employ highly unorthodox tactics. In addition to extremely mobile, aggressive operations, these tactics embrace all aspects of psychological warfare, including the use of sabotage and terrorism. Although this type of warfare occurs throughout history, the word guerrilla (the diminutive of Spanish *guerra*, "war") stems from the Duke of Wellington's Iberian campaigns (1809–13), during which Spanish–Portuguese irregulars, or *guerrilleros* (also referred to at the time as partisans and insurgents), helped drive the French from the peninsula. In World War II the word partisan became synonymous with guerrilla; later the word insurgent came into vogue.

Guerrilla warfare is by tradition a weapon of protest employed to rectify real or imagined wrongs levied on a people either by a foreign invader or by the ruling government. As such it may be employed independently or used to complement orthodox military operations, in which case it can be employed either inside enemy territory or in areas that have been seized and occupied by an enemy.

The importance of guerrilla warfare has varied considerably through history. After World War II it came to play a significant role in what has been termed revolutionary or insurgency warfare or what Communists call people's wars and wars of national liberation.

Since World War II, guerrilla warfare has been employed by non-Communist insurgencies in such countries as Indonesia, Cyprus, and Algeria, where it was successful, and by Communist insurgencies in Malaya and the Philippines, where it ultimately failed. In a complementary role, in which the guerrilla force first fights independently and later evolves into an orthodox insurgent army, it has been successfully employed by Communist insurgencies in China, Indochina, and Cuba.

HISTORY

Ancient and medieval chronicles offer countless examples of guerrilla actions, usually of an independent type undertaken by peasant bands and normally resulting in little more than temporary embarrassment to the incumbent ruler or temporary harassment to the invader. These chronicles also describe numerous campaigns undertaken by marauding tribes that practiced an offensive style of warfare often marked with definite guerrilla overtones. The genesis of modern guerrilla warfare, however, is found in the American Revolution, during which the colonists, many of them veterans of Indian fighting, formed loosely knit bands of riflemen that practiced highly unorthodox tactics against the formally trained British redcoats. Despite George Washington's later, more standard approach to warfare, vestiges of the guerrilla tendency remained. In 1780–81 one of the former Indian fighters, Francis ("the Swamp Fox") Marion, organized a ragtag group of guerrillas that complemented orthodox warfare in South Carolina by continual, devastating raids in the rear of British Gen. Charles Cornwallis' lines.

Guerrilla campaigns of the Napoleonic wars

A far more important role, however, was played by Spanish–Portuguese guerrillas in Wellington's campaigns in Portugal and Spain. Throughout this long war, effectively commanded guerrilla bands made life miserable for the French armies by completely disrupting their lines of communication—"by blocking the roads, or intercepting couriers and convoys" and even "waging regular war" (Charles Oman, *A History of the Peninsular War*, 6 vol., 1902). Numbering no more in the field than 20,000 and

> despite their weakness in the open field, their intestine quarrels, their frequent oppression of the countryside, and their ferocity, they rendered good service . . . by pinning down . . . twice their own numbers of good French troops.

In 1812 Napoleon was to suffer heavily from guerrilla strikes during the long retreat from Moscow. Bands of Russian peasants, working with mounted Cossacks, harassed the French until they had been driven out.

Guerrilla warfare, in both its independent and its complementary roles, has been employed extensively since the time of Napoleon. A striking example of the protest role of guerrilla warfare is the Taiping Rebellion (1850–64) in China. Begun by impoverished peasants and by jobless coolie porters, opium smugglers, and pirates, the unsuccessful rebellion against the Manchu dynasty cost an estimated 20,000,000 lives and, in the opinion of some sinologists, constituted one of the great social upheavals of modern times.

Lesser but, nonetheless, significant independent guerrilla actions were fought against the British in India and Africa, the French and Spanish in Morocco, the Turks and Austro-Hungarians in the Balkans, and the Americans in the opening of the West. In 1899–1900 the Boxer Rebellion in China constituted a protest action against a foreign invader (in the form of the Western powers whose influence, ironically, had grown as a result of the Taiping Rebellion), as did both the Philippine insurrection (1899–1902), in which the guerrillas ultimately lost to American regulars, and the South African War (1899–1902), in which the Afrikaners quickly abandoned orthodox tactics in favour of highly mobile, irregular operations undertaken by mounted groups called commandos, which the British regulars defeated only with the greatest difficulty.

Equally impressive is the concurrent record of complementary guerrilla operations. The most successful guerrilla leader in the American Civil War was a Confederate cavalry officer, John Mosby. Leading a small band of mounted volunteers, Mosby so disrupted Union operations by his constant, dashing raids in northern Virginia that Union forces were finally forced to devastate the region in order to deprive the guerrilla force of its base. Mexican guerrillas led by Emiliano Zapata and Pancho Villa played a leading role in the Mexican Revolution.

The static nature of World War I prevented guerrilla warfare on the western front, but subsidiary theatres offered scope for guerrilla activity. In the Middle East a British officer, T.E. Lawrence, led a revolt of Arab tribesmen in a prolonged guerrilla action that claimed the lives of some 35,000 Turkish soldiers and resulted in another 35,000 captured or wounded; the guerrillas finished the war in control of about 100,000 square miles (259,000 square kilometres)—a significant contribution to the British victory in Palestine. In German East Africa (modern Tanzania), a German officer, Lieutenant Colonel Lettow-Vorbeck, led a small force of German regulars supplemented by a few hundred tribesmen in a holding operation against much larger British forces, which could have been used on the western front. Although bereft of supply and physically nearly exhausted, the group had still not surrendered when the war ended.

Guerrilla activity in World War I

Guerrilla fighting of a different nature broke out in southern Ireland, which was in rebellion against British rule. Beginning in Dublin on Easter Monday, 1916, the original insurrection did not prove popular and was instantly put down by the British army garrison. But then the military authorities made a major political and psychological error by court-martialling and condemning to death the 15 principals. The easygoing Irish public was horrified, and the result was a guerrilla war characterized by the most brutal terroristic killings and ambushes, which lasted until 1921.

A different type of guerrilla action was fought in Russia, where in 1918 Lenin's Bolsheviks had taken control of the revolution and were fighting White Russian counterrevolutionary forces supported by various of the great powers, including the United States. This support was probably unwise, since the intervention of foreign powers brought a great wave of patriotism to the Russian masses, many peasants joining partisan movements.

During the interwar period the Communist Party in China and its army, after many vicissitudes and under the leadership of Mao Tse-tung, fought the invading Japanese and, after World War II, wrested control of the country from Chiang Kai-shek's Nationalist government. In Spain the Popular Front left-wing government had to rely primarily on guerrilla forces to hold the Nationalist armies while the government built up conventional forces. The war assumed a distinctively ideological character, the Nationalists being supplied with arms and air power primarily by the Fascist governments of Germany and Italy, the Loyalists being supplied by Russia.

Communist guerrilla activity in World War II

Guerrilla warfare in World War II was also marked with strong ideological overtones. Since Communist parties had been operating, usually clandestinely, in most of the invaded countries, their members were ideally suited for guerrilla warfare. In the West, primarily in France and Italy, the Communists either formed their own bands or joined other bands, such as the French and Belgian maquis, covert organizations engaged in espionage, sabotage, and terrorist activities. Communist cadres in the Balkans and the Far East formed guerrilla bands that usually operated independently, sometimes in competition with guerrillas representing the legal governments, as Tito did in Yugoslavia. Although some of these groups spent as much time eliminating indigenous opposition while consolidating their own hold on the country as in fighting the enemy, they, nonetheless, contributed sufficiently to the war effort to win impressive shipments of arms and equipment from the Western powers—the result of an Allied decision in which the political goal was subordinated to the demands of military strategy. The decision resulted in Communist bands in Yugoslavia, Greece, Burma, Thailand, Indochina, the Philippines, and Indonesia receiving arms from the Allies.

Another important guerrilla action of World War II was fought in the Ukraine. The peasantry, stung by German atrocities, formed into numerous partisan bands. Once these semi-independent bands were organized by the Soviet high command (which never entirely trusted them), they caused widespread and, at times, vital damage to German communications. In the autumn of 1943, in addition to large police and security forces, the German command in the U.S.S.R. was expending 10 percent of its strength—25 field divisions—in fighting the partisans. Although estimates vary, these guerrillas probably killed more than 250,000 German soldiers, while blowing up

thousands of trains and trucks and inflicting an inestimable psychological pressure.

In some countries the Communist guerrilla forces formed in World War II facilitated the quick establishment of Communist regimes. In Yugoslavia the take-over of government was simple and direct, while in other cases, such as Czechoslovakia and China, it was complicated and delayed. In Vietnam it was only partially accomplished; in Malaya and the Philippines it was foiled. Non-Communist insurgencies used guerrilla warfare with considerable success in Cyprus, Kenya, and Algeria. By the early 1970s widespread guerrilla activity was continuing in Indochina (including South Vietnam, Laos, Cambodia, and Thailand). In Latin America the failure of several attempts to emulate the guerrilla campaign that resulted in the overthrow of the Batista regime in Cuba in 1959 led to a concentration on revolutionary activity within the cities, or urban guerrilla warfare, as it came to be termed. The extent to which the intermittent bombings and kidnappings in such countries as Brazil, Argentina, and Guatemala indicate the existence of the discipline, organization, and overall strategy that are the hallmark of guerrilla warfare remains uncertain. But the increasing urbanization of the population does suggest that the cities present the best opportunities for guerrillas to engage in disruption and to engender the lack of confidence in the ability of the government to control the situation that is essential to the success of a guerrilla campaign.

METHODS OF GUERRILLA WARFARE

Strategy and tactics. The broad strategy underlying successful guerrilla warfare is that of protracted harassment accomplished by extremely subtle, flexible tactics designed to wear down the enemy while gaining time either to develop sufficient military strength to defeat him in orthodox battle or to subject him to internal and external political and military pressures sufficient to cause him to seek peace. This strategy embodies political, social, economic, and psychological factors to which the military element is often subordinated. It is essentially a strategy for the morally strong and materially weak.

Writings of Sun-tzu

Many of the essential rules of guerrilla tactics are to be found in *The Art of War* by the Chinese general Sun-tzu (*c.* 350 BC). Sun-tzu instructed his generals in words familiar to successful, latter-day guerrilla leaders: "And therefore I say: Know the enemy, know yourself; your victory will never be endangered. Know the ground, know the weather; your victory will then be total." A successful general "avoids strength and strikes weakness"; the use of tactics based on deception and surprise is the hallmark of a victorious commander (Sun-tzu, *The Art of War*, trans. by S.B. Griffith, 1963).

Sun-tzu's indirect approach was largely ignored in the written commentary on wars of later centuries. Such an approach does appear now and again—Xenophon wrote in the 4th century BC of the importance of psychological factor in warfare, while in the 18th century the French commander Marshal Saxe suggested that it is possible to win a war without fighting battles. Saxe was writing in a time of limited, formal wars, which soon gave way to the total warfare introduced in the Napoleonic era and which was subsequently treated by the Prussian officer-scholar Carl von Clausewitz.

Clausewitz argued that a weaker adversary does not have to destroy the enemy's army in order to gain victory, but rather that he must destroy the other's will to wage war. He argued that partisan warfare could further the wearing process, provided the theatre of operations was large enough, the terrain sufficiently rugged, and the partisans themselves temperamentally suited to this type of fighting. A contemporary, the Cossack Gen. Denis Vasiliyevich Davidov, who led a partisan force during Napoleon's retreat from Moscow, later wrote that this type of warfare "is concerned with the entire area which separates the enemy from his operational base." Its objectives are

> to cut the communication lines, destroy all units and wagons wanting to join up with him, inflict surprise blows on the enemy left without food and cartridges and at the same time block his retreat. This is the real meaning of partisan war (Otto Heilbrunn, *Warfare in the Enemy's Rear*, 1963).

Tactics of T.E. Lawrence

Nearly a century later T.E. Lawrence offered the world a dramatic demonstration of Davidov's definition. Sent to lead dissident Arab tribes in revolt against the Turks, Lawrence followed a Clausewitzian precept by isolating the Arab political aim, which "was unmistakably geographical, to occupy all Arabic-speaking lands in Asia."

Lawrence wrote,

> The Turkish army was an accident, not a target. Our true strategic aim was to seek its weakest link, and bear only on that till time made the mass of it fall. The Arab army must impose the longest possible passive defense on the Turks (this being the most materially expensive form of war) by extending its own front to the maximum. Tactically, it must develop a highly mobile, highly equipped type of force, of the smallest size, and use it successively at distributed points of the Turkish line.

By making the Arabs "an influence, a thing invulnerable, intangible, without front or back, drifting about like a gas," Lawrence would gain "five times the mobility of the Turks [thus] the Arabs could be on terms with them with one-fifth their number."

About the time that Lawrence was incorporating these thoughts into an article for the *Encyclopædia Britannica*, Mao Tse-tung was developing a doctrine of peasant warfare in China. Mao was a young, devoted student of revolution as preached by Marx, practiced by Lenin, and qualified by Mao's own considerable experience. Since 1927 he and a band of comrades had been on the run from the Nationalist Generalissimo Chiang Kai-shek. In the Fukien–Kiangsi borderlands, Mao had helped turn peasants and bandit bands into the first crude Chinese Communist army, one that spent the next eight years fighting for its life against Chiang's forces. Mao's experience had led him to defy his Russian teachers by concluding that the Communist revolution in China could come only from the country peasants, not from the urban proletariat. His theory was tested when pressure from Chiang's armies forced him and his followers to undertake a 6,000-mile (9,656-kilometre) march to the north, to Yen-an, a mountain hideout in Shensi Province.

The rebel leader then began to codify a doctrine of revolutionary warfare. Mao saw two enemies: the Japanese invader and the regular Kuomintang armies headed by Chiang Kai-shek. He looked on a country

> half colonial and half feudal; it is a country that is politically, militarily, and economically backward . . . a vast country with great resources and tremendous population, a country in which the terrain is complicated and the facilities for communication are poor. All these factors favor a protracted war; they all favor the application of mobile [that is, orthodox] warfare and guerrilla operations (Mao Tse-tung, *On Guerrilla Warfare*, trans. by S.B. Griffith, 1961).

Mao's view of the role of guerrilla warfare

Mao came to the conclusion that

> The concept that guerrilla warfare is an end in itself and that guerrilla activities can be divorced from those of the regular forces is incorrect . . . in sum, while we must promote guerrilla warfare as a necessary strategical auxiliary to orthodox operations, we must neither assign it the primary position in our war strategy nor substitute it for mobile and positional warfare as conducted by orthodox forces.

He borrowed freely from Sun-tzu's thesis of the indirect approach:

> Guerrilla strategy must be based primarily on altertness, mobility, and attack. It must be adjusted to the enemy situation, the terrain, and the existing lines of communication, the relative strengths, the weather, and the situation of the people.

It should be used

> to exterminate small forces of the enemy; to harass and weaken large forces; to attack enemy lines of communication; to establish bases capable of supporting independent operations in the enemy's rear; to force the enemy to disperse his strength; and to coordinate all these activities with those of the regular armies on distant battle fronts.

To accomplish these goals, Mao demanded tactics based on surprise and deception:

> In guerrilla warfare, select the tactic of seeming to come from the east and attacking from the west; avoid the solid, at-

tack the hollow; attack, withdraw; deliver a lightning blow, seek a lightning decision.

As opposed to orthodox warfare, which is frequently static, Mao wanted

> constant activity and movement. There is in guerrilla warfare no such thing as a decisive battle; there is nothing comparable to the fixed, passive defense that characterizes orthodox war. In guerrilla warfare, the transformation of a moving situation into a positional defensive situation never arises. The general features of reconnaissance, partial deployment, general deployment, and development of the attack that are usual in mobile warfare are not common in guerrilla war.

Instead of fixed defense, Mao calls for

> alert shifting . . . when the enemy feels the danger of guerrillas, he will generally send troops out to attack them. The guerrillas must consider the situation and decide at what time and at what place they wish to fight. If they find that they cannot fight, they must immediately shift.

Although the guerrilla will defend his own operational bases, these must be abandoned when necessary.

> We must observe the principle, "To gain territory is no cause for joy, and to lose territory is no cause for sorrow."

Such tactics demand

> careful planning . . . those who fight without method do not understand the nature of guerrilla action. A plan is necessary regardless of the size of the unit involved; a prudent plan is as necessary in the case of the squad as in the case of the regiment.

As Lawrence put it, "Guerrilla war is far more intellectual than a bayonet charge."

Good planning depends on superior intelligence, of course, and this can be gained only from the people, who, in turn, must withhold such from the enemy:

> Many people think it impossible for guerrillas to exist for long in the enemy's rear. Such a belief reveals lack of comprehension of the relationship that should exist between the people and the troops. The former may be likened to water and the latter to the fish who inhabit it. How may it be said that these two cannot exist together? It is only undisciplined troops who make the people their enemies and who, like the fish out of its native element, cannot live.

Mao's basic strength came from the people—from the water that produced, then supported, the fish. From the Yen-an haven, his agents went forth to select suitable base areas for organization and consolidation, a process in which volunteers were trained and indoctrinated as agitators and propagandists, who in turn went forth to the countryside to enlist peasant support.

In Mao's scheme of things, this phase merges into one of limited direct action, mainly sabotage and terrorism designed to eliminate members of the opposition, and to gain arms and supplies for the embryo guerrilla force. This expansion phase may last for years, but if it succeeds it merges into a decisive phase: the destruction of the enemy largely with orthodox military forces.

Mao's teachings, though perhaps only partially utilized, nonetheless underlie most of the revolutionary wars fought since World War II. In fact, his doctrine has become a blueprint for the "national wars of liberation" that China and Cuba have promised to foment and support in Asia, Africa, and Central and South America.

Motivation. Fundamental to the revolutionary process is a cause, which unfortunately is not difficult to find in the underdeveloped countries of the world. The cause may assume several guises: to the world it may be presented as liberating a country from the colonial yoke; to the peasant being converted to Communism it may be freedom from serfdom, from oppressive taxation, or from payment of oppressive rents to absentee landlords.

Whether real or artificial, whether inspired by Communism or by virulent nationalism, the political goal is fundamental in motivating people to action. Mao leaves no doubt as to its importance:

> Without a political goal, guerrilla warfare must fail, as it must if its political objectives do not coincide with the aspirations of the people and their sympathy, cooperation, and assistance cannot be gained.

Popular support. The guerrillas' affiliation with the people is constantly stressed in revolutionary writings. Guerrillas spring from the people, who in turn support their spawn, not only by furnishing their sons to the cause but also, when called upon, by furnishing money, food, shelter, refuge, transport, medical aid, intelligence—support that they must attempt to deny the enemy. Although Lawrence called for no more than

> a friendly population, not actively friendly, but sympathetic to the point of not betraying rebel movements to the enemy,

he also wrote that his rebels

> had won a province when the civilians in it had been taught to die for the ideal of freedom: the presence or absence of the enemy was a secondary matter.

Gen. Georgios Grivas, the non-Communist professional soldier who led the Cypriot rebellion, wrote that a guerrilla war stands no chance of success unless it has "the complete and unreserved support of the majority of the country's inhabitants."

Organization. Protracted revolutionary warfare as defined by Mao demands a complicated organization on both the political and the military levels. Mao recommends a clandestine system of parallel hierarchy beginning with the cadre or cellular party structure at the hamlet–village level and proceeding to the top via district, province, and regional command structures.

The tactical organization of guerrilla units varies according to operational demands. Mao called for a guerrilla squad of nine to 11; Grivas employed sabotage groups of four or five. In the Vietnam fighting, the Viet Minh and, later, the Viet Cong ranged from small squads up to battalion and even regimental strengths.

Arms. The guerrilla by necessity employs a wide variety of weapons, some self-manufactured, some captured, and some supplied from outside sources. In the earlier stages of the war, the weapons are usually primitive. Americans in Vietnam have frequently encountered homemade rifles, hand grenades, and Claymore mines; trails booby-trapped with *punji* stakes soaked in urine; and shallow pits lined with nail boards. Nearly every guerrilla war has produced ingenious improvisation, both from necessity and to avoid a cumbersome logistic "tail." Nothing can be simpler to construct and use than a Molotov cocktail or a *plastique* bomb, yet under certain conditions nothing can be more effective.

Rural- and urban-based guerrilla campaigns

Terrain. It is axiomatic to Mao and his followers that revolution begins in the country. Once sufficient base and guerrilla areas are established, it is possible to extend operations to include cities and lines of communication susceptible to attack. This rural strategy is influenced by such factors as the political goal, geography, the insurgent strength, and the government's strength.

Such was the combination of these in Russia that the 1917 revolution was decided in the cities and only later successfully defended in the country by orthodox Communist armies employing guerrilla forces in a complementary role. The Irish Rebellion was also fought largely in the cities, and General Grivas opened the semisuccessful Cypriot rebellion with a few combat groups especially trained in terrorist–sabotage tactics. As his strength grew, he resorted to guerrilla warfare across the entire island. On the basis of this and other examples, Grivas later argued that, contrary to Mao's teachings, guerrilla warfare need not be rural based and, further, that it is sometimes possible for guerrilla warfare alone to accomplish the political objective.

Terror. One of the most hideous characteristics of guerrilla warfare is the use of terror: assassination, a hand grenade thrown into a crowd, an indiscriminate bombing—actions familiar to any insurgency.

Terror is used for several reasons: to focus world attention on the rebel cause, to eliminate opposition leaders, to paralyze normal government activity, to intimidate the general populace, and to keep one's own guerrillas from defecting. It is difficult to assess the psychological impact of terrorist tactics on the general population. It would seem that even those sympathetic to the guerrilla cause may be alienated by the indiscriminate use of terrorism. The defending forces, moreover, may reply in kind, so that the population is subject to terror from both sides.

The question of political sympathy or loyalty may then become irrelevant, the local populace being ready to cooperate with whichever side is in control at a particular moment.

Sanctuary. Guerrilla forces cannot fight all the time. They must control safe areas to which they can retire, voluntarily or involuntarily, for rest, recuperation, and repair of arms, clothing, and equipment and where recruits can be indoctrinated, trained, and equipped. Such areas traditionally are located in remote, rugged terrain, usually mountains, forests, and jungles; but guerrilla areas may be developed in which whole villages and hamlets serve a sanctuary role. The sea can also provide sanctuary, as in the Peninsular War, when the British navy succored Wellington's cooperating Portuguese–Spanish guerrillas.

Sanctuary may also be provided by sympathetic neighbouring countries: during the Greek Civil War (1946–49) the Communist guerrillas frequently retreated into Yugoslavia, which offered not only physical sanctuary but also arms and supplies; and it was only after the Yugoslavs closed the border that the guerrillas were finally defeated, though not for that reason alone. Similarly, Ho Chi Minh's guerrillas, in the later stages of the war against France, relied on China for refuge, training, and supply of arms and equipment.

The people offer a final form of sanctuary. At one time during the Cypriot revolt, Grivas was surrounded by a British force for nearly two months but, though spotted, was repeatedly able to escape capture or death. An Algerian rebel leader was able to install himself within 200 yards of the army commandant's headquarters in Algiers, avoiding capture for several months. In South Vietnam in 1964 American officials discovered that several thousand supposedly government-controlled, "fortified" hamlets were in fact controlled by Viet Cong guerrillas "who often used them for supply and rest havens" (Staff of the Senate Republican Policy Committee, *The War in Vietnam*, 1967).

OTHER ASPECTS OF GUERRILLA WARFARE

Guerrilla forces. *Leaders.* The unusual requirements of guerrilla warfare call for outstanding leadership at all levels if a guerrilla force is to survive and prosper. The vicissitudes of these wars demand a leader not only endowed with extraordinary intelligence and courage but also buttressed by an almost fanatic belief in himself and his cause. Lenin, Trotsky, Lawrence, Mao, Tito, the Filipino Luis Taruc, the Kenyan Jomo Kenyatta, Ho Chi Minh, Vo Nguyen Giap, the Algerian Ahmed Ben-Bella, Castro, Ernesto "Che" Guevara—these and dozens of their lieutenants at lower levels have all been unusual, unorthodox personalities, generally with civilian backgrounds. But all were able to attract followers, to organize them, and to instill a disciplined zeal matched only in the most elite military organizations.

Recruits. Selectivity is the key to effective guerrilla recruitment. The guerrilla recruit must be resourceful and enduring and must be committed totally to the cause if he is to withstand the hardships and dangers that guerrilla fighting involves. The strength of a guerrilla movement is thus directly related to the degree to which the objectives of the campaign can evoke a response from youths of military age. Historically, the cause has invariably been a desire for national independence and autonomy, sometimes combined with an ideological commitment to Communism or the overthrow of corrupt and repressive regimes or both. Recruitment to such causes has rarely presented much difficulty to guerrilla leaders, although, in those cases in which the conflict has been large-scale and extended over a long period of time, it has been necessary to abandon selectivity and resort to conscription. Such has been the case in Indochina, where Communist recruiting normally begins at the village level, generally by inducing peasant candidates to join one or more front groups and participate, if only indirectly, in the war effort. After exposure to political indoctrination, the candidate joins the village guerrilla cell, after which he can be promoted to the regional and regular forces.

Use of conscription

Discipline. Since it is essential for the guerrilla to win and retain popular support, he is also taught to practice circumspect behaviour when among the people. Communist leaders in China, Cuba, and Vietnam have drawn up lengthy codes of individual behaviour: the Chinese guerrilla, for example, was required to pay a peasant for food, to respect his property, and not to offend propriety by undressing in front of a peasant woman.

It is questionable to what depth party-imposed discipline descends in the average Communist guerrilla. Unquestionably, the hard-core guerrilla practices an almost ascetic association with the people, while approaching his military tasks with dogged determination. But, judging from interrogations of Viet Cong guerrilla prisoners and from the number of Viet Cong defectors, the guerrilla's discipline varies as ideological beliefs ebb and flow in the physical and moral tides of war.

Counterguerrilla warfare. In waging this type of warfare, which calls for location, isolation, and elimination of the entire guerrilla apparatus (political as well as military), orthodox military commanders have employed and continue to employ a wide range of weapons and tactics that, judged by results, are more appropriate to a conventional-warfare situation. Wholesale bombings and mass artillery interdictions of suspected sanctuary areas, division- and corps-strength "sweeping" operations in which only a few guerrillas are captured or killed but whole villages are destroyed, the establishment of defended but isolated chains of military outposts, mass arrests and interrogations—each has failed to achieve triumphs.

Throughout history, nations have impelled insurgencies because of political errors, and military commanders have failed to quell insurgencies because of political ignorance. In Communist revolutionary warfare, especially, the political factor is paramount. If the Communist guerrilla is not supported by the people—if he is not a fish in the sea of humanity—he cannot effectively operate for any length of time. Consequently, the government must win the people's support, both to deprive the guerrilla of this support and to obtain information on which to base tactics of destruction. It is not enough to break up guerrilla bands and kill individual guerrillas. A government can claim victory only when the subversive organization behind each level of an insurgency has been destroyed and when viable government has been achieved.

Mixed strategy of counterguerrilla warfare

Such counterinsurgency campaigns as those conducted in the Philippines and in Malaya prove that the Communist guerrilla ultimately can be defeated (but not necessarily eliminated). The means of defeat, however, lie only in a patient and judicious application of a host of civil and military measures, involving social and economic reform, effective policing, and military security. Although in the course of a counterinsurgency campaign one or another of these factors may assume a temporary supremacy, in the end each must remain integral to an overall political consideration.

Indeed, political realism is the first essential in conducting a counterinsurgency: the recognition of weakness as well as strength, of failure as well as success. An insurgency indicates a breakdown of government in that a minority is able to defy law and order while coercing others to offer either active or passive support to the cause. The opening phase of an insurgency, in which subversion is supported by selective terrorism, must be met by specific governmental measures, both covert and overt. Because this phase is generally covert, the government, usually the police, must practice considerable subtlety in a difficult environment in which internal weakness, ineptness, or corruption is at work. If the insurgency is not contained at this level it usually flares into the second, "armed struggle" phase, which brings guerrilla warfare into the open.

In the opening phase of an insurgency, a government is usually on the defensive. In Malaya this was a period in which the government was able to prevent the enemy from taking over and to keep the insurgency from escalating. The general strategy was security, both by maintaining police functions and, militarily, by splitting up (but not attempting to destroy) the larger guerrilla units. These

holding operations gave the government time to marshal its forces (not just police and military) in order to fight the second, or offensive, phase, in which the enemy's power was broken, and, finally, the third, or victory, phase, which destroyed the last remnants of guerrilla forces while establishing a stable, independent government.

One veteran of the Malayan campaign ascribes the government's success to certain basic principles, which he holds essential for the conduct of any counterinsurgency: (1) the government must have a clear political aim, ideally "to establish and maintain a free, independent and united country which is politically and economically stable and viable"; (2) in ferreting out, neutralizing, and destroying guerrillas, the government, no matter how tempted, must function in accordance with law and with a carefully developed counterinsurgency plan, which grants priority to defeating the political subversion, not the guerrillas per se; and, (3) finally, in fighting the offensive phase the government must first develop base areas before commencing aggressive tactics (Robert Thompson, *Defeating Communist Insurgency*, 1966).

These principles need not unduly restrict the counterguerrilla efforts. Most authorities agree that emergency regulations, often harsh, must be legally invoked. In Malaya these included compulsory census, an enforceable identity-card system, suspension of habeas corpus (but with carefully publicized safeguards), permission to search private property without a warrant, the death sentence for persons caught with unauthorized weapons, harsh sentences for those aiding the Communists, flexible power of curfew; later extraordinary measures included the right to shoot on sight in prohibited areas, the right to resettle whole villages, and the right to control food distribution with harsh penalties, including death, for those found guilty of aiding the enemy.

Such regulations, or course, are not attractive. If indiscriminately applied, as, unfortunately, is sometimes the case, they will lead to an increasing alienation of the civil population from the government. When properly applied, however, they will greatly aid the police and military forces in their essential mission of providing security to the civil populace, which, in turn, will then feel more free to provide essential information on which to base further counterguerrilla operations.

Holding and clearing operations

The exact nature of such operations must vary in accordance with the enemy's strength and the area concerned. The first priority of government is to re-establish law and order, which, in a rural area, means revitalizing the rural police function. The military effort, the strength of which is dictated by necessity, concentrates on clearing operations, designed to break up and disperse large guerrilla formations, then to keep them deprived of the initiative by small-unit tactics, mainly patrols and ambushes based on valid intelligence. The clearing operation is followed by the holding operation, which is designed to "restore government authority . . . and to establish a firm security framework" (Thompson, *op. cit.*). The holding operation is the period of "winning the hearts and minds" of the people, first by providing security, which will be maintained by strategic hamlets defended by organized hamlet militias working in conjunction with government forces where necessary, and second by providing social reforms (land reform, schools, hospitals, community projects) that will identify the government with the people's best interests. Once won over, the people will deprive the guerrillas of vital support, besides furnishing information necessary for police and military forces to penetrate and destroy the local insurgent organization.

The clearing and holding operations provide the key to successful counterguerrilla warfare. When they have been carefully applied, as in Malaya, they have proved successful; when applied quantitatively, as in Vietnam, they have in large part failed. Even under the most favourable circumstances, most governments lack the necessary civil, police, and military resources to carry out clear and hold operations simultaneously in all areas. For this reason, the military effort may have to extend to secondary operations in lower priority areas. These are designed to keep the guerrilla off balance until the civil effort can be enlarged. Such operations may include large-scale sweep and clear actions, in which large numbers of aircraft and helicopters are used; they may include long-term, deep-penetration operations, in which units are parachuted into guerrilla sanctuaries and supplied by airdrop while establishing and maintaining permanent ambushes, sometimes with the aid of friendly tribes.

Such may be the strength of the insurgency and the weakness of the legal government that outside aid is called for, as happened in Vietnam. Unless limited to supply, technical training, and professional advice, outside aid may well prove a two-edged sword. If the donor government underestimates the dimensions of the conflict, as happened with the United States in the case of Vietnam, it is persuaded to a military intervention that, by escalating to the extent needed for victory, tends to take over the war from the host government, thus widening the gulf between the people and their government and providing the guerrillas with propaganda for the charge of imperialist aggression.

Legal status. For understandable reasons, the orthodox military commander has always placed the guerrilla in an extralegal status. After the British were stung several times by Francis Marion in the Revolutionary War, they complained that he fought neither "like a gentleman" nor like "a Christian." Napoleon's marshals on the Spanish peninsula were driven to violent reprisals against Spanish–Portuguese guerrillas, with the result that for every guerrilla shot a French prisoner paid with his life, a "barbarous system" finally concluded by mutual agreement. The problem arose again in the American Civil War; when Gen. Eleazar A. Paine, the Union commander in western Kentucky, was unduly harassed by guerrillas, he published this proclamation:

> I shall shoot every guerrilla taken in my district, and if your Southern brethren retaliate by shooting a Federal soldier, I will walk out five of your rich bankers, and cotton men, and make you kneel down and shoot them. I will do it, so help me God" (Richard Bennett, *The Black and Tans*, 1959).

Rules applicable to guerrillas

The Brussels international conference of 1874 provided that, in order to be recognized as lawful belligerents, guerrillas must answer to a specific commander, wear a distinctive badge, carry arms openly, and conform in operations to the laws and customs of war. The Hague conferences on the rules of land warfare in 1899 and 1907 adopted this definition with a few modifications, and it is also contained in the Geneva Conventions (1949) on the laws of war.

The Hague ruling has not been complied with, mainly because conformance would nullify the advantages of guerrilla warfare but also because sabotage and terrorist tactics often breed brutal reprisals. The guerrilla has invariably been held fair game for torture or for execution without trial. As in the Peninsular War of the early 19th century, the guerrilla, unable to expect just treatment, has continued to render unjust treatment, a cycle of horror reaching its zenith in the Spanish Civil War, in the partisan actions of World War II, and in Vietnam.

BIBLIOGRAPHY. No definitive history of guerrilla warfare exists. Nearly all ancient chroniclers offer examples of guerrilla warfare, if only in passing, as do most classical and medieval historians. In addition to the writings of Theodor Mommsen, Charles W. Oman, J.B. Bury, A.R. Burn, and John Beeler, see REGINALD HARGREAVES, *Beyond the Rubicon: A History of Early Rome* (1966); FERDINAND SCHEVILL, *History of the Balkan Peninsula, from the Earliest Times to the Present Day* (1922, reprinted 1966); J.E. MORRIS, *The Welsh Wars of Edward I* (1901, reprinted 1969); R.C. SMAIL, *Crusading Warfare, 1097–1193* (1956); and EDOUARD PERROY, *La Guerre de Cent Ans* (1945; Eng. trans., *The Hundred Years War*, 1951). Also helpful are general military histories such as JOHN FORTESCUE, *A History of the British Army*, 14 vol. (1899–1930; 6 vol. of maps and plans, 1906–30); J.F.C. FULLER, *The Decisive Battles of the Western World*, 3 vol. (1954–56); R.A. PRESTON and SYDNEY F. WISE, *Men in Arms*, 2nd rev. ed. (1970); CORRELLI BARNETT, *Britain and Her Army, 1509–1970* (1970); RUSSELL WEIGLEY, *History of the United States Army* (1967); and R.D. HEINL, *Soldiers of the Sea* (1962). Lesser known but invaluable works include C.E. CALLWELL, *Small Wars*, 3rd ed. (1906); and CHARLES GWYNN, *Imperial Policing*, 2nd ed.

(1936). For the American Revolution, see especially CHRISTOPHER WARD, *The War of the Revolution*, 2 vol. (1952); and JOHN ALDEN, *The South in the Revolution, 1763–1789* (1957). Studies of more recent guerrilla wars number in the hundreds, and only a few can be mentioned. General studies include M.R.D. FOOT, *SOE in France* (1966); OTTO HEILBRUNN, *Warfare in the Enemy's Rear* (1963); DAVID GALULA, *Counterinsurgency Warfare* (1964); CHARLES THAYER, *Guerrilla* (1963); and GEORGE TANHAM, *Communist Revolutionary Warfare: The Vietminh in Indochina*, rev. ed. (1967). The following studies of specific actions are recommended: LEON WOLFF, *Little Brown Brother: How the United States Purchased and Pacified the Philippine Islands at the Century's Turn* (1961); RONALD ATKIN, *Revolution! Mexico, 1910–1920* (1969); T.E. LAWRENCE, *Seven Pillars of Wisdom* (1935, reprinted 1966); EDGAR HOLT, *Protest in Arms: The Irish Troubles, 1916–1923* (1960); LEONARD MOSLEY, *Duel for Kilimanjaro* (1963); DAVID WOOLMAN, *Rebels in the Rif* (1968); FITZROY MacLEAN, *Disputed Barricade: The Life and Times of Josip Broz-Tito, Marshall of Jugoslavia* (1957); JOHN ARMSTRONG (ed.), *Soviet Partisans in World War II* (1964); MAO TSE-TUNG, *On Guerrilla Warfare* (1961); N.D. (R.B.A.)

Guevara, "Che"

A prominent figure in the Cuban Revolution of the 1950s and '60s and an important official in Fidel Castro's first Communist government there, Ernesto "Che" Guevara exerted an important influence on the theories and tactics of guerrilla warfare.

Lee Lockwood—Black Star

Guevara.

Ernesto Guevara de la Serna was born in Rosario, Argentina, on June 14, 1928. The eldest of five children in a middle class family of Spanish-Irish descent and leftist leanings, Ernesto was known for his dynamic and radical views even as a boy. Though suffering from the crippling bouts of asthma that were to handicap him throughout his life, he excelled as an athlete and a scholar, completing his medical studies in record time in March 1953. He spent many of his holidays travelling in various countries of Latin America, and his first-hand observations of their economic and political problems—specifically of the great poverty of its masses—convinced Guevara that the only solution lay in violent revolution. His travels also taught him to look upon Latin America not as a collection of separate nations but as a cultural and economic entity, the liberation of which would require an intercontinental strategy.

In 1953 Guevara went to Guatemala, where Colonel Jacobo Arbenz Guzmán headed a progressive régime that, through various reforms, especially land reform, was attempting to bring about a social revolution. Around this time Guevara acquired his famous nickname, "Che," from a verbal mannerism of Argentines who punctuate their speech with the interjection *che*.

The overthrow of the Arbenz régime by a United States Central Intelligence Agency-backed coup in 1954 persuaded Che that the United States would always oppose progressive leftist governments in Latin America and in the other developing countries of the world. This conviction, which he later expressed in many of his speeches and writings, became the cornerstone of his plans to bring about Socialism through a world revolution. Che left Guatemala for Mexico, where he met the Cuban brothers, Fidel and Raúl Castro, political exiles who were preparing to return to Cuba with an expeditionary force in an attempt to overthrow the dictatorship of Fulgencio Batista. Che joined Castro's force and began to train for guerrilla warfare. On November 25, 1956, Che and 82 other young men left Mexico on the yacht "Granma" and landed in the Cuban province of Oriente a few days later. Immediately detected by Batista's army, they were almost wiped out in the first encounter; the few survivors, including the wounded Che, were able to reach the mountain chain known as the Sierra Maestra, where they set up the nucleus of a guerrilla army. The rebels slowly gained in strength, seizing weapons from the enemy, winning support and new recruits from the local peasantry and the intellectuals and workers in the cities. Che exhibited great courage and skill in combat and soon became one of Castro's ablest and most trusted aides. In July 1957 he was made a major and appointed leader of the rebel army's second column. Che recorded the two years spent in overthrowing Batista's government in a detailed account entitled *Pasajes de la guerra revolucionaria* (English trans., *Reminiscences of the Cuban Revolutionary War*, 1968), first published in 1963.

Association with Castro

After Castro's victorious troops entered Havana on January 2, 1959, and established a progressive government along Marxist lines, Che became a Cuban citizen, divorced his Peruvian wife, Hilda Gadea, by whom he had one daughter, and married a member of Fidel's army, Aleida March, by whom he had four children. He became as prominent in the new government as he had been in the revolutionary army, representing Cuba on many commercial missions and delegations to African, Asian, and Socialist countries. He also became well-known in the West for his outspoken opposition to all forms of imperialism and neocolonialism and for his fiery attacks on U.S. foreign policy in Africa, Asia, and especially Latin America. An active participant in the economic and social reforms brought about by Castro's government, he occupied such important posts in his adopted country as chief of the Industrial Department of the National Institute of Agrarian Reform, president of the National Bank of Cuba, and minister of industry. During this period, he defined Cuba's policies and his own views in many speeches, articles, letters, and essays, the most important of which are "El socialismo y el hombre en Cuba" (1965; "Man and Socialism in Cuba," 1967), which is an examination of Cuba's new brand of Communism, and a highly influential manual on guerrilla strategy and tactics (Eng. trans., *Guerrilla Warfare*, 1961).

Disappearance from public life

After April 1965 Che dropped out of public life and then vanished altogether. His disappearance was variously attributed to the relative failure of the industrialization scheme he had advocated while minister of industry, to pressures exerted on Castro by Soviet officials disapproving of Che's pro-Chinese Communist outlook, and to serious differences between Che and the Cuban leadership regarding Cuba's economic development and ideological line. In October of that year, Castro revealed a letter written to him by Che some months earlier in which Che reaffirmed his enduring solidarity with the

Cuban Revolution but explained that "other nations are calling for the help of my modest efforts" and that, having "always identified with the world outcome of our Revolution," he had decided to go and fight as a guerrilla in other liberation struggles being waged in different parts of the world.

Che's movements and whereabouts remained a secret for the next two years, although he sent a letter that was read aloud at the first conference of the Tricontinental Solidarity Organization, held in Havana in April 1967. In this letter, known as the "Message to the Tricontinental," Che analyzed the world situation and called for all-out war against imperialism and the forces of reaction. During this period, Che may have gone to North Vietnam and to several countries in Latin America; it is also probable that he secretly returned to Cuba in 1966, but the facts have never been established positively. It was later learned that he had spent some time in the Congo with other Cuban guerrilla fighters, helping to organize the Patrice Lumumba Battalion, which fought in the civil war there.

In the autumn of 1966, Che went to Bolivia, incognito, to create and lead a guerrilla group in the region of Santa Cruz. He spent the next 11 months training the Bolivian guerrillas and fighting with them, meticulously recording their progress and setbacks in a diary that was found and published after his death. On October 8, 1967, the group was encircled by a special detachment of the Bolivian Army and almost annihilated. Che was captured after being wounded and shot soon afterward.

Capture and execution

While pictures of the dead guerrilla chief were being circulated and the circumstances of his death were being debated, Che's legend began to spread. Demonstrations in protest against his death occurred in many parts of the world, and articles, tributes, and poems were written about his adventurous life and tragic death. Even those liberal elements that felt little sympathy with Che's militantly Communist ideals during his lifetime expressed regret for his death and admiration for his integrity and spirit of self-sacrifice. He is singled out from other revolutionaries by many young people in the West because he rejected a comfortable middle class background to fight for those who were deprived of political power and economic stability. An intellectual and a thinker, Che believed in putting his theories into action. Called "the most complete human being of our age" by the French philosopher Jean-Paul Sartre, Che's supporters believe he may yet prove to be the most important thinker and activist in Latin America since Simón Bolívar, leader of the South American independence movement.

Guicciardini, Francesco

The *Storia d'Italia* ("History of Italy") of the Italian historian and statesman Francesco Guicciardini has remained one of the monuments of Italian historiography. Written by a statesman closely associated with many of the events he described, and by a historian who in his critical use of evidence followed and surpassed his humanist predecessors, the work is the most important contemporary history of Italy during the Italian wars.

Francesco Guicciardini was born at Florence on March 6, 1483. He came of an aristocratic family that played a prominent role under Lorenzo de' Medici ("The Magnificent"). From 1498 to 1505 Guicciardini studied civil law at Florence, Ferrara, and Padua and subsequently set up legal practice at Florence. In 1508 he married Maria, daughter of Alamanno Salviati. In the same year he began to write his family memoirs and his *Storie fiorentine* ("History of Florence") from 1378 to 1509. The latter constitutes one of the major sources for the history of the republican regime after 1494; it reveals Guicciardini's gifts for historical analysis and narrative. Elected in 1511 as Florentine ambassador to King Ferdinand of Aragon, he was at the Spanish court when in 1512 the Florentines restored the Medici, exiled in 1494, under the pressure of Spanish troops. On his return to Florence in 1514, he resumed his legal practice; in 1514 he was member of the Otto di Balìa, who were in charge of internal security, and in 1515 of the Signoria, the highest magistracy. In 1513 Cardinal Giovanni de' Medici became Pope Leo X; in 1516 he appointed Guicciardini governor of Modena, and in 1517 also of Reggio. Until 1534 Guicciardini served the papacy almost continuously.

Guicciardini, oil painting by an unknown artist. In the Galleria degli Uffizi, Florence.

Appointed governor of papal states

As governor of an exposed and recently acquired part of the papal states, in which he had to face internal disorders as well as external dangers, Guicciardini showed outstanding administrative gifts. His severe and sometimes ruthless measures were effective in restoring order but also caused him unpopularity. The outbreak of the war in northern Italy between King Francis I of Spain and the Holy Roman emperor Charles V, with whom Leo had concluded an alliance, turned Reggio into a military outpost of the papal states, and in July 1521 Guicciardini was appointed commissioner general of the papal army. During this time, Guicciardini became also a prolific political writer, composing numerous memoranda and treatises, mostly in the form of discourses on political problems of the day, often in connection with his official duties. A number of them deal with the government of Florence, on which he also wrote, between 1521 and 1525, the *Dialogo del reggimento di Firenze* ("Dialogue on the government of Florence"). In this he advocates an aristocratic regime on the Venetian model as the ideal constitution for his city. In his capacity as commissioner general, he prevented, by his courage and determination, Parma from falling into French hands in December 1521. But the death of Leo X in the same month jeopardized his career temporarily; after the election of Adrian VI, he was at first deprived of the governorships of Modena and Reggio but recovered them at the end of 1522. In 1523, after Adrian's death, he had to defend both cities against their original ruler, the Duke of Ferrara. Reggio capitulated, but Modena was held by Guicciardini against superior odds. After the election of Cardinal Giulio de' Medici as Clement VII, he earned his reward by being appointed, in 1524, president of the Romagna, the northernmost papal province. In the critical situation after the battle of Pavia, when the army of the emperor Charles V was preparing to advance south, Guicciardini conveyed to the Pope much advice, and in January 1526 he was summoned to Rome. There he

played a prominent role in the papal counsels, advocating an alliance with France against Charles V. The resulting League of Cognac, concluded in May 1526, was to no small extent his work, and in June he was appointed papal lieutenant general with the army of the league. The failure of the league to prevent the imperial army under the duke of Bourbon from advancing on Florence and Rome involved him once more in the fate of his native city.

The danger in which Florence found itself as a result of Clement's policy had increased the opposition to the Medici regime. When, on the arrival of the Duke of Urbino with his army near Florence, the Medici left the city to welcome him (April 26, 1527), a revolt broke out. Guicciardini, who had arrived shortly before to help protect the city, succeeded in preventing the Duke from assaulting the palace of the Signoria by negotiating a free pardon in return for surrender. A few days later, Bourbon's army captured Rome, and this was followed by the expulsion of the Medici from Florence and the restoration of republican government in that city.

The collapse of Pope Clement's authority in Rome rendered Guicciardini's position as his lieutenant general untenable, while his long association with the Medici made him suspect in republican Florence. The victory of the intransigent republican faction and the fall of the gonfalonier Niccolò Capponi, who had been trying to come to terms with the Pope (April 1529), followed by the advance of the imperial army on the city, endangered Guicciardini's position and, in September 1529, he left Florentine territory for the papal court. Thereafter he fully supported Clement's bid for a Medicean restoration in Florence, while seeking to obtain favourable conditions for the Florentines. In March 1530 he was condemned as a rebel at Florence. Between 1528 and 1530 Guicciardini worked on his second history of Florence and compiled the most concise and varied expression of his views on society and politics in his collection of maxims and observations, the *Ricordi*. His political thought is frequently akin to, and sometimes more radical than, that of his friend Niccolò Machiavelli, with whom he shares, despite his long service with the papacy, a criticism of the contemporary church. He disagreed, however, in his *Considerazioni intorno ai "Discorsi" del Machiavelli* ("Considerations on the 'Discourses' of Machiavelli," *c.* 1530), with Machiavelli's interpretation of Roman history as evidence for a political science. After the city's surrender, he returned as papal representative and took a leading part in the persecution of the republicans. In 1531 Clement appointed him governor of Bologna, but he lost this post after the accession of Paul III in 1534. Back in Florence, he acted as legal adviser to Duke Alessandro de' Medici and began work on a history of Italy during his lieutenantship that, redrafted during the following years, became the nucleus of his far more ambitious *Storia d'Italia* (*History of Italy*) from 1494 to 1534. He began the work probably in 1536; the final revision was not completed when he died.

His history of Italy

After the murder of Alessandro in 1537, he helped secure the succession for Cosimo, probably hoping to limit the ducal powers which he considered excessive. Disappointed in his hopes and personal ambitions, although still holding high office under the new ruler, he devoted the last years of his life, in his villa at S. Margherita a Montici, to the composition of his *Storia d'Italia*, the crowning achievement of his life. He died on May 22, 1540.

BIBLIOGRAPHY. *La Storia d'Italia* was edited by ALESSANDRO GHERARDI, 4 vol. (1919); and by CONSTANTINO PANIGADA in *Scrittori d'Italia*, 5 vol. (1929); most of Guicciardini's other works were published in 10 vol. between 1857 and 1867 by G. CANESTRINI in *Opere inedite*. New editions of the *Storie fiorentine*, the *Dialogo del reggimento di Firenze* and other political treatises, the *Ricordi*, the family memoirs and diaries, by ROBERTO PALMAROCCHI, are included in *Scrittori d'Italia* (1931–36). The fundamental critical edition of the *Ricordi* is by RAFFAELE SPONGANO (1951); the draft of the second history of Florence was edited for the first time by ROBERTO RIDOLFI under the title *Cose fiorentine* (1945). There are English translations of the *Storia d'Italia* by SIDNEY ALEXANDER (1968, abridged); of the *Storie fiorentine* (1970) and of the *Ricordi* (*Maxims and Reflections of a Renaissance Statesman*, 1965, introd. by NICOLAI RUBINSTEIN), both by MARIO DOMANDI; of the *Ricordi*, the *Considerazioni intorno ai "Discorsi" del Machiavelli*, and the diaries by MARGARET GRAYSON (*Selected Writings*, 1965, introd. by CECIL GRAYSON). The new edition of Guicciardini's letters (*Carteggi*), in the *Fonti per la storia d'Italia*, is almost completed (1938–70): vol. 1–4 (1499–1521) ed. by ROBERTO PALMAROCCHI; vol. 5–16 (1522–40) by P.G. RICCI. The definitive biography is ROBERTO RIDOLFI, *Vita di Francesco Guicciardini* (1960; Eng. trans., 1967); see also ANDRE OTETEA, *François Guichardin, sa vie publique et sa pensée politique* (1926). On Guicciardini as historian and political thinker, see FELIX GILBERT, *Machiavelli and Guicciardini: Politics and History in Sixteenth-Century Florence* (1965).

(N.Ru.)

Guinea

The Republic of Guinea (République du Guinée) is an independent nation of West Africa. It is bordered by the Atlantic Ocean to the west; by Portuguese Guinea, Senegal, and Mali to the north and east; by the Ivory Coast to the southeast; and by Liberia and Sierra Leone to the south. Its area of 94,925 square miles (245,857 square kilometres) supports a largely rural population of more than 4,000,000. The national capital of Conakry is the country's main port and its only city.

In 1958 Guinea became the second sub-Saharan nation after Ghana and the third French African possession after Tunisia and Morocco to achieve independence. Beset with difficulties of adjustment and reorganization, the nation successfully avoided being overwhelmed by internal discord or external pressures under the leadership of its president Ahmed Sékou Touré and his Parti Démocratique de Guinée. Since the 1960s Guinea has continued to occupy a special position among African states in its unqualified rejection of colonial control or economic domination by more developed nations. A militant pan-Africanist stance on the continent, "positive neutralism" in the Cold War, and a unique articulation of African Socialism and cultural revolution in internal affairs contribute to Guinea's image as one of the most radical experiments in social and political development in West Africa. (For history, see WEST AFRICA, HISTORY OF. For related physical features, see GAMBIA RIVER, NIGER RIVER, and SENEGAL RIVER.)

The landscape. *Relief.* There are four geographic regions; Lower Guinea, the Fouta Djallon, Upper Guinea, and the Forest Region. Lower Guinea includes the coast and coastal plain. The irregular coast is marked by drowned river valleys that form inlets and tidal estuaries and by offshore islands. There are few lagoons or sandbars, but the estuaries are muddy and lined with mangrove swamps.

Immediately inland the gently rolling coastal plain rises to the east, being broken by rocky spurs of the Fouta Djallon highlands in the north at Cape Verga and in the south at the Kaloum Peninsula. Between 30 and 50 miles wide, the plain is wider in the south than the north. Its base rocks of granite and gneiss (coarse-grained rock containing bands of minerals) are covered with laterite (red soil with a high content of iron oxides and aluminum hydroxide) and sandstone gravel.

The Fouta Djallon highlands rise sharply from the coastal plain in a series of abrupt faults. More than 5,000 square miles of the highlands' total extent of 30,000 square miles lie above 3,000 feet. The enormous sandstone block is comprised of level plateaus broken by deeply incised valleys and dotted with dykes or peaks of igneous rock, such as the Kakoulima Massif, which attains 3,273 feet (998 metres) northeast of Conakry. The highest point in the highlands, Mt. Loura, rises to 4,970 feet (1,515 metres) near the town of Mali in the north.

Upper Guinea is comprised of the Niger Plains, which slope northeastward toward the Sahara. The flat relief is broken by rounded granite hills and outliers of the Fouta Djallon. Composed of granite, gneiss, schist (crystalline rock), and quartzite, the region has an average elevation of about 1,000 feet.

The Forest Region, or Guinea Highlands, is an isolated area of hills in the country's southeastern corner. The region attains 5,747 feet (1,752 metres) at Mt. Nimba, which rises at the borders of Guinea, Liberia, and the Ivory Coast. The area is composed of the same rocks as those of Upper Guinea.

Three major West African rivers

Drainage and soils. The Fouta Djallon is the source of West Africa's three major rivers. The Niger River and several tributaries, including the Tinkisso, Milo, and Sankarani, rise in the highlands and flow in a general northeast direction across Upper Guinea to Mali. The Bafing and Bakoye rivers, headwaters of the Sénégal River, flow northward into Senegal before uniting to form the main river. The Gambia River flows northwestward before crossing Senegal and Gambia.

The Fouta Djallon also gives rise to numerous smaller rivers, such as the Fatala, Konkouré, and Kolenté, which flow westward across the coastal plain to enter the Atlantic. The Forest Region generally drains to the southwest through Sierra Leone and Liberia. The St. Paul River enters the Atlantic at Monrovia, Liberia, and the Moa River has its mouth at Sulima, Sierra Leone.

The most common soils are formed of hydrated aluminum silicates and other materials that often concretize into hard iron-rich conglomerates called laterites. In the northeast, sandy brown soils predominate, while along the coast black, heavy clay soils accumulate in the backwaters. There are alluvial soils along the major rivers. Soil conservation is extremely important because most soils are thin, and the heavy rainfall causes much erosion.

Climate. The average temperature of Guinea is more than 68° F (20° C). There are two alternating seasons—a dry season (November through March) and a wet season (April through October). The low-pressure zone caused by the summer solstice and its rapidly rising humid air brings the June rains. As the low-pressure area shifts southward in November, the hot, dry wind known as the harmattan blows southwest off the Sahara.

On the coast a rhythm of six months of dry weather is followed by six months of rain. The average rainfall at Conakry is 170 inches a year, and annual temperatures average about 81° F (27° C). In the Fouta Djallon, January diurnal temperatures range between 86° F and 95° F (30° C and 35° C), while evening temperatures dip to 50° F (10° C). Rainfall varies between 91 and 63 inches annually, and the average annual temperature is about 77° F (25° C).

In Upper Guinea rainfall drops to about 59 inches a year. During the dry season temperatures of more than 104° F (40° C) are common in the northeast. The drying harmattan winds blow hot in the day, but the night can be uncomfortably cool. In the Forest Region at Macenta, there may be 106 inches of rain annually. Only the month of January is relatively dry, with less than one inch of precipitation. At low altitudes, temperatures resemble those of the coastal areas.

Vegetation and animal life. The coast is fringed with mangrove trees, and the coastal plain supports stands of oil palms. The Fouta Djallon is mostly open, with trees growing along the wider stream valleys. In Upper Guinea, the savanna grassland is comprised of several species of tall grasses that reach heights of five to ten feet during the rainy season. Deciduous trees grow in scattered clumps, but few have commercial value; baobab and shea trees furnish fruit and oil. The Forest Region contains several extensive patches of rainforest, with teak, mahogany, and ebony trees; agriculture, however, has diminished the forests and resulted in a shift largely toward open savanna.

Vanishing animal life

Guinea is not a big-game hunter's paradise. Baboons, a variety of monkeys, and hyenas are common, while an occasional wild boar, several types of antelope, and a rare leopard may be sighted. Two or three small elephant herds exist in the savanna woodlands; several chimpanzee families are still found in the Fouta Djallon valleys; and lions have been noted in the northeast. The hippopotamus and manatee inhabit the rivers of both Lower and Upper Guinea. Poisonous snakes include mambas, vipers, and cobras, along with pythons and a variety of harmless snakes. Crocodiles and several varieties of fish are found in most rivers.

The landscape under human settlement. In the Fouta Djallon, the Fulani (Fulbe or Peoul) live in small hillside hamlets of 75 to 95 persons each, and the lower classes occupy the valleys. In the heart of the highlands the countryside is thickly settled with hamlets every few miles, while in the east the land is less settled.

In Lower Guinea, villages are grouped together at the bases of hills, in the open plain, or in a valley floor. Village solidarity is more marked in this area than in the highlands, and each village may contain between 100 and 200 people.

The majority of the Malinke (Mandingo) people of Upper Guinea live in moderately large villages of about 1,000 inhabitants located near permanent water sources, the adjacent soils of which are used for cultivation. The villages are tightly grouped; there are empty brush areas in which farming is unprofitable.

In the Forest Region the effects of human occupation are less apparent. Among the Kissi people in the west, rice is grown on most hillsides and in every low-lying and swampy area. Villages are small and rarely contain more than 150 people; they are often tucked away inside a grove of kola, mango, and coffee trees. Further east among the Loma and Kpelle people, fire-cleared land is used to plant vegetables and rice. Larger villages are usually located on remote hillside terraces that are often surrounded by secondary forest growth.

Guinea's urban centres

The only true urban centre is Conakry, with more than 197,300 inhabitants. The old city, located on Tumbo Island, retains the segregated aspect of a colonial town, while the Kaloum Peninsula community, which has grown up since the 1950s, has a few buildings of the colonial period. From the tip of the peninsula, a 20-mile long industrial zone has a growing salaried population that is truly urbanized.

The second largest town of Kankan (population 40,000), in Upper Guinea, is more a cluster of Malinke villages around an administrative and trading core area than a Westernized town. Labé (30,000), located well into the Fouta Djallon, serves as an old market town and an administrative and educational centre. Nzérékoré (23,000), in the Forest Region, serves the same functions as Labé. Other important towns are the trading centres of Kindia and Mamou and the industrial settlements of Fria and Boké (11,000).

People and population. *Population groups.* The four major geographical regions largely correspond to the areas inhabited by the major linguistic groups. In Lower Guinea the major language of Susu has gradually replaced many of the other indigenous languages and is a lingua franca for most of the coastal population. In the Fouta Djallon the major language is Fulani (Poular), while in Upper Guinea the Malinke language is the most widespread. The Forest Region contains the linguistic areas, from east to west, of Kpelle, Loma, and Kissi.

Eight official languages besides French are taught in the schools. They are Basari, Fulani, Kissi, Koniagi, Kpelle, Loma, Malinke, and Susu. All official texts are written in French and at least one of the indigenous languages, and all governmental personnel are required to have bilingual reading and writing ability. It is hoped ultimately to replace French with the Susu or Malinke languages.

All of Africa has been plagued by a proclivity on the part of Europeans to overemphasize distinctions between ethnic groups. Most definitions of what constitutes an ethnic group in Guinea are incomplete and subject to criticism because they often emphasize one criterion at the expense of others. The Fulani have come to dominate the Fouta Djallon culturally; the Malinke have widely influenced Upper Guinea and the northern Forest Region; and the Susu are dominant in Lower Guinea. In the Forest Region, however, the Kissi, Loma, and Kpelle each retain their own common historical and cultural identities.

Except for the diplomatic community and some expatriate teachers and technical advisors, there are few foreigners. The alien community also includes about

1,000 Lebanese and Syrian traders and a few Frenchmen engaged in plantation agriculture and technical occupations.

Religious affiliations

At least 62 percent of the population is Muslim, and about 2 percent of the population is nominally Christian, mostly Roman Catholic. Since 1967, all priests have been required to be either Guinean nationals or Africans. There are about 2,200 Protestants.

Demography. Guinea's population was estimated at 4,010,000 in 1971. The growth rate is about 2.2 percent per year. The birth rate is a high 47 per thousand, with ten births for every female; the infant mortality rate, however, is such that only five or six children in ten reach 18 years of age. Mortality is also high (25 per thousand), with an average life expectancy in 1955 of 28 years for females and 26 years for males.

Immigration is minimal, but emigration—especially from the Fouta Djallon and Upper Guinea—is high. About 15 percent of the male population from these areas has migrated in search of work, leaving an imbalance of females. Emigration is directed toward the neighbouring countries of Sierra Leone, Senegal, Mali, the Ivory Coast, and Liberia.

The heaviest population concentration is in the Fouta Djallon; the area around Pita and Labé sustains more than 130 people per square mile. The rich rice areas around Guékédou and some of the land around Nzérékoré in the Forest Region have a density of 65 to 130 people per square mile. Most of the rest of the country has fewer than 65 people per square mile, and over half the land area has fewer than 26 persons per square mile. Conakry and the Kaloum Peninsula suffer from rapid population growth caused by a never-ending exodus from the rural areas to the city.

The population is projected to be 5,016,000 by 1980. Except for the Fouta Djallon, this population explosion poses no serious immediate threat to development because there is no pressure on the land and no landholding class.

The national economy. *Natural resources.* There are more than 1,000,000,000 tons of bauxite reserves at Boké, Dabola, and Fria. Guinea has among the largest iron-ore deposits in the world, totalling at least 200,000,000 tons at the Kaloum Peninsula and the Nimba and Simandou mountains. Gold occurs along the Niger and its tributaries, and diamonds occur in the gravels of the Makona River tributaries. The southeastern rain forests offer valuable tropical hardwoods, and the ocean and rivers contain food fishes. Hydroelectric potential is considerable because of the high rainfall and deep gorges of the Fouta Djallon.

Bauxite and diamonds

Sources of national income. Guinea is an agricultural nation. The high plateaus of the Fouta Djallon are little more than part-time pastures, with hillsides given over to the growing of peanuts (groundnuts) and fonio (a sorghum-like grain). Along the streams and rivers, rice, bananas, tomatoes, strawberries, and citrus fruits are grown commercially. Most families have truck gardens, and tsetse resistant Ndama cattle, sheep, goats, horses, donkeys, chickens, and an occasional Muscovy duck are raised.

In Lower Guinea, oil and coconut palms, rice, bananas, salt, and fish are important elements of trade. Except for poultry, there are relatively few domestic animals. In Upper Guinea, grains and manioc (cassava) are important food crops; vegetables, tobacco, and *karite*, or shea butter, are traded locally; and domestic animals are common.

In the southeast rice is the chief food crop along with manioc, peanuts, and maize (corn). Gardens of tomatoes, peppers, and tobacco are scattered in the shade of fruit trees, and coffee trees and oil palms provide important cash crops. Goats and fowl are the most common domestic animals.

By the early 1970s, experiments with large-scale cooperative agricultural production had failed. Relatively low government farm prices and the high cost and scarcity of consumer goods caused many producers to return to subsistence agriculture or to resort to smuggling. The production of coffee—the major cash crop—varied little between 1958 and 1968. Rice output has grown, but the staple continues to be imported. Other cash crops, such as palm kernels, peanuts, pineapples, and citrus fruit, only began to be important in the 1970s.

Commercial fishing is little developed, although two boats furnished by the Soviet Union have raised production considerably. Traditional ocean and inland fishermen continue to be important, and smoked and fresh fish are sold in local markets.

Forestry is hampered by the lack of transportation. The government-owned sawmill and plywood plant at Nzérékoré and wood panelling plant at Seredou cannot function to capacity because neither area has sufficient forests to continue exploitation.

Mining and quarrying

Guinea depends heavily upon the bauxite plant at Fria, owned by an international consortium of private companies from the United States, France, the United Kingdom, Switzerland, and West Germany. Guinea's production of alumina furnishes more than 60 percent of all exports, and Guinea is the sixth largest producer of bauxite. The Boké project, which is scheduled to begin in 1972, will produce 5,000,000 tons of bauxite annually and have a total yearly capacity of 8,000,000 tons. Combined with Fria's production of about 1,600,000 tons annually, the Boké project will eventually raise Guinea's total yearly bauxite production to more than 9,000,000 tons. Two other projects of the 1970s were a Soviet-financed mining operation at Dabola and a Swiss-aided scheme for the exploitation of bauxite in the Tongue Mountains of the Fouta Djallon.

The iron-ore deposits of the Nimba and Simandou mountains are scheduled to produce for export in the 1970s, replacing the nearly exhausted Kaloum Peninsula deposit. Limestone deposits in the northeast were to be developed by a Spanish company that was constructing a cement works in Lebekere. Diamond and gold production are minimal.

Food-processing plants do not run at full capacity because agricultural production is insufficient. Establishments include a fruit-juice factory at Kankan, a tea factory in Macenta, a palm-oil works at Kossa, and a peanut-oil works at Dabola. Government factories produce leather, shoes, matches, cigarettes, processed meat, textiles, and furniture. Semiprivate operations include the brewery in Conakry, a soup cannery, and several small-scale fruit-juice and plastics concerns.

In 1970 the hydroelectric station near Pita began to supply electricity to Pita, Labé, Dabola, and Mamou. The hydroelectric plant at Kale, backed by two diesel-powered thermal centres, supplies power to Conakry. There is a small hydroelectric station in Tinkisso; Fria has its own thermally-produced electricity supply; and many regional towns have their own diesel-operated generators. In the late 1960s total electric production amounted to 212,000,000 kilowatt-hours annually.

Financial services

Guinea has a nonconvertible currency; it is not tied to any foreign currency, and its value is dictated by the Guinean government. In consequence, domestic financial affairs are really a matter of national bookkeeping. The national bank, the Banque Centrale de la République de Guinée, issues currency, the Banque Guinéenne du Commerce Extérieur handles all foreign exchange, and the Crédit National pour le Commerce, l'Industrie et l'Habitat serves as a savings-and-loan bank. Agricultural credit is obtained through the Banque Nationale de Dévéloppement Agricole.

All foreign trade is theoretically a state monopoly. Specialized government agencies, such as Alimag, are in charge of importation of various goods: Guinexport is the sole export agency. Guinea trades in about equal measure with the east European Socialist bloc countries and China; the franc-zone nations, such as France and Senegal; and other Western countries, including the United States and West Germany.

Management of the economy. The private sector is largely a paper presence or a clandestine operation. Approximately 500 private businesses continue to operate, but they must obtain merchandise from government

sources. Most of the larger foreign companies are local capital investments that are no longer profit-making enterprises.

The wholesale trade is largely controlled by the Ministry of Commerce, while the retail trade is theoretically in the control of the state. Retail stores are operated in the larger towns, but, within rural areas, cooperatives are expected to distribute imported and some local produce.

Government revenue is chiefly derived from mining concessions, import and export duties, excise taxes, a petroleum-products tax, and taxes on commercial transactions and production. There are also various other surtaxes, stamp duties, and registration fees. Business and other licenses and personal-property, building, dwelling, and vehicle taxes are handled by the regional administration. Taxes on salaries and wages contribute little revenue because few people are salaried and because most of the wage earners work within the government.

The national trade union

All workers in Guinea are required to join the National Confederation of Guinean Workers (CNTG), which is affiliated with the Union of the Workers of Black Africa (UTAN). Both organizations are actually an arm of the party-government apparatus. Wages are fixed by government decree and a 48-hour workweek is officially in force for industrial workers. The Chambre Économique de Guinée (Chamber of Commerce) is a vestige of the former French- and Lebanese-owned "free-enterprise" establishments. Banana marketing boards and other cooperative agricultural marketing systems have given way to state enterprises.

Guinean policy seems to be based on the belief that increased mining will stimulate the entire economy. Associated projects are viewed as improvements of transportation and communications that will, in turn, help agricultural production. There is a serious shortage of trained personnel, and finances suffer from misappropriation, tax evasion, and smuggling. Many of the processing industries are held back by inadequate supplies of raw materials. Internal production is not sufficiently high, in agriculture particularly, and there is a permanently deficient trade balance. It is doubtful whether the disproportionate development of bauxite to the neglect of capital investment in agriculture will redress economic problems.

Transportation. Guinea's transportation system is largely based upon the road and railway from Conakry to Kankan and a lesser road to Nzérékoré. This forked axis is intersected at Mamou by a road north to Senegal. East of Kouroussa the main road branches northeastward through Siguiri to Bamako, Mali. The main road continues northeast of the railhead at Kankan to Sikasso, Mali. The regional centres, like pods strung out on a vine, lie along thin lines of communication that, in turn, radiate feeder routes.

There are an estimated 4,725 miles (7,604 kilometres) of roads, of which 1,650 miles were unimproved in 1970. The 411-mile railroad from Conakry to Kankan is a single-track metric line. It needs track and roadbed repairs throughout most of its length from Kindia. There is also an 89-mile line linking Conakry to the Fria bauxite mines.

The port facilities of Conakry are extensive. There is a channel 26 to 66 feet deep that needs constant dredging, and more than 7,400 feet of dock space with modern loading equipment. Coastal shipping, however, is limited.

The international airport at Conakry serves jets of all sizes. Air Guinée operates weekly domestic flights to the packed-earth landing strips at Kankan, Boké, Labé, Kissidougou, Nzérékoré, and Siguiri and maintains occasional service to Bamako, Mali; Dakar, Senegal; Freetown, Sierra Leone; and Monrovia, Liberia.

Administration and social conditions. *Governmental structure.* Guinea is a one-party state in which the Parti Démocratique de Guinée (PDG) and government are one. Since 1968, major government functions have been in the hands of the president and the six ministers of foreign affairs, economics, finance, social affairs, internal affairs, and trade. There are also four deputy ministers, appointed by the president, who represent each of the four supra-regions in the council of ministers. The president and ministers also compose the Bureau Politique National (BPN), which, as party executive, controls administration. The BPN is elected by the party's National Congress every four years. The president is charged with general supervision of the party and the presidency, with secretaries of state in charge of ideology, the army, scientific research, and administrative coordination.

The 75-member National Assembly ratifies the party's decisions. Its members are elected by universal suffrage for a five-year term from a single slate of candidates. The president is elected for a seven-year term. Those who hold key posts in government or national enterprise also hold party positions and may be leaders in the national trade union.

Local government

Local administration is theoretically straightforward. The village commune is administered by a council that consists of the party's village executive council, the president of which also serves as mayor. The village council and mayor are, in practice, appointed by the commandant of the next administrative level, the *arrondissement*. The commandant is appointed by the president. A party executive council of 12 members constitutes the *arrondissement* council, with the commandant as 13th member, party executive, and chairman. The *arrondissements* are grouped into 29 regions, each of which has an assembly.

Each of the four supra-regions of Upper Guinea, Forest Guinea, Middle Guinea, and Maritime Guinea is headed by a governor appointed by the president. The Regional Assembly is composed of the party's executive group at the regional level; party leaders from the *communes* and *arrondissements* act in an advisory capacity. Administrative affairs are coordinated by the governor and the federal secretary, who heads the assembly. At the top of this structure are four minister delegates, one for each of the four supra-regions appointed by the president.

Citizen participation in government is a function of participation in the party. At the village or neighbourhood level, the general assembly of the Base Committee meets every Friday. At the *arrondissement* level the Sectional Congress of Base Committee delegates meets every two years, while the Federal Congress, composed of members elected by the Sectional Congress, meets every three years and the National Congress of delegates from the federal congresses meets every four years. PDG membership is universal for all over 17 years of age who have no criminal record since independence and who are not "exploiters." The party decides most civil-court matters; the criminal courts are controlled by appointment from the presidency and are closely linked to the PDG.

The army consists of 5,000 men dispersed throughout the country who are employed in rural economic development projects. The 200-man air force is one of the best equipped in black Africa; the navy consists of 200 men equipped with patrol boats. As well as these regular forces, the PDG has a People's Militia of about 30,000; militia instruction is compulsory in all schools. Functions of the militia include party mobilization, internal police services, and external defense. All forces are united under the Defense Council, which is headed by the president.

Administrative services. Education is free and compulsory for nine years. The government sees it as one of the chief means of restoring authentic African values. Teaching of the French classics and arts curriculum has been reduced in favour of an emphasis on technical training. In the early 1970s there were about 1,600 primary schools, and about 35 secondary schools. The country's three colleges—Institut Polytechnique de Conakry, École Nationale des Arts et Métiers, and École Supérieure d'Administration—are all located in Conakry. In the mid-1960s, 18 percent of the primary school-age children attended classes.

Health and welfare services

Since independence, Guinea has devoted much effort to health services. In 1970 there were five major hospitals, 29 regional hospitals, and almost 300 *arrondissement* dispensaries. Vaccinations against smallpox and polio were not universally available in the early 1970s, but malaria,

Market day in Dabola, Guinea.
Paul Conklin—Pix from Publix

trypanosomiasis (sleeping sickness), and onchocerciasis (river blindness) had been curbed. Medical care and personnel, however, are inadequate. The Institute of Traditional Medicine was created in 1967 to aid in making indigenous medical remedies more available. Such social-welfare services as infant clinics and child-care services are largely a function of the extended family.

A housing problem exists only in the most urbanized areas because local construction materials are otherwise available. In the industrialized areas near Conakry, attempts have been made to construct low-cost prefabricated housing in workers' cities near the plant sites.

Social conditions. The salaried labour force numbers little more than 110,000. In general, salaries are low, and little more than subsistence is the lot of more than half of the salaried workers. Rents have been lowered by government decree; purchasing cooperatives have been established; and salaries have been progressively adjusted in favour of the least paid. Inflation, however, has produced a continual need to resort to extra-salary means in order to eke out a livelihood.

Guinea has largely succeeded in creating a classless society. Although there are inequalities in wealth and although party and government officials abuse their positions for self-gain, the general Guinean pattern has been one of control of corruption and excessive profit taking. The rural farmer is perhaps no better off in the 1970s than he was in the 1950s, but neither is he much worse off.

Cultural life and institutions. A profound cultural revolution was launched in 1967, aimed at involving all of the people in national construction by developing a sense of national responsibility and an awareness of the part that communal action must play to achieve complete decolonization of the mind, the economy, and national politics.

Members of the professional Ballet National Guinéen are chosen from ballet, theatre, and traditional and modern music groups from each village, section, and federation. They form two national troupes that are creating a national Guinean form of the performing arts. Because the performers are often from *griot* families (traditional families of artistic specialists) and because they are often paid by the federation or village groups they represent, their traditional roles are still maintained.

A distinctively Guinean literature is difficult to define. Such authors as Camara Laye, Djibril Tamsir Niane, and Mamadou Traore Rayautra have made contributions to a fusion of traditional forms and patterns into a universally understandable literary genre.

Handicrafts have almost become extinct because they are unable to compete with manufactured consumer goods. Those remaining include leatherwork, masks, statuettes, art objects, and jewelry for the tourists.

The mass media

The PDG is the only source of information in Guinea. The only daily newspaper published is *Horoya*, the party daily written in French, and Radio-Conakry, the "voice of the revolution," is the main source of foreign and national news. Daily programs reach a large percentage of the population with broadcasts in French, English, Portuguese, Krio (a language derived from English and spoken in coastal Guinea and Sierra Leone), Arabic, and the official Guinean languages.

Prospects for the future. Guinea is underpopulated and has a rich natural-resource base, and its government has largely succeeded in creating a strong sense of national identity. Whatever problems its anticolonial and revolutionary stance may have created, the country is in control of its own political and economic future. The vocabulary of the PDG has, perhaps, been more Socialist than libertarian, but the pragmatic course of political and social progress seems to have created a truly Guinean system based upon an African model.

The main problem is that the somewhat simplistic reliance on inevitable progress and the overdependence upon mineral resources has yet to be tempered with a consistent and realistic appraisal of world economics. Neither bauxite nor iron ore are Guinean monopolies, and, without the cooperation of international capital, they have little practical value. Agricultural production must be improved in order to maintain internal harmony and to achieve self-sustaining economic growth.

BIBLIOGRAPHY. There are two major sources of information on Guinea. JEAN SURET-CANALES, *La République de Guinée* (1970), is the best single source by a trained social scientist and long time resident of Guinea. The *Special Warfare Area Handbook for Guinea* (1961), from the American University for the Department of the Army is dated and less reliable. GUY DE LUSIGNAN, *French Speaking Africa Since Independence* (1969), though somewhat simplistic and superficial, should also be consulted for political and economic interpretations. More current and accurate information may be found in the yearly *Africa Contemporary Record*. Statistical information may be gleaned from the *United Nations Statistical Yearbook* and the *AID Economic Data Book: Africa* (1970). The yearly encyclopaedia *Africa*, available from the African Publishing Corporation, is also useful. LADIPO ADAMOLEKUN, "Politics and Administration in West Africa: The Guinean Model," in the *Journal of Administration Overseas*, 8:235–242 (1969), is a lucid examination of political and administrative realities. Works by President SEKAU TOURE describing social and political change within Guinea are *Toward Full Re-Africanization: Policy and Principles of the Guinea Democratic Party* (1959) and *La Révolution guinéenne et le progrès social* (1963).

Guinea, Gulf of

The Gulf of Guinea, narrowly defined, is part of the eastern tropical Atlantic off the West African coast, from Cape Lopez, near the Equator, to Cape Palmas at 7° west. Its coastline forms part of the western edge of the African tectonic (rock structure) plate and is the mirror image of the South American coastline of Brazil and the Guianas. The remarkable coincidence between the geology and the geomorphology of these two coastlines constitutes one of the clearest confirmations of the theory of continental drift.

The continental shelf of the Gulf of Guinea is almost uniformly narrow, widening to as much as 100 miles only from Sierra Leone to the Bijagós Archipelago, Portuguese Guinea, and in the Bight of Biafra. The shelf deposits are predominantly of Quaternary sands, with linear Holocene (Recent) fossil coral reefs near the shelf edge. Recent river muds overlie these deposits off the mouths of the rivers—Casamance, Volta, and Niger—which empty

into the Gulf. The Niger has built a great delta of Holocene muds—and it is only here that the fit between the African and South American tectonic plates is seriously disturbed—while the Congo has built a unique submerged delta on the continental slope.

The only active volcanic region is the island arc aligned with Mt. Cameroon (13,353 feet, or 4,070 metres) on the coast of the Cameroon Republic; the islands (Fernando Po, Príncipe, São Tomé, and Annobón) extend 450 miles offshore to the southwest.

The entire northern coast of the Gulf is washed by the eastward flow of the Guinea Current, which extends 250–300 miles offshore from Senegal to the Bight of Biafra. Its tropical water is separated from the cool Equatorward flow of the Benguela and Canary currents by sharp frontal regions off the Congo and Senegal rivers respectively. The Benguela Current, as it swings westward, forms the South Equatorial Current to the south of, and running counter to, the Guinea Current.

The warm tropical water, of relatively low salinity because of river effluents and high rainfall along the coast, is separated from deeper, more saline, colder water by a shallow thermocline (a layer of water, between upper and lower levels, in which temperature drops more than 1° C per metre of depth) lying usually less than 30 metres deep. Coastal upwelling, and hence rich production of plant and animal life, occurs seasonally and locally off Senegal and the Congo, and off the central Gulf coasts of Ghana and the Ivory Coast.

The variety of the marine flora and fauna of the Gulf of Guinea is limited, when compared with the western tropical Atlantic and, especially, with the Indo-Pacific biogeographic realm. This relative biological poverty results from (1) a lack of coral reef ecosystems (except on Annobón Island) because of low salinity and the high turbidity of Guinea Current water, and (2) the climatic regression to cool conditions during the Miocene Epoch during which far fewer faunistic refuges for tropical species of animals and plants were available in the Atlantic than in the Indo-Pacific region.

Because of the difficulty of the coast, most of which is low-lying and without natural harbours, and which is largely separated from the dry land of the interior by a belt of muddy mangrove-infested creeks and lagoons, the African coastal peoples have usually not taken easily to seafaring on the Gulf. Tribes located in Senegal and Ghana, where the coast is easier, and coastal fisheries are relatively productive, form an exception. Demersal (*i.e.*, sea bottom) fisheries of the continental shelf are restricted to a coastal zone only a few miles wide and can support only modest fleets of small trawlers, though in some areas shrimp resources may yet prove to be a valuable export resource.

Sardine fisheries off Senegal and Ghana are incapable of supporting exploitation by large factory trawlers, such as the Soviet vessels that have fished there in recent years; the offshore tuna fisheries, on the other hand, now support a large and modern fleet of Spanish, French, and American purse-seining vessels and yield about 30,000 tons annually, little of which is consumed in West Africa.

Exploration for offshore oil proceeds rapidly, and exploitation on a large scale has begun off the Niger Delta. Extraction of heavy metals (titanium from rutile sands) from beach sand deposits in Sierra Leone has begun, and continental shelf deposits in this region may also prove rich in metal ores and diamonds.

Phoenician, Roman, and—from the 15th century—European trading vessels sailed the Gulf of Guinea, which was also the scene of naval efforts to suppress the slave trade in the 19th century. In the future, development of its resources will depend primarily on the availability of capital from outside Africa. Perhaps the major question now posed is to what extent the African states bordering the Gulf will share in the economic benefits from its exploitation.

BIBLIOGRAPHY. For sources of additional information on the oceanographic region of which the Gulf of Guinea forms a part, see bibliography of the article ATLANTIC OCEAN; for information on fisheries, see the bibliography of the article FISHING, COMMERCIAL.

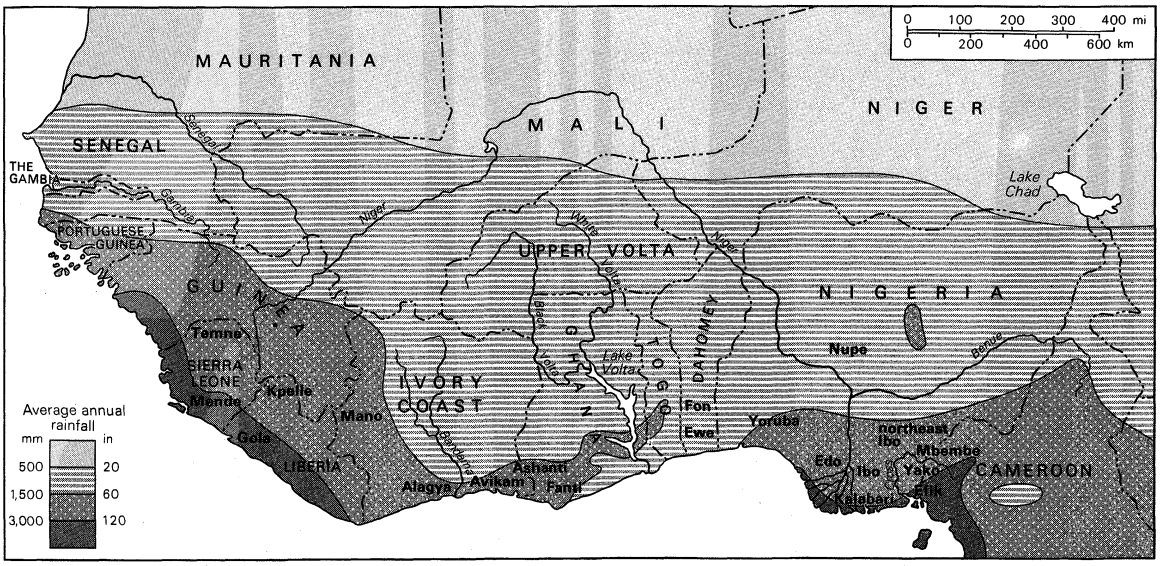
(A.R.L.)

Guinea Coast, Cultures of the

Guinea is a term used for the coastlands and adjacent forests of West Africa between the Republic of Guinea and Equatorial Guinea. There have been conflicting interpretations of the derivation of the name Guinea, but it would seem to be a version of the Berber word *aguinaw*, or *gnawa*, meaning "black man," or "Negro."

THE ENVIRONMENT AND THE PEOPLE

In West Africa, in the general absence of major mountainous areas, natural regions are determined primarily by climate and vegetation, and the Guinea coast societies are those broadly associated with the equatorial forest zone. This forest has been erased by agriculture in some areas, but it is the natural vegetation of most districts within 100 miles of the coasts—that area within which average monthly temperatures always exceed 70° F (21° C) and the annual rainfall is well distributed, with a dry season that does not exceed three months (from December to the end of February) and with a total precipitation that is more than 45 inches (110 centimetres). In the east a heavy forest formerly extended from the borders of the Cameroon highlands to the west of the Niger River. In the west a forest stretched from



Distribution of Guinea coast peoples.

Sierra Leone to the west of Ghana. Between these two belts of forest there is, for very complex reasons, a drier region, and here for centuries the forest has been thin, and the land, when cleared for farming, has changed to grassland if left fallow. Societies here have been culturally very similar to the true forest societies but have shown some significant differences.

Cultural effects of the forest

The forest greatly influenced the cultural development of the Guinea coasts, for it influenced the movements of peoples and the development of agriculture and commerce. Men occupied the forest areas relatively late, because farming there had to await the development of suitable tools and new crops. Iron axes are needed to clear equatorial forests efficiently, and, although iron was introduced south of the Sahara between 500 BC and AD 200, the quantities available were too small to be significant until much later. Moreover, the crops that were indigenous or introduced early to West Africa were unsuited to the dense shade of small forest clearings. The yam, for long the most important staple crop in much of the forest region, succeeds only where large areas are cleared. Only with the introduction of shade-tolerant crops, the plantain and cocoyam (taro or eddo) brought from Asia in the 9th century AD, could forest farming become an economic alternative to hunting and gathering. Moreover, until recently forest farming did not include animal husbandry, for the forest has harboured species of tsetse fly that are particularly virulent to cattle and horses. This fact, however, had its advantages for the forest peoples, because the tsetse fly and the trees protected them from marauding cavalry. Gradually, too, the forest gave its inhabitants commercial advantages: kola nuts and later palm oil were so highly desired by distant peoples that traders by caravan and ship were drawn to the Guinea coasts.

Language distribution

The cultural significance of the original forest environment seems shown even today in the linguistic map of West Africa. In detail there is a host of different languages in the forest area, some spoken by millions, some by a few thousand people. What is striking, however, is that the boundaries between the major language families roughly coincide with the old boundaries of the forest. In the extreme west, in the area of Sierra Leone, a history of multiple small invasions has brought a confused linguistic pattern to the forest areas, but there is a clear division between these forest language groups and the great groups of Mande languages in the bordering savanna belt. The forests of Liberia and the western Ivory Coast are inhabited mainly by speakers of Kru languages and bordered again by Mande speakers in the grasslands. From the Bandama River in the Ivory Coast eastward beyond the Niger River there is the clearest evidence of all of a cultural boundary between the old forest zone and the grasslands to the north, for almost all the different languages of the forest region, including those of the forest gap, are classified as belonging to the Kwa family and are bordered in the grasslands to the north by Gur and Hausa languages. Only in the extreme east does this clear division disappear. The linguistic division between the Guinea coast and the hinterland, in any event, provides good grounds for distinguishing Guinea coast societies.

This article cannot deal individually with all the groups in the area but only the more important: (1) certain peoples of the western forest, including the Mende and Temne of Sierra Leone, the Kpelle of Liberia, and the Akan of Ghana; (2) certain peoples living mainly in the lightly forested gap, including the Fanti of Ghana, the Fon and Ewe of Dahomey, the Yoruba of western Nigeria, and the Nupe; and (3) certain peoples of the eastern forest, including the Edo of Benin, the Ibo, the Cross River peoples, and, on the coast, the Efik and Delta peoples.

CULTURAL PATTERNS

Guinea coast societies vary enormously. Today, differences between groups emerge most clearly in differences in density of population and types of settlement. Even within a small area such as southern Nigeria great variations exist: in certain Ibo rural areas there are 700 or more people per square mile, whereas in the equally fertile forest hinterland of the Cross River densities are well under 100 per square mile (40 per square kilometre). Moreover, Ibo live characteristically in scattered hamlets, whereas to the west the Yoruba have built the largest indigenous towns in Africa.

Interplay of environmental and historical influences

Such cultural differences are usually caused by the complex interplay of environmental and historical factors, even when the direct influence of the physical environment seems most obvious. This can be seen by looking at patterns of crop production. Sometimes crop choice seems dictated solely by physical factors—for instance, when farmers in dense forest have to grow cocoyams rather than the yams that they would prefer. But sometimes tradition seems also to be involved. In the Ivory Coast, for instance, the staple crop to the west of the Bandama River is rice, whereas to the east it is the yam. Although this difference seems, in a general way, to correspond to a difference in rainfall—the yam, requiring even watering, growing in an area of better distributed rainfall—the fact that the Bandama River also marks a linguistic boundary suggests that there is a strong element of historically determined cultural choice in this crop boundary.

That other types of cultural differences also have explanations less exclusively environmental than at first appears can be seen from a study of house types. Most Ibo, for example, live in typical forest-area houses—mud-walled, rectangular structures with gable-ended roofs thatched with mats made from single palm fronds. The northeastern Ibo, however, having moved into a grassland region where palm trees are scarce, today build a house with low circular walls and a conical roof thatched with grass. Environmental factors forced these people to adopt new materials, but the design details of their present houses owe as much to cultural borrowings from their new neighbours as to environmental necessity.

The more complex the cultural pattern is, the more complex is the interplay of environmental and historical factors behind it. The development of the large Yoruba towns owed much to the necessity for defense in a relatively open territory; the Ibo, by contrast, in their sheltering forests, needed less protection from attack and could risk living in scattered houses. Here at first sight is a simple relationship of environmental and military factors. But not all forest dwellers live like the Ibo. The farming villages next in size to the Yoruba settlements were built by the Cross River Yako, even though they live in a heavily forested area and have experienced little serious warfare. Thus, a full explanation of differences in settlement pattern would require the detailed examination of many factors influencing tradition.

Historical background of trade and politics. Given the circumstances outlined above, it can be appreciated that factors accounting for the political variations of Guinea coast societies are extremely complex. At the end of the 19th century, there existed both tiny, independent political units of four or five villages and large kingdoms of medieval foundation holding sway over hundreds of thousands of people. Older writers sometimes tried to account for such differences in simple environmental terms. Environmental factors undoubtedly were extremely important, but explanations must also take account of the economic patterns and political struggles of past centuries, and especially of the contacts between the Guinea coasts and the outside world, both northward and across the seas.

Shift from Arab to European trade

Before the end of the 15th century, most of the region's external contacts were made through the savanna kingdoms to the north, whose merchants wanted slaves, gold, and kola nuts. From the end of the 15th century, however, the interests of the Guinea coast peoples were partly reoriented toward trade with European merchants, who sought successively gold, slaves, and palm oil. European trade was significant partly because within the Guinea coast areas it was entirely controlled by local people. Europeans were prevented by climate and disease and

also by the express action of African authorities from penetrating inland. Consequently, all the inland traffic in gold, slaves, and palm oil was organized by African traders; Europeans merely provided inducements to sell.

The European trade was significant also because of the nature of the goods involved. Imports from Europe consisted mainly of such consumer goods as clothes but also included such capital goods as iron, guns, and gunpowder, which gradually introduced a crucial new factor into Guinea coast warfare, making it militarily vital for groups to acquire the new weapons. Moreover, even imported consumer goods had a political significance, for often it was the political authorities able to tax European merchants or their own traders who were able to acquire most goods. This put new wealth, new economic and political resources, and thus new power into the hands of some authorities, with important political repercussions.

Effects of the slave and palm-oil trade

The development of Guinea coast societies was also strongly influenced by the nature of what they exported. Slave trading did not everywhere lead to raiding and depopulation. Ibo slaves, for example, seem to have been sold mainly by authorities as a punishment for crime or by senior kinsmen who had got into debt; there is no evidence of depopulated Ibo districts. Nevertheless, the slave trade was commonly associated with warfare directed toward the acquisition of captives for sale. Sometimes, as in an area of northern Ghana, a low population even today is considered attributable to such raids. More generally significant for political development was the stimulation that raiding gave to military and political organization; groups that raided for slaves roused the antagonism of their neighbours, who made retaliatory attacks, and all this increased the tendency to military centralization, as, for example, in Dahomey, where a strong government was closely involved with slave raiding in every dry season. Moreover, wherever war captives were important as slaves, the trading position of central authorities who controlled captives was better than that of private traders.

In the 19th century, palm oil gradually became the most important Guinea coast export because of its rising use as an industrial lubricant and because of the overseas restraints on the slave trade imposed by European humanitarians. Nevertheless, slave dealing and raiding remained important internally throughout the century. Even when slave exports declined, to the anger of the local traders, the increased palm-oil traffic in itself stimulated internal slaving; the reason was that the transportation of the bulky oil required the use of slaves, either to paddle the canoe transports or to headload the oil to the ports. Whenever a trader had many men engaged in oil transport, moreover, he needed other slaves to produce food for them; thus, slaves were important economically and politically to the Mende, Ashanti, Fanti, Dahomean, Yoruba, Niger Delta, and Efik peoples.

The growth of the palm-oil trade brought other economic and political changes. African traders exporting palm oil needed more capital than slave dealers did, because slaves transported themselves and worked while awaiting shipment, whereas oil was expensive to transport and constituted idle capital while at the ports. Palm-oil exporters therefore needed capital and became increasingly reliant on European firms who advanced them goods on credit and took increasing interest in their affairs. This was politically significant when the African exporter was also a political leader, and it was one factor leading to colonialism. Paradoxically, in the rural areas many men who could never have been slave traders could easily gather and sell palm nuts. In Dahomey most palm oil came from government-fostered large plantations, but elsewhere the oil was drawn mainly from trees growing naturally in the bush; in the eastern forest area especially, participation in this production and trade was very general.

Markets and traders

By the end of the 19th century, a network of local markets had been developed over much of the hinterland of the Guinea coasts. One indication of the importance of markets is that in many societies the days of the week are named after local places holding markets on those days—village life revolved around "our" market and those of "our" neighbours. The great centralized kingdoms were naturally associated with great trade routes, but there is evidence that traders travelled quite safely, even in the absence of strong governments able to enforce peace, because the desire for regular supplies of trade goods protected the accredited trader even from ambitious headhunters.

Kingdoms and chiefdoms of Guinea. Although trade could flow across political boundaries, the political development of West African societies was much influenced by the growth of trade—through the warfare and struggle for trade routes that accompanied it. In the area of Sierra Leone and Liberia, where trade was initially rather limited, most political units remained very weak, making possible the later settlement there of freed slaves. Yet later, however, Mende tribes, located in rich oil-palm areas, fought for the control of trade routes and developed into more centralized groups under warrior chiefs. At the other end of the western forest, the Ashanti confederation developed quite differently. The area early had commercial importance as a source of gold and of the best kola nuts (one stimulant allowed to Muslims), which were wanted by northern traders. From the 17th century the Ashanti exploited their gold resources, easily made a government monopoly, in order to gain local control over the import of firearms. Extending their influence over their immediate neighbours by diplomacy and over those more distant by warfare, they eventually subjugated peoples as far southeast as Accra and as far north as the savanna.

In the gap in the forest, where there was easier movement, there developed particularly powerful kingdoms. Dahomey, essentially a militaristic state of 18th-century origins, had centralized control of raiding and trading. The Yoruba kingdoms, whose medieval growth was linked to northern trade, became in the 18th and 19th centuries increasingly concerned with southern trade routes. This, plus a complex internal power struggle, helped to plunge the Yoruba kingdoms into war with one another. Northward, the Nupe kingdom owed much of its original importance to its key position on trade routes to the north.

In the eastern forest, northwest of the Niger Delta, the Kingdom of Benin was also of medieval origin and was so well established in the 16th century that it became the first sub-Saharan state to exchange ambassadors with a European power (Portugal). From the 16th century Benin rather unsuccessfully competed with its Yoruba neighbours for the control of trade routes to the coast. Eastward across the Niger there grew up very different political systems. The Niger Delta is one of the greatest mangrove swamps in the world, an area without land for farming and unsuited to the development of large states. Here there developed small, independent trading towns wherever a deep-water anchorage suitable for European ships existed adjacent to rivers giving good access to the interior. These towns were interested in exerting commercial control rather than political power over the slave-rich and oil-rich Ibo hinterland.

It was once assumed that Guinea coast kingdoms must have borrowed their political institutions from northern Islāmic states, but this idea is no longer accepted. In contradistinction to the situation in Islāmic states, the Guinea coast king was usually the keystone of the political system because of his ritual relation to royal ancestors believed to exercise power over the kingdom. Moreover, the king, sometimes transformed into a semidivine personage through his installation rites, had contact with the gods so close that all his actions had to be circumscribed lest by breaking taboos he brought disaster to his people.

Political structure of the kingdoms

In Oyo, one of the best described Yoruba kingdoms, the king, at the culmination of his installation rituals, ate the heart of his predecessor and was transformed into a personification of his ancestors. Thereafter, on his only public appearances, at rituals held three times a year,

he appeared veiled, his face hidden by a beaded fringe. Those who formally represented him in judicial, religious, military, and administrative capacities were slave eunuchs, chosen because, having neither kin nor affines, they presumably had no interests to serve but their master's. Though secluded, the king was involved in important political manoeuvrings, playing one group of hereditary chiefs off against a second and trying to avoid the great danger that would ensue if both groups were to unite against him.

This description gives the barest outline of the political structure of Oyo, which, at its most powerful, in the 18th century, controlled an area from the borders of Benin to present-day Ghana. Its political structure had many parallels in other Guinea coast kingdoms. Such political structures can be described as if they were well-integrated systems of checks and balances persisting unaltered for generations, but modern research suggests that these structures were altered whenever the balance of political power altered. Kings and hereditary chiefs might compete, for example, over the rules for choosing the king's successor, for it was recognized that the greater the freedom of choice possessed by the hereditary kingmakers, the weaker the king would be. Similarly, there was competition between king and hereditary chiefs over the king's power to appoint subordinate officials. In the Oyo and the Ashanti kingdoms there is evidence that this was a cause of struggle whenever new territories were conquered, for there was competition to claim the administrative offices essential to the new territories. In Ashanti, successfully, and in Oyo, unsuccessfully, the king tried to gain in these territories the right of appointment that he lacked in the metropolitan districts.

Variety of chiefdoms

In many ways the small chiefdoms of the Guinea coast had political characteristics similar to those of the kingdoms. Even the very small groups of the Cross River area, for example, surrounded their priest-chiefs with ritual similar to that of the Oyo. On the other hand, some small chiefdoms had completely different political systems. Mende chiefs, for instance, were essentially secular leaders. The chiefs or kings in the Niger Delta towns were hardly more than ritual figureheads, for power lay openly with wealthy traders. In many Ibo groups there were few formal political roles at all, and decisions were often taken through public discussions at village meetings.

Kin groups and other associations. In most tribal societies a man's household is the main unit of production, and consequently a husband and wife or a man and his junior kin are bound by strong economic bonds. Understandably, however, the more wealthy the community is, the greater is the value of inheritance; the heavier the population is, the more important is the position of those who control land; and the more farmers are involved in the market, the more commercial considerations will influence ties between kinsfolk.

Husband–wife relations

In the Guinea coast areas the marketing of crops is intimately involved in the rights and obligations of husband and wife and tends to add monetary considerations to domestic arrangements. Among the Cross River Mbembe, for example, the husband has the right to sell yams that his wife has helped to grow, but she is traditionally regarded as justified in seeking divorce if her husband spends the acquired money irresponsibly—especially if he uses it to make marriage gifts for another wife. Among the Nupe and Yoruba the men work the farms and the women market the produce. A husband must freely give his wife the staple crops for sale or home consumption; other crops, however, she must buy from him. She, in turn, is obliged to cook without charge her husband's staple foods but not his delicacies, which he must buy if he wants them. Even in the modern urban environment the tradition of financial independence between husband and wife continues. One of the problems associated with slum clearance in the Yoruba city of Lagos has been that wives, moved out to suburbs, can no longer earn by trading in the central markets, and this has led to matrimonial stress.

Age-sets

In most tribal societies age is an important basis for group formation, and in some there are what are called "age-sets"—compulsory groupings of individuals of comparable age who advance through life together. Age-sets had greatest political power in East Africa but they were significant on the Guinea coast in either of two circumstances: (1) wherever there were highly competitive kin groups, there tended to be age-sets as a kind of compensating factor to link non-kin together; (2) wherever, in highly competitive societies, kinsmen were wont to quarrel over inheritance, there were age-sets to provide the individual with loyal partisan friends. Mbembe villages, for example, are deeply divided by kin-group competition, but age-sets unite everyone of the same age throughout the village. Girls early form strong ties with one another, because each age-set of girls collectively undergoes public rites and ceremonies before its members are allowed to marry. This produces such collective solidarity that recently teen-age sets have acted like trade unions, stipulating the minimum personal gifts necessary before any member will accept a suitor. Relationships with age-mates remain important throughout a woman's life, especially in matrimonial quarrels. Boys also form very close ties with their age-mates and from their mid-teens onward can be called to work collectively on tasks that are necessary for the village as a whole. A man in need of financial help may meet with selfish refusal from his kinfolk, but his age-mates will generally always help him; indeed, in all the crises that an individual faces, especially in sickness and death, his age-mates are there to support him. Age-mate links are of enormous value when kin-group elders meet to deal with intergroup arguments, because the heads of the disputing parties often have the closest personal links with one another.

Secret societies

One of the most characteristic of Guinea coast institutions, especially in areas in which central government was weakly developed, was the so-called secret society. Such societies had a significance similar to that of age-sets since they cut across kin-group lines and united men (and sometimes women) of different groups. The influence of secret societies was even greater, because membership often cut across village and sometimes even tribal boundaries. Moreover, the fact that members were often of different grades and that membership in higher grades was open to those who could pay the fees meant that these societies provided the means whereby successful individuals could exercise wide, if covert, influence. In two major areas—in Sierra Leone and Liberia, and in the area east of the Niger Delta—these associations exercised real political power and were crucial to the traditional systems of law and order. Among the tribes in the former area, the men's Poro Society and women's Sande Society were primarily responsible for punishing such serious offenses as incest and homicide; moreover, if the death sentence were imposed, it was imposed and executed by a masked Poro member. There were local Poro councils composed of members of the highest grade, and a chief's authority often rested on his Poro rank. Among the Gola, Kpelle, and Mano of Liberia and the Mende of Sierra Leone, Poro forged links between autonomous chiefdoms; in 1898 the Poro of the Mende even organized a general uprising to try to oppose British expansion in Sierra Leone.

Similarly, though on a smaller scale, among the Yako and Mbembe in the Cross River area social control was largely vested in important secret societies. The most interesting development took place in 19th-century Calabar, where the Ekpe Society became the main instrument of the trading oligarchy. In the absence of a strong government Ekpe members ensured that commercial debts were honoured and united members and freemen in countering any signs of rebellion among the many slaves owned by the rich traders of Calabar. Even among the Ibo there were rich men's societies, whose leaders exerted considerable influence on village life. Thus, in general, secret societies were institutions for translating slight advantages of wealth into political influence. Moreover, for Africa, they reflected an unusual measure of social stratification.

Social stratification. Stratification among freemen seems to have been greatest among the most wealthy and centralized states: the Nupé had a clear division between commoners and aristocrats, and the tendency was incipient in Ashanti, Dahomey, and Benin. Among the Yoruba there was a kind of stratification through occupational craft inheritance, but deliberate efforts were made to prevent the emergence of a royal aristocracy. Slavery was an element in stratification mostly in Ashanti, Dahomey, Yoruba, and Calabar, where slaves were used in the commercial production of crops.

Freed slaves from North America

In the 19th century new forms of stratification emerged in Sierra Leone and Liberia when freed slaves educated in North America and more receptive to missionary education settled there to become shopkeepers and white-collar workers—an elite vis-à-vis the natives. Some Sierra Leonians moved to other British West African possessions on the coast, where they joined with tiny indigenous elites drawn from wealthy, educated coastal families to form with them a new bureaucratic class.

Belief systems. The similarity between the various belief systems on the Guinea coast demonstrates the great measure of contact between the various tribes and peoples. Most systems contain these features: belief in a withdrawn high god; belief in lesser gods of lesser power but useful because easily manipulated; reverence for the dead, usually ancestors, who exercise influence over the groups to which they belonged in life; belief in witches and sorcerers, whose existence explains undeserved misfortune; and, finally, the existence of diviners who can determine the cause of a particular misfortune. The pantheon of gods tends to be more hierarchical and complex in kingdoms such as Dahomey that have more social stratification and differentiation. There are countless cults, some of the same name, occurring over wide areas, some being adopted ad hoc to guard against some temporary misfortune. Distant cults are often deemed more powerful than local ones, so that priests may be brought long distances to establish local shrines to protect against misfortune.

Metaphysical explanations of individual success

Most significantly, many of these belief systems make special provision for explaining the success of an outstanding individual. The Kalabari of the Niger Delta believe in a special supernatural being whose activities aid in individual success. Among the Cross River societies there is a belief in a kind of sorcerer who achieves individual riches and influence by sacrificing, in a supernatural or spiritual sense, the lives of his junior kinsmen; an individual identified as such a sorcerer is not abhorred. Very widespread from the Niger Delta to Ghana is the concept of prenatal fatalism; individuals choose before birth success or failure in life, and this accounts for individual variation in wealth, as well as in fertility and health.

PROBLEMS OF MODERNIZATION

When the new states of the Guinea coast are considered in the context of the modern world, it is important to be aware that the several peoples in the area are culturally more distinct from one another than, for example, are the peoples of different European nations. This cultural diversity poses a real threat to national cohesion. Traditional social cohesion depended on the ritual authority of leaders, on the active political interests of kin groups, and on the influence of age-sets and secret societies—not on the administrative authorities governing within colonially determined boundaries. Although missionaries and colonial powers did tend to undermine traditional authorities and although national party politics today are no longer based on the old groups, old loyalties remain remarkably intact beneath the surface of modern politics. The Nigerian civil war of the 1960s showed that. Indeed, as long as most of the people remain primarily subsistence farmers, much of the old tribal order will remain.

On the other hand, in such major centres as Freetown and Ibadan, tribalism is simply a veneer of traditionalism that masks radically new associations, as rural migrants seek to cope with the problems of city life by banding together. In all the new states, moreover, education has developed new elites. Except in Liberia, where the Afro-American minority hangs on to its elite status, it is the indigenous educated people who are in control in all walks of life. The emergence of this elite is one factor that makes for the growth of a sense of national unity across the old tribal boundaries. It is a development, however, that brings social problems in its wake. There are now vast differences in income and power between many rural farmers and the politically—and economically—successful minority. One of the greatest political problems is that the man who achieves success through politics alone, without other claims to elite status, clings to power at all costs, because, should he fall, he loses economically so much.

Sometimes those who write about tribal societies suggest that most of their modern ills spring from a new selfishness and individualism engendered by modernization. A study of the Guinea coast societies suggests, on the contrary, that, although modernization may give the selfish individual more room to manoeuvre, it has not created him. These societies have undergone much social change over past centuries, and some individuals always have seized the advantage of the moment. Change today is perhaps more rapid, and the differences in wealth between individuals is perhaps greater, but it is doubtful if modern social problems arise from any new development of self-interest.

BIBLIOGRAPHY. The literature on West Africa is very considerable, and much of it is in French because much of the area was formerly under the control of France. A most valuable source of French material is the *Bulletin I.F.A.N.* (Institute français d'Afrique noire). Two other journals that are important general sources of information are *Africa* and the *Journal of African History* (both issued quarterly). For an understanding of the area some standard geographical text, such as WALTER FITZGERALD, *Africa*, 10th ed. rev. (1967), is useful. On the prehistory of West Africa, see the review article on African prehistory in the *Biennial Review of Anthropology* (1965). On the general history of West Africa, a most valuable book is the collection of essays by different authors edited by J.F.A. AJAYI and MICHAEL CROWDER, *History of West Africa*, 2 vol. (1972). JOHN R. GOODY, *Technology, Tradition, and the State in Africa* (1971), is interesting in its attempts to account for the differences in state organization between the forest and the savanna regions; a very important book on kingdoms in both areas is that edited by C. DARYLL FORDE and P.M. KABERRY, *West African Kingdoms in the Nineteenth Century* (1967). There are many ethnographic studies of Guinea Coast peoples. Particularly relevant to this article are the following: on the Mbembe, ROSEMARY L. HARRIS, *The Political Organization of the Mbembe* (1965); on the Ibo, M.M. GREEN, *Ibo Village Affairs* (1947); on the Nupé of the Niger–Benue confluence, S.F. NADEL, *A Black Byzantium* (1942); on the Yoruba, P.C. LLOYD, *Yoruba Land Law* (1962); on the Akan states, K.A. BUSIA, *The Position of the Chief in the Modern Political System of Ashanti* (1951, reprinted 1968); on Dahomey, MELVILLE J. HERSKOVITS, *Dahomey: An Ancient West African Kingdom*, 2 vol. (1938, reprinted 1967); on the Mende, KENNETH L. LITTLE, *The Mende of Sierra Leone* (1951). Most ethnographic accounts give some information on religious beliefs, but particularly recommended are the relevant articles on the Mende and the Ashanti in C. DARYLL FORDE (ed.), *African Worlds* (1954); and an unusual book dealing mainly with peoples in Ghana is MEYER FORTES, *Oedipus and Job in West African Religion* (1959). There are a number of useful books that examine the modern political problems of Guinea Coast states against the social background of their peoples. Particularly interesting are DAVID E. APTER, *Ghana in Transition*, rev. ed. (1963); and J.G. LIEBENOW, *Liberia: The Evolution of Privilege* (1969). For information on the urban situation, the following are recommended: MICHAEL P. BANTON, *West African City: A Study of Tribal Life in Freetown* (1957); HILDA KUPER (ed.), *Urbanization and Migration in West Africa* (1965); and the introduction and relevant chapters in P.C. LLOYD (ed.), *The New Elites of Tropical Africa* (1966).

Guise, House of

The House of Guise played a dominant role in France during the 16th-century Wars of Religion, when it stood for Roman Catholic intransigence against the Calvinist Huguenots. It was a branch of the House of Lorraine, a ducal dynasty of royal descent ruling territory external to

France; thus its members ranked in France as "foreign princes" and so claimed precedence over the purely French nobility.

The founder of the Guises' fortunes was Claude de Lorraine (1496–1550; see Table), who inherited a number of fiefs in France, including the countship of Guise (in the modern *département* of Aisne), and served so well in France's wars that King Francis I made him duc de Guise and a peer of the realm in 1528. His brother Jean (1498–1550), cardinal de Lorraine, further promoted the family's prestige in France by political and diplomatic services.

(Right) Henri de Lorraine, 3rd duc de Guise, *c.* 1585. In the Musée Condé, Chantilly, France. Portraits by the School of Clouet.

François de Lorraine (1519–63), Claude's eldest son, already high in King Henry II's favour, became duc d'Aumale in 1547 before he succeeded his father as the 2nd duc de Guise three years later. He then ceded Aumale to his brother, Claude. His military successes—the defense of Metz against the Germans in 1552 and the capture of Calais from the English in 1558—greatly enhanced his reputation. His niece Mary Stuart, heiress to the Scottish crown, was married to Henry II's eldest son in 1558; and when the latter ascended the throne as Francis II, in 1559, the Duc de Guise and his brother Charles (1524–74), known first as the cardinal de Guise, then as the cardinal de Lorraine, became the most influential men in France. They completely overshadowed their erstwhile rivals, the constable of France, Anne de Montmorency and the princes of the House of Bourbon, a cadet branch of a former ruling house, the Capetians. In 1560 an attempt by the Huguenots, with Bourbon connivance, at a coup d'etat against the Guises—the so-called Conspiracy of Amboise—was savagely put down.

The Conspiracy of Amboise

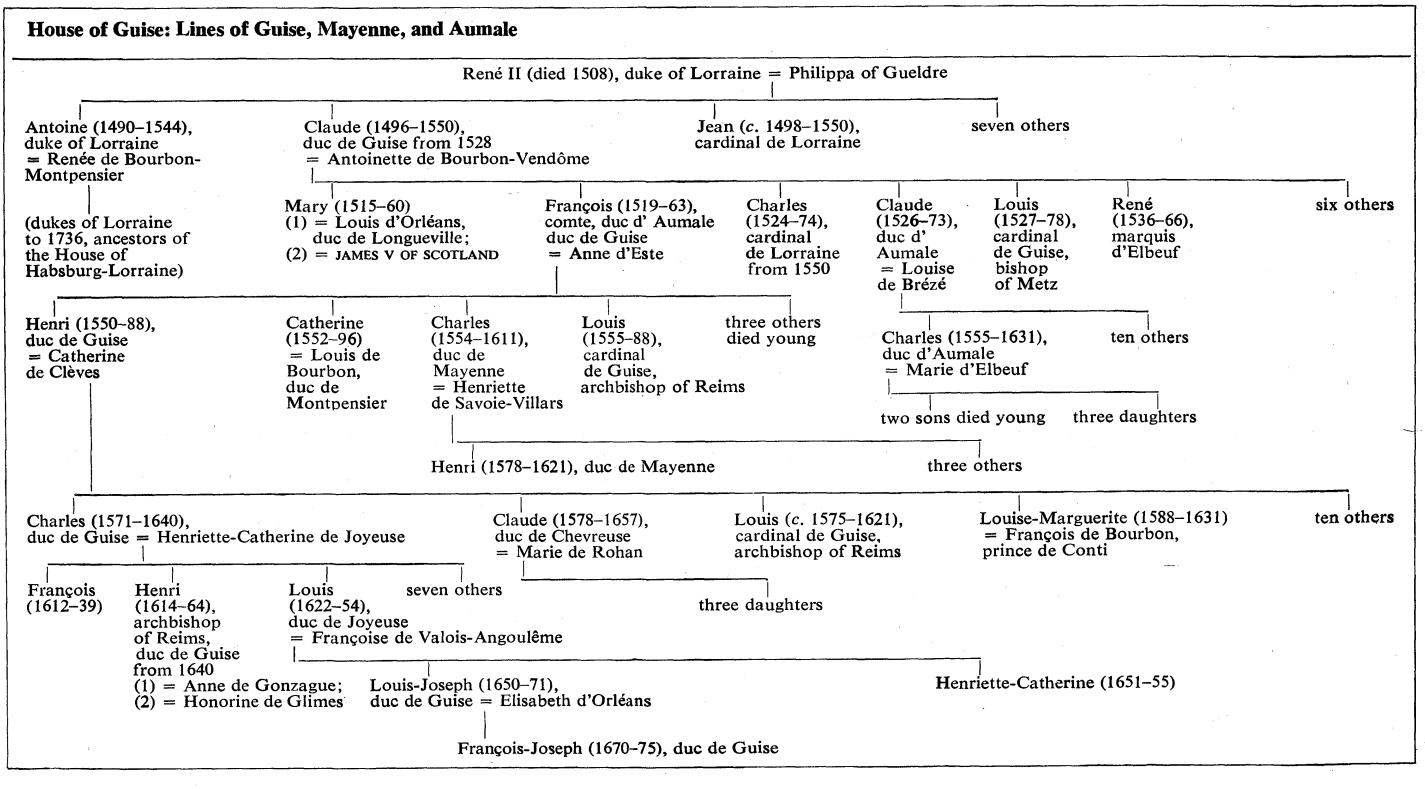
Francis II's sudden death in the same year led to a realignment of forces. Catherine de Médicis, regent for the new king, her son Charles IX, decided to try a policy of religious toleration and brought both Montmorency and the Bourbons back into the government. Guise, however, in 1561 reconciled himself with Montmorency in order to form a Catholic front against the Huguenots and their Bourbon sponsors. His attack on a Huguenot congregation at Vassy in 1562 led to France's Wars of Religion. The Battle of Dreux, where his intervention ensured the Huguenot defeat, returned virtual control of the government to him; but in February 1563, besieging Orléans, he was mortally wounded by a Huguenot assassin.

Henri de Lorraine (1550–88) succeeded his father as 3rd duc de Guise. Though he did not play a great role in the second of the Wars of Religion (1567–68), his conspicuous bravery in the third (1568–70) made him the idol of the young nobility at court; and after that war he began to ingratiate himself also with the people of Paris. Meanwhile, he was biding his time for vengeance on the Huguenot leader Gaspard de Coligny, whom he regarded as the instigator of his father's assassination.

In the summer of 1572, when Coligny's growing influence over Charles IX was drawing France toward open war against Spain, Catherine de Médicis seems to have appealed to the Guises to eliminate him. At that moment many Huguenots had come to Paris for the marriage of the Bourbon king of Navarre (later Henry IV of France); and when the attempt on Coligny's life miscarried, Catherine decided that it must not only be repeated with success but also accompanied by a general slaughter of his infuriated supporters. In the Massacre of Saint Bartholomew's Day (August 23–24), Guise supervised the killing of Coligny; but he sheltered 100 other Huguenots in his house before leaving Paris for a campaign in the provinces (fourth of the Wars of Religion, 1572–73).

Charles IX's brother became king of France, as Henry

House of Guise: Lines of Guise, Mayenne, and Aumale



III, in 1574. He married a princess of Lorraine, one of Guise's cousins; and in October 1575, during the fifth of the Wars of Religion (1574–76), Guise saved Paris for him by defeating the Huguenots' German mercenaries at Dormans. The peace terms of 1576, however, appeared to Guise as a betrayal of Catholic interests; and so, to promote the latter, he formed a Holy League of Catholic nobles—an almost overt challenge to the King's authority. The King countered by declaring himself head of the league and by denouncing the peace; but at the end of the sixth of the Wars of Religion (1577) he dissolved the league and again granted a measure of toleration to the Huguenots. The Guises in resentment strengthened their links with Spain, the one reliably Catholic power.

Formation of the Holy League

When Henry III's last brother died in 1584, Henry of Navarre became heir presumptive to the French throne. To exclude this Huguenot from the royal succession, the Guises promptly revived the league, with firm support from Spain. Henry III submitted to their dictation (1585), and religious war broke out once more. Guise won two notable victories over the Huguenots in 1587; but Henry III was now more anxious to be rid of Guise's tyranny than to consolidate it by helping to destroy its opponents, Henry of Navarre and the Huguenots. On the Day of the Barricades (May 12, 1588), when the Parisians rose in favour of Guise against Henry, Guise might easily have deposed the King: instead he pacified the insurgents and Henry was able to escape. The Edict of Union (July 1588) was a further surrender by the King to the league; and in the following month Guise was nominated lieutenant general of the realm. The States-General, in session at Blois from October, were dominated by the league until, on December 23, 1588, Guise was suddenly called to the King's apartments: on entering the antechamber he was stabbed to death by the bodyguards. His brother Louis, cardinal de Guise, was murdered the following day.

The 3rd Duc's sister Catherine, duchesse de Montpensier, was active in exciting the Parisians against Henry III and Henry IV; her brother Charles, duc de Mayenne, continued the military struggle against Henry IV until 1595; and their cousin Charles, duc d'Aumale, was energetic in the same cause until 1594. The family remained prominent in the 17th century but ceased to play any dominant role.

BIBLIOGRAPHY. The only reasonably complete accounts of the House of Guise are RENE DE BOUILLE, *Histoire des ducs de Guise*, 4 vol. (1849–50); and HENRI FORNERON, *Les Ducs de Guise et leur époque*, 2nd ed., 2 vol. (1893). AUGUSTE BAILLY, *Henri le Balafré, duc de Guise* (1953), is a popular biography of the 3rd Duc. For a useful up-to-date survey of the background, see GEORGES LIVET, *Les Guerres de religion (1559–1598)*, 2nd ed. (1966). Relevant sources are indicated in HENRI HAUSER, *Les Sources de l'histoire de France au XVI^e siècle (1494–1610)*, 4 vol. (1906–15).

(R.J.K.)

Gujarāt

One of the 21 states of the Indian Union, Gujarāt lies on the west coast of India. It is bounded by the Arabian Sea to the west, by Pakistan to the northwest, the Indian states of Rājasthān to the north, Madhya Pradesh to the east, and Mahārāshtra to the south. Its coastline is 992 miles long, and no part of the state is more than 100 miles from the sea. Its area is 72,236 square miles (187,091 square kilometres), and its population at the 1971 census was about 26,700,000.

The capital of the state is Gandhinagar on the northern outskirts of Ahmadābād (Ahmedabad), the former capital, largest city in the state, and one of the greatest cotton-textile centres in India. It was here that Mahatma Gandhi built his Sābarmati *āśrama* ("retreat," or "hermitage") as a headquarters for his campaigns.

Gujarāt derived its name from the Gurjara (supposedly a subtribe of the Huns), who ruled the area during the 8th and 9th centuries AD. The state in its present form came into existence in 1960 when the former Bombay state was divided between Mahārāshtra and Gujarāt on a language basis.

Though most of the people are engaged in agriculture, there is a cohesive and comparatively prosperous merchant community that thrives on the trade and commerce generated in Gujarāt because of its long coastline. For general historical background, see INDIAN SUBCONTINENT, HISTORY OF THE.

History. Human settlements have been traced back to the Stone Age period in the valleys of the Sābarmati and Mahi rivers in the eastern part of the state. The historic period is linked with the spread of the Harappan (Indus Valley) civilization, which flourished in the 3rd and 2nd millennia BC. Centres of this civilization have been found at Lothal, Rangpur, Amrī, Lakhabaval, and Rozdi (mostly in the Saurāshtra [Kāthiāwār] Peninsula).

The known history of Gujarāt began with the extension over the area of the rule of the Mauryan dynasty, as is evidenced by the edicts of the emperor Aśoka (*c.* 250 BC), carved on the Girnār Rocks in the Saurāshtra Peninsula. After the fall of the Mauryan Empire, Gujarāt came under the rule of the Śakas (Scythians), or western Kṣatrapas (AD 130–390). The greatest of these, Mahākṣatrapa Rudradāman, established his sway over Mālwa, Saurāṣṭra (Saurāshtra), Kutch, and Rājasthān.

The Mauryan period

During the 4th and 5th centuries, Gujarāt formed a part of the Gupta Empire, until the Guptas were succeeded by the Maitraka dynasty of the kingdom of Valabhī, which ruled over Gujarāt and Mālwa for three centuries. The capital Valabhīpura (near the eastern coast of the Saurāshtra Peninsula) was a great centre of Buddhist, Vedic, and Jain learning. The Maitraka dynasty was succeeded by the Gurjara-Pratihāras (the imperial Gurjaras of Kannauj), who ruled during the 8th and 9th centuries; they, in turn, were followed shortly afterward by the Solaṅki dynasty. The boundaries of Gujarāt reached their furthest limits in the time of the dynasty, when remarkable progress was made in the economic and cultural fields. Siddharāja Jayasiṃha and Kumārapāla were the best known Solaṅki kings; the famous writer Hemacandra flourished during this period (12th century). Karṇadeva Vāghelā, of the Vāghelā dynasty that followed, was defeated in about 1298 by 'Alā'-ud-Dīn Khaljī, sultan of Delhi; Gujarāt then came under Muslim rule. It was Aḥmad I, the first independent sultan of Gujarāt, who founded Ahmadābād (1411). The end of the 16th century saw Gujarāt under Mughal rule; this lasted until the mid-18th century, when the Marāthās overran the state.

The founding of Ahmadābād

Gujarāt came under the administration of the British East India Company in 1818. After the Indian rebellion of 1857, the area became a province of the British crown and was divided into Gujarāt province, with an area of 10,000 square miles, and numerous native states. With Indian independence in 1947, all of Gujarāt except the states of Kutch and Saurāshtra was included in Bombay state; the province was enlarged in 1956 to include the two states. In 1960 Bombay state was split into present-day Gujarāt and Mahārāshtra states.

In April 1965 fighting broke out between India and Pakistan in the Rann of Kutch, an area that had long been in dispute between them. A ceasefire came into force on July 1, and the dispute was submitted to arbitration by an international tribunal. The tribunal's award published in 1968 gave nine-tenths of the territory to India and one-tenth to Pakistan.

The landscape. *Physical geography.* The present-day state of Gujarāt is one of great contrasts; it stretches from the wet, fertile, rice-growing plains of the west coast, north of Bombay city, to the almost rainless salt deserts of Kutch. It is easiest to treat the state on the basis of its natural divisions. In the northwest, Kutch comprises a single district so arid as to be almost desert; it is bounded on the south by the Gulf of Kutch and on the north and east is separated from Pakistan and the mainland of India by the Rann of Kutch, best described as a vast salt marsh covering about 8,000 square miles. The Rann floods during the rainy season, slight though the rains may be, and Kutch is converted into an island; in the dry season it is a sandy, salty plain, plagued by duststorms. To the south of Kutch is the large peninsula of Saurāshtra (Kāthiāwār), lying between the Gulf of Kutch and the Gulf of Cambay. It also is arid and rises

The Rann of Kutch

from the coasts to a low, rolling area of hill land in the centre, covered with scrub or sparse woodland. The chief towns are found in the more fertile spots and were formerly the capitals of small states. Soils are mostly poor, having been derived from a variety of old crystalline rocks, but among the state's valuable products are the fine building stones of Porbandar. Rivers, except for seasonal streams, are absent. On the southern shores of the peninsula is the former Portuguese territory of Diu. Northeastern Gujarāt is mainly a country of small plains and low hills, through which runs the main line of a railway from Bombay to Delhi. Rainfall is low; January temperatures may drop almost to freezing point, while a temperature of 118° F (48° C) has been recorded in the hot season. Crops grown are millet and some cotton.

Southward in central Gujarāt the rainfall increases; temperature ranges are less; and soils are more fertile, being derived partly from the basalts of the Deccan region. The focus of this area is the city of Baroda, formerly the capital of a rich and powerful state. South of what is now the Baroda district, the important river, the Narmada, empties into the Gulf of Cambay, and it is the silt deposited by this river and the Tāpti that is responsible for the shallowness of the Gulf of Cambay and the decline of its former ports.

Southern Gujarāt, the districts of Broach and Surat, are famed for their rich soils and fine crops of cotton. The great Tāpti River, flowing in a deep trench from the east, cuts through Surat; and in the eastern parts of south Gujarāt the country is mountainous. This is, indeed, the northern extension of the Western Ghāts, which attract a heavy rainfall from the rain-bearing summer monsoon winds. Farther south, the mountains are forested. The small district of the Dangs is in this area. Along the coastal plains conditions begin to approach an equable climate, with rainfall nearing 80 inches.

Vegetation. Rainfall and altitude variations are such that the vegetation changes from north to south and from the east highlands to the west coast. With less than 25 inches of rainfall, the species in the scrub forests are the babul acacia, the caper, the Indian jujube, and the toothbrush tree (*Salvadora persica*). Where rainfall is up to 40 inches the following deciduous species are found: teak, catechu or cutch, bakligum, axlewood, and Bengal kino or butea gum. These are found in the tablelands of Saurāshtra and the east mainland area. Most of the deciduous forests are concentrated in areas with more than 40 inches of rain in the south and east. They produce valuable timbers: wooly tomentosa, Vengai padauk (resembling mahogany), Malabar simal, and the heartleaf adina. The west coast of Saurāshtra is known for its algae, and the east coast produces the paper-making plant *Cyperus papyrus* (a sedge known as the paper reed or paper rush).

Animal life. The forests of Gīr in Saurāshtra contain the last Indian lions, the only remaining numbers of the Asiatic species; in the Little Rann of Kutch the only surviving Indian wild asses are found.

The peacock is common throughout the state, and there is a bird sanctuary at Lake Nalsarovar, near Ahmadābād, which attracts about 140 species of birds migrating from the Siberian plains and elsewhere in winter. These include the sarus crane, the Brahmini duck, the bustard (a game bird), the pelican, the cormorant, the ibis (a wading bird related to the heron), the stork, the heron, and the egret.

There is excellent offshore and inland fishing in Gujarāt. Catches include pomfret (a food fish), salmon, hilsa (a type of shad), jewfish (scianid fish), prawn, Bombay duck, and tuna.

Population. Ethnically, there are two dominant racial strains in Gujarāt: a brachycephalic (short-headed) leptorhinian (straight-nosed) element, represented by the Parsi and the Nāgar Braham, Bhāṭiā, Bhādela, Rabāri, and Miana castes; and a dolichocephalic (long-headed) mesorrhinian (broad-nosed) element, represented by the aboriginal Bhīl and the Bhaṅgī, Kolī, Dubla, Naikda, and Mācchi-Khārwā tribes. The rest of the population are in intermediate groups; Gujarāt as a whole is a mesocephalous region (*i.e.*, one in which heads are approximately midway between brachycephalic and dolichocephalic). Members of the former untouchable castes (about 7 percent) and of the aboriginal tribes (about 13 percent) formed nearly one-fifth of the state's population at the time of the 1961 census. Of India's tribal population, about 10 percent lived at that time in Gujarāt, with the highest accumulation in the entirely tribal district of Dangs. Ahmadābād district had the highest proportion of scheduled (untouchable) castes.

The Gujarati language

The Gujarati language belongs to the Indo-Aryan family of languages and is derived from Sanskrit through Prākrit, ancient Indic languages other than Sanskrit, and Apabhraṃśa, a language spoken in northern and western India from the 10th to the 14th century. Gujarāt's contact by sea with foreign countries has also led to the introduction of Persian, Arabic, Turkish, Portuguese, and English words. The prodigious writings in Gujarati of Mahatma Gandhi (*q.v.*; architect of India's freedom and apostle of the doctrine of nonviolence), which are noted for their vigour and simplicity, have had a strong influence on modern Gujarati prose.

Hinduism was the religion of almost 90 percent of the population at the time of the 1961 census, whereas 8 percent adhered to Islām and 2 percent to Jainism. The policy of the state has always been marked by the religious tolerance of its rulers.

The density of population in the state was 369 per square mile in 1971, as compared to 434 per square mile for India as a whole. Of the total population, about 28 percent was urban, as compared to 20 percent for India as a whole. The most highly urbanized part of the state was the Ahmadābād-Baroda industrial belt. More than half the urban population lived in 24 of the 217 towns in the state. The major industrial towns are Ahmadābād (population, 1971 census, 1,600,000), Baroda (470,000), and Surat (470,000). Major towns that were once capitals of princely states are Rājkot (300,000), Bhavnagar (Bhaunagar) (230,000), and Jāmnagar (215,000).

Administration. A governor, appointed by the president of India, is the head of the government of Gujarāt. A council of ministers, led by the chief minister, aids and advises the governor in the exercise of his functions. The Legislative Assembly, an elected unicameral legislature, consists of 168 members.

Justice. The High Court, with 14 judges, including the chief justice, is the highest judicial authority in the state. There are also city courts, the courts of district and sessions judges, and courts of civil judges in each district.

Local government. The state is divided into 19 districts, the revenue and general administration of each being looked after by the district collector, who also functions as the district magistrate for the maintenance of law and order. The 19 districts are: Ahmadābād; Baroda; Banās Kāntha; Broach; Mehsāna; Kaira; Pānch Mahāls; the Dangs; Surat; Sābar Kāntha; Jāmnagar; Bhavnagar; Amreli; Junāgadh; Kutch; Rājkot; Surendranagar; Bulsār; and Gandhinagar.

The *pañcāyats*

With a view to associating the people living in the remotest villages with the administration, rule by *pañcāyat* (local governing committee) was introduced in 1963. The scheme comprised (1) a *grām* (village) *pañcāyat* for each village or group of villages or a *nāgar* (town) *pañcāyat* for towns with a population of between 10,000 and 20,000; (2) a *taluka* (an administrative unit similar to a county) *pañcāyat* for each *taluka* (called a *tahsil* in some states); and (3) a district *pañcāyat* for each district. There were 182 *taluka pañcāyat*s in the early 1970s, 59 *nāgar pañcāyat*s, and almost 12,000 *grām pañcāyat*s covering about 19,000 villages. In addition, 2,000 *nyay* (judicial) *pañcāyat*s and 12,000 conciliation *pañca*s (committee members) had been constituted to administer justice in certain matters in rural areas. There were 59 municipalities and three municipal corporations (in Ahmadābād, Baroda, and Surat). These worked under the supervision of the director of municipalities.

Social conditions. *Health.* In the early 1970s health and medical services were still being extended to remote

and backward areas. There were programs for the eradication of malaria, tuberculosis, leprosy, and other communicable diseases as well as for improving supplies of drinking water and preventing food adulteration. Steps had also been taken to expand hospitals and medical colleges. There were 250 primary health centres, five hospitals, and a dental college.

Education. Primary schools for all children between seven and 11 had been opened in the early 1970s in nearly all villages with 500 or more inhabitants. Besides these, special schools were teaching arts and crafts. There were 2,000 secondary schools with 730,000 pupils, as well as seven universities and more than 250 institutions for higher education, with an enrollment of 125,000 students. Technical education was provided by seven engineering colleges, three junior technical, and 42 technical schools. Research institutions included the Physical Research Laboratory, the Ahmadābād Textile Industry Research Association, the Bholabhai Jesinghbhai Research Institute for Oriental Studies, the Indian Institute of Management, the National Institute of Design, and the Sardar Patel Institute for Economic and Social Research. There were also institutes doing research in agriculture and fisheries.

Welfare. At the same time there were state institutions under the director of social welfare for the welfare of children, women, the physically handicapped, the aged, infirm, and destitute, for delinquents, beggars, orphans, and released prisoners. There is also a Backward Class Welfare Department for the education, economic uplift, health, and housing of the backward class, which constitutes about 20 percent of the population.

The economy. About two-thirds of the population were engaged in agriculture in the early 1970s, the gross crop area amounting to about 50 percent of the total land area. Wheat and millets were the staple food crops, with rice production being concentrated in the wetter areas. Sugar production was increasing, while cotton, tobacco, and oil seeds (especially peanuts) were profitable cash crops. Cash crops were, indeed, a characteristic feature of the state's agricultural economy, slightly exceeding food crops in value.

The role of agriculture

Food requirements of the state were 5,740,000 tons and food production 3,950,000 tons. Lack of irrigation was a major handicap, only 10 percent of the crop area being irrigated, as compared with an all-India average of 21 percent. There had, nevertheless, been a distinct improvement in agricultural yields in recent years.

Gujarāt occupied third place, after Mahārāshtra and West Bengal, in the industrial economy of India. Output of soda ash amounted to 94 percent of the national production, salt about 55 percent, clocks about 40 percent, and cotton textiles about 30 percent. There were 116 textile mills, of which 70 were in Ahmadābād, "the Manchester of India." The pharmaceutical industry, concentrated at Baroda, Ahmadābād, and Atul (Bulsār), manufactured one-third of the national product. The steady growth of small industries has been significant. The Gandhian approach to labour problems—strict reliance on the truth, nonviolence, settlement by arbitration, minimal demands, and the use of the strike only as a last resort—has had a great impact in the field of industrial relations in Gujarāt, which has remained free from labour unrest.

Lacking in hydroelectric power, the state had a 250-megawatt thermal-power station using coal, natural gas, and oil built at Dhuvaran, the capacity of which would be doubled by 1973. From July 1969 the state was receiving power from the Tarapore nuclear station in Mahārāshtra. The total generating power in the state was due to increase to 1,452 megawatts by 1972.

Transport and communications. There were 3,500 miles of railways in the state in the early 1970s and 20,000 miles of roads. Road passenger transport had been nationalized and operated with about 2,600 vehicles and a staff of 24,000.

Transport by land was supplemented by water transport, particularly by coastal shipping. There were 45 ports besides the major international port of Kandla. Of these, 25 were open to foreign ships and 20 to coastal shipping. Six of these were all-weather ports.

Gujarāt had nine airports, and there were more than 6,000 post offices and 500 telegraph offices.

Cultural life. The folklore and folk culture of Gujarāt can be traced to the mythology of Lord Kṛṣṇa (Krishna; an incarnation of the god Viṣṇu, or Vishnu), as told in the *Purāṇas*, a class of Hindu sacred literature. The *rāsnṛtya* and *rāslīlā* dances in honour of Lord Kṛṣṇa have survived in the form of the popular folk dance, the *garabā*. This dance is performed at the *Navarātrī* festival, which honours the goddess Durgā, the dancers moving in a circle and singing and keeping time by clapping their hands or clashing together sticks called *daṇḍa*. A folk drama, the *bhavai*, has also survived.

Śaivism (Shivaism), the cult of the god Śiva (Shiva), characterized by ritual devotion, has long flourished in Gujarāt; so, too, has Vaiṣṇavism (Vishnuism, the worship of the god Viṣṇu), the devotional practices of which, with the emergence of the cult of *bhakti* ("devotion"), inspired its devotees to compose songs to be sung in temples or other religious gatherings. Vaiṣṇavism has encouraged the emergence of a number of saints, poets, and musicians, such as Narsiṃha, who composed *padas* (verses) in the 15th century; Mīrā Bāī, a 16th-century Rājput princess who renounced her royal home and composed *bhajanas* ("devotional songs"); Premanand, an 18th-century poet and writer; and Dayarām, an 18th-century composer of songs who popularized the *bhakti* cult. Jainism, with its nonviolence and vegetarianism, gained a stronger hold in Gujarāt than in any other part of India.

The architectural style of Gujarāt is well-known for its luxuriousness and perfection. The style is preserved in such monuments and temples as those at Somnāth, Modhera, Thān, Ghumli, Girnār, and Pālitāna. A happy synthesis of Hindu-Muslim culture has also been preserved in many ancient monuments. Gujarāt is famous, too, for some of its art and craft products. These include the *jari* (gold and silver embroidery) of Surat; the *bāndhaṇī* (a sari) of Jāmnagar; the *paṭolā*, a fine silk fabric of Pātan, woven with hereditary skill; the toys of Idar; the perfumes of Pālanpur; the hand-loomed products of Konodar; and the decorative woodwork of miniature temples and mythological figures at Ahmadābād and Surat.

Among the most durable and effective of the state's cultural institutions are the trade and craft guilds known as the *mahājans*. Often coterminous with castes and largely autonomous, the guilds have in the past solved disputes, acted as channels of philanthropy, and encouraged arts and culture.

The *mahājans*

Gulfs and Bays

Terminology and configuration

Any concavity of a coastline or re-entrant of the sea, regardless of size, depth, configuration, and geological structure, may be called a gulf or bay. Though the two terms are not strictly defined, the term gulf usually refers to large water bodies. Some large gulfs and bays preserve local names such as bight (Australia), channel (England), firth (Scotland), sound (U.S.), fjord (Norway), fjörd (Sweden), fjördhur or *floi* (Iceland), *zaliv* or *guba* (U.S.S.R.), ria or *río* (Iberian peninsula and South America), and *wan* (China and Japan). A number of pronounced concavities of oceanic margins have no proper name at all.

The problem of terminology extends to the difference between gulfs and seas. There are many small seas, such as the Sea of Marmara (0.011×10^6 square kilometres) and the Sea of Azov (0.038×10^6 sq km), which, strictly speaking, are really gulfs of the ocean or other seas (the Sea of Azov is a gulf of the Black Sea). The Gulf of Aden (about 0.270×10^6 sq km), another example, is part of the Arabian Sea and these water bodies have a common regime (similar tides, precipitation, evaporation, etc.). The narrow sound of Bab el-Mandeb connects the gulf with the vast Red Sea (0.438100×10^6 sq km) and exhibits a number of specific geomorphic features. The Red Sea, in turn, has two small gulfs to the north, namely, those of Suez and Aqaba.

The Bay of Bengal and the Arabian Sea are approximately the same size and have the same monsoonal water circulation. The Bay of Bengal is, in fact, the largest of the gulfs and bays, with a surface area of 2.172×10^6 sq km, volume of 5.616×10^6 cu km, and a length of 1,850 km (Table). The width of a gulf may exceed its length. The Great Australian Bight has the widest mouth (2,800 km). The Gulf of Guinea is deepest; its maximum depth (6,363 metres) exceeds that of the Bay of Bengal by more than 1,000 metres.

The shape and bottom topography of gulfs and bays are amazingly diverse. They depend on the geological structure and development of the region. Homogeneous bedrock of low strength or resistance results in simple shapes and shallow depths. The Gulf of Riga (at the Baltic Sea) is a possible example of the type. Long narrow arms with approximately parallel shores of the south Kara Sea extend inland for about 800 kilometres. They occupy troughs that originated by erosion during a period of lower sea level (Baidaratskaya Guba, Obskaya Guba with Tazovskaya Guba tributary, Yenisei Bay, Gydanskaya Guba). Deep, angular gulfs, on the other hand, are created along fractures, faults, and rifts (*e.g.*, Varanger Fjord); they usually have irregular bottom topography. Parallel fractures form very deep, narrow gulfs with parallel shores, such as the Gulf of California. Genuine fjord-gulfs are notable for their very high length to width ratios (up to 50:1). In regions that have undergone nonuniform deformation and uplift, gulfs and bays of complicated and irregular shape and bottom topography are consequently formed; the Gulf of St. Lawrence is an example.

Gulfs are connected with the sea by means of one or more straits. Sometimes there may be an archipelago in the mouth of the gulf as in the Gulf of Bothnia. There are some gulfs that open into the sea or into another gulf on opposite sides (Baffin Bay, Gulf of Aden, and the Gulf of Oman).

Single gulfs usually are formed along linear shores of the continent. If the shoreline is irregular and has a complex geological structure, groups of gulfs of a similar nature may occur. Most shorelines have small reentrants of various size that are called bays. These features are strongly influenced by local conditions, and they are not described or classified within the context of this article, which treats major water bodies of the world. For additional information on the dynamics of water within gulfs and bays, see WATER WAVES; TIDES; and OCEAN CURRENTS. For a further discussion of coastal morphology and shoreline features in general, see COASTAL FEATURES; RIVER DELTAS; and BEACHES. See also HOLOCENE EPOCH for a discussion of recent changes of sea level.

FACTORS THAT INFLUENCE THE NATURE OF GULFS AND BAYS

Climates, sills, and river runoff

Gulfs and bays may differ from the adjacent sea by virtue of water properties and dynamics and processes of sedimentation. Such differences are determined by the size and the shape of a given gulf, by the depth and bottom topography, and to a considerable extent by the degree of isolation from the ocean. Climatic conditions also are important. Isolation from an adjacent sea or ocean depends on the ratio of width of mouth to total surface area of a gulf or on the cross section of the mouth to total water volume. If there is a sill, the ratio of depth above the sill to the depth of the gulf is of great importance. No extensive comparisons of these ratios have been made to date; hence analysis of controlling variables must remain somewhat qualitative.

A high sill hampers the water exchange between an ocean and gulf and may lead to stagnation (oxygen deficiency) as is found in some fjords of Norway, in the Red Sea, and, particularly, in the Black Sea. Also, the presence of a sill causes independent circulation of gulf waters, created by local winds and the runoff of rivers. Sills are not indispensable for the formation of an independent circulation, however. A narrow mouth, as in the Gulf of Bothnia, leads to the same result.

In humid climates, the waters of gulfs are freshened by river runoff. Salinity is particularly low in the gulfs of the Baltic Sea and along the southern coast of the Kara Sea. Water becomes almost fresh in their heads, especially in the spring when snow begins to thaw. Gulfs of the arid zone suffer from intensive evaporation and receive little river runoff. Thus, salinity increases markedly in this climatic regime—up to 60 parts per thousand in the Persian Gulf and up to 350 parts per thousand in Kara-Bogaz-Gol (Caspian Sea). In addition to its effect on salinity, river runoff delivers organic matter and nutrient salts that may determine the specific features of life in the gulfs. The number of genera and species of organisms is small, but the organisms present tend to develop in quantities. That is why shrimp, oyster, and other fisheries are concentrated in many gulfs.

Funnel-shaped gulfs, in which the depth gradually decreases headward, usually have resonant tides. The tidal range at the head of such gulfs is several times greater than that in the open sea (Bristol Channel, Río de la Plata, Mezenskaya Guba, Zaliv Shelikhova, etc.). The world maximum tidal range has been registered in the Bay of Fundy (18.0 metres). The regularity (magnitude and frequency) of the flood tide may be distorted in such instances and the duration of the flood tide may become much shorter than that of the ebb tide. This may cause the phenomenon of bore, or mascaret, in which a steep wave will move rapidly upstream for dozens of kilometres.

Gulfs of simple shape with narrow mouth and a high degree of isolation from the ocean commonly are subject to seiches. These free oscillations can result from rapid changes of atmospheric pressure and, of course, from tectonic movements such as earthquakes. Seiches gradually decrease but some oscillation continues long after their cause disappears. A high rise of the water (storm surge) occurs in long and shallow gulfs if winds from the sea are protracted. Such phenomena are difficult to predict, and the high water levels may cause floods. Seiches often occur at the heads of Helgoländer Bay in the North Sea and in the Gulf of Finland.

Certain aspects of sedimentation are affected by the isolation of gulfs from the sea and river runoff. The rate of sediment accumulation in gulfs of limited area may be very high. This, of course, is a function of river discharge; sediment composition is usually similar to that of the load transported by entering rivers. Deposition of calcium carbonate often occurs in shallow gulfs in the arid zones where few if any perennial streams exist. The

*Data in this table may differ from those given elsewhere in set for some features because of differing definitions of geographical limits of each feature. Data adapted in part from Kossina (1921, 1933) and Lyman (1961). †Cook Inlet's head. ‡Davis Strait. §Up to ten metres at the Colorado River mouth. ‖Up to the Minas Bay head. ¶Not given because of the complicated outlines. ♀The value for the Red Sea's head. ♂In shallow parts along the south coast. □Up to 4 metres at the Mae Nam Chao Phraya. °South Quarken Strait—40 kilometres. ▲From the Laichow Wan head to Liao-tung Wan's head.

bottoms of long gulfs (or gulfs having sills) are usually covered with silt even at the shallowest depths (*e.g.*, Hudson Bay, the Gulf of Chihli, the inlets or *gubas* of the Kara Sea, the Gulf of Riga). Only strong tidal currents can prevent this siltation and, in some cases, cause the opposite phenomenon of bottom erosion. Currents maintain the existence of or actively deepen bottom troughs in narrow-mouthed gulfs whose depths are over 200 metres, whereas depths of adjacent parts of the open sea are only on the order of some dozens of metres.

Waves of the open sea either do not penetrate into comparatively isolated gulfs or, if they do, they become greatly reduced after entry. Small local waves that are related to gulf size prevail there. This tends to make gulfs quite navigable, and seaports and harbours have generally been situated on them.

CLASSIFICATION OF GULFS AND BAYS

The waters of gulfs and bays fill any depression in the earth's surface. Their geological structure and history of development are as varied as are those of the continents proper. The factors discussed above influence the morphological peculiarities of gulfs, and the latter, in turn, permit some general division or classification of these features to be made. The several groups in one possible scheme will be discussed here using typical gulfs and bays of each group as examples (Table).

Open concavities and isolated areas

Areas situated in open concavities of the continental coast (Gulf of Alaska, Bay of Biscay, Gulf of Guinea, Great Australian Bight, Bay of Bengal, Gulf of Tehuantepec etc.) are classified as the A_1 group. The depth of these gulfs in the region of the mouth usually is on the order of kilometres. The continental shelf and slope are generally pronounced. The general shape of such gulfs is simple; width of mouth usually exceeds its length. Water circulation and its physical properties are similar to those of the ocean. The character of the marine faunas does not differ from that of oceanic areas.

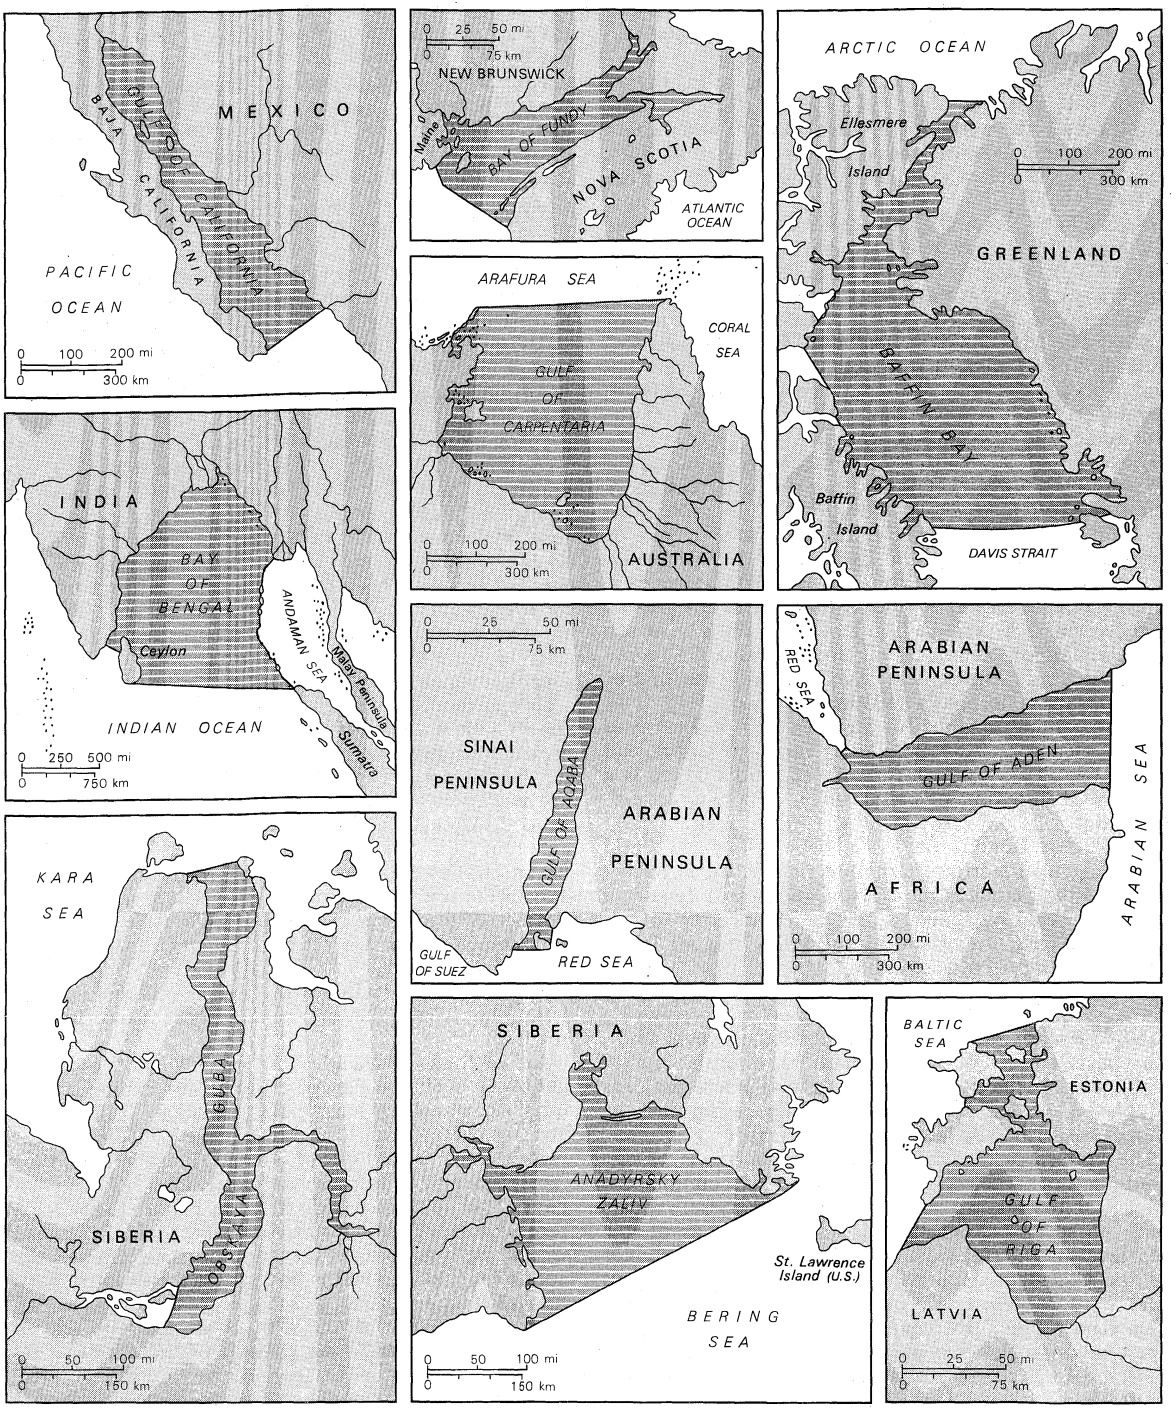
Large areas considerably isolated from the ocean, such as the Gulf of Mexico and Baffin Bay, are designated as group A_2 (Table). The former includes a geosynclinal hollow, founded in Mesozoic time and finally shaped during the Tertiary Period (2,500,000 to 65,000,000 years ago). It is connected with the ocean by the narrow and relatively shallow straits of Florida and Yucatan. Baffin Bay is a rift hollow that is connected by straits with the Atlantic and the Arctic oceans.

Ocean gulfs, such as the Gulfs of Oman, California, Aden, and some others have smaller areas and are isolated to a lesser degree. These gulfs and bays, in group A_3, have shapes that are determined by young faults and fractures. Depths in these gulfs generally exceed one kilometre. Unlike the previous group, in which gulfs might be of composite geological structure, these occupy areas that have undergone only a single episode of deformation.

Gulfs situated on the oceanic shelf, such as the Bay of Fundy, Hudson Bay, Río de la Plata, Golfo-St.-Mathias, and others, are in group B. The depth of such gulfs is up to 200 metres or more, and their configuration is determined by geological conditions. Because shelf areas repeatedly became dry land when the sea level fell during the ice ages, these gulfs received their final shape during the Pleistocene Epoch. The Gulf of St. Lawrence is included in this group (Table), though it is really intermediate between groups A_3 and B. It contains both a pronounced shelf and a long trough up to 530 metres deep.

Marginal and shelf areas

Gulfs of intercontinental and marginal seas are considered to be a third category. These may be divided into group C_1, which consists of gulfs of basin seas, including the deepwater part only (Aqaba) or both the deepwater and the shelf parts (the Gulf of Honduras), and group C_2, the shelf gulfs of the same seas (the Persian Gulf, Gulf of Suez, Anadyrsky Zaliv, Bristol and Norton channels, Zaliv Shelikhova, etc.).



Plans of typical gulfs and bays.

Finally, there are the gulfs of the shelf seas (*gubas* of the Arctic seas of the U.S.S.R., gulfs of the Baltic and the White Seas, the Gulf of Carpentaria, the Gulf of Chihli, and many others), which are placed in group D (Table). The shallow character of the shelf seas influences the water dynamics of the gulfs. Water exchange is weakened, and sediments may accumulate in the gulf mouths, thus forming submarine barriers and further reducing exchange.

Certain characteristic features of these groups of gulfs and bays are enumerated in the Table. Some additional group characteristics can best be seen by describing in greater detail selected typical gulfs and bays exhibiting common and distinctive features.

TYPICAL GULFS AND BAYS OF THE WORLD

Gulf of Alaska. The Gulf of Alaska is a wide concavity of the North American Pacific coast. Its water properties and circulation are those of the ocean. Along its entire shore there are mountains and fractures that form fjord type bays and mountainous islands. The continental shelf in this area is rather broad to the north and west of the gulf, but it is dissected by troughs and contains other depressions. The main elements of coastal relief and continental shelf are of tectonic origin (related to earth deformation), but they received a final molding during the last glaciation. Glaciers still flow down into the heads of some bays and form icebergs. The shore of the gulf has high seismicity and is part of the Pacific earthquake belt.

Diatomaceous ooze (muds composed of unicellular organisms termed diatoms) is widespread in the deeper part of the gulf. An important peculiarity of the bottom topography of the Gulf of Alaska is the occurrence of submarine mountains with flat tops (guyots). These are ancient volcanoes that were abraded and planed off at or

near sea level. Subsequently, these volcanoes were submerged and their present depth is as much as 1,000 metres or more.

Bay of Bengal. The Bay of Bengal is part of the Indian Ocean. It washes the Indian and Sri Lanka (formerly Ceylon) shores in the west and borders on Burma and a chain of the Andaman and Nicobar islands in the east. Its basin occupies a tectonically stable area. It has a flat bottom and steep continental slopes. The shelf is narrow though developed all along the continental coast. It is fairly wide at the head of the bay where a broad delta of the Ganges and the Brahmaputra rivers is situated. A large submarine canyon begins at the mouth of the Ganges, which almost crosses the entire shelf. Submarine canyons of smaller size were discovered recently along the coasts of India and Sri Lanka. The Indian coast is relatively flat and is bordered with broad sand beaches. Coral reefs are developed along the Sri Lanka shores and those of the Andaman and Nicobar Islands.

Deltas, coral reefs, and submarine canyons

The water of the bay has certain oceanic features, but its salinity is somewhat lower. It exhibits a seasonally fluctuating circulation that changes with the monsoons. In spring the current moves clockwise with a velocity of three to five knots along the Indian coast. Subsequently, a counterclockwise and weaker circulation appears. During this period the salinity of the water falls sharply because the rainy season begins. During the dry season an upwelling of deep water takes place along the Indian coast (Waltair), the content of oxygen falls, and that of nutrient salts (phosphates and nitrites) rises.

The prevailing sediment of the deep part of the bay is Globigerina ooze. Alluvial mud accumulates in the head of the bay at a very high rate of deposition. There is a zone of shell-sediment and calcium carbonate concretions along the outward part of the Indian shelf.

Baffin Bay. Baffin Bay is a deep, elongated basin stretching in a northwestern direction between Greenland and the islands of the North Canadian Archipelago. It is connected by Smith, Jones, and Lancaster sounds with the Arctic Ocean and by the much broader Davis Strait with the Atlantic Ocean.

Ice molding and Holocene terraces

The flat bottom of Baffin Bay originated as a result of sinking (possibly along faults) that took place during pre-Quaternary time (more than 2,500,000 years ago). Its coasts consist of igneous and metamorphic rocks. They are mountainous and are cut by numerous fjords of glacial origin. In the northern part of the bay the shores are formed by the Greenland Icecap.

The bottom of Baffin Bay near its margins is of discontinuous character; broad troughs that continue the trends of the largest fjord systems occur there. Apparently these were molded by ice during periods of low sea level of Pleistocene time. It is possible that sounds of the Canadian Archipelago are ancient river valleys that were deepened by as much as 600 metres in pre-Quaternary time. Holocene terraces on the coasts have been raised to heights of more than 240 metres. The bottom of the central hollow is covered by land-derived mud; ice-rafted sediment is ubiquitous. Coarse sediment is deposited on the shelf and the continental slope.

Along the east shore of Baffin Bay the comparatively warm, northward flowing West Greenland Current occurs. Cold arctic water penetrates through Smith sound, over a sill that is less than 300 metres deep. Mixing with Atlantic water, these currents form the southerly flowing Baffin Island Current. Hence the general water circulation is counterclockwise. The waters of Baffin Bay also exhibit vertical stratification (layering), which results in an oxygen deficiency at great depths. The open part of the gulf is ice-free from July to September.

Gulf of Mexico. The Gulf of Mexico has a comparatively simple oval shape. Its shores lack large bays, but lagoons are abundant. There are two stretches of broad shelf to the north; these are off western Florida and Texas-Louisiana. The shelf areas are divided by the Mississippi Delta, in front of which a wide submarine trough is developed. There is a still broader area to the south that is termed the Yucatan (Campeche) Shelf. The shelf is very narrow in the west. A significant element of the bottom topography is a submarine cone descending to abyssal depth, which is derived from recent deposits of the Mississippi River. Steep continental slopes border the abyssal Sigsbee Plain, one of the flattest regions of the sea floor. There is a group of knolls, with a relative height of 370 metres, and smaller knolls have been discovered at the outer shelf zone and continental slope region of the northern Gulf of Mexico. Both groups of knolls are thought to be related to the intrusion of salt domes (*q.v.*).

Knolls of the Sigsbee Plain

In the middle of the gulf, the Earth's crust is of oceanic type, and a comparatively thin layer of continental type is present. In the north, there is a zone of crustal sinking that contains thicknesses of about 15 kilometres of Cretaceous and Tertiary sandy-clay sediments. To the east these alluvial sediments are replaced by a calcareous facies (lateral carbonate gradation). This elongated depression is called the Gulf Coast Geosynclinal.

The waters of the gulf have normal ocean salinity. They enter through the Yucatan Channel (1,500–1,900 metres deep) and form a mighty current. The latter makes a loop in the eastern part of the gulf at velocities as high as two metres per second and flows out through the Strait of Florida. This produces the Gulf Stream Current; an average of 25×10^6 cubic metres of water passes through the strait per second. In the western part of the gulf the currents have temporary character; their speed and direction depend on the winds.

Though the tidal range is small, the water level along the western and northern shores of the gulf may rise by as much as five metres during hurricanes. Destructive floods take place when this occurs. The waves of the gulf are much weaker than those of the ocean and their height generally does not exceed five metres.

Bottom sediments in the gulf are largely of terrigenous origin; silt occurs on the continental shelf and slope, and clay in the central parts of the gulf. A thin layer of carbonate sediments has been deposited on the shelves of Florida and Campeche. These rest upon a limestone surface of Quaternary and Tertiary age, which exhibits karst topography (pitted with caverns and sinks). The latter was formed during the Pleistocene lowerings of sea level.

Gulf of Oman and Gulf of Aden. The gulfs of Oman and Aden open into the Arabian Sea and exhibit similar physicogeographical conditions. They are fairly deep and are nearly equal in width, but the Gulf of Aden is twice as long as the Gulf of Oman. The salinity and the temperature of their waters are very high. The basins of both are of tectonic origin; they are related to the fracture system of the northwestern part of the Indian Ocean. Both gulfs have very narrow shelves and steep continental slopes, and the bottoms of their central parts are irregular.

Water circulation of the gulfs, connected with that of the ocean, depends on the changes of the monsoon regime. In the Gulf of Aden there is an established surface-water circulation. In summer it is clockwise and in winter counterclockwise. The same regularity may be observed in the Gulf of Oman, but it is less pronounced.

Gulf of California. The bottom of the Gulf of California consists of oceanic type crust with a thin (10–11 kilometre) overlying sialic (continental type) layer. It is part of a long trough that connects the San Andreas continental fault system and the mid-American deep-water trench. A number of recent, northwest-trending faults have broken the bottom into several isolated deepwater hollows; the gulf area is one of high seismicity. The continental slopes are very steep and the western slope is cut by a number of submarine canyons. There is a narrow shelf along the eastern side, and some rivers deposit their sediment loads on it.

Relation to the San Andreas fault

Three different areas of sedimentation occur from north to south. Alluvium of the Colorado River, principally silts and sands, is followed by diatomic silts, and oceanic clays occur farthest south. Carbonate sands are spread along the steep western shore.

The deep water of the gulf is oceanic in character. Thermal stratification (temperature zonation) causes an oxygen deficiency in intermediate layers. Surface-water circulation depends on the winds. Winter winds from the north produce an outflowing current, which is compensated for by upwelling of waters at the head of the gulf. Deep-sea water is rich in nutrient salts, and this upwelling leads to extensive plankton development. In summer, south winds direct the surface current toward the head, and water from the intermediate layer goes out into the ocean.

Bay of Fundy. The Bay of Fundy is remarkable for its high tides, which reach 18 metres in the head of Minas Bay (a world record). It is caused by the funnel-like shape of the bay and by a gradual rise of the bottom. This configuration results in resonance of the tidal wave, which is less than five metres high in the open sea. The same phenomenon raises tides sharply in the bays of Shelikhova, Cook Inlet, in the Mezenskaya Guba, and elsewhere.

High current velocities (two to four knots in the bay proper and up to 11 knots in Minas) are related to the coarse character of the bay sediments, which are mainly gravel. In the mouth of the bay these currents maintain a furrow that is more than 200 metres deep. Fine muds are deposited in protected areas near shore; broad tidal flats form in these parts of the bay.

Hudson Bay. Hudson Bay is situated within the Canadian Shield of Precambrian (more than 570,000,000 years ago) age. It has a simple rounded shape, but James Bay extends farther inland at the south. The shallowest part of the bay with a flat bottom is to the southwest. This is in the region of horizontally bedded Paleozoic rocks. The eastern part, which consists of Precambrian metamorphic rocks of greater surface irregularity, has a deeper and more irregular bottom, and a number of islands appear on the surface of the bay. Some irregularly shaped depressions about 200 metres deep exist in the central and the northern part of the bay. Recent research has shown that these hollows are the remnants of an ancient drainage net that led to the ancestral Hudson Strait. This strait connects Hudson Bay to the Atlantic Ocean today.

Drainage and Quaternary history

Coarse sand and gravel and much ice-rafted material are deposited in shallow places near shore. In the open part of the bay, to the west, the sediment is coarser (silt) in comparison to that in the east (silty clay). Sediment cores of the deep part of the bay reveal the presence of varved clays and till. This proves that the bottom of the bay was not submerged during the Quaternary regressions of the sea. During late phases of the glacial period, the area of Hudson Bay was one of the centres from which ice spread radially in all directions. Recently (during the last 8,000 years, approximately) the shores of the bay were subjected to isostatic uplift as a consequence of removal of the overburden of ice.

Hudson Bay receives a number of rivers, and its character is somewhat estuarine; pronounced water stratification exists in summer. Water coming through the Hudson Strait is of about 33.5 parts per thousand salinity, whereas the surface water is comparatively fresher. General water circulation is counterclockwise but this changes during periods of intensive river runoff. Hudson Bay is ice-free for only a few months a year, and the surface water is always very cool.

Gulf of St. Lawrence. The Gulf of St. Lawrence is situated between the crystalline rocks of the Canadian Shield and the folded Paleozoic rocks of the Appalachians. Its complicated shape and bottom topography are strongly determined by faults. The gulf is connected with the ocean by the Cabot Strait. Another narrow strait is called Belle Isle and is situated to the north of Newfoundland. A comparatively deep and smoothly curved trench leads from Cabot Strait to the mouth of the St. Lawrence River. It has some branches to the north of Anticosti Island and in the direction of Belle Isle. The southern part of the gulf (between Cape Breton and the Gaspé Peninsula) is quite flat and shallow.

The Earth's crust is up to 45 kilometres thick in the Gulf of St. Lawrence. The bottom topography of the gulf and its hilly shores received their modern shape through the influence of Quaternary glaciers. It is thought that a glacier excavated the comparatively deep furrows along the axis of the gulf. The northern shores of the gulf have undergone isostatic uplift at a rate of 40 centimetres per 100 years. The rate of uplift is zero in the direction of the southern shore, however.

The water of the cold Labrador Current penetrates the gulf, and St. Lawrence River water is mixed with this, reducing its salinity and raising its temperature (in summer). The general surface circulation is counterclockwise. Oceanic water forms the bottom layer with a salinity of 34 parts per thousand. The water stratification is subjected to seasonal changes. Ice cover is present from November through April in the western part of the gulf and until June in the eastern part.

Persian Gulf. The Persian Gulf is situated in a pronounced depression and is connected with the Gulf of Oman through the Hormuz Strait. The Arabian shore on the south consists of crystalline rocks of the Arabian Shield, upon which sedimentary rocks rest. This shore is fairly high but is bordered by a low-lying plain. Lagoons and small coral islands are present.

The Zagros Mountains extend along the northern shore. They were formed during Tertiary episodes of folding, and the thickness of rocks in the Zagros is over 12 kilometres. The Persian Gulf depression was created as a result of mountain-building processes. Salt plugs may be observed at the bottom and on the shores of the gulf, and there is some evidence of recent submergence in the deltaic area, while, to the south, there are uplifted terraces on both shores.

Topography, currents, and salinity

The bottom topography of the gulf is rather discontinuous, save for its northern and southern parts. Bottom deposits form three different regions, or zones. There is a thick layer of sand and clay with up to 20 percent calcium carbonate in the head of the gulf. In the centre, calcareous sediments of chemical and biogenic origins prevail. Coarse carbonate sands are deposited in shallow parts of the gulf, especially along its southern shore. These sands contain shell fragments, corals, and organic remains in general. Windblown material from the adjoining deserts is present everywhere.

Due to strong evaporation in the Persian Gulf, the surface waters of Oman penetrate the gulf waters as a compensation current. As their salinity increases, they become denser and flow back to the Gulf of Oman along the bottom. Strong tidal (up to four knots in the Hormuz Strait) and wind currents are superimposed on these salinity currents. Distinct vertical stratification probably does not exist because of strong currents and the shallowness of the gulf.

Zaliv Shelikhova. The Zaliv Shelikhova is an enlarged copy of the Bay of Fundy. The resonance of its tidal wave raises water levels in its forked head (Penzhinskaya Guba) by almost 13 metres. Tidal currents determine the coarseness of the bottom sediments, and a trough over 400 metres deep, stretching from the Sea of Okhotsk into the gulf, also is related to these tidal currents.

Zaliv Shelikhova is frozen for some months. In summer the upwelling of its deep cold waters takes place near the mouth, and the surface circulation is counterclockwise.

The Gulf of Thailand and the Gulf of Carpentaria. These gulfs have much in common. Both are vast shelf areas with rectangular contours (determined by tectonics) that open widely into the sea. The Gulf of Thailand is in the humid tropical zone, however, and the Gulf of Carpentaria, in the arid tropical zone.

The water of the South China Sea penetrates into the Gulf of Thailand at its bottom, and the freshwater of the Mae Nam Chao Phraya (Chao Phraya River) is spread on the surface. This forms stratification of estuarine character. The surface water circulation, depending on the monsoons, is clockwise in autumn and winter and coun-

Water circulation and swamp occurrences

terclockwise in summer. Upwelling of bottom water of high salinity (up to 34 parts per thousand) takes place in areas of divergent currents. Muddy alluvium of the Mae Nam Chao Phraya covers the entire gulf bottom, and a considerable part of its low shores with mangrove swamps were similarly derived.

The Gulf of Carpentaria extends into the northern shore of Australia. Its flat basin is bordered by faults that separate Precambrian rocks of the western coast from Mesozoic and Tertiary rocks of the east. These rocks are not visible everywhere because the low shore is bordered by mangrove swamps. The gulf was not filled by seawater until Holocene time.

Mezenskaya Guba. This bay is distinguished from other gulfs and bays of the White Sea by the high tides at its head. In this respect it is similar to the Bay of Fundy. Because of the strong currents, the flat bottom of the bay is covered by coarse gravel and exposed outcrops of Permian carbonate rocks. Clay and peat shores of the bay retreat at a rate of up to ten metres a year. This is due to the influence of drift ice (the bay is frozen for some months) and melting of the permafrost within the shores. Muddy tidal flats, many kilometres in width, exist in estuaries of Mezenskaya Guba and in some open areas. These flats also constitute a characteristic physical feature of the area.

Obskaya Guba. The longest inlet of the southern shore of the Kara Sea is the Obskaya Guba. It receives the runoff of the Ob and Taz rivers, and its currents tend to have runoff characteristics. In summer, water emerging from the *guba* is six to eight degrees warmer than that in the adjoining part of the sea.

The shores of the *guba* consist of loose Quaternary alluvium. They are precipitous on the west, where they are being attacked and destroyed by the sea. On the east they are mainly low-lying.

Gulf of Chihli. This gulf is noteworthy because it receives the water of the Yellow River, which has the largest sediment discharge in the world (up to $1{,}380 \times 10^6$ tons a year). The flat bottom of the gulf is covered by yellowish mud, which is derived from erosion of the loess of China. The southern and the western shores of the gulf are also muddy because the mouth of the Yellow River has repeatedly migrated through time.

The turbid water of the gulf is warmed down to the bottom by strong tidal currents, and productivity (fish, shrimp, and oyster) is high. The Río de la Plata of South America is quite similar; this gulf is in a basin that is completely filled by alluvium of the Paraná River.

Gulf of Bothnia and Gulf of Finland. These gulfs of the tideless Baltic Sea have much in common. They receive the runoff of many rivers and their turbid waters are especially freshened at the basin heads. Local, unstable circulations that depend on the winds and river floods are characteristic of both of them. Fluctuations of water level due to seiches are peculiar. In the Gulf of Finland these reach a height of 120 centimetres, and high storm surges (up to 375 cm) at its head can cause disastrous floods. In winter both gulfs are frozen for some months.

Ice retreat and isostatic uplift

During the last glaciation the basins of both gulfs were filled with ice. When glacial retreat and ice melting occurred, fresh glacial lakes were formed in this region. Subsequently, as the world sea level rose and the isostatic uplift of Fennoscandia (Norway, Sweden, and Finland) occurred, the shape, water composition, and marine population of the gulfs changed several times. A complicated history has been deciphered from study of terrace altitudes and ancient deposits of the shores and the bottom of the gulfs. The shores are still rising today. In the head of the Gulf of Bothnia the rate of uplift is over one metre a century. This diminishes to the south and is essentially zero in the head of the Gulf of Finland.

The mouth of the Gulf of Bothnia is partitioned off by the Aland Skerries Archipelago, and it is only to the west that a deep strait remains. The hollows of the two gulfs occupy ancient depressions of the crystalline Baltic Shield. There also are pre-Paleozoic fractures along some parts of the shores that may have undergone renewed movement during the Tertiary Period. The southern shore of the Gulf of Finland is formed by horizontal layers of Paleozoic rocks. The basins of the gulfs were considerably influenced by glaciers, and moraine ridges are still preserved at the bottom of the Gulf of Finland. The northern shore of the Gulf of Finland and the whole of the southern part of the Gulf of Bothnia are strongly dissected by *fjärds* and skerries islands.

The sediments of the central part of the Gulf of Bothnia consist of terrigenous muds that overlie varved glacial clays and till (see VARVED DEPOSITS). Sediments of the Gulf of Finland are coarser, and in many places sands are deposited on its bottom. There is an admixture of ice-rafted stones in the sediments of both gulfs.

BIBLIOGRAPHY. Information on the properties and general characteristics of large gulfs and bays of the world may be found in R.W. FAIRBRIDGE (ed.), *The Encyclopedia of Oceanography* (1966). A.J. HUXLEY (ed.), *Standard Encyclopedia of the World's Oceans and Islands* (1962), contains abbreviated information on numerous gulfs and bays, including some of the smaller ones. For morphometric and physical-geographical data on some of the larger gulfs and bays, see E. BRUNS, *Oceanologie*, vol. 1 (1958). Recent monographs on particular gulfs and bays include: F.P. SHEPARD *et al.* (eds.), *Recent Sediments, Northwest Gulf of Mexico* (1960), a summary of all aspects of the Gulf of Mexico as known through the late 1950s; T.H. VAN ANDEL and G.G. SHOR (eds.), *Marine Geology of the Gulf of California* (1964); and V.P. ZENKOVICH (ed.), *Tikhiy okean:berega Tikhogo okeana* (1967), a fairly detailed description of geological and geomorphological conditions in most of the gulfs and bays of the Pacific Ocean region (in Russian).

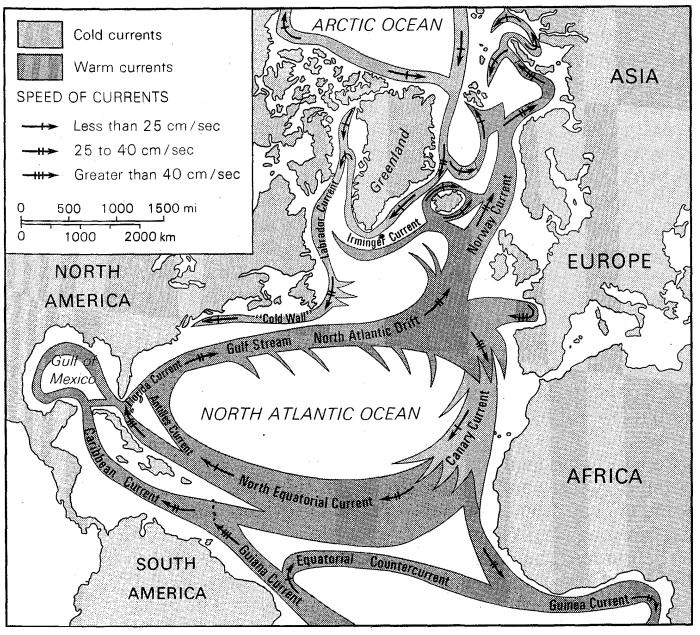
Gulf Stream

The name Gulf Stream often is used in reference to the entire warm ocean current flowing northeastward from the Straits of Florida to the coast of northwestern Europe. It refers properly, however, only to that portion of the western Atlantic current extending from the vicinity of Cape Hatteras, North Carolina, to the area southeast of the Grand Bank off Newfoundland. In deference to popular usage and to the importance of the continuous current, this article will cover the larger, though less correctly named, phenomenon. (For information on related topics, see the articles ATLANTIC OCEAN; OCEAN CURRENTS.)

Origins and components

The Gulf Stream is part of a general clockwise-rotating system of currents in the North Atlantic. It is fed by the westward-flowing North Equatorial Current moving from North Africa to the West Indies. Off the northeastern coast of South America, this current splits into the Caribbean (Florida) Current, which passes into the Caribbean Sea and through the Yucatán Channel into the Gulf of Mexico; and into the Antilles Current, which flows to the north and east of the West Indies. The Caribbean Current re-emerges into the Atlantic through the 95-mile-wide Straits of Florida between the Florida Keys and Cuba. It is then deflected to the northeast by the submerged Great Bahama Bank southeast of the Florida Peninsula. North of the Bahamas it is joined by the Antilles Current and flows roughly parallel to the eastern coast of the United States to about Cape Hatteras. Here it veers more to the east and passes close to the Grand Bank, south of Newfoundland, before turning eastward as the North Atlantic Drift (or current). The drift later subdivides, one branch moving southeast and south as the relatively cool Canary Current, while the warm North Atlantic Drift continues northeast off the British Isles and into the North and Norwegian seas.

History of scientific study. The Gulf Stream was first described by the Spanish navigator and explorer Juan Ponce de León early in the 16th century. Later it was studied by such scientists as Benjamin Franklin and the American naval officer Matthew Fontaine Maury, and in 1844 systematic surveying of the stream was begun by the United States Coast and Geodetic Survey. Concentrated modern efforts were inaugurated only in the early 1930s by the ketch "Atlantis" of the Woods Hole Oceanographic Institution in Massachusetts. Since then a great



The Gulf Stream in relation to other North Atlantic currents.

many surveys have been made, particularly by a number of scientists from Woods Hole.

One of the difficulties of scientific study of the Gulf Stream is its extremely complex makeup. It is not a simple ribbon of moving water but rather a complicated network of currents that tend to shift course over time, to disappear and then reappear, and to develop eddies along the margins. To supplement the work of individual research vessels, two multiple-ship surveys have been carried out. Seven ships took part in "Operation Cabot" in 1950; and, a decade later, in "Gulf Stream '60," four ships obtained hydrographic data over a three-month period in the general area east and southeast of Cape Cod, Massachusetts.

Movement and physical features. Most of the waters that enter the Gulf Stream system first have been driven westward across the Atlantic by the Northeast Trade Winds. In the Caribbean and the Gulf of Mexico the current is gradually narrowed, and its velocity increases to about 3.5 knots (four miles [6.5 kilometres] per hour) as it passes through the Straits of Florida. The volume of flow here has been measured at 920,000,000 cubic feet per second, or about 1,000 times that of the Mississippi River. As it turns north between Florida and the Bahamas, the Florida Current flows at a depth of some 2,600 feet and then follows the continental slope beyond the edge of the shelf. Velocities gradually decrease to about one knot (one mile [two kilometres] per hour) off Cape Hatteras. In the vicinity of St. Augustine, Florida, the current is about 30 miles off the coast; at Savannah, Georgia, 85 miles; and at Cape Hatteras, less than 20 miles.

Salinity and temperature

In the western Atlantic, the current's deep-blue water, with its higher temperature and salinity, is readily distinguishable from surrounding waters, particularly along its well-defined western margin. This edge corresponds closely with the 650-foot depth, whereas the eastern edge gradually moves seaward as the current moves northward. The water between the current and the mainland, with its lower salinity and temperature, forms a boundary known as the "Cold Wall." This water, overlying the continental shelf, frequently has a southerly flow, counter to that of the Florida Current.

Water in the eastern portions of the current is warmer than that in the western part. The lateral mixing of current and ocean waters results in eddy formations along the margin. Off the coast of the United States, the Gulf Stream system separates the relatively warm waters of the Sargasso Sea in the mid-Atlantic region from the colder waters to the west and north. In winter, for example, average surface temperatures of the Gulf Stream off New England may be 20° F (11° C) higher than those of surface waters only 150 miles to the northwest, although there is less than a 10° F (6° C) change in surface-water temperatures over a 1,000-mile distance to the southeast.

Beyond Cape Hatteras the Gulf Stream broadens and moves into deeper water. Here it crosses the Western Boundary Undercurrent, which consists of cold, southward-flowing water that sinks to considerable depths in the vicinity of Greenland. About 1,500 miles northeast of Cape Hatteras, in the area of the Grand Banks, the warm Gulf Stream waters come in close proximity with the cold, southward-flowing Labrador Current. The contact of cold, humid air moving over the Labrador Current with the warm surface waters of the Gulf Stream causes widespread condensation. This climatic condition causes the region to have one of the highest incidences of fog in the world.

Easterly and southerly currents

Moving out into the North Atlantic, the current becomes shallower and begins to break down into a meandering pattern of disconnected filaments flowing in the same general direction. The pattern itself often changes, and marginal eddies may detach themselves completely from the main body of flow. Much of the initial force of the current has been dissipated by this time, and momentum is afforded primarily by the westerly winds. Part of the water here is diverted southward into the Sargasso Sea area. Near the middle of the ocean, the North Atlantic Drift divides into the Canary Current, which flows southward past the Iberian Peninsula and northwestern Africa, and the North Atlantic Drift, which moves toward northwestern Europe. One branch of the drift, the Irminger Current, is diverted northwestward toward the south and west coasts of Iceland.

Effects on marine and human life. The marine organisms of the Gulf Stream system are not of great commercial value. Principal species include the bluefin tuna, the Atlantic salmon, and the flying fish. Its warm waters, however, in mingling with the colder waters both on the Grand Bank and off northwestern Europe, contribute to turbulence and the availability of nutrient salts that have made these regions among the most productive commercial fishing grounds in the world.

Warming of northwestern Europe

A major contribution of the Gulf Stream system is its warming effect upon the climates of adjacent land areas. In winter the air over the ocean west of Norway is more than 40° F (22° C) warmer than the average for that latitude, probably the greatest temperature anomaly in the world. The prevailing westerly winds carry the warmth and moisture of the ocean to northwestern Europe, giving Bergen, Norway, at 60° north latitude, the high average temperature for its coldest month of 34° F (1° C), while Reykjavík, Iceland, 4° of latitude farther north, has a 30° F (−1° C) average for its coldest month. In southwestern England the climatic modification produced by the current is reflected in the extraordinary mildness of the winters at this northern latitude, including the growing of winter vegetables and flowers and the presence of subtropical vegetation and lemon trees in southern Devonshire. Along the western margins of the North Atlantic, however, where the winds are predominantly from the shore, the Gulf Stream has little effect. Halifax, Nova Scotia, nearly 1,000 miles south of Bergen, averages only 23° F (−5° C) during its coldest month.

Gunnery

Gunnery is the technique of developing, operating, and maintaining all weapons of war classed as guns; that is, all weapons that fire large-calibre projectiles. (For a description of small arms, see SMALL ARMS, MILITARY.) Modern guns employ explosive charges as propellants, but the earliest missile-throwing weapons, such as ballistas and catapults, used torsion, tension, and counterweights. A few modern small-calibre weapons use the word gun in their nomenclature; *e.g.*, machine gun and shotgun.

From the introduction in the 14th century of explosives for propelling projectiles until about the second decade of the 20th century, classification was not difficult. Land-based weapons were known as artillery and those used at sea as naval guns. All these were surface-to-surface weapons. The advent of aircraft, long-range rockets, and guided missiles has vastly complicated classification, and there are now four dimensions: surface-to-surface, surface-to-air, air-to-surface, and air-to-air.

The most modern types are highly sophisticated, as are their projectiles, means of movement, and ancillary equipment. Many are closely guarded secrets, and all are subject to changes and short life because of supersession by improved types. For every weapon in service there is likely to be another in an experimental stage and yet another on a drawing board. In these circumstances, a description of contemporary artillery weapons can be made only in general terms.

History of gunnery

"ENGINES OF WAR" AND MEDIEVAL GUNS

Objectives of the attacker and defender

Throughout history, battles and engagements have almost invariably been fought with one side on the offensive, the other side defending. The attacker's object is to bring his assault troops—infantry, cavalry, and in modern times tanks—to close quarters as quickly and as economically as possible. To accomplish this he has sought means to inflict casualties and cause confusion before delivering his assault—a process called "softening up" in modern military parlance. Similarly, the defender has sought means to inflict losses on the attacker and cause the assault to break down before reaching its objective.

Among the earliest ancients this was done by means of light, short-range weapons such as slings and bows and arrows. Later, more sophisticated weapons were introduced with longer ranges and capable of discharging heavy stones and spears by means of springs and balancing devices. Little is known of the detailed design or methods of employing these weapons. It would appear that their chief value was in siege warfare against fortifications; but it is known that both the Greeks and Romans used them as field weapons. Their material value in the field must have been quite limited, though their large size and awe-inspiring appearance were no doubt a morale factor. Although their missiles were large and formidable in appearance, they did not fragment like modern shells, and there must have been a long interval between shots.

As with modern weapons a wide variety of names have been given to similar types—catapult, ballista, mangonel, scorpion, springal, falarica, and many others—all with the common characteristic of being able to discharge a heavy missile a longer distance than was possible with a hand-operated weapon. (See also WEAPONS AND DELIVERY SYSTEMS.)

In the earliest types, two methods of propulsion were used; namely, torsion, which was the twisting of thick rope, and tension, the bending of a spring or piece of wood. Later, in medieval times, a third method was employed: the trebuchet (and others of similar type) propelled a stone by means of a balance or counterweight.

With the introduction of gunpowder, or black powder, the whole conception of long-range weapons changed. Gunpowder set in motion a process of development that over the centuries produced more and more massive bombardments. As has remained the case throughout history, the older weapons continued to be employed after the introduction of the new. The "engines of war" operated concurrently with guns using explosives for several decades.

Considering the lack of communications in the 14th century and the revolutionary nature of the invention, it is remarkable how quickly gunpowder was adapted to military purposes. It is quite certain that it was not introduced into Europe before the first decade of the 14th century, although it, or some similar explosive, seems to have existed in China before then. Doubts exist as to when guns were first employed in battle. Some historians give credit for making the first gun to a German monk, Berthold Schwarz. Claims for the first use of guns in battle have been made for the siege of Metz (1324) and at Cividale in Italy (1331). There is little doubt that after 1325 cannon existed all over western Europe and were certainly used by the English under Edward III at Crécy (1346).

First use of guns in battle

The probable inefficiency of these early guns would account for the continuance for a considerable time of some of the older weapons, particularly the longbow used by English archers.

The missiles for these early guns were originally in the form of a spear, somewhat like a harpoon; later, shaped stones, and later still, iron balls were employed. The guns themselves were mostly made of cast bronze or brass. These materials were followed by wrought-iron guns, but it was not until the 15th century that cast iron was used.

DEVELOPMENT OF GUNPOWDER ARTILLERY

One of the difficulties of early gunnery was the erratic behaviour of gunpowder, the ingredients of which did not readily mix and which tended to deteriorate after mixing, particularly when transported. This made it unpredictable in use. Early in the 15th century, however, a new process, known as "corning," was invented; this improved method of mixing went a long way toward producing a standardized powder.

Nevertheless, the progress made in the development of artillery during the next 300 years, although steady, was far from sensational. As with some new weapons in modern times, guns did not at first fulfill the expectations of their protagonists. This was not altogether the result of the extremely crude structure of the first types; the high efficiency of some of the older weapons, the paucity of communications, and the general conservatism of the times contributed. As a result, as late as the reign of King Henry VIII of England (1509–47), 200 years after the introduction of gunpowder, weapons of the old "engines of war" type were still in use.

During the 15th century a number of very large guns, known as bombards, were manufactured in widely different countries. Edinburgh Castle's famous "Mons Meg" weighed some five tons and was said to throw a 19.5-inch iron ball nearly a mile; a 13-ton bombard, "Dulle Griete" of Ghent, had a 25-inch calibre and threw a 700-pound missile; an even larger weapon was the "Tsar Cannon" of Moscow, which had a 36-inch bore and weighed some 40 tons. Details are lacking of the formidable pieces known to have been used by the Turks when they captured Constantinople in 1453. All of the above were smoothbore weapons. It is said that rifling (*i.e.*, grooving the inside of the gun barrel to impart spin to the projectile) was attempted in the 15th century and again in the 17th, but with little success.

It must be appreciated that these heavy and cumbersome weapons, using ammunition difficult to produce and handle, were of little value except as part of the armament of a fortress or for siege operations planned well in advance. During the 15th century a good deal of experimental work took place with a view to producing guns sufficiently mobile to accompany field armies and take part in encounter battles. Early attempts by mounting guns on sledges drawn by oxen proved unsatisfactory. Under Charles VIII of France (1483–98) guns were mounted on wheeled vehicles drawn by especially trained horses. About the same time trunnions were introduced —a pair of wooden devices forming a cradle to balance

Efforts to produce mobile weapons

the gun on the carriage, by which the muzzle could be elevated or lowered for range adjustment, and through which some of the shock of discharge was transferred to the carriage. These measures succeeded in producing weapons that could keep pace with marching infantry on reasonably good roads over flat country. The Italians also produced field guns, and an Italian condottiere, Bartolomeo Colleoni (died 1475), introduced a special form of tactics for field artillery in which the guns fired from the rear through gaps left by the infantry.

There is evidence that the 15th century also saw the introduction of what has become known as "case shot," in which, instead of a single missile, a large number of round bullet-sized shots were fired, which scattered widely like the pellets of a shotgun, for use at short ranges.

The 16th century did not mark any revolutionary step forward in artillery techniques but rather an improvement on existing types of guns and their better classification and organization.

Weapon standardization

Hitherto standardization had been unknown, but in 1544 Charles V of Spain decided on seven different types of cannon for use in his armies. These included a 40-pounder (firing projectiles weighing 40 pounds, or 18 kilograms), a 34-pounder, two types of 12-pounder, two 6-pounders, and a 3-pounder. In France in 1550 Henry II standardized with six types, the heaviest a 33-pounder (drawn by 21 horses) and the lightest a 2-pounder (drawn by 2 horses). Later (in 1584) a 12-pounder and a 24-pounder were added. In the German states, standardization, although attempted, did not progress to the same extent. In the period 1550–1600 there were said to be 11 different types of gun, from a 1-pounder to a 94-pounder, which with variations in each type brought the total to around 40.

In England, Henry VIII took a personal interest in the provision of guns, but in the absence of a home industry was forced to rely on overseas products. By employing a Fleming, Hans Poppenruyter, he acquired some 150 guns of varying calibres, including the celebrated bombards known as the "Twelve Apostles." About 1515 he imported a number of foreign armourers and established schools of instruction for English craftsmen. Largely because of Henry's encouragement, two crude types of shell were introduced, which can be recognized as the forerunners of the explosive shell and the incendiary missile of modern times.

Perhaps the most important development of the 16th century was the beginning, in Italy, of the science of ballistics, which in time was to promote gunnery from an empirical rule-of-thumb operation to one of scientific precision.

By the first half of the 17th century artillery was taken seriously. In an attempt to improve mobility, Gustavus II Adolphus of Sweden introduced the "leather gun" in 1626. By making the external casing of the barrel of leather, and the bore of copper tubes, he reduced the weight of the gun to 90 pounds (40 kilograms), with a corresponding reduction in the weight of the carriage. Its mobility was excellent, but it generated excessive heat and was dangerous to operate. In 1631 it was discarded in favour of a less mobile but safer weapon.

Although the organization and standardization of the artillery of most countries became less haphazard than in the previous century, ammunition supply remained a problem, and there appears to have been no arrangement for the supply of spare parts for either guns or carriages.

Siege warfare, and operations in mountainous country, demanded a weapon with a high trajectory. This requirement was met by the mortar, sometimes called a bombard or howitzer, which could lob a missile into a fortress or castle or over a small hill. These were smoothbore weapons with very short barrels; the length of the barrel was sometimes no more than its calibre.

Not long after the introduction of artillery its potential in sea warfare was recognized. As early as 1509 a Venetian fleet, equipped with guns adapted to the galleys of the time, rowed up the Po to within a few miles of the capital of the Duke of Ferrara. The guns of the Venetians, however, proved no match for the Duke's land artillery, and the Venetian fleet was destroyed. In addition to greatly increasing the prestige of artillery, this action gave birth to a principle that lasted for more than 400 years; namely, that, unless in overwhelming strength, naval guns are always at a disadvantage against shore-based artillery.

The progress of naval gunnery, and the differing doctrines for its employment during the Middle Ages, is well illustrated by the series of actions in the English Channel in July and August 1588 between the Spanish Armada and the English fleet. In these engagements the Spanish fleet relied on large ships equipped with heavy but comparatively short-range guns (average weight of shot 17 pounds). The English, on the other hand, relied on much smaller but more mobile ships with light guns (average weight of shot 7.5 pounds) with a longer range than those of the Spaniards. The English tactics paid a good dividend as they were mostly able to keep out of range of their enemy's big guns while inflicting damage with their own weapons. Moreover, the heavy guns of the Spaniards soon ran out of ammunition. The extent to which guns had come to play an active part in naval warfare by the end of the 16th century is demonstrated by the number judged to have been available to the two sides; namely, Spain 1,124 (44 percent heavy, short-range and 56 percent lighter, medium-range); England 1,972 (5 percent heavy, short-range and 95 percent light, long-range).

Defeat of the Armada

THE 18TH-CENTURY IMPROVEMENTS

In the nearly 400 years from the introduction of gunpowder until the end of the 17th century there had been a considerable increase in the range of guns, and this in turn had produced changes in the tactical handling of artillery. There had also been a steady increase in the number of pieces available. Apart from this, however, little progress had been made in the guns or their projectiles. Gunnery remained haphazard, uninfluenced by ballistics and other sciences still in the experimental stage.

This slow pace quickened during the 18th century. In France measures were introduced for the better classification of guns, and in 1776 the organization of the French artillery was greatly simplified by a reduction in the number of calibres and improvements in the design, and particularly the uniformity, of ammunition. It was not until their Revolutionary Wars, however, that the French introduced horse artillery—guns light and mobile enough to accompany cavalry in the field.

The Seven Years' War in Europe (1756–63) found Prussia in the process of making a series of artillery experiments, as was Austria, particularly with the more precise weighing and measuring of ammunition with a view to achieving uniformity of flight.

Perhaps the greatest progress was made in Great Britain, where Benjamin Robins published his *New Principles of Gunnery* in 1742. This work exposed the fallacy of many of the old theories and methods and, for the first time, brought science into the field of practical gunnery. Robins' invention of the ballistic pendulum enabled the velocity of missiles to be judged accurately at any stage of their flight. The year 1784 marked the invention by Henry Shrapnel, a British officer, of the form of ammunition that bears his name—an antipersonnel projectile timed to burst in the air toward the end of its flight and discharge a large number of small, bulletlike balls over a wide area. Shrapnel remained a major artillery missile until World War I.

Invention of shrapnel

An important 18th-century advance was the introduction of limbers, vehicles towed behind the gun carriage for the carriage of ammunition, tools, and spare parts and for carrying some members of the gun team. In most European armies artillery was divided into three main categories: horse, for use with cavalry; field, for use with infantry; garrison, for coast defense and other static roles.

Despite the increasing attention devoted to artillery and its increased prestige as a battle-winning factor, the number of guns deployed was still, by modern standards, modest. In one of the greatest battles of the 18th century, Blenheim (1704), the French and Bavarians had approxi-

mately 120 guns and the British and their Allies under Marlborough about 60. During the whole of Marlborough's campaign in Europe the average proportion of guns to infantry in his Allied army was about nine guns to 10,000 men.

THE 19TH-CENTURY ADVANCES

The 19th century saw remarkable developments in every aspect of gunnery: the pieces, the projectiles, and the propellants.

There were three main reasons for this rapid progress. The first was the influence of Napoleon, whose sensational victories, in many people's view, were the result of his use of artillery. This was probably an exaggeration, but it undoubtedly added to the prestige of the arm. Napoleon introduced the method of using massed artillery at what he judged was the vital point of battle; he also raised the status of his artillery men by making them a *corps d'élite*. Second, the advance of science made possible improvements in both guns and ammunition. Third, the number of wars—the Napoleonic Wars ending in 1815, the Crimean War (1853–56), the American Civil War (1861–65), the Franco-Prussian War (1870–71), and many colonial wars in Africa and Asia—provided an incentive to produce better guns. The better organization of armed forces, including the general staff system initiated by Prussia, promoted greater and more efficient use of artillery.

Introduction of rifled barrels

As a result of scientific progress and war experience, several improvements came about. Rifled gun barrels were introduced. These imparted spin to the missile, resulting in greater accuracy, less deflection by wind, and a heavier and shaped missile in place of the mostly round balls previously used.

Improved powder to propel the heavier ammunition was made available by the researches of Capt. (later Gen.) Thomas J. Rodman (U.S. Army); but this in turn (in the 1860s) was superseded by the introduction of guncotton by Baron General von Lenk of the Austrian Army. This explosive had the advantage of being smokeless. It was, however, dangerous in storage until a French chemist, Paul Vieille, in 1887 produced a process that made it safe.

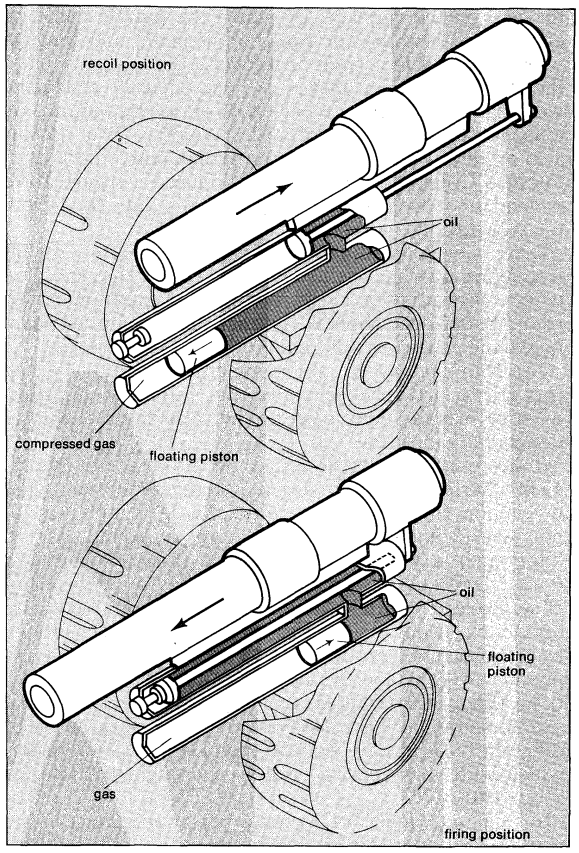
The provision of guns sufficiently robust to withstand the increased charges that had become available posed a serious problem. Various attempts to solve this problem were made in France, in the United States, and in Britain. The answer came in 1851, when Alfred Krupp of Germany displayed in London an all-steel gun drilled out of a single block of cast metal. This weapon was only a six-pounder, but within ten years Krupp was producing guns of cast steel of more than eight-inch bore.

Toward the end of the century two problems were solved that had defied the efforts of inventors; namely, a satisfactory breech-loading mechanism and a satisfactory recoil system. Breech loading was achieved in the 1860s and 1870s almost simultaneously in a number of countries—France, Germany, Spain, and the United States. About the same time, the recoil problem was overcome by the introduction of a system for absorbing the shock of discharge and leaving the gun in approximately the same position after firing as before (see illustration).

Introduction of pack guns

Consideration was also given to other types of artillery. In the second half of the century pack guns were introduced; these were light weapons broken down into convenient loads for carriage on packhorses or mules, for use in mountain warfare. These were employed extensively by the British on the northwest frontier of India and survived in World War II when they were used in Italy and other mountainous theatres. Attention was also given to guns of larger calibre than had hitherto accompanied field armies, with the use of railroad transport. One of the surprises of the early weeks of World War I was the German deployment of heavy guns of Austrian manufacture to bombard the forts around Liège.

The 19th century saw a radical change in artillery tactics. In the Napoleonic Wars the short range of guns made it necessary to site them well forward. The increasing range of artillery gradually made this unnecessary; it became the custom to deploy the guns well in rear of the infantry to shoot over their heads.



Simple recoil system used on field gun. When the gun is fired, oil is forced into the cylinders, compressing the gas and absorbing the recoil.
Adapted from I.V. Hogg, *The Guns 1939–45*.

Finally, there was a brief revival of interest in rockets, with which British warships were equipped during the Napoleonic Wars. The development of artillery temporarily put an end to rocketry as a military weapon.

WORLD WAR I GUNNERY

When in August 1914 World War I began, conventional artillery and the techniques for its employment had approached their zenith. Improvements made during the war did not touch fundamentals. Heavier types of gun were developed, and quantities of both guns and ammunition startled the military world, but basically the artillery pattern remained quite similar to that in the Franco-Prussian War of 1870–71. Light (or field) artillery, plus a few heavier guns, formed part of divisional artillery in all major armies, with more of the heavy pieces under higher direction. As the war progressed it became common practice for all light artillery plus a few medium guns to remain with divisions, most of the medium artillery (including counterbattery pieces) under corps control, and heavy, superheavy, and antiaircraft under army headquarters control.

In the opening stages of the war the artillery of a British division comprised three brigades each of three batteries of 18-pounder guns, and one brigade of three batteries of 4.5-inch howitzers and one heavy battery of 60-pounder (5-inch) guns. The divisions of other major belligerents were equipped on much the same lines with only minor differences. French batteries were four-gun; British, six-gun. The French medium and heavy pieces within the division were 4.8-inch guns and 5.9-inch howitzers; the Germans employed 5.9-inch and 8-inch howitzers.

Light guns of World War I

Practically all the light guns in service in 1914 stood the test of war. Special mention, however, must be made of the French 75-millimetre guns, first brought into use in 1897, that not only remained the French Army's chief artillery weapon throughout the war but also was the

main equipment for the American divisions during the latter stages.

To understand the vastly increased ammunition requirements of World War I it is necessary to understand the change in the pattern of fighting. The armies of the great powers had been equipped in peace in the belief that the next war would be a short one and the fighting open and fluid in character. These conditions required highly mobile light artillery firing mainly antipersonnel projectiles (*i.e.*, shrapnel). By the end of 1914 the opposing armies on the Western Front had settled down to siege warfare —continuous lines of trenches with deep dugouts and concrete machine-gun emplacements, protected by barbed wire. This setting required a higher percentage of heavy guns and high-explosive shells, and a vastly greater number of all types of guns and projectiles, if either side was to carry out a successful offensive. On the Eastern Front the same trend toward trench warfare was present but in a less marked degree than in France and Belgium.

Production of artillery

In the continental countries of Europe, with their large conscript armies, the problem was difficult but not desperate. They had a good proportion of heavy guns, and their industries had been geared in peace to the production of large quantities of guns and ammunition. In Britain, with its small volunteer army and original Expeditionary Force of no more than six infantry and one cavalry division, the position was very different. It was necessary to create the industries for war production at the same time as the nation expanded its army to many times its peace strength. The United States was to experience similar difficulties when it entered the war in April 1917.

Some idea of the immense increases in artillery as the war progressed can be seen in statistics: In August 1914 the first six divisions of the British Expeditionary Force (BEF) in France had a total of about 486 guns, all but about 24 being light fieldpieces. By May 1915 the total of guns with the BEF had risen to 700 18-pounders; 200 15-pounders; 125 13-pounders; 80 4.7-inch guns; 28 60-pounders; 50 5-inch howitzers; 130 4.5-inch howitzers; 40 6-inch howitzers; and 12 9.2-inch howitzers, for a total of 1,365. At the Armistice in November 1918 the total of all types was 6,437.

On the opening day of the Battle of the Somme, July 1, 1916, the number of heavy guns on the 18-mile front of the British attack was 455, or one heavy gun every 57 yards. In addition there was the whole of the light artillery of some 19 divisions (about 72 per division).

By the Battle of Messines (Mesen) in 1917 the number of guns supporting the attack was 2,266. Of these 756 were heavy pieces—one to every 20 yards. The preliminary bombardment began on May 21, and the attack was made on June 7. Altogether 3,500,000 shells were fired at an estimated cost of £17,500,000.

In the attack on the Saint-Mihiel salient by United States troops in September 1918, on a front of about 12 miles, the attacking divisions were supported by 3,010 guns of all calibres, or one every seven yards.

Technical improvements in guns

In addition to the greatly increased size of guns, there were several areas of technical improvement. The first was range. All light artillery achieved ranges of at least 10,000 yards (9,000 metres), and the German 21-centimetre gun, known as "Big Bertha" and used for shelling Paris in 1918, attained a range of 76 miles (122 kilometres). Night firing became a matter of normal routine, and defensive fire or counterpreparation, usually a static barrage or line of bursting shells, was introduced. Later, the creeping barrage, a line of fire that moved forward slowly, and behind which the infantry advanced, became normal practice in attack. Finally, artillery communications were greatly improved by field telephones and radio, and the location of targets by means of aircraft and captive balloons.

The greatly increased use of aircraft brought into use special guns, firing shrapnel, for anti-aircraft purposes. In the absence of adequate fire-control methods, which came later, these weapons were not very effective in World War I.

Along with the developments in guns came improvements in ammunition and increases in the variety of shells. Except with a few heavy guns and howitzers, in which the propelling charge remained separate, all artillery projectiles used in World War I were self-contained, with propelling charge, bursting charge, shrapnel (if any) all in one piece, commonly called a "shell." Many different types of shell were used in addition to the shrapnel and high explosive of 1914. Smoke and gas shells were used by most armies.

Conditions of trench warfare on the main battlefronts, and technical improvements, resulted in changes in artillery tactics. Guns had to be more dispersed and concealed and protected by earthworks and sandbags and their crews by deep dugouts. With the introduction of defensive fire and creeping barrages, guns had to be deployed differently and more attention devoted in defense to counterpreparation, to counterbattery fire and fire to disperse enemy troops during the process of concentration and forming up for attack.

In some of the secondary theatres, such as the Middle East, the new trends did not apply, and artillery was used more in the manner prescribed in peace for mobile warfare.

The introduction of tanks by the Allies on the Western Front in 1916 eased the role of their artillery, as two of the main tasks of the latter, crushing and making gaps in the wire and silencing machine-gun posts, were carried out increasingly by tanks. The reverse was the case for the Germans, who, until they produced their own tanks in the closing months of the war, had to deploy a proportion of their light artillery in an antitank role.

Trench warfare increased the importance of high-angle fire, leading to a revival of the use of mortars. Mostly small and of smooth bore, these were easy to produce. They were, however, very different in design from those of an earlier age. The Germans were the first to use these weapons extensively in World War I, but they were quickly followed by the British, whose three-inch Stokes mortar was the archetype of several produced later. In comparison with its small bore it had a relatively long (three feet, or one metre) barrel. The missiles were dropped down the barrel from the muzzle end, the fall of each round on the base of the barrel exploding the propellant charge. This enabled a high rate of fire for a short period; as many as six rounds could be in the air at one time.

During the early decades of the 19th century, naval gunnery had lagged behind land-based artillery in design of guns and gunnery technique. By the beginning of the 20th century this gap had been closed. It was realized in all major countries that the formidable battleships of the times made ideal platforms for modern guns. By the beginning of World War I, naval guns of up to 13.5-inch calibre existed, firing shells at ranges exceeding 10,000 yards. The fire of these weapons was controlled by what was known as "director fire," a device that calculated movement of target, movement of own ship, effect of wind and temperature, and even effect of wear-and-tear of gun barrels.

Battleships as gun platforms

World War I also saw major developments in the employment, particularly by the Germans, of torpedoes fired from submarines, and occasionally from destroyers.

WORLD WAR II GUNNERY

Except in anti-aircraft guns the interwar period saw little advance in artillery pieces or their projectiles; some advance was made in gunnery technique, and aids such as radar were introduced.

As a generalization it can be said that artillery and naval gunnery played a less important part than they did in 1914–18. The tank had partly relieved the gun of its destructive role of crushing wire and earthworks, and tactical bomber aircraft often relieved it of its bombardment role. At sea, aircraft played an increasingly important role, and in some naval operations—particularly in the Pacific in the latter stages of the war—the decision was reached by aircraft action before the opposing fleets had come within gun range or sight of each other.

Even on the Russian front the density of artillery did

not reach the heights of World War I. In some of the bigger battles the concentration of guns was considerable, but it was never equal to the vast arrays of 1916–18 with their huge expenditure of ammunition. The demand was for light, mobile guns and a consequent reduction in the heavier types. There were, however, a greater variety of artillery weapons, particularly in the field of anti-aircraft and antitank guns.

Except for two new types, few important changes were made in ammunition. The two exceptions were proximity-fuzed ammunition, an American product used by American and British forces, which, by means of a small electronic device, exploded in the air just before reaching the target; and armour-piercing ammunition, used by all major belligerents against tanks.

Toward the end of the war the Germans used two new types of long-range weapons, mostly against Antwerp, London, and southern England—these being known as V-1, flying bombs or pilotless aircraft, and V-2, high-angle rockets. These weapons were fired from static launching sites mainly in Belgium and The Netherlands.

By the outbreak of World War II the horse had been almost entirely replaced by motor vehicles (wheeled or tracked) for towing artillery. This, and the introduction of self-propelled guns (guns mounted on vehicles similar to tanks but less heavily armoured), greatly increased the mobility of all artillery.

Improved anti-aircraft guns

During the latter years of the interwar period, considerable progress was made in all major countries in the design of anti-aircraft guns, and this progress was greatly accelerated during World War II. For European countries, including Britain, there were two aspects of anti-aircraft defense—the defense of their homeland cities, towns, and installations and the protection of their warships by special anti-aircraft guns and their field armies by mobile anti-aircraft artillery. The weapons used for these purposes increased in size, velocity, range, and efficiency as the war progressed. For these roles the British used special guns of mostly 3-inch, 3.7-inch, and 4.5-inch calibre; the United States used the 90-millimetre and—the biggest of all—the 120-millimetre (4.7-inch) "stratosphere" gun firing a 50-pound shell to a height of 50,000 feet (15 kilometres). The Germans relied very largely on their multirole 88-millimetre gun—probably the outstanding gun of the war.

Other specialized forms of gun were those mounted on tanks, of small calibre when the war began but of much greater size and range by 1945.

Mortars, as an adjunct to artillery and mostly in support of infantry, were employed extensively by all countries in a variety of calibres. The Soviet Army used several heavy types, including one of 240 millimetres. The Germans developed a variety of types and tended to replace guns with mortars, particularly among their airborne troops.

Improvements in gun operation

Although the basic artillery weapons did not greatly change in World War II, great advances were made in the technique and methods of operating guns and gunlike weapons. The technique known to artillerymen as "survey" (employing map grid coordinates), enabled selected targets to be located in relation to the guns with great accuracy. This made the old method of actually firing trial shots at selected targets (known as ranging by registration) unnecessary, which in turn greatly increased the chances of surprise in offensive operations. The invention of radar enabled moving objects to be located, and their movements followed, long before human senses could detect them, and in the case of aircraft it was possible to distinguish friend from foe. This was of special assistance to anti-aircraft gunners. In addition, there were marked increases in the efficiency of radio communication.

These inventions, together with increased ranges and mobility, improved the flexibility of artillery. Whereas in World War I gunfire was largely confined to the particular sector behind which the guns were deployed, it now became possible to concentrate the artillery of one, or even more, divisions on a single small target area in a matter of minutes. It was common practice for a single battalion performing some special task, or in difficulties, to receive the support of the whole divisional artillery, without the necessity of redeploying the guns.

The heavier types of artillery, now much more mobile than in previous wars, tended to be concentrated under higher command but ready at short notice to proceed to any part of the battle area where they might be required. Typically a unit of this kind attached to an army or army group headquarters contained proportions of heavy, medium, and anti-aircraft guns and howitzers.

DEVELOPMENTS SINCE 1945

The explosion of two nuclear bombs on Japanese cities in August 1945 changed the whole conception of war in almost a flash. It was clear that any nation, or group of nations, with a monopoly of this weapon could impose its will on those not in possession of it. By the 1960s this situation had changed, with the two giants—the United States and the Soviet Union—reaching near parity in nuclear weapons and thereby creating a deterrent to nuclear war. Meanwhile, wars have taken place in many parts of the world—in Korea, Vietnam, and the Middle East on a large scale, and in many other places on a smaller scale—with conventional weapons mostly of World War II pattern.

Strategic and tactical nuclear weapons

Nuclear weapons. By 1970 there existed a situation in which all defense matters involving gunnery in its widest concept had to be considered in two tiers. First was the nuclear aspect, in which East and West faced each other with massive armouries of strategic nuclear weapons; some land-based, others seaborne, with ranges up to 8,000 miles (13,000 kilometres), any one of which was capable of causing devastation over a wide area. Strategic bomber aircraft, although still in service, were of diminishing importance and on the way out. There were tactical nuclear weapons with shorter ranges, up to about 410 miles (660 kilometres), which could be used for the bombardment of rear areas with low-yield missiles.

Neither strategic nor tactical nuclear weapons were used in any of the conflicts mentioned because of their two-edged nature and the realization of the indiscriminate destruction they would cause.

Conventional weapons. Conventional artillery and gunlike weapons, although overshadowed by the publicity given to the nuclear types, have remained in widespread use and have undergone considerable development either as new weapons or in improved versions of World War II types.

The principal major developments outside nuclear technology have been in guided missiles: surface-to-surface, surface-to-air, air-to-surface, and air-to-air.

Modern artillery and gunlike weapons

Up to the end of World War II, guns, and gunlike weapons, were one of many agencies that influenced the course of military and naval operations. In the 1970s the weapons at the top of the scale, the intercontinental ballistic missiles with nuclear warheads, do much more than that. The threat of these weapons has produced a nuclear deterrent; and not only do they influence the general policy of the greatest nations but their cost also affects national economies and the way of life of all mankind. This form of gunnery has greater influence on human affairs than almost any other single factor in the modern world.

At the other end of the scale, conventional guns and howitzers are being gradually superseded by short-range rockets, usually combined with a guidance system and known as guided missiles. This applies particularly to the heavier types of artillery, whose role is particularly suitable for the longer range missiles, with or without nuclear warheads.

Influence of guerrilla fighting

To a certain degree the advent during the past two or three decades of the well-organized and well-trained guerrilla fighter has contributed to the decline in the usefulness of conventional artillery. Even the lightest traditional artillery pieces are too heavy for the guerrilla fighter, and in close country he usually offers a target too small and too difficult for the regular gunners to locate. For both types of fighter the light and inconspicuous

mortar is often a better weapon. Thus although traditional surface-to-surface artillery still plays a part in modern war and will continue to do so into the foreseeable future, many of its roles are better suited to the new weapons. This is even truer in the surface-to-air dimension, where the guided missile has very largely superseded the anti-aircraft guns of the two World Wars.

Two points should be noted in connection with the survey of contemporary guns and gunlike weapons that follows. First, the various types of weapons mentioned are those in use in mid-1970; second, the names given to weapons of the Soviet Union are the code names used by the North Atlantic Treaty Organization (NATO) alliance.

TECHNOLOGY

Gun design and manufacture. The process by which sophisticated war material, including guns, is produced involves a number of stages, of which the following is a simplification:

1. General staff specification. This states the military requirement in some detail—weight, calibre, range, type of projectile, etc.
2. Drawing-board design.
3. Manufacture of prototypes.
4. Trial of prototypes with troops under varying conditions of terrain and climate.
5. Mass production (if trials prove satisfactory).
6. Issue to troops.

In most Western countries the production of a high proportion of artillery weapons is carried out by private firms, under close government supervision and sometimes with the government as a major shareholder. In the Communist countries all arms production is, of course, carried out in nationally owned factories. Some countries, of which Sweden is a notable example, make arms for export as well as for their own defense forces. Indeed, the export trade in arms is almost universal, partly to help allies and partly to reduce the cost by producing in economic quantities.

The number of private firms making guns and other war material is too numerous to list; some, such as Krupp in Germany and Vickers in Britain, have been designing and manufacturing guns and other war equipment for generations and have become household names.

Special problems in gun production

The production of arms, and gunlike weapons in particular, involves problems that are not usually encountered in most other manufacturing industries. In addition to being meticulously accurate, a gun must be simple to operate and maintain; it must be robust against rough treatment and severe weather conditions, but light enough to ensure maximum mobility.

But perhaps the most important factor is the quality of the material of which the gun is made. Armed forces continually demand longer and longer ranges and, in most categories of gun, ever-greater velocity, in order to reduce the missile's time of flight between the gun and a moving target. These improvements nearly always result in an increase in the propelling charge, which in turn makes it necessary to ensure that the metal of which the firing mechanism is made can withstand the additional shock of discharge. Because of the rough treatment to which war material is subjected, a good margin of safety must be allowed.

In practice under modern conditions the design and planning of a weapon is, almost invariably, entrusted to a team of experts who combine the necessary skills required for the project. The most important of these skills in the case of a gun, or gunlike weapon, are metallurgy and ballistics. Metallurgy is the science and technology of metals. Ballistics is the branch of applied physics concerned with the propulsion, flight, and effect on the target of missiles of all kinds (see BALLISTICS).

Although these two skills are the most important, there are many others, including the production and operation of computers to analyze and store data, and, in the case of weapons for which training with live ammunition is difficult or impossible, the production of simulators for training purposes.

It is apparent that the problems connected with rockets —in which the propulsion charge is contained within the missile—are more difficult and exacting than with a shell from a conventional gun. If a guiding device is added to the rocket the problem becomes even more complicated.

Projectiles. Until the time of the Napoleonic Wars the missile was comparatively simple compared with the gun itself. Today it is highly complex, and in some cases it far exceeds the launcher in intricacy of design and manufacture.

For the purpose of this article the term projectiles includes all missiles fired from guns or gunlike weapons.

There are two main classes of projectile—shells and rockets. A shell is a missile propelled entirely by an explosive charge fired within the launching agency (*i.e.*, the gun, howitzer, or mortar) and not repeated during flight. The characteristic of a rocket is that the propelling mechanism is contained within the missile itself and continues to operate during flight. This characteristic gives rockets much longer ranges than shells.

Each of these two groups of projectile is subdivided into many different kinds. Shells are high-explosive shrapnel (rarely used today), antitank, anti-aircraft, canister or case shot (still used occasionally in mid-20th century), chemical, smoke, nuclear, etc. Rockets include intercontinental ballistic missiles, medium-range and submarine-launched; and many types of short-range, or tactical, rockets.

There are also a few varieties of projectile that do not fall conveniently within the two above definitions, among them torpedoes and recoilless rifle ammunition.

In nontechnical language a shell consists of two parts—one containing the propelling charge and the other a bursting charge. A rocket contains an additional mechanism for boosting its propulsion during flight.

The explosives used in shells are of two kinds, the propellant charge and the bursting charge.

The ideal propellant charge should be smokeless and flashless to avoid detection and should have no tendency to absorb moisture. An explosive with all these qualities has been difficult to obtain; the one in most common use is known as "smokeless powder."

The requirement for the bursting charge is an explosive with great shattering effect that at the same time can withstand the shock of the propellant charge without exploding.

During the first half of the 20th century the most common fillers for high-explosive shells were TNT (trinitrotoluene) and amatol. The TNT was particularly satisfactory, but ordnance scientists continued to seek improvements. Among those produced were that called cyclonite by the United States and RDX by the British, which, with some special processing, was used extensively in World War II; haleite, named after a U.S. chemist; PETN (pentaerythritol tetranitrate); and pentolite, half TNT and half PETN, used for antitank shells.

Nuclear weapons have, of course, completely eclipsed in destructive effect all other explosives. As early as 1953 the United States demonstrated a 280-millimetre atomic shell with a diameter of about 11 inches and a range of about 20 miles (32 kilometres). The tactical atomic shell, with limited and manageable effect, for battlefield use, is now a part of the armament of several major armies, although its use is restricted by the deterrent effect of nuclear weapons in general.

Range-finding, guidance, and related systems. The object of gunnery is to propel a missile onto a selected target—enemy personnel or material objects such as buildings, earthworks, equipment, or industrial centres. The main technical consideration is the determination of the distance and direction from gun to target, the technique known as range-finding.

Early range-finding procedure

Until the second half of the 19th century, range-finding was done by direct and quite simple methods. The range was either estimated or established by means of an optical instrument known as a range finder; the sighting equipment of the gun was then adjusted to the range and aligned on the target, and the missile was sent on its way. Certain adjustments had, of course, to be made for wind, the known error of particular guns, and other factors.

After the first one or two rounds, corrections were made. The technique was much the same in naval gunnery as on land. The essential was for the gunner to see his target. If it was hidden by a hill, woods, or buildings, shooting was little more than guesswork. Except at close range, firing by night or in fog was impracticable and shooting at moving targets at long range very difficult.

The position is quite different today. Modern science and technology not only offer a variety of methods of range-finding but also provide missiles that can be guided to the target during flight or are attracted to it in the latter part of their flight.

In World War I improved maps and aerial photographs often made possible reasonably accurate shooting at unseen static targets. The lack of reliable air-to-ground radio communication made spotting from the air ineffective, however. The system known as registration ensured great accuracy in the conditions of trench warfare. By this means one gun could, by firing trial shots, ascertain the range of a number of prominent landmarks in a given area. From this information other targets could be judged with considerable accuracy, and other guns in the vicinity of the registering guns could make use of the same data. The drawback of this system was its slowness and forfeiture of surprise. Field telephones facilitated the employment of forward observing officers, and observers in captive balloons were used, but both were in danger from enemy fire.

During the interwar years (1918–39) three factors increased the efficiency of gunnery. First, the rapid development of air-to-ground radio, improving spotting from aircraft; second, the system known as "survey," enabling certain points in the target area to be plotted in relation to the gun positions; and, finally, improved line and wireless communications that, combined with survey methods, made it possible to concentrate quickly the fire of many guns on a single target.

All these methods for increasing the accuracy, speed in action, and general effectiveness of artillery fire were further developed in World War II, whose most important innovation, introduced late in the war, was the proximity fuze, which caused the charge to explode when the projectile reached the vicinity of the target. Since 1945 science has provided the gunner with many new devices, enabling targets to be engaged at vastly longer ranges and with much greater accuracy than formerly. Nevertheless, operations in the Middle East and Asia show that in the absence of sophisticated equipment, or in conditions in which it is impracticable to use it, the methods developed and employed so successfully in World War II are still practiced extensively.

The increased range of traditional artillery and gunlike weapons, and the introduction of rockets of much greater ranges, accentuated the difficulties connected with the identification and selection of targets and the methods of directing projectiles onto them. To a very great extent these problems have been solved by a series of new inventions and by the adaptation of older ones to new purposes. There has also arisen a classification of the types of target best suited to the increased variety of weapons. These are:

1. Strategic targets, long-range targets outside the operational area that can be engaged by weapons in the intercontinental ballistic missile (ICBM) class.
2. Battlefield rear-area or interdiction targets, up to a range of some 500 miles (800 kilometres) behind the battle area, such as centres of rail and road communications, areas of known troop concentrations, airfields, military depots, and other installations.
3. Battlefield support targets, engaged by traditional artillery types that include mortars and also some antitank guided missiles of post-World War II design.

In the case of (1) and (2) the question of "extreme" accuracy does not arise; the target is an area, not a point. The longer the range and more powerful the projectile the less important its accuracy. A strategic rocket with a nuclear warhead, fired at a range of 5,000 miles, may be a mile or more off the centre of the target and still have a shattering effect. There is no difficulty in calculating the exact range of targets for these weapons: the distance from any prominent place on earth to another is known, or easily obtainable by well-established methods, and the necessary data can be recorded in advance. Some doubt must exist, however, as to the accuracy of the missiles themselves, which, because of their power, complexity, and high cost, cannot be as readily tested as less sophisticated types. Their reliability must be assessed largely by the scientist's opinion and will depend largely on the accuracy of calculations relating to factors other than range and direction.

Accuracy of the strategic rocket

Similarly, weapons used against targets classified under (2) above, with ranges between about 85 and 500 miles, such as the United States Sergeant and Pershing missiles, present little problem as regards range-finding. With modern computing equipment, it is now routine practice to integrate quickly all the factors—range, wind and other atmospheric conditions, error of the weapon—to direct the missile onto what are mostly area targets.

Battlefield targets present a different problem: a high proportion demand pinpoint accuracy. An enemy tank, machine-gun position, or occupied building requires a direct hit or a very near miss. If the target can be seen, the range is quickly obtainable by established methods in the case of traditional guns and howitzers, or the target may be engaged by one of the wire-controlled guided missiles such as Swingfire (Britain), Dragon (U.S.), or Snapper (U.S.S.R.).

In addition to wire-controlled guided missiles, systems based on radar are employed to locate unseen targets at longer ranges and direct the missile toward them. "Homing" devices within missiles also exist; these attract the missiles to the target when they get within close range.

Carriages and mobility systems. Until World War I the problem of conveying artillery pieces to the battlefield quickly remained difficult. The march of armies was frequently delayed and operations postponed because of the slow forward movement of guns and ammunition. Horses, mules, oxen, and even camels and elephants were used to haul cumbersome pieces along unmetalled roads, or as pack animals for mountain artillery and other light guns capable of being broken down into pack loads.

During the 19th century the mobility of artillery appreciably increased, but mobility remained a problem and continued so until World War I. Such progress as was made was the result of the improved design of the mount or carriage on which the piece was fixed and which in reality became part of the gun itself. Teams of horses were able to move light pieces and, if the terrain was favourable, bring them into action at a gallop. But even in the early stages of World War I the movement of heavier artillery pieces was a slow and difficult matter.

By World War II the developments in mechanical vehicles in general, and tracked vehicles in particular, together with increases in the number of hard-surfaced roads, revolutionized the movement of all artillery. With modifications, and minor improvements, the position is much the same today. Guns and howitzers rely on two main systems for movement: mechanical towing vehicles, which usually also carry the ammunition and crew; and as self-propelled weapons—that is, mounted on the vehicle that propels them. Sometimes, but not always, the gun team and ammunition are also carried on the vehicle. The vehicle may be wheeled or tracked, the modern tendency favouring the latter. The earliest example of the self-propelled gun was one mounted on a tank, although its main purpose was, and still is, to protect the tank against enemy tanks while it carries out its assault role. In contrast, self-propelled guns perform the normal supporting role of artillery; the vehicles on which they are mounted are designed to enable them to perform this role and are less heavily armoured than tanks.

Systems for gun movement

Although self-propelled guns are becoming increasingly popular, and have many obvious advantages, they also have a higher silhouette and are consequently more difficult to conceal in action. Also, a mechanical breakdown immobilizes a self-propelled gun, not necessarily the case with a towed gun, whose vehicle can usually be replaced.

The strategic movement of artillery has been greatly facilitated by the use of modern aircraft. All but the heaviest pieces, including some self-propelled weapons, can be transported by air, and artillery is now part of the equipment of all modern airborne forces. Helicopters are capable of carrying light guns.

Despite modern mechanization there are occasions in mountain and jungle country when the only means of providing artillery support is with mountain artillery, broken down into light pack loads for horses or mules. Indian troops on India's northeast frontier are equipped in this manner, as are other armies likely to be involved in difficult terrain.

Essential as it is for modern armies to take advantage of mechanical progress, the advent of large numbers of mechanical vehicles, of which towed and self-propelled artillery and its supporting administrative vehicles form a considerable part, provides major staff problems. In large-scale operations, columns of mechanical vehicles many miles long are normal. All vehicles travelling in such columns must be capable of moving at approximately the same speed. A distance of 100 miles or more in a day is not uncommon, and at the end all personnel must be fed, vehicles replenished with fuel, and running repairs carried out. Staff work of a very high order is required if movements of this kind are to run smoothly. Failure in this respect caused considerable confusion in the German forces when Hitler's troops moved into Austria in March 1938; the lesson was noted by the general staffs of all the nations that went to war 18 months later, when the technique of modern road movement had been greatly improved.

Problems of movement

CLASSIFICATION AND FUNCTIONS

There are some gunlike weapons that were first developed for the close support of infantry and therefore classed as infantry weapons. In recent years, however, circumstances have arisen that leave the validity of this classification in doubt. These circumstances are partly technical and partly the result of changes in the pattern of warfare since 1945. The weapons concerned fall into two categories: recoilless rifles and mortars.

Recoilless rifles. At a very early stage in World War II it became apparent that a short-range, light, manhandled and one-man or two-man operated, antitank weapon was required. The British began the war with the Boys .55-inch antitank rifle, a weapon of the elephant-gun type. It was effective against lightly armoured vehicles but made little impression on German battle tanks. The first truly recoilless rifles were produced in the United States, first as a 57-millimetre bore weapon, later in 75-millimetre and 105-millimetre versions.

Today, one of the most notable weapons of this kind is the 84-millimetre infantry antitank gun that is in common use in a number of NATO countries. In Sweden, where it originated, it is known as the Carl Gustav. It is shoulder-controlled and capable of destroying any known tank at a range of 500 metres (1,600 feet). Its weight is 36 pounds (16 kilograms), and it can be carried and operated by one man; a second man is required to carry the ammunition and act as loader.

Guerrilla fighters in the Middle East and Asian theatres of war have used Soviet or Chinese weapons of this kind in recent years. The Israeli Army is equipped with 106-millimetre recoilless rifles mounted on jeeps.

Mortars. During the trench warfare of World War I, greatly improved mortars came into use, with much longer ranges, greater accuracy, and very much greater rates of fire. Improved methods of transporting these weapons and their ammunition resulted in their increased use in open warfare in World War II.

Conditions since 1945 have increased still further the usefulness and popularity of mortars and also have improved their performance. In the fluid conditions of European warfare, modern mortars often provide more mobile and less vulnerable weapons than guns or howitzers. In mountain and jungle country their high-angle fire enables them to reach targets inaccessible to other supporting weapons, and their light weight and inconspicuousness enable them to be brought into action quickly in difficult terrain. They are easily transportable by air, and they provide useful and early close support for troops carrying out an opposed landing from the sea. In some cases they can be fired from a vehicle. Moreover, they are inexpensive to manufacture, simple to operate, and robust and easy to maintain. With these advantages it is not surprising that sophisticated armies, particularly that of the Soviet Union and other Warsaw Treaty countries, should turn to mortars as an alternative to some of their light artillery. In the Soviet Army a considerable proportion of the divisional artillery has been replaced by mortars.

Advantages of mortars

The types of mortar in service in the various armies and guerrilla forces throughout the world are legion. All are improved models of the original Stokes mortar invented by the British in World War I. Typical of modern mortars is the United States's 81-millimetre mortar.

Light and medium artillery. The classification of "light" and "medium" artillery is basically the same everywhere, varying only slightly in detail from country to country.

Today, surface-to-surface guns and howitzers, classified as light, form the bulk of the artillery of a division or similar mixed force, such as a brigade group, combat group, or army task force. The improvement in the mobility of artillery pieces, by reason of tracked towing vehicles and the introduction of self-propelled guns, has, however, made it possible for weapons classified as medium to be added to the establishment of divisions and similar mixed forces in greater numbers than formerly.

The position today is that both light and medium artillery is usually available to support the close combat arms (armour and infantry) at very short notice. Additional medium artillery is normally retained under higher control as corps or army artillery, but readily available as a reinforcement in the combat area. Not all countries use the terms light and medium (*e.g.*, the British term for light normally is "field"). As a general rule, however, it can be said that pieces of a calibre up to about 105 millimetres (about four inches) are classified as light and those over 105 millimetres, but not more than about 155 millimetres (about six inches), as medium. All major armies have guns in these categories. Soviet medium artillery includes truck-mounted multibarrelled rocket launchers.

Some light and medium artillery pieces rely for movement on a towing vehicle, others are self-propelled.

There are a few categories of specialized artillery that come within the light classification; *i.e.*, artillery used solely in an antitank role, mountain artillery pieces that can be broken down into loads for pack animals or light aircraft, and artillery pieces especially designed for the use of airborne troops and conveyance by air.

The function of light artillery is to support combat troops in attack and defense, including antitank defense. That of medium artillery is the same, with the additional roles of counterbattery fire and bombardment of troop concentrations, installations, and communications in the immediate rear of the combat area.

Recently improved techniques and changes in the pattern of warfare have resulted in an increasing tendency to substitute mortars for light artillery as the close support of infantry.

Heavy artillery. Until the end of World War II the term heavy artillery applied to pieces of large calibre that were too immobile to accompany and support the leading troops in fluid operations. Heavy guns were reserved for static operations, such as those on the Western Front in 1914–18; for siege operations; and as fixed armaments in fortresses and coastal-defense installations. Since 1945, however, the term has been given a wider implication and may now be taken to include the various types of long-range strategic rockets.

The pattern of World War I, combined with the limited range and weight of shells of light artillery, gave rise to demands by all belligerent armies for heavy and extra-heavy artillery. Since 1918 there has been a progressive decline in this demand, for a variety of reasons, includ-

ing the development of bomber aircraft and rockets to take on bombardment roles and improvements in towing vehicles and self-propulsion that have made many heavy pieces classifiable as light from the point of view of mobility. In the 1960s it was found that the armed helicopter was often able to perform the harassing role that heavy artillery alone could carry out in the past.

Decline of heavy artillery

The defense of ports and fortresses by conventional guns, known variously as fortress, coastal, and garrison artillery, has now been almost entirely discontinued by the leading powers. Gone too are the cumbersome heavy guns and howitzers that took days to move a few miles and could only fire a few shots per hour. There are, however, a number of guns, howitzers, and rockets of large bore, and firing projectiles of considerable weight, that still form part of the equipment of the armies of both West and East. The conventional artillery pieces are either self-propelled or have mobile towing vehicles; the rocket launchers have been made reasonably mobile by similar means or have been given sufficient range to compensate for lack of mobility.

Anti-aircraft artillery. In modern military parlance the term anti-aircraft artillery covers a wide variety of weapons, all products of the 20th century and mostly of post-World War II origin. They range from rockets with a ceiling of over 100,000 feet (30 kilometres) down to highly mobile weapons for dealing with aircraft flying at treetop level.

Innovations in anti-aircraft defense

Two developments since 1945 have changed the basic pattern of anti-aircraft defense. These are the increased height at which modern aircraft can fly and the development of intercontinental ballistic missiles (ICBM's).

These two innovations have resulted in the production of the surface-to-air guided missile for dealing with aircraft at the higher altitudes, and the search for a practical antimissile missile.

It appears likely that in the foreseeable future the rocket missile will entirely replace aircraft as a means of long-range bombardment, and in consequence there will be an acceleration in the development of antimissile missiles. A foreseeable trend is the development of two distinct types of antimissile/anti-aircraft weapons: one to intercept and destroy long-range missiles, the other to deal with enemy aircraft in the operational or battle area.

There are many factors that make it impossible to classify or describe these weapons with precision. In addition to the secrecy that shrouds operational characteristics, new types are being produced at bewildering speed.

The most powerful and sophisticated weapons are deployed in the strategic-air-defense forces of the two major powers: the joint U.S.-Canadian North American Air Defense Command (NORAD) and the Soviet Union's Air Defense Command (PVO-Strany). These two organizations exist to defend their countries' homelands against attack by aircraft and to give warning and, to a limited degree, protection against attack by ballistic missiles.

Among the antimissile missiles are the Nike-Zeus (U.S.) and the Galosh (U.S.S.R.). A difficulty in the development of this type of weapon is the immense cost and the fact that, in order to be effective against a saturation (all-out) attack, they must be deployed thickly on the ground.

Air artillery. These weapons include two distinct classes, air-to-surface and air-to-air, the latter being in reality anti-aircraft weapons.

The projectiles usually associated with aircraft are the small-calibre machine gun for air-to-air and air-to-surface use, and the bomb for air-to-surface. During and after World War II a series of rockets was developed for use by normal aircraft and helicopters.

The short-range air-to-surface rocket is still in service, in both winged aircraft and helicopters, for harassing convoys of vehicles, troop concentrations, and other targets. The longer range, or "stand-off," type is in service for use with or without a nuclear warhead. Its purpose is to attack heavily defended targets from outside the zone of enemy defensive fire.

Rockets and guided missiles. The technique of guiding projectiles to a target is so closely associated with rockets as to make it convenient to consider them together.

From a technical gunnery point of view a rocket is a missile that is propelled by a rearward flow of hot gases generated in the rocket itself during flight, as distinct from the propellant charge of a conventional gun or howitzer shell, which ceases to operate after the initial explosion within the launching weapon.

A guided missile is one capable of receiving postlaunching guidance during flight. There are three main methods of guidance. Wire control is used for short-range surface-to-surface weapons within sight of the firer, a thin wire being trailed out to connect the missile and the operator. By this means the firer, who can see the missile in flight, directs it onto the target. Radio guidance can be used for longer range missiles. Finally, "homing" devices based on heat sensing attract the missile to the target.

Techniques of missile guidance

The classification of rockets and guided missiles is complicated by a number of factors. The design, technique for use, and even the existence of some is highly secret; some are strategic weapons with ranges of thousands of miles; some with shorter ranges are for battlefield use; most can use either nuclear or conventional warheads, but a few are confined to one or the other; they are in service with all combat services—land, sea, and air; and their organization and method of employment vary from country to country. (For information on specific rockets and missiles, see ROCKETS AND MISSILE SYSTEMS.)

Modern surface-to-surface rockets have three functions. The first is strategic, for the long-range bombardment of cities, military installations, docks, and similar targets at ranges from about 500 up to 8,000 miles (800 to 13,000 kilometres). Equipped with nuclear warheads, they are part of the nuclear deterrent maintained by East and West, to be used only in conditions of all-out nuclear war.

The second function is tactical, for bombardment within the operational area, which may be taken as up to some 500 miles (800 kilometres) behind the battlefront. They can be used with or without nuclear warheads.

The third is for battle support; for use, almost invariably in an antitank role, in support of front-line combat troops, and operated by a wire control system.

The primary purpose of surface-to-air rockets is to destroy enemy aircraft flying at heights beyond the range of conventional anti-aircraft artillery. Another role, of increasing importance, is the interception and destruction of enemy intercontinental ballistic missiles while they are still outside harmful range and altitude.

Surface-to-air rockets combined with guiding devices, particularly those designed for anti-ICBM purposes, are highly secret and subject to constant improvements, a process likely to continue indefinitely. One of the main limitations is the enormous cost of providing protection against ICBM's, even for a small area such as a port or military installation.

During World War II short-range air-to-surface missiles were introduced for action against such targets as columns of vehicles and troop concentrations. Since 1945 the emphasis has been on long-range missiles. The purpose of these latter weapons is to enable aircraft to bombard an important target with missiles, with or without nuclear warheads, from a distance outside the range of the enemy's defense system. These weapons are commonly known as "stand-off" missiles because the aircraft launching them "stands off" from the target.

Partly because of the high speed at which the launching aircraft is travelling, considerable difficulty has been experienced in devising satisfactory guiding systems for long-range air-to-surface missiles. Programmed systems have not proved feasible, and reliance has had to be placed on highly technical and delicate systems, such as the inertial-guidance system (see also GYROSCOPE).

The main purpose of air-to-air rockets and guided missiles is to engage enemy aircraft. A possible future role is against ICBM's, the aircraft engaging the missiles before they come within effective range of their targets; but much research and experiment will be necessary before this becomes a viable method.

The main characteristics of rockets and guided missiles, when used for war purposes, can be summarized briefly. The limit of range of the most powerful rocket (the ICBM) was in 1970 about 8,000 miles, but increases were anticipated for the near future.

Limitations of missile defense

The cost of rockets, especially the guided-missile variety, is prodigious. The cost of an anti-ICBM system protecting only a small area amounts to hundreds of millions of dollars. The high cost, combined with the long range of some types and their destructive powers, means that rockets and guided missiles undergo less rigid preservice tests than most other weapons. Although simulator training devices have been produced for many, personnel get little training with live missiles of the larger type. These limitations for training and testing would almost certainly reduce the expected effectiveness of many of these weapons in war. But the potentialities of the rocket and guided missile are immense and by no means exhausted. Development is likely to continue indefinitely.

(C.N.B.)

MODERN NAVAL GUNNERY

Data processing. The amount of information provided by the sensors carried by modern warships (such as radar, radio, sonar, and passive devices) is so extensive, and the armament and its associated fire-control equipment is so complex, that computers must be employed to sift the information and present it to the command in a way enabling prompt action by the appropriate weapons system. This computer system calculates the course and speed of any air, surface, or subsurface target encountered, and indicates the threat it poses to the force or ship. It determines the course to be steered for interception by the ship or by the aircraft she controls, and by means of converters known as decoders it can control the operation of missiles, guns, and torpedoes.

Missiles. The main armament of the modern warship is the guided missile, four types of which are mounted in ships: strategic, surface-to-surface, surface-to-air, and surface-(or submarine)-to-submarine. There are also the air-to-surface missiles with which carrier-borne aircraft are armed.

Submarine-launched ballistic missiles

The most formidable weapon in the naval armoury today is the submarine-launched ballistic missile. Developed initially by the United States as Polaris, the latest model, Poseidon, has a range of about 3,000 nautical miles and carries a multiple independent re-entry vehicle containing ten nuclear warheads targeted hundreds of miles apart. Each submarine carries 16 missiles fitted with inertial-guidance systems (see GYROSCOPE) linked through a computer, up to the moment of firing, to the submarine's inertial-navigation equipment, thus ensuring that it is continuously fed the correct coordinates of the target at which it is aimed. Some Soviet submarines are armed with ballistic missiles having a range of 750 miles (1,200 kilometres), but these are being superseded by those equipped with missiles of the Polaris type.

Until recently, intership combat, except through the intermediary of aircraft, appeared unlikely, but Soviet development of ship-to-ship missiles has recreated the possibility. Antiship missiles with a range extending beyond the radar horizon, which is 6 percent greater than that of the eye, require the cooperation of a satellite or aircraft to provide the necessary geographical coordinates or, alternatively, radar illumination of the target. The technique of using such missiles has not yet been fully developed, though doubtless such a system is employed for the ship-to-ship missiles with which many Soviet ships are equipped.

There are about ten types of close-range surface-to-surface missiles at sea, primarily designed for mounting in fast patrol boats. A typical missile of this type is the French Exocet, weighing 1,600 pounds (725 kilograms), which carries a conventional warhead with a shaped charge weighing 330 pounds (150 kilograms) with an impact equal to that of a 15-inch (380-millimetre) shell. It attains a speed of Mach 0.96 (just under supersonic; one Mach is about 700 miles per hour at sea level) and is guided by an inertial system to the vicinity of the target; then a nose-fitted radar takes over and ensures impact. This missile has a low trajectory, which makes it difficult to detect and intercept.

The ability of a warship to defend herself against air attack is of primary importance, but it is too costly to arm every ship with sufficient ship-to-air missiles in the way in which they were formerly equipped with anti-aircraft guns. A system of area defense is therefore employed. The first line of defense of a naval force is still interceptor aircraft controlled by the ships, and behind the zone in which they operate is that in which ship-to-air missiles are used. Although these are generally capable of dealing with any high-flying aircraft that elude the combat air patrol, against low-flying aircraft and missiles, close-range missiles and gunfire are desirable. Typical of the ship-to-air missiles in use is the British Sea Dart, in which the first stage is a rocket motor using a solid propellant and the second is a ramjet motor. The guidance system is semi-active homing; a radar receiver in the nose picks up the pulses reflected by the target when illuminated by the firing ship's radar, and it includes a means of detecting small changes in target movement. The missile also has a ship-to-ship capability. The whole weapons system comprises a search radar, two tracking radars, a twin launcher and automatic handling system, and a computer linked with the central computer system.

The close-range missile and gun defense zones are closely integrated. Short-range ship-to-air missiles are generally fitted with radio command or semi-active homing guidance. Those in service include the British Seacat (shortly to be replaced by Sea Wolf), the Swiss-made Sea Indigo, and the United States Sea Sparrow. An essential feature of their equipment is a stabilized target indication and control sight. These missiles are also used in an antimissile role against nonballistic and cruise-type missiles like the Soviet Styx and its successors.

Antisubmarine missiles

Surface ships and submarines designed to attack enemy submarines are armed with special antisubmarine missiles such as the Australian Ikara, the Norwegian Terne, the French Malafon, and the United States Astor, Asroc, and Subroc. Ikara and Malafon are rocket-assisted torpedoes using radio-command guidance. Terne is a rocket-propelled depth charge in which detonation is achieved by a combination of acoustic proximity, time fuse, and impact. Astor is a wire-guided torpedo with a range of 11 miles, while Asroc is an antisubmarine missile that can carry either a homing torpedo or a nuclear depth charge to a distance of about 6 miles. Subroc is also an antisubmarine missile with a nuclear warhead and a range of about 26 miles (42 kilometres) especially designed for launching from the torpedo tubes of a submerged submarine. On being fired it rises to the surface and, after an air trajectory to the vicinity of the target as determined by sonar, the propulsion and bomb units separate, the latter re-entering the sea and detonating.

There are a number of air-to-surface weapons with which naval aircraft are equipped, one of the most successful being the United States Bullpup, which carries a 1,000-pound (450-kilogram) warhead a distance of nine miles (14 kilometres). Longer range missiles are under development, among them the U.S. Condor, with a range of 35 miles (56 kilometres). Employing radio-command, visual, and television guidance systems, these missiles offer a serious threat to surface ships.

Guns. Guns are still needed in ships for shore bombardment in support of land forces, for close-range air defense, and for such peacetime duties as fishery protection. Apart from the 16-inch guns in four U.S. battleships now on reserve ("mothballed"), the largest gun afloat today is the eight-inch (203-millimetre) with which some U.S. cruisers are armed, a calibre considered to be the minimum for effective shore bombardment. But the high rate of fire necessary for anti-aircraft defense cannot be attained with a calibre greater than 5-inch (127-millimetre); the majority of modern ships are armed either with such guns or with 4.5-inch (115-millimetre) or 3-inch (76-millimetre) types. The essential function of target acquisition is assured by new types of stabilized radar, protected against electronic countermeasures and capable of

detecting low-flying aircraft. Tracking is done by radar assisted by computers. A fire-control system widely employed is the N.V. Hollandse Signaalapparaten of The Netherlands; another offering a wide choice of missiles and guns is Contraves Sea Hunter 4 of Switzerland. The efficiency of the modern gun as measured by the firepower-to-weight ratio is twice the level of World War II, and crew requirements have been greatly reduced. The Italian Oto Melara three-inch (76-millimetre) gun has a rate of fire of 90 rounds per minute, weighs 6.3 tons, and has a crew of three. It features fully automatic loading to ensure instant readiness, and reaction time is less than ten seconds.

Torpedoes. The torpedo, still a very effective antiship weapon, is today mainly used against submarines. The diameter varies from 22 inches (559 millimetres) to 12.75 inches (324 millimetres). As mentioned, various means are employed for airlifting torpedoes to the vicinity of their targets. Propulsion systems used include compressed air, electric cells, solid propellant, and liquid monopropellant. Guidance is active acoustic, passive acoustic, wire, or terminal acoustic, or a combination. In active acoustic a sonar transmitter in the head seeks out the target and homes the torpedo on to it; in passive acoustic a listening device in the head picks up the propeller noise of the target and homes the torpedo on to it; in terminal acoustic the torpedo follows a preset path to the target area and on reaching it circles or zigzags to and fro, the charge being triggered by an acoustic proximity fuse when the target comes within range. Guidance by means of a wire is also employed. This system enables the controlling ship to direct the torpedo towards the target. The torpedoes are launched directly from ships and submarines, by rockets, aircraft, and helicopters (see also NAVAL SHIPS AND CRAFT). (B.B.S.)

Guns, Sporting and Target

Sporting and target guns are the firearms used in hunting game and in target-shooting competitions and practice. Compressed air and gas weapons are fairly numerous in some places; firearms are much more popular. For hunting in general, see HUNTING, SPORT; for competitive target, trap, and skeet shooting, see SHOOTING. For general details about firearms, see SMALL ARMS, MILITARY.

HISTORICAL DEVELOPMENT

Firearms, introduced in the Western world in the 14th century, were originally military in purpose, but even the earliest small arms were undoubtedly used for informal matches and perhaps for taking game. Within 200 years weapons were being made specifically for hunting and target shooting.

Fine early muzzle-loading wheel-lock rifles can still be shot accurately by those who understand proper loading procedures. Some that survive were produced more than 300 years ago.

Flintlock fowling pieces, which made wing shooting (shooting at game birds in flight) practical, appeared in the 17th century, firing either small projectiles or shot pellets in fairly even patterns. Skillful hunters could kill game birds in the air, though range was limited. Many improvements were introduced to increase both range and accuracy. The Industrial Revolution brought factory production, followed by such 19th-century refinements as cartridge breechloaders; chokebores in shotguns; small calibre high-velocity rifles; and smokeless powder. Sporting and target arms are today among the most efficient and advanced of mechanical devices.

FIREARMS DESIGN AND OPERATION

Rifles. A rifle is a shoulder firearm that fires a single projectile or bullet and is usually classified on the basis of the type of action it employs and on the size or calibre of ammunition it fires.

Types of actions. Bolt-action rifles similar to military weapons of the 1890–1940 era are still the most common type for hunting throughout the world. Bolt action is efficient, reliable, and easy to manufacture. Most weapons of this type have magazines for quick reloading after each shot. When a bolt-action rifle is properly assembled, fitted to the stock, and supplied with appropriate ammunition, it can be extremely accurate. The disadvantage of all bolt-action weapons is that the total overall length for any given barrel is greater than "break-open" actions with one or more barrels. A double-barrelled sporting rifle can also deliver a second shot more quickly than any manually operated repeater.

There are three other types of sporting rifles. Semi-automatic hunting rifles are rare, save in Cal. 22 rimfire, but are gaining in popularity. Lever-action rifles were more common half a century ago than today. Slide or pump-action weapons are used largely by sportsmen who have grown accustomed to this type in their shotgun shooting.

Calibres. The diameter of the bore in inches or millimetres is generally called calibre. The full title of a rifle ammunition generally contains other information. For example, Calibre (or Cal.) .30–30 means a rifle with a bore diameter of .30 inch and a cartridge case designed to hold roughly 30 grains of black powder. Cal. 30–'06 indicates a .30 inch bore and a cartridge originally standardized in 1906. The new Calibre 6 x 47 means a bore 6 millimetres in diameter (.236 inch) and a cartridge case 47 millimetres long.

Bore diameter gives only a partial indication of power. The performance of a rifle depends on the weight and shape of the bullet and its velocity. A larger bore does not necessarily fire a heavier bullet; velocity usually decreases with increased diameter. For instance, a Cal. 257 Weatherby (the name of the inventor of the rifle and the cartridge) is considerably more powerful than weapons with larger bore diameters like the Cal. 30–30 because the Weatherby bullet travels faster.

Shotguns. A shotgun is a shoulder firearm that fires a cluster of shots or pellets, as opposed to a single bullet for a rifle.

Types of actions. In general, shotguns have actions similar to those of rifles, but "break-open" shotguns are far more numerous than "break-open" rifles. These are probably still the most popular type worldwide and can be made with one, two, or more barrels. A single barrel with this type of action is a single-shot weapon. Although cheap to produce and reliable, it has the disadvantage of an extremely slow second shot. Double-barrelled shotguns are most common. These are made in both side-by-side and over-and-under configurations. Three-barrelled and even four-barrelled "break-open" weapons are rare; they usually include one or two rifle barrels.

Double-barrelled shotgun

Popular in America for many years, slide or pump-action shotguns have gained favour in Europe. To chamber a new round after each shot, the fore-end is pulled smartly to the rear as far as it will go and then pushed forward again. A hunter experienced with a pump shotgun is not conscious of operating this mechanism and can give his entire attention to shooting. In general, weap-

ons of this type are the cheapest and most reliable of the popular repeaters.

Semi-automatic shotguns have been made since the early 20th century; early weapons of this type were the long recoil Brownings. Since 1945, gas-operated shotguns have become more popular. In these weapons, the pressure of the gas generated by the fired shell ejects the spent shell, cocks the action, and moves a fresh shell into the firing chamber. Gas-operated shotguns are now considered reliable and effective on both game and clay targets. All semi-automatic shotguns require more careful maintenance and cleaning than similar pumps. "Automatic" shotguns tend to absorb part of the recoil rather than communicating it to the shoulder of the shooter in the form of "kick."

Lever-action and bolt-action shotguns have been produced, but neither type is popular. The inherent defects of all bolt-action weapons are excessive length and slow second shots. The lever-action shotgun never became popular because it was clumsy in appearance and operation.

Gauges. Shotguns are made in several standard barrel or bore diameters. The bore or gauge number designation originally indicated the number of spherical lead balls of bore diameter that weighed one pound. The derivation of the term accounts for the paradox of having a smaller number indicate a larger weapon. There are five standard-gauge bores in use today: 10-, 12-, 16-, 20-, and 28-gauge. There is also the so-called .410, which borrows its designation from rifle nomenclature; it is a calibre .410, often described as .410-gauge. The 12-gauge shotgun is the most popular in America and Britain; elsewhere the 16-gauge is often preferred. Other sizes are far behind everywhere. The 10-gauge is now obsolescent.

A shotgun usually fires a charge of spherical pellets of uniform size. By trial and error, sportsmen and target shooters have established which sizes are best for various types of shooting. Though large shot carry farther, their pattern is less dense because there are fewer pellets per given weight of charge.

Chokes and patterns. A shotgun's effectiveness depends on the uniformity of its pattern. A good weapon places its charge evenly in a circular pattern on a surface perpendicular to the line of flight. Density of the pattern depends on the number of pellets in the charge and the distance of the muzzle from the target. The farther the patterning surface from the muzzle, the less dense the pattern. For quick shooting at close range, a pattern of maximum size and minimum density is desired. Normally, a shotgun with a uniform cylindrical bore (the same size from breech to muzzle) is used to provide such a pattern.

Shot patterns

For longer ranges, a tighter pattern is desirable. Such concentrations of shot are obtained by reducing the diameter of the bore close to the muzzle (choking) in various ways. Full chokes effect maximum concentration of normal charges concentrating 70 percent or more of the shot in a 30-inch circle at 40 yards. A modified choke is about halfway between a full choke and a cylindrical bore; ¼ and ¾ chokes exist. Great skill is required to hit fast-flying birds at long range regardless of the choke of the shotgun. Any reduction in pattern size handicaps a shooter at close range; full chokes hinder more often than they help.

Any single-barrelled weapon can be equipped with a device attached to the muzzle that allows a shooter to change his choke at will, either by attaching a new tube or adjusting the muzzle diameter. These can be combined with recoil-reducing buffers that turn some of the muzzle gases to hold the weapon where it is, rather than allowing it to recoil.

Handguns. A handgun is a small firearm that can be held in one hand. It usually fires a single projectile or bullet.

Types of action or operation. Single-shot pistols are still used, though they are less popular than revolvers or semi-automatic pistols. Full-automatic pistols have been made but are illegal in many countries. In fact, private ownership of pistols of any sort is restricted throughout a good portion of the world.

Target. Where more than one shot must be delivered within a time limit, revolvers or "automatics" are preferred. A top-quality target pistol can place five shots in a 2-inch (50 millimetre) group in 20 seconds at 25 yards (24 metres), although only a few competitors have the skill to utilize this accuracy.

Sport. Many sportsmen throughout the world carry a small pistol with them when hunting and fishing, generally Cal. 22 rimfire weapons, not practical for use on game larger than grouse and rabbits. On the other hand, powerful pistols have been manufactured for centuries for use by hunters as secondary weapons, even against dangerous animals. Typical are the heavy revolvers that take Cal. 44 Magnum ammunition. Weapons and cartridges of this type are more powerful than many rifles. Some men hunt with pistols only and equip their handguns with telescope sights. Such pistols are satisfactory for medium-sized game, including deer, if the hunter has sufficient skill to place his bullets accurately.

Hunting with pistols

Self-defense. Occasionally, a hunter in primitive territory carries a pistol for self-defense against other human beings. Revolvers of medium to high power are popular for this type of service. Though a pistol is more likely to be at hand when required than a rifle, it takes far more skill for effective use. Pistols are also purchased throughout the world by homeowners and others for personal defense, despite legal and other risks.

SIGHTS AND STOCKS

Rifle. The portion of a rifle normally made of wood is known as the stock. It usually consists of a single piece extending from the butt to the fore-end in bolt-action types or of two pieces in most other weapons. The stock supports the barrel and action and temporarily joins the entire mechanism to the shooter. A rifle stock is designed so that when held against the shoulder it permits the shooter to sight along or through the rifle sights. Stocks vary widely, however, depending on the use for which the rifle is intended, the type of sights installed, the size of the user, and the desire for ornamentation. Though not often embellished with gold, silver, or ivory today, stocks are frequently carved in various ways and finished with resins and plastics of unusual variety and beauty. There are even some laminated stocks made of thin pieces of different woods chemically bonded to each other.

Iron sights are sights in which no glass is used. The front sight can be a blade, a bead, or an aperture surrounded by metal. It can be seen through or over a rear sight that may have an open "V" section, a "U" section, or a small, round hole called a peep. Various combinations are used for both hunting and target shooting.

Special telescopes are also installed on rifles to replace or supplement iron sights. Scope sights magnify the target and indicate precise location of the bullet's point of impact by "cross hairs" or a similar device. Telescope sights add to the effectiveness of semiskilled marksmen and provide additional minutes of effective shooting because of their light-gathering power early in the morning and late in the evening.

Telescope sights

Shotguns. Shotgun stocks resemble those of rifles; fit is even more important. Shotgun sighting equipment is less complicated, however, because aiming is less precise. A shotgun normally has only a bead front sight, though a few now have additional small beads located about the middle of the barrel. Sighting is accomplished by looking along the barrel and placing the front bead on or under the target. This is usually done quickly and to some extent intuitively. Both normal iron sights and scope sights have been tried on shotguns, but without much success.

Pistol. Pistol stocks or grips are designed to fit men with normal-sized hands. Target shooters often adapt them to their individual requirements. Pistols have a bead or rectangular front sight and an open rear sight with either a "U" or a rectangular opening. Most target weapons have adjustable rear sights. Techniques have been worked out for precise shooting in which the front sight

is seen through the opening of the rear sight with the tops of both level. The target is then "placed on" the front sight. Since the human eye can see only one thing at a time clearly, both the rear sight and the target are slightly blurred. Telescope sights are occasionally mounted on pistols but are not effective for target shooting. They are useful in hunting, especially with powerful weapons.

AMMUNITION

Rifle and pistol. Many different types of ammunition have been developed, each for specific purposes. Rifle and pistol ammunition is frequently rated on the basis of effectiveness, accuracy, and range.

Game effectiveness. The effectiveness of a hunting rifle depends on where the bullet hits the game and its power or energy at the time it strikes. Both are important. A bullet's power or energy varies directly with its weight and the square of its velocity. Weight remains constant throughout flight, but velocity decreases rapidly with increasing range.

Big-game ammunition

To kill large game normally requires at least 2,500 foot-pounds of bullet energy. This can be achieved by a 200-grain bullet travelling at 2,500 feet per second (fps), by a 300-grain bullet travelling at 1,960 fps, or by a 500-grain bullet travelling at 1,700 fps (a grain is $\frac{1}{7000}$ of a pound). These velocities and bullet weights correspond to projectiles from standard Cal. 30 rifles out to about 100 yards, Cal. 375 rifles out to 175 yards, and Cal. 45 rifles out to about 300 yards. High-intensity "Magnum" cartridges like those in the Weatherby series extend power for any given calibre at least one class; the Cal. 300 Weatherby Magnum loaded with a 180-grain bullet is almost as powerful as a Cal. 458 Winchester. The 460 Weatherby Magnum has more power than the Cal. 577 British Nitro Express cartridges.

Large bullet energy increases hunter security when going after dangerous game on foot at close range because of its greater knockdown capability. More bullet power, however, means more recoil to be absorbed by the firer and can lead to inaccurate and less effective shooting than having less power more accurately placed.

Accuracy. High accuracy is essential for hunting at long range and for target competition. Cartridge-case design plays an important part; so does the shape and weight of the bullet. Both the ammunition and the rifle must be manufactured carefully, in accordance with principles of quality worked out over the years. Bullets must be uniform in weight with solid concentric jackets and core. The powder charge from round to round must not vary more than $\frac{1}{10}$th of a grain. Contact between the action of a rifle and the stock should be even and solid. Heavyweight barrels appear to shoot better when free-floating; *i.e.*, anchored firmly in the action but not touching the fore-end.

Ammunition accuracy is equally important for pistol competition. Top-flight target shooters continually try new combinations of weapons and ammunition, varying bullet shapes, weights, and materials. Powder and primers are also important.

Range and noise. Maximum effective range is determined for rifles and pistols by the velocity of the bullets they fire. The higher the initial velocity the farther the bullet travels before it loses accuracy and target effectiveness. Maximum power rifles like the Cal. 460 Weatherby and the Cal. 577 Nitro Express are seldom fired at long range, whereas some weapons designed primarily for varmint (small animal pest) shooting, especially the high-velocity Cal. 22 centre-fires, are rarely shot below 50 yards. The latter type are accurate out to at least 200 yards and are often fired at targets much farther away.

Noise is also directly related to rifle power. Basically, the more power the rifle has, the more noise it makes. Many small-game hunters in the more heavily populated areas of the world use Cal. 22 rimfire rifles because they fire light bullets at low velocities and make less noise.

Shotgun. Shotgun ammunition varies in effectiveness, maximum range, and evenness of pattern formed by the pellets.

Killing power and range. Some of the factors in effective killing power of rifles apply to shotguns as well. The weight of projectiles hitting a target determines effectiveness. To some extent, velocity at the time the game is struck also plays a part, although shotgun pellet velocity does not vary widely in standard loadings.

The smaller the shot size, the more shot in a given charge and the thicker the pattern at a given range. But small shot have less power than larger pellets and do not penetrate the feathers of larger game birds as well. In general, smaller shot are used for smaller game birds. Small shot loses velocity and effectiveness more quickly with range than larger shot. Ducks and geese, which require more penetration and are normally shot at medium to long range, require larger shot. Shot sizes vary from country to country, but larger numbers indicate smaller pellets. In the U.S., #8 and #9 are for quail, #6 and #7½ for pheasant, and #2s, #4s, and #5s for waterfowl.

As a practical consideration, shooting at what a hunter considers moderate range is more rewarding than when he believes he is just inside maximum effective range. There are two reasons for this. First, the shooter usually underestimates the distance to birds in flight. Second, almost all hunters overestimate the effective range of their combination of weapon and ammunition.

Shooting at moderate range

Even patterns. Patterns vary with chokes as discussed above. They also vary with ammunition. Distribution of the total shot charge varies slightly from round to round in any given gun even with the same type cartridges. Recent improvements in ammunition, including elimination of the overshot wad (the wad that is placed over the shot), and surrounding of the shot charge with a plastic cup while in the barrel, have increased the number of undamaged shot that fly truly out to maximum effectiveness. This means a thicker pattern.

USES OF GUNS

Local hunting. Only a few areas in the world still have wild game available close to large concentrations of people. Even when game exists in populated areas, hunting is frequently illegal because of the danger to humans and domestic animals. In some parts of western Europe, wild game hunting is still possible close to cities because of controlled conditions that generally include feeding the game during a portion of the year and careful protection of them from their natural enemies. In these areas, hunters must take courses in game recognition, firearms, field safety, and other similar subjects. This preparation greatly reduces the incidence of unsafe shooting.

In other areas like the Rocky Mountains of the U.S. and Canada, and in Australia and New Zealand, human population density is low and game population high. A farmer or rancher may even kill animals because they destroy his crops or take grass from his cattle. Game birds have been so plentiful in New Zealand that normal hunting did not keep their numbers within bounds. Many wild geese were destroyed with dynamite.

Game farm and distant hunting. Hunters who do not wish to travel long distances often pay for the privilege of shooting in nearby areas where game is preserved. Guides and outfitters in the Western U.S., Canada, and Alaska frequently charge high fees but may guarantee success against big game or at least guarantee a fair shot at an animal of a desired species.

Preserved hunting of game birds is increasingly popular in America and Europe. Game on preserves is usually partially wild, supplemented by pen-raised birds. They may or may not be varieties that were once wild in the particular area. Chukars, or Hungarian partridges, are now found in many countries besides Hungary.

Competitive shooting. A major area of gun use is in competitive or target shooting. Rifles, pistols, and shotguns are so used.

Rifle. Man has engaged in target competition with military and sporting weapons since the dawn of history. As archery declined, firearms became important. Olympic rifle shooting is only one of at least a dozen types currently popular throughout the world. Rules, weapons,

time limits, ranges, positions, and other details vary widely.

Rules of rifle competition

Rifle competition usually resembles either military or big-game shooting or a combination of the two. In Britain and America, the major competitions are conducted with rifles similar to those used in the Armed Forces at different ranges. Firing positions resemble those used in the military. Rapid fire, that is, the firing of more than one shot within a limited time, is included. Olympic rifle competition, on the other hand, includes no rapid fire.

A new type of competition that tests the ability of a competitor to collect accurate equipment more than his marksmanship has recently come into being. Matches are fired from shooting benches where the gun is clamped under conditions that approximate laboratory testing of weapons and ammunition. Some of the rifles used in these matches are not even practical for game hunting or normal target competition. Ten shots at 100 yards may be fired into an area smaller than the U.S. ten-cent piece.

Pistol. Pistol matches are always fired without support for the weapon or the shooter's arm. A complete match generally includes deliberate or slow fire and one or two forms of timed or rapid fire. Weapons used, trigger pulls, sighting radius, and other details are sometimes, but not always, controlled.

Shotgun. In the two worldwide popular forms of shotgun matches (trapshooting and skeetshooting), shots are fired at artificial or "clay" targets thrown by machine in flight patterns designed to resemble those of birds. These targets break when hit by shot and are scored as "dead."

Live pigeons and occasionally other game birds are also shot competitively in some areas of the world. Live bird competition rules normally require a shotgun that delivers two shots quickly in pattern of maximum tightness. Since a released bird may fly directly away from the shooter, a competitor needs a weapon effective at long range. Kills at 45 yards and beyond are not unusual.

GUNSMITHING

Guns, like most things made by man, require maintenance. Small parts break; complicated mechanisms need adjustment. Even more important, commercially available weapons may not give maximum effectiveness for specialized types of shooting. A gunsmith familiar with rifles can generally improve the accuracy of a weapon.

Competent gunsmithing can be even more important for competitive pistol shooters. Military semi-automatic pistols vary widely in accuracy as manufactured, but when worked on by a knowledgeable mechanic, shot group size can be reduced dramatically. Gunsmiths can also install special sights and stocks.

Shotguns often need changes in stock, triggers, and shot patterns, in addition to normal adjustment, repair, and cleaning. Considerable skill is required here, but competent gunsmithing can improve a shooter's chances of hitting his target.

Gunsmithing at home

Many shooters throughout the world perform some or all of their gunsmithing chores for themselves. They may even make weapons or parts of them to their own specifications. There is ample literature in this connection, as well as tools, including specially designed machine tools.

Most amateur gunsmiths and many other shooters handload some or all of their ammunition, usually by refilling used cartridge cases, the most expensive component of a complete round. Equipment varies greatly in simplicity, cost, and effectiveness, but skillful handloading can improve on factory ammunition accuracy for both rifles and pistols. Reloading reduces the cost of trapshooting by about 40 percent.

COMPRESSED AIR AND GAS GUNS

Guns resembling firearms but using compressed air to project either a single bullet or a charge of shot relatively short distances have been used for hundreds of years. Originally, a tank in the stock of the gun was pumped full of air. A trigger released this suddenly into the barrel behind the bullet or charge of shot. Range, accuracy, and power were always limited, but the weapon was nearly ideal for a hunter who wanted to avoid making a loud noise and was able to creep up on game, especially at night.

The compressing of air into a reservoir was always a problem. This form of air gun was good for only one discharge and was costly to produce. During the 16th century a spring was substituted for the air reservoir. When the trigger released the spring, the latter actuated a piston that compressed air that in turn drove a pellet through the bore. This is the principle used by most air "rifles." It can also be used in air pistols.

More recently, weapons have been constructed that use cylinders of compressed gas, usually carbon dioxide. A single cylinder will give a number of shots before replacement is necessary.

Air or gas weapons are sometimes used in military training and for informal indoor shooting, especially by family groups. An air rifle can stun or even kill small game, but accuracy, range, and power are all limited. On the other hand, an air rifle is not a safe plaything. A pellet that hits a person in a spot covered by two or three thicknesses of clothing will sting only, but a shot in the eye or some other sensitive part can have tragic results. Weapons of this type are illegal in some areas.

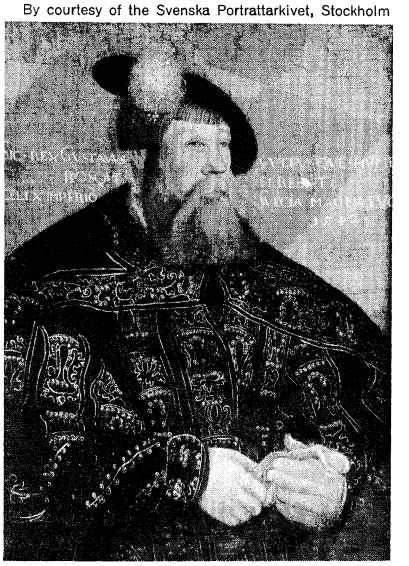
(J.We.)

Gustav I Vasa, of Sweden

Gustav I Vasa (known before his coronation as Gustav Eriksson), one of the great rulers of the 16th century, made Sweden an independent state; gave his country, for the first time in a century, nearly 40 years of stable and intelligent government; ensured the triumph of Lutheranism; established the first truly national standing army of modern times; and founded the Swedish navy.

By courtesy of the Svenska Portrattarkivet, Stockholm



Gustav I, portrait after J. Binck, 1542. In the University of Uppsala, Sweden.

Early life. Gustav was born in 1496 (?), the son of a Swedish senator and of a noble family whose members had played a prominent part in the factious aristocratic politics of 15th-century Scandinavia and that was connected by marriage with the family of Sture, which had supplied Sweden with three regents. Gustav fought in the

army of Sten Sture the Younger against Christian II of Denmark in 1517–18 and was one of the hostages sent by Sten to Christian in 1518 as part of the terms of an armistice. Christian violated the agreement and carried Gustav off to Denmark. In 1519 Gustav fled from his captivity to Lübeck, where he made friends who were to be of great importance later. On May 31, 1520, he returned to Sweden. Sten Sture had meanwhile died of wounds, and Christian was master of almost all Sweden save Stockholm. In November, by the "Stockholm bloodbath," Christian removed the most dangerous of his opponents, including Gustav's father and two of his uncles.

Rise to prominence

Faced with the alternative of rebellion or flight, Gustav chose the former. He succeeded in rousing the midland province of Dalarna to resist, purchased by judicious concessions the support of lay and ecclesiastical magnates to whom a union of the three Scandinavian kingdoms under Christian had become unwelcome, and was able (since Sten Sture's son was a mere boy) to pass as leader of the surviving Sture party. A considerable body of folk legend deals with his real and supposed adventures at this period. For the eviction of the Danes, as he soon found, outside help was necessary; and he obtained it from the rich free city of Lübeck, whose merchants felt themselves threatened by Christian's aggressive economic policies. This aid enabled Gustav to establish Sweden's independence and may have been responsible for his election as king (June 6, 1523). In return for it, Lübeck extorted far-reaching commercial privileges; and it was to be one of Gustav's main concerns to emancipate his country from its dependence on his former backers.

His monarchy. Gustav's crown continued for some years to be precarious. Christian II had been driven out of Denmark by his uncle, who succeeded him as Frederick I, and a common fear of Christian's restoration soon drew Frederick and Gustav together, so that despite recurrent periods of tension the threat from Christian, and afterward from his heirs, enforced a measure of harmony between Sweden and Denmark. But Gustav had to face serious internal dangers: from aggrieved members of the old Sture party who resented his favour to some of their former enemies; from the men of Dalarna, who added to this grievance complaints on economic and religious grounds; and from great nobles, who found Gustav a more formidable ruler than they had expected. Indeed, Gustav proved to be a harsh master and an exigent lord; he became known for being suspicious, mendacious, cruel, vengeful, demagogic, and capricious; and to his enemies, he seemed to have most of the attributes of a tyrant.

The need to pay his debts to Lübeck, and to strengthen the royal authority, forced Gustav to impose heavy taxes; and it was essentially with a view to tapping the church's wealth that he embarked on the measures that led to the Reformation in Sweden. The Diet at Västerås in 1527 put the church's property at his mercy. Gustav had few theological interests or preferences; but he resented the presence in Sweden of any authority that challenged his own, and he had some sympathy with the idea of services in Swedish, for he was an indifferent Latinist himself. The move toward Lutheranism, however, was both accelerated and retarded by purely political considerations. Sweden did not become irrevocably a Lutheran country until 1544 at the earliest, and it was a long time before Protestantism was popular outside Stockholm.

Role in the Swedish Reformation

The last great revolt of the reign, in 1542–43, had a strong anti-Protestant strain. Gustav's vain attempts to become a member of the Schmalkaldic League, formed by the German Protestants, were dictated by a desire to provide himself with allies rather than by religious convictions. In foreign policy, indeed, he inclined always to caution and a husbanding of resources. If he intervened in the so-called Count's War between pretenders to the Danish crown (1534–36), it was because he saw at last a chance of liberating Sweden from Lübeck's tutelage; and his only other adventure was the later war with Muscovy (1555–57).

Gustav's greatest achievement was the creation of a strong monarchy. He based his power on a massive agglomeration of crown and family lands, acquired for the most part by confiscation from the church, which put him beyond the rivalry of any other noble house. The supervision and exploitation of these lands was his personal concern, and with it went an infinite solicitude for the least detail of fiscal policy. In the 1540s, due to a lack of trained Swedes, he imported German administrators. This was a brief episode, but their work had a lasting effect in Sweden. It enabled Gustav to maintain his personal supervision and to combine it with high efficiency.

As the political heir of a faction, he found it expedient to bribe his nobility with church lands, and he was successful in many policies that the Stures had only attempted. In 1544, for instance, he induced the Diet to declare the monarchy hereditary rather than elective. He summoned the estates frequently in the uncertain years at the beginning of his reign, though less often thereafter; and his use of them to endorse his policies undoubtedly aided their development as an effective parliamentary body. On the other hand, he reduced to a position of relative insignificance the aristocratic council of state, which had played the leading part in the constitutional struggles of the preceding century.

He died on September 29, 1560, and was succeeded by his son, who became Eric XIV.

Gustavus II Adolphus, of Sweden

Gustavus II Adolphus, king of Sweden from 1611 to 1632, inherited a weak and divided country and transformed it into one of the greatest powers of all Europe, by creating a Swedish Empire of the Baltic that endured for almost a full century. His intervention in the Thirty Years' War (1618–1648), at a moment when the armies of the Habsburg emperor and the German princes of the Catholic League controlled almost the whole of Germany, ensured the survival of German Protestantism against the onslaughts of the Counter-Reformation. The consequences, for Germany and for Europe, extended far beyond the religious field. By supporting the German princes against the Emperor, Gustavus Adolphus defeated the attempts of the Habsburgs to make their imperial authority a reality, and thus played a part in delaying the emergence of a united Germany until the 19th century. As a military commander, he was responsible for military innovations that marked an epoch in the history of the art of war. But from the point of view of his own country, these achievements were less significant than his domestic labours—his extraordinarily wide-ranging creative work in the fields of administrative organization, economic development, and education. If Gustavus Adolphus had never won a battle, or conquered an inch of territory, he would still rank as the greatest of Swedish kings, and one of those who were largely responsible for laying the foundations of the modern Swedish state.

Gustavus was born in Stockholm on December 9, 1594, the eldest son of Charles IX and his second wife, Christina of Holstein. He was still some weeks short of his 17th birthday when he succeeded his father in 1611, and it was only in exchange for important constitutional concessions that the Swedish Estates (the Riksdag or Assembly) permitted him to assume full control of the government. He found himself in an extraordinarily difficult position. Charles IX had usurped the throne, having ejected his nephew Sigismund (who was also king of Poland) in 1600, and the resulting dynastic quarrel involved Sweden and Poland in a war that continued inter-

Problems of the monarchy

mittently for 60 years. Until 1629 Gustavus had always to reckon with the danger of a legitimist invasion from Poland and the attempted restoration of the elder Vasa line. Charles had also begun a war in Russia in an attempt to put forward a Swedish candidate for the vacant Russian throne, and then, when his armies were deeply committed in Russia, had rashly provoked war with Denmark. Not only had Charles placed Sweden in a calamitous situation internationally but he had left behind him a legacy of domestic troubles. His usurpation of the throne had meant not only expulsion of a Catholic sovereign whose rule seemed to threaten Sweden's Lutheranism, but also the defeat of the aristocratic constitutionalism of the Council of State, and it had been followed by the execution of five leading members of the high aristocracy. Charles's rule had been arbitrary and violent; his religious views (he was suspected of leaning toward Calvinism) had involved him in an incessant struggle with the Lutheran church. At his death the country was exhausted by constant warfare, the monarchy was generally unpopular, and the accession of a new king seemed to offer the opportunity to extort from the crown guarantees against a recurrence of misgovernment.

Resolution of foreign wars. Thus, in 1611 Gustavus had three foreign wars and a major constitutional crisis upon his hands. As the war with Denmark was as good as lost, he set about to end it on the best possible terms.

Peace of Knäred

By the Peace of Knäred (1613) Sweden was forced to leave its only North Sea port, Älvsborg, in Danish hands as security for the payment of an enormous war indemnity. That indemnity entailed crushing taxation and, even with the aid of last-minute loans by the Dutch, was not paid off until 1619. The war left bitter hatred behind it, and Gustavus never forgot that Denmark was the national enemy and might be expected to take advantage of any Swedish weakness. Meanwhile, the war with Poland remained largely in abeyance, although in 1617 Gustavus sent an abortive expedition to seize the fortification of Dünamünde outside Riga (in present Latvian S.S.R.). The main danger, however, seemed to be Sigismund's attempts to pursue his claims by fifth-column activities in Sweden and propaganda in Europe.

The war in Russia was much more serious, and it was here that Gustavus, in a succession of difficult and indecisive campaigns, learned the rudiments of warfare. It dragged on until ended by the Peace of Stolbova in 1617, by which time it had clearly changed its character. Charles IX had intervened in Russia to prevent the Poles from placing their own candidate on the Russian throne; the election of the Russian Michael Romanov in 1613 had ended that danger, and Gustavus continued the struggle with the deliberate intention of annexing as much of Russian territory as possible. He feared Russia's military and naval potential; he feared that once the country's position was stabilized, a new tsar might try to make Russia a Baltic maritime power. He was determined, therefore, to exploit Russia's momentary weakness to cut it off from direct maritime contact with the West and to channel Russian trade through Swedish middlemen, thus enriching his impoverished exchequer with tolls and duties. In this last respect the outcome proved disappointing, but politically and strategically Stolbova was a treaty of European importance. By annexing Ingria and Kexholm, Sweden came to possess a continuous belt of territory connecting Finland with the Swedish province of Estonia. It thus cut Russia off entirely from the Baltic, thrust it back toward Asia, and postponed its emergence as a major European power until the time of Peter the Great.

Annexation of Russian land

Resolution of internal problems. Meanwhile, the internal tensions that Gustavus Adolphus had inherited had been largely resolved. The charter that the Estates extorted from Gustavus when he became king in 1611 might well have entailed the virtual subjection of the monarchy to the council and the high aristocracy. This, however, did not happen; for the man who had drawn the charter, the chancellor Axel Oxenstierna, became, in fact, the King's closest collaborator and remained so for the whole of the reign—a great historic partnership in which the temperaments and gifts of each supplemented those of the other. The King observed the spirit of the charter, and the aristocracy did not always insist on the observance of its exact provisions. They found in Gustavus a king favourable to their interests. He enlisted the nobility in the service of the state and thus provided them with numerous economic benefits. It was one of the healthiest features of Swedish society during this period that the nobility served the state, prepared to sacrifice even its privileges in the interests of the country. Thus the long-standing constitutional struggle between crown and aristocracy was suspended during his reign, largely because of the personality of the sovereign and the unique collaboration between himself and Oxenstierna. In this improved climate it was possible to undertake measures of sweeping reform.

Administrative reforms

The first decade of the reign, therefore, saw the creation of a new Supreme Court (1614) and the establishment of the Treasury and the Chancery as permanent administrative boards (1618); and by the end of the reign an Admiralty and a War Office had been created—each presided over by one of the great officers of state. The Form of Government of 1634 summed up these reforms in a general statute giving Sweden a central administration more modern and efficient than that of any other European country. Stockholm became a true capital with a permanent population of civil servants, the most important of whom were noblemen. And in the 1620s a thorough reform professionalized local government and placed it securely under the control of the crown. The Council of State became, for the first time, a permanent organ of government, able to assume charge of affairs while the King was fighting overseas. An ordinance of 1617 fixed the number of Estates in the Riksdag at four (nobles, clergy, burghers, and peasants) and regulated its procedures on a basis that lasted until 1866. Both council and Riksdag were identified with the King's policies, not least because of Gustavus' brilliant gift for expounding them: his speeches reveal him as a master of debate and an orator of extraordinary eloquence and force. And the decisions were always his, though they were usually arrived at after intimate consultation with Axel Oxenstierna. His hesitations, his vacillation in the face of grave decisions (such as that of intervening in the Thirty Years' War in Germany), reflect his profound sense of responsibility to the nation. Of all these domestic reforms, however, none had a more enduring and more beneficial effect upon his country than his work for education: his creation of the *Gymnasia* in the 1620s gave Sweden, for the first time, an effective provision for secondary education; his splendid munificence to the University of Uppsala gave it the financial security that was essential to its development; and his foundation of the University of Dorpat (now Tartu State University) provided the first centre for higher learning in the Baltic languages.

Educational reform

In 1620 he married Maria Eleonora of Brandenburg. In 1621, taking advantage of a Turkish attack upon Poland, Gustavus renewed the war with Sigismund. His capture of Riga was followed by a gradual conquest of Livonia (present Latvian and Estonian S.S.R.'s). His object was to compel Sigismund to renounce his claims to Sweden; and he hoped to gain his end by the economic pressure which would result from Poland's loss of access to its main export routes to western Europe. It was in pursuit of this policy that, in 1626, he transferred the seat of war to Prussia: a stranglehold on the Vistula River, he hoped, would bring Poland to its knees. But already he was concerned with the larger question of the danger to German Protestantism entailed by the victorious campaigns of the Habsburg commanders, Tilly and Wallenstein. He saw his Polish campaigns as one aspect of the general struggle of Protestantism against the Counter-Reformation: if Sigismund were restored to the Swedish throne, the re-Catholicization of Scandinavia would follow soon after; the Habsburgs and their allies would be able to close the passage into the Baltic to Dutch shipping, and the United Netherlands might then be unable to continue their struggle against Spain.

Prologue to intervention in Germany

Thus, the fate of Europe was bound up with what happened in Livonia or Prussia. Protestant Europe was slow to appreciate the connection; but as the Protestant cause plunged to disaster in Germany, its leaders increasingly turned their eyes to Gustavus as a possible saviour. But before he was prepared to commit himself to any Protestant league, Gustavus required adequate assurance of support. The disastrous defeat (1626) of Christian IV of Denmark, who had intervened in Germany without such an assurance, justified his caution, but it also made Swedish intervention inevitable. The Imperialists' occupation of the German Baltic shore and their plans for a Habsburg-Polish navy seemed to pose a direct threat of invasion. In this emergency, Gustavus and Christian joined forces to send an expedition to Stralsund, the last remaining Protestant bastion in Pomerania, which arrived just in time to prevent its capture by Wallenstein (1628). From this moment, full-scale involvement in the German war became simply a question of time. The Polish war was resolved in 1629 by the Truce of Altmark, and Gustavus was at last free to turn his attention to Germany. In June 1630 the Swedish expeditionary force landed at Peenemünde.

Entrance into Thirty Years' War. The motives prompting his intervention have long been a subject of historical controversy. An older generation of historians saw him, as his contemporaries did, simply as the Protestant Hero, the "Lion of the North"; later, he was viewed as having been moved by purely political considerations; and in recent days he has been characterized as an economic imperialist who sought to remedy Sweden's poverty by seizing control of the whole Baltic coastline, and thus to monopolize trade between Russia and western Europe. The most probable explanation, however, is the one which he himself adduced: that he sought security from dangers which seemed to threaten the Swedish state and the Swedish church; that he considered his actions essentially defensive; and that he had no precise long-range plans, either economic or political, when he landed on German soil.

Military innovations

He had, however, an army of unusual quality, fighting in a style new to Germany, and he combined tactical innovations with a grander concept of strategy than Europe had seen for many years. By reducing the size of the tactical unit, by opposing a flexible linear formation to the cumbrous massive formations of his opponents, by solving (at least for his time) the perennial problem of combining infantry and cavalry, missile weapons and shock; and, lastly, by producing the first easily manoeuvrable light artillery, he completed the transformation of the art of war begun by the Dutch commander Maurice of Nassau, prince of Orange, earlier in the century. The vastness of his operations in Germany initiated a permanent increase in the size of European armies. The whole process had profound social effects on the history of Europe.

Gustavus landed in Germany without allies. Whatever the feelings of the Protestant populations, the Protestant princes resented Swedish interference; and the refusal of George William of Brandenburg to cooperate with the Swedes thwarted Gustavus' attempts to save Magdeburg from capture and sack at the hands of Tilly's armies. His position was strengthened, however, by the Treaty of Bärwalde in January 1631, an alliance with France in which almost all the advantage lay with Sweden; in June he extorted by force the reluctant collaboration of Brandenburg; in September John George of Saxony, provoked by violations of his neutrality, formally allied himself with Sweden. In September, at Breitenfeld, the Swedish-Saxon forces shattered Tilly's army in a battle that was a landmark in the art of war and a turning point in the history of Germany. In the ensuing months Gustavus swept triumphantly through central Germany, systematically consolidating his base areas as he advanced: by Christmas he had established himself at Mainz. It seemed that the fate of Germany lay in his hands.

These developments forced Gustavus to reassess the limited and vague plans with which he had embarked on the expedition. In 1630 he had defined his aims as security and indemnity, the indemnity to be a cash payment to cover his war expenses, the security to be provided by a permanent Swedish alliance with Pomerania. By the close of 1631, with most of north and central Germany under his control and the liberation of the south German Protestant states already in prospect, his plans had broadened. He had always insisted that the German Protestant princes must work for their own salvation, and he saw the best hope for their future preservation in the creation of a comprehensive, permanent Corpus Evangelicorum (or Protestant league). His experience of the feckless and selfish German princes convinced him that such a league could be effective only if it were organized and directed by himself, and military necessity in any case demanded a unified command that could not be directed by anyone other than himself. Security, then, was to be achieved by a Protestant league of which he would be patron, military director, and political head. For indemnity he no longer claimed monetary compensation but large territorial cessions, particularly, the transference of Pomerania to Sweden. Thus, the old security had become the new indemnity. Many Germans feared, and some Swedish diplomats now believed, that a final settlement must probably entail the deposition of the German emperor Ferdinand II and the election of Gustavus as emperor in his place. It was a solution he must certainly have contemplated, but there is no firm evidence of his attitude; probably he considered it only as a last resort. Certainly it would have alienated those German allies who had no wish to exchange a Habsburg domination for a Swedish one. They already resented Gustavus' dictatorial methods as well as the Swedish army's practice of making war support war. A Swedish administration was being organized in the occupied areas; Gustavus rewarded his generals and supporters by conferring the conquered lands on them; in some of the treaties he concluded with German princes there was more than a hint that he regarded them as his feudal inferiors. In October 1632 he did, indeed, lay the basis for a league of Protestant princes; but it was confined mainly to southern Germany, where the peril from an Imperialist reaction was greatest, and the two greatest Protestant states—Saxony and Brandenburg—never became part of it.

The Protestant league

Last phase of Gustavus' campaign. The prospect of success depended upon the outcome of the campaign of 1632, which was designed to cripple Bavaria as a preliminary to the conquest of Vienna in 1633. Up to a point, it was highly successful. The brilliant crossing of the Lech River in Bavaria, in the face of Tilly's armies, opened the way to the occupation of Munich. In this crisis, Wallenstein, whom the Emperor had dismissed from his service in 1630, was recalled to lead the imperial armies. His threat to Nürnberg forced Gustavus to leave Bavaria in order to relieve the city. His attack on Wallenstein's entrenchments on the Alte Veste—an operation that probably no other contemporary com-

mander would have attempted—was unsuccessful; and for the next few weeks there followed a tense war of manoeuvre that ended when Gustavus fell upon Wallenstein's army at Lützen (November 6, 1632) as it was dispersing to winter quarters. Morning mist robbed Gustavus of the advantage of surprise, and gave Wallenstein time to reunite his forces. The fight raged fiercely all day, but when night fell the Swedes had won a clear tactical victory and an important strategic success. It was, however, dearly bought; for while leading a cavalry charge Gustavus became separated from his men, and perished in the *mêlée*.

His death came at a moment when it had already begun to appear that the victory he believed to be essential to the stability of Germany and the security of Sweden might be more difficult to achieve than he had imagined. But he had lived long enough to deflect the course of German history; he had launched his country upon a career as a great power that it was really not strong enough to pursue; and by his domestic reforms he had bequeathed to Sweden things more durable and more important than all the captured standards of Breitenfeld and Lützen.

NILS AHNLUND, *Gustav Adolf the Great* (Eng. trans. 1940), is a classic study of selected aspects of the reign by the leading Swedish authority. JOHANNES PAUL, *Gustav Adolf*, 3 vol. (1927–32), is the best account in German, with its main emphasis on the military and diplomatic history of the Thirty Years' War. For a discussion of the King's motives and objectives for intervention in the war, see MICHAEL ROBERTS, *Essays in Swedish History* (1967), which also includes studies of his significance for the art of war, and of the constitutional implications of the reign. Some illustrative documents are printed, in English translation, in MICHAEL ROBERTS, *Sweden as a Great Power, 1611–1697* (1968).

(M.Ro.)

Gutenberg, Johannes

Johannes Gutenberg, a German craftsman and inventor, originated a method of printing from movable type that was used without important change until the 20th century. The unique elements of his invention consisted of a mold, with punch-stamped matrices (metal prisms used to mold the face of the type) with which type could be cast precisely and in large quantities; a type-metal alloy; a new press, derived from those used in wine making, papermaking, and bookbinding; and an oil-based printing ink. None of these features existed in Chinese or Korean printing, or in the existing European technique of stamping letters on various surfaces; or in woodblock printing.

Gutenberg, whose full name was Johannes Gensfleisch zur Laden, alternatively called (zum) Gutenberg from a family estate, was born in the last decade of the 14th century, the son of a patrician of Mainz, Germany. What little information exists about Gutenberg, other than that he was associated with the goldsmith's guild and had acquired skill in metalwork, comes from documents of financial transactions. Exiled from Mainz in the course of a bitter struggle between the guilds of that city and the patricians, Gutenberg moved to Strassburg (now Strasbourg, France) in 1430. Records of his association with the goldsmith's guild put his presence there between March 14, 1434, and March 12, 1444. In partnership with business associates, he engaged in such crafts as gem cutting and the production of mirrors, and he also taught these crafts to a number of pupils.

Some of his partners, who became aware that Gutenberg was engaged in work that he kept secret from them, insisted that, since they had advanced him considerable sums, they should become partners in these activities as well. Thus, in 1438 a five-year contract was drawn up between him and three other men: Hans Riffe, Andreas Dritzehn, and Andreas Heilmann. It contained a clause whereby in case of the death of one of the partners, his heirs were not to enter the company, but were to be compensated financially. When Andreas Dritzehn died at Christmas 1438, his heirs, trying to circumvent the terms of the contract, began a lawsuit against Gutenberg in which they demanded to be made partners. They lost the suit, but the trial revealed that Gutenberg was working on a new invention. Witnesses testified that a carpenter named Conrad Saspach had advanced sums to Andreas Dritzehn for the building of a wooden press, and Hans Dünne, a goldsmith, declared that he had sold to Gutenberg, as early as 1436, 100 guilders' worth of printing materials. Gutenberg, apparently well along the way to completing his invention, was anxious to keep secret the nature of the enterprise.

Invention of the press

After March 12, 1444, Gutenberg's activities are undocumented for a number of years, but it is doubtful that he returned immediately to Mainz, for the quarrel between patricians and guilds had been renewed in that city. In October 1448, however, Gutenberg was back in Mainz to borrow more money. By this time his printing experiments had apparently reached a considerable degree of refinement, for he was able to persuade Johann Fust, a wealthy financier, to lend him 800 guilders—a very substantial capital investment, for which the tools and equipment for printing were to act as securities. Two years later Fust made an investment of an additional 800 guilders for a partnership in the enterprise. Fust and Gutenberg eventually became estranged, Fust, apparently, wanting a safe and quick return on his investment, while Gutenberg aimed at perfection rather than promptness.

Gutenberg's dream was to create a way of mechanically reproducing medieval liturgical manuscripts without losing any of their colour or beauty of design. His dream was destroyed, however, when Fust won a suit against him, the record of which is preserved, in part, in what is called the Helmaspergersches Notariatsinstrument (the Helmasperger notarial instrument), dated November 6, 1455, now in the Library of the University of Göttingen. Gutenberg was ordered to pay Fust the total sum of 2,026 guilders, which included the two loans and compound interest. Instead of the chance to perfect his invention, he faced complete financial ruin. There is no reason to doubt that the printing of certain books (*werck der bucher*, specifically mentioned in the record of the trial, refers to the 42-line Bible that was Gutenberg's masterpiece) was completed, according to Gutenberg's major biographers, in 1455 at the latest. Its sale, it has been estimated, would have produced many times over the sum owed Fust by Gutenberg, and there exists no explanation as to why these tangible assets were not counted among Gutenberg's property at the trial.

After winning his suit, Fust gained control of the type for the Bible, and for Gutenberg's second masterpiece, a Psalter, and all of Gutenberg's other printing equipment. He continued to print, using Gutenberg's materials, with the assistance of Peter Schöffer, his son-in-law, who had been Gutenberg's most skilled employee and a witness against him in the 1455 trial. The first printed book in Europe to bear the name of its printer is a magnificent Psalter completed in Mainz on August 14, 1457, which lists Johann Fust and Peter Schöffer.

The Psalter

The Psalter is decorated with hundreds of polychrome initial letters and delicate scroll borders that were printed in a most ingenious technique based on multiple inking on a single metal block. Most experts are agreed that it would have been impossible for Fust and Schöffer alone to have invented and executed the intricate technical equipment necessary to execute this process between November 6, 1455, when Gutenberg lost control of his printing establishment, and August 14, 1457, when the Psalter appeared. It was Gutenberg's genius that was responsible for the Psalter decorations. In the 1960s it was suggested that he may also have had a hand in the creation of copper engraving, in which he may have recognized a method for producing pictorial matrices from which to cast reliefs that could be set with the type, initial letters, and calligraphic scrolls. It is at present no more than a hypothesis, but Gutenberg's absorption in both copper engraving and the Psalter decorations would certainly have increased Johann Fust's impatience and vindictiveness.

A number of smaller printings, many preserved only in

fragments, and printed in what appear to be experimental stages of Gutenberg's types, used to be attributed to him. They are now considered the work of other minor printers; among these is a 36-line Bible printed in Bamberg, a typographic resetting of the 42-line Bible. Attributed to Gutenberg himself is a *Türkenkalender*, a warning against the impending danger of Turkish invasion after the fall of Constantinople in 1453, printed December 1454 for 1455 use, some letters of indulgence, and some school grammars. The identity of the printer of a *Missale Speciale Constantiense* is still not established. One group of scholars believes it was printed by Gutenberg before the 42-line Bible, another group considers it to be a product of type acquired after Gutenberg's death in the 1470s.

After Gutenberg's financial ruin, a Mainz municipal official, Dr. Konrad Humery, lent him printing tools and equipment, but what these were, and what use Gutenberg made of them is not known. There is increasing doubt that the 1460 *Catholicon*, a weighty folio once attributed to him, could have been his work because of the book's size and the inferior quality of the types used. Toward the end of his life, when, according to one source, he was partially or totally blind, the elector Adolph von Nassau took pity on the destitute inventor and made him a member of his court, a tax-free sinecure that provided him with a yearly allowance of cloth, grain, and wine. He died most probably on February 3, 1468, and was buried in the Franciscan church in Mainz.

Guyana

Guyana is an independent republic and member of the Commonwealth of Nations located in the northeastern corner of South America. It is bordered by Venezuela to the west, Brazil to the southwest and south, Surinam to the east, and the Atlantic Ocean to the north. Its total area of 83,000 square miles (215,000 square kilometres) is largely uninhabited, and most of the country's 714,000 inhabitants occupy the narrow coastal strip. The national capital of Georgetown is located on the Atlantic coast and is one of the country's major ports. The name Guyana is derived from the term *guiana*, an Amerindian word meaning "land of waters," which applies to the entire region of South America between the Amazon, Orinoco, and Negro rivers.

Present-day Guyana continues to reflect its colonial past. Its economy is dominated by the sugar industry, which is still conducted by plantation agriculture and remains in British hands. The growing bauxite industry is also under British control, as is much of the country's commercial life. Guyana's social composition is also of colonial origin. The indigenous population is small and unintegrated, and the coastal peoples are largely descendants of slaves and indentured labourers who were imported to work the sugar plantations.

THE LANDSCAPE

The natural environment. *Relief features.* The narrow plain that stretches along the country's Atlantic coast is largely a man-made feature. Between three and four miles wide, the area lies below the high-tide level and has been reclaimed from the sea by canals and about 140 miles of dikes. Its inland border is also marked by canals that protect the plain from alluvial swamps.

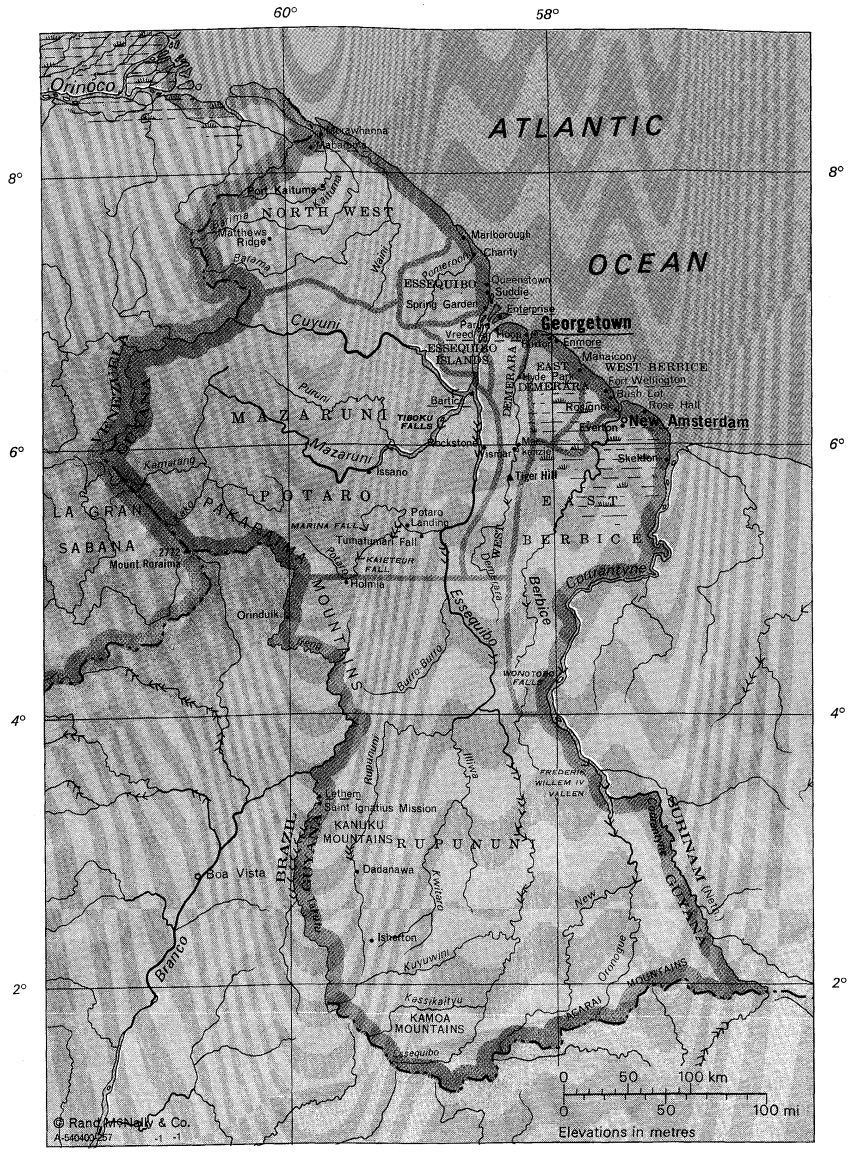
The coastal plain

About 40 miles from the coast is a region of undulating hills that rise inland from 50 feet on the coastal side of the region to 400 feet on the western side. The area is between 80 and 100 miles wide and is widest in the southeast. It is covered with sands, from which it takes its name as the white-sands (*zanderij*) region. A small savanna region in the east lies about 60 miles inland from the coast and is surrounded by the white-sands belt.

The sands partly overlie a low crystalline plateau that is generally less than 500 feet in elevation. It forms most of the country's centre and is penetrated by igneous intrusions that cause the numerous rapids of Guyana's rivers.

Beyond the crystalline plateau, the Kaieteurian Plateau lies generally below 1,640 feet above sea level. It is overlain with sandstones and shales that, in the south, form the extensive Rupununi savanna region. The plateau culminates in the Acarai Mountains (Serra Acarai), which rise to about 2,000 feet on the southern border, and is crowned on the western frontier by the Pakaraima Mountains, which rise to 9,094 feet (2,772 metres) in the Roraima massif. The Rupununi savanna is bisected by the Kanuku Mountains, which trend from west to east and rise to almost 3,000 feet above sea level.

Drainage and soils. Guyana's four main rivers—the Courantyne, Berbice, Demerara, and Essequibo—all flow from the south and empty into the Atlantic along the eastern section of the coast. Among the tributaries of the Essequibo, the Potaro, Mazaruni, and Cuyuni drain the northwest, and the Rupununi drains the southern savanna. The western coast is cut by shorter rivers, including the Pomeroon, Waini, Barima, and Kaituma.



GUYANA

The country's rivers are part of the watershed of the Amazon and Orinoco rivers (*qq.v.*), and the headwaters of the Rupununi in Brazil are often confused with those of the Amazon. Drainage is poor, because the average gradient is only one foot per mile, and there are swamps and flooding in the mountains and savannas. The rivers are not suitable for transportation because they are broken by interior falls and their mouths and estuaries are blocked by mud and by sandbars that may occur two to three miles out to sea.

Coastal soils

The coastal soils are fertile but acidic. The clays of the coastal plain are composed of alluvium from the Amazon that is deposited by the south equatorial ocean current and of alluvium from the country's rivers. They overlay white sands and clays and can support intensive agriculture but must be subjected to fallowing to restore fertility. *Pegasse* soil, a type of tropical peat, occurs behind the coastal clays and along the river estuaries, while silts line the banks of the lower rivers. Reef sands occur in bands in the coastal plain, especially near the Courantyne and Essequibo rivers. The rock soils of the interior are leached and infertile, and the white sands are almost pure quartz.

Climate. Guyana has the climatic characteristics of an equatorial lowland, with high temperatures, heavy rainfall with relatively small seasonal differences, high humidity, and high average cloud cover. Temperatures are remarkably uniform. At Georgetown the average monthly temperature varies from 79° to 82° F (26° to 28° C), with a daily range of about 15° F (8° C). The effects of constant heat and high humidity are mitigated near the coast by the northeast trade winds.

Rainfall derives mainly from the movement of the intertropical front, or doldrums. It is heavy everywhere on the plateau and the coast. The annual average at Georgetown is about 90 inches, and on the interior savannas it is about 70 inches. On the coast a long wet season from April to August and a short wet season from December to early February are sufficiently well marked on the average, but in the southern savannas the short wet season is not experienced. Total annual rainfall is variable and years of drought occur.

Vegetation and animal life. Many plants of the coast, such as the mangrove and various saltwater grasses, grow in shallow brackish water and help to protect or extend the land. The wet savanna behind the coast has coarse tufted grasses and a wide scattering of palms, notably the coconut, truli, and manicole. High rain forest, or selva, covers 73 percent of the land area and is of extraordinary variety and magnificence. Prominent trees include the greenheart and the wallaba on the sandy soils of the northern edge; the giant mora and crabwood on swampy sites; the balata and other latex producers; and many trees such as the siruaballi and hubaballi that yield handsome cabinet woods. The interior savanna is mostly open grassland, with much bare rock, many termite hills, and clumps of ita palm.

All forms of animal life are immensely varied and

King George VI, or Great, Falls, on the Kamarang River, near the Venezuelan border.
UPI Compix

abundant, though few, apart from birds and insects, are normally visible. The tapir is the country's largest land mammal, the ocelot the fiercest, and monkeys and deer the commonest. Among the more exotic species are the sloth; the great anteater; the capybara, or bush pig; and the armadillo. Bird life includes the vulture, kiskadee, blue sacki, hummingbird, kingfisher, and scarlet ibis of the coast and lower rivers; and the macaw, tinamou, bellbird, and cock-of-the-rock in the forest and savanna. The cayman (a reptile similar to the alligator) is the commonest of the larger freshwater creatures. The giant anaconda, or water boa, is the largest of many kinds of snakes and the bushmaster the most vicious. Lizards are numerous and include the iguana in the lower rivers. Sharks and stingrays are found offshore. The snapper and grouper are the most esteemed of the ocean fish commonly landed.

The landscape under human settlement. *Traditional regions.* The country is divided traditionally between the coast, which is inhabited by about 95 percent of the population, and the interior. The coastal population is heterogeneous, its inhabitants descended from Dutch settlers and the labourers brought in to work the sugar plantations. The interior, despite scattered ranching and mining settlements, is largely the province of the Amerindian.

Rural settlements

Settlement patterns. Guyanese society is predominantly rural, most of the people occupying small villages strung out along the coast. The highest concentrations of villages are found along the estuary of the Demerara River and near the mouths of the Berbice and Courantyne rivers. The villages range in size from several hundred to several thousand inhabitants and are separated from each other by drainage ditches. Buildings are usually constructed on stilts and are connected to the streets by foot bridges over the drainage canals that run parallel to the streets.

Georgetown, with a population of about 167,000, is the country's main port and its largest city. Located at the mouth of the Demerara River, it lies below sea level and is protected by dikes along both the river and the sea. The second largest town is Mackenzie, a mining centre with 20,000 inhabitants located 55 miles (88 kilometres) upstream from Georgetown. The market centre of New Amsterdam is located on the mouth of the Berbice River; it is the third largest town, with a population of 18,000. The city's general layout and central canals are reminiscent of The Netherlands. Most construction is of wood, painted light blue; houses have a rectangular boxlike appearance.

PEOPLE AND POPULATION

The Amerindians

Population groups. The indigenous peoples of Guyana are collectively known as Amerindians. Their numbers in 1970 were approximately 33,000, which represented more than a threefold increase since 1930 and a reversal of centuries of decline. They comprise less than 5 percent of the population. Indian groups include the Warraus, Arawaks, Caribs, Wapisianas (Wapishanas), Arecunas, the mixed "Spanish Arawaks" of the Moruka River, and many more in the forest areas. The Makusí (Macussí or Macushí) are the most prominent of the savanna peoples. The Amerindians are rarely seen in the populated coastal areas. Since 1953 they have had important rights of occupation in reservations totalling more than 6,000 square miles but are not confined to them. They are increasingly employed in the cattle and logging industries.

The other major elements in the population are all predominantly coastal dwellers. Descendants of African slaves form the oldest group of nonindigenous peoples; they abandoned the plantations after emancipation in 1834 to become independent peasantry or town dwellers. The Afro-Guyanese comprised 31 percent of the population in 1970. The East Indians came predominantly as indentured labour from India to replace the Africans in plantation work. They form the largest racial group in the country—51 percent of the total in 1970—and have been increasing more rapidly than any of the others. They are the mainstay of plantation agriculture, and many are independent farmers and landowners, have done well in trade, and are well represented among the professions.

The Chinese and Portuguese also entered originally as agricultural labourers but are now rarely found outside the towns. They are active in business and the professions, and their influence is disproportionate to their numbers; they have not been increasing, however, and together comprise only about 2 percent of the population. Europeans other than Portuguese are few, and most are short-term inhabitants. While every kind of racial mixture may be found, mulattos (persons of mixed white and black ancestry) are by far the most common. Most of them live in towns, and a high proportion are in clerical and professional work.

Over 33 percent of the population are Hindu. Approximately 40 percent are Christians, belonging to the Anglican, Roman Catholic, or Methodist churches. Another 9 percent practice Islām. Animistic religions are still practiced by some of the indigenous peoples. The official and principal language is English, but a creole patois is spoken throughout the country. Hindi and Urdu are also spoken.

Source: Official government figures.

Demography. In 1965 the population was estimated at 647,000, a figure almost two-thirds greater than the 375,000 in 1946. By 1970 it had grown to 714,000. This

growth is attributable to improved health conditions, resulting in a greatly reduced death rate. In 1970 there was an average of 6.4 registered deaths per 1,000 inhabitants and 35.7 registered live births per 1,000.

Migration patterns

Immigration is no longer important, and by the 1970s the number of foreign-born, long-term residents was insignificant. Emigration has fluctuated from as low as 1,500 persons per annum in the mid-1960s to 4,200 persons in 1970. Internal migration is also minimal, and there is no significant movement to the cities.

In 1967 more than 90 percent of the population lived on 4 percent of the land. The average population density in 1970 was nine persons per square mile. There were, however, more than 300 per square mile on the coastal plain and more than 1,000 per square mile on the east coast, where villages are most highly concentrated.

HISTORY

The Dutch period. The coast of Guyana was sighted by the Genoese explorer Christopher Columbus in 1498, but the area, long known as the Wild Coast, proved unattractive to the Spanish and Portuguese because of its lack of gold and difficulties of movement. Although Spain resisted, the Guiana coast was left to the Dutch, French, and English, whose attempts at colonization and exploration were almost wholly abortive until early in the 17th century. During the 17th and 18th centuries the Dutch were the leading colonists; most British activity was an offshoot of developments in the West Indies.

The early settlements were typically a few miles up the larger rivers. Dutch settlements existed on the Courantyne, Essequibo, and Cayenne rivers by 1616. The Dutch West India Company was founded in 1621; the slave trade was established; and official appointments in command of settlements were made. A successful British colony was planted on the Suriname River by Lord Willoughby of Parham in 1651, the colonists coming mainly from Barbados. Cayenne was finally established as French in 1674.

Early in the 18th century, colonists were attracted to the seacoasts by the fertility of the soil. The Berbice estuary was settled in 1732, and a fort was established on Fort Island in the Essequibo estuary. The greatest figure in 18th-century Guyanese history was Laurens Storm van's Gravesande, who was in Essequibo from 1738 to 1772. He began the orderly development of the Demerara region, kept the slave population in order by firm but humane action, established free immigration for all nationalities and remitted taxation for the immigrants' first ten years, and encouraged exploration.

Settlements changed hands with bewildering frequency during the wars (mostly between the British and the French) from 1780 to 1815. During a brief French occupation, Longchamps, later called Georgetown, was established at the mouth of the Demerara; the Dutch renamed it Stabroek and continued to develop it. The British took over in 1796 and remained in possession, except for short intervals, until 1814, when they purchased Demerara, Berbice, and Essequibo in the settlement that ended the Napoleonic Wars. Surinam went to the Dutch and Cayenne to the French. The 19th-century pattern was finally established when Berbice, Demerara, and Essequibo were united in 1831 as the colony of British Guiana.

The British period. The slave trade was abolished in 1807, when there were about 100,000 slaves in the three British colonies (Berbice, Demerara, and Essequibo). After emancipation in 1834 African labour left the plantations, and large areas of land went out of cultivation. Of the many attempts to organize immigration of suitable labour, only that for Asian Indians was at all successful. During the rest of the 19th century, the colony was almost overwhelmed with difficulties and was not helped by the indifference of Great Britain. Reliance on a single crop, sugarcane, was the main fault, and this was not corrected until well into the 20th century.

Settlement began on the Rupununi savanna in 1860 but proceeded very slowly. Gold was discovered in 1879, and a boom in the 1890s helped the colony over a difficult spell. The North Western District was organized in 1889 and was the cause of a sharp international flurry in 1895 when the United States supported Venezuela's claims to the territory. In the early 1960s Venezuela revived its territorial claims on British Guiana.

Masked dancers in the streets of Georgetown celebrating Guyana's independence from Great Britain on May 26, 1966.
Joseph Fabry, *Life* © 1966, Time Inc.

Governmental origins

The British inherited from the Dutch a singularly complicated constitutional structure. Except for a major change in 1891 that simplified it, the structure remained until 1928, when a typical crown-colony system was introduced. In 1953 a new constitution—with universal adult suffrage, a bicameral elected legislature, and a ministerial system—was introduced and, subject to several revisions, has remained in force.

From 1953 to 1966, the political history of the colony was stormy. The first elected government, formed by the People's Progressive Party (PPP) led by Cheddi Jagan, seemed so pro-Communist that the British government suspended the constitution in October 1953 and dispatched troops. The constitution was not restored until 1957. The PPP split along racial lines, Jagan leading a predominately East Indian party and Forbes Burnham leading a party of African descendants, the People's National Congress (PNC). In the elections of 1957 and 1961, the PPP was returned with working majorities and formed governments which pursued moderate policies. From 1961 to 1964 severe rioting and a long general strike led to the return of British troops to keep order, and the country was in grave economic difficulties.

To answer the PNC allegation that the existing electoral system unduly favoured the East Indian community, the British government introduced for the elections of December 1964 a new system of proportional representation. The result reflected racial divisions with considerable accuracy. The PNC formed a coalition government thereafter with the United Force Party, a group broadly representative of European and mixed racial interests. This government, led by Forbes Burnham, took the colony into independence under its new name, Guyana, on May 26, 1966. The PNC was returned to power by the general elections of December 1968 and on February 23, 1970, Guyana became a republic within the Commonwealth. Arthur Chung, a high court trial judge and the son of a Chinese farmer, was elected by the National Assembly as the first president of the republic of Guyana.

THE NATIONAL ECONOMY

Natural resources. The most important mineral resource is that of the extensive deposits of bauxite located between the Demerara and Berbice rivers. There are also significant deposits of manganese at Matthews Ridge in

the northwest, about 30 miles east of the Venezuelan frontier. Diamonds occur in the Mazaruni and other rivers of the Pakaraima Mountains. Gold is found in both alluvial and subsurface deposits. Other minerals include oil in the Rupununi savanna, copper, iron ore, molybdenite (a blue mineral that is the source of molybdenum, a metallic element used in strengthening steel), nickel, white sand (used in glass manufacture), kaolin (china clay), and graphite.

The main biological resource consists of the hardwoods of the tropical rain forest and especially the greenheart tree, which is resistant to termites, decay, and marine erosion. The shrimps off the coast and various inland fishes form the basis of the nation's fishing industry, and the grasses of the savanna regions are used for cattle grazing.

Hydroelectric potential in Guyana is considerable, especially at Tiger Hill on the Demerara River and Tiboku Falls on the Mazaruni. Development is hampered, however, by the remoteness of the falls and the large amounts of capital needed for generation and transmission facilities.

Sources of national income. *Agriculture, forestry, and fishing.* Agriculture is concentrated on the narrow coastal plain between the Essequibo and Courantyne rivers, where it supports about 90 percent of the population on 10 percent of the land. Because of the coast's relief and climate, certain agricultural features have evolved. Arable land is laid out in strips between the sea or a river and inland swamps. It is protected on all sides by dikes and canals that are used for both irrigation and drainage during the alternating dry and wet seasons. The land reclaimed from the sea is fertile but acidic; fertility must be returned to the soil by the process of periodic flood fallowing in which the fields are plowed, flooded for at least six months, drained, and planted.

Food crops include cassava, maize (corn), vegetables, and citrus fruit. Cash crops include sugarcane, rice, coffee, and cocoa. The production of sugarcane occurs almost totally on plantations owned by British companies. Bookers Sugar Estates Ltd. produces about 94 percent of the annual crop on 11 large estates. Two other estates are operated by the Demerara Company of Liverpool. Rice, however, is grown primarily on small private holdings by manual labour. Although agricultural production has generally increased since the 1960s, food must be imported to meet the demands of the expanding population. Further agricultural development is hampered by the high cost of mechanization and of preparation of new land.

Livestock production is concentrated mainly on the Rupununi savanna and on the coastal plain. Animals include beef cattle, dairy cattle, goats, sheep, pigs, and poultry.

Forestry activities are hampered by the lack of adequate transportation, the difficulty of cutting the extremely hard wood of Guyana's trees, and the shortage of facilities for the sawing, storing, and shipping of timber. Most of the timber produced for the domestic market and export is from the greenheart tree.

In the early 1970s fishing was not well developed, and fish were imported for food. The government hoped to improve activity through improved facilities and the promotion of fishponds. Shrimping is carried out primarily for export and is dominated by two companies from the United States and the United Kingdom.

Mining. Mining operations grew throughout the 1960s and produced 38 percent of all exports by value in 1970.

Bauxite production

Guyana is the fifth largest producer of bauxite after Jamaica, Australia, Surinam, and the Soviet Union. All alumina (aluminum oxide occurring in hydrated form in bauxite) and 85 percent of the bauxite mined is produced at Mackenzie by a Canadian company. The Mackenzie complex includes a processing plant for bauxite and alumina. The rest of the country's bauxite production is mined by a United States company at Kwakwani on the Berbice River; the company also operates a processing plant downriver at Everton.

The mining of manganese by a United States company was suspended in 1968 because of depressed market conditions. The faltering gold industry is expected to revive following the discovery of two subsurface deposits in 1966 and the anticipated introduction of large-scale land and alluvial operations. Diamonds continue to be mined by hand and by suction dredges in the interior rivers.

Manufacturing. The vast industrial conglomerate of Bookers Sugar Estates Ltd. operates subsidiaries throughout the manufacturing sector of the economy. Guyana's industry centres upon the processing of agricultural products, and Bookers' companies operate nine of the country's 11 sugar plants; the other two plants are owned by the Demerara Company of Liverpool. Bookers also operates distilleries, a department and grocery store in Georgetown, and outlets for the sale of motor vehicles, agricultural machinery, hardware, electrical goods, office supplies, and pharmaceuticals. Its subsidiaries manufacture drugs and feed for livestock, process shrimp, produce concrete building blocks, retread tires, and engage in printing and the manufacture of boxes.

The Bookers industrial holdings

The country's 200 rice mills, like its rice fields, are generally small-scale individual units. Other domestic industries are oriented toward the replacement of consumer imports such as cigarettes and matches, edible oils, margarine, beverages, soap and detergents, and clothing.

Energy. The Guyana Electricity Corporation, the country's largest single supplier of electricity, has an installed capacity of 82,800 kilowatts. Private plants are also operated by the sugar estates and rice mills. Despite the country's large hydroelectric potential, all electricity in the early 1970s was produced by thermal generation and was available only on the coastal plain and at towns, such as Mackenzie, on the lower rivers.

Financial services. The Bank of Guyana, established in 1965, has the sole right of issue and acts as banker to the government and other banks. The country's four commercial banks are branches of British, Canadian, Indian, and United States banks. The Post Office Savings Bank mobilizes the deposits of small savers. Other financial services are provided by the New Building Society, which raises funds through the sale of shares at a fixed rate of interest; almost 40 insurance companies, most of which are foreign-owned; more than 700 cooperative societies, which serve as savings institutions and offer agricultural credit; and the Guyana Credit Corporation, which offers medium- and long-term loans for economic development.

Foreign trade. Guyana's major trading partners are the United States, the United Kingdom, Canada, and Trinidad and Tobago. About 36 percent of the country's exports are represented by bauxite and alumina, 27 percent by sugar, and 7 percent by rice. Shrimp, diamonds, molasses, rum, and timber are also sold abroad. Major imports include machinery, petroleum products, vehicles, textiles, footwear, and foods.

Management of the economy. The economy is primarily one of private enterprise, regulated by the law of supply and demand. Government participation is largely indirect, through its economic plans and the Guyana Development Corporation (GDC). Founded in 1963, the GDC is the only government agency for industrial development. The government's Private Investment Fund also promotes development, however; it offers medium- and long-term loans through the commercial banks. Guyana became a member of the Caribbean Free Trade Area (Carifta) together with Barbados and Antigua in 1965 in an attempt to expand the market for its domestic industrial products.

Sources of revenue

Most government revenues are derived from indirect taxes, which include customs, excise, and export duties. Direct taxes are largely derived from the corporate income tax, which is fixed at a flat rate of 45 percent, and a personal income tax. Revenues are dependent upon foreign trade, because customs duties are important (approximately 28 percent of the annual total revenue in 1970) and because most corporations are engaged in the exportation of sugar, rice, bauxite, and other commodities.

The country's most important labour organization is the

Trade Union Council, an association of the major unions. Its largest member is the Man-Power Citizens Association, an organization of sugar workers. Other organizations include the Guianese Agricultural Workers Union and unions of public service, mining, and industrial workers. The oldest employers' association is the Georgetown Chamber of Commerce and the largest is the Guyana Sugar Producers Association. Other organizations include the Consultative Association of Guyanese Industries, the Rice Millers and Landlords Association, and associations in the fields of mining, forestry, shipping, public works, and construction. Labour disputes are largely settled by informal collective bargaining and government arbitration.

Economic policies and problems

Government economic policy is based on the encouragement of foreign trade through Carifta, the GDC, and incentives to companies such as tax holidays and tax deductions. The government also plans to diversify local production in order to reduce imports and to provide employment and actively promote both public and private investment from abroad. These policies reflect the problems of an unfavourable balance of trade, the concentration of the production of goods subject to world price fluctuations, and growing unemployment. Guyana's economic prospects continue to depend, as in the past, on foreign aid, the slow development of the coastal plain, improved exploitation of the country's forests, and mineral exploration.

Transportation. There were about 1,200 miles (1,960 kilometres) of road in the early 1970s, of which about 450 miles were paved and the remainder were of burnt clay. A development scheme envisages the improvement of 400 miles of existing road and the building of 300 miles of new road; the Demerara River has been bridged at Mackenzie. There are also 400 miles of "vehicular trails" in the Rupununi savanna. The interior has few roads.

Coastal railways run from Georgetown to the Berbice and Essequibo rivers. A 30-mile (48-kilometre) line connects the manganese mines at Matthews Ridge with Port Kaituma on the Kaituma River.

Internal airways services of commercial and private aircraft use landing strips and the quieter stretches of rivers. Passengers and equipment are the chief freight. Timehri International Airport, 25 miles from Georgetown, is the country's main airport and is served by several international airlines.

Water transport constitutes by far the greatest mileage. It was used along the coast, on the canals of the sugar estates, by the ferry and steamer services of the lower rivers, and by the light craft of the interior.

Bauxite is loaded into oceangoing ships at Mackenzie and manganese ore at Port Kaituma, but, otherwise, the whole of the country's external trade passes through Georgetown, which maintains direct connections with the West Indies, Surinam, French Guiana, the United Kingdom, Canada, and the United States.

ADMINISTRATION, SOCIAL CONDITIONS, AND CULTURAL LIFE

The structure of government. *Constitutional framework.* In 1970 Guyana became a cooperative republic. The president is a ceremonial head of state who is elected to a six-year term by the country's unicameral legislative body, the National Assembly. Actual executive power resides in the prime minister, who is an elected member of the National Assembly and a member of the party with a majority of the assembly's seats. He serves upon the advice of the Cabinet, which is appointed by the president on the advice of the prime minister from members of the assembly or ministers who qualify to be elected. Ministers not of the assembly may not exceed four, and they may sit only as nonvoting members. The prime minister and the Cabinet are responsible to the assembly of 53 elected members, who serve four-year terms. The minority members of the assembly elect a leader of the opposition.

The executive structure also includes an ombudsman, who is charged with the investigation of administrative actions for malpractice or racial discrimination. The ombudsman is appointed upon the recommendation of the prime minister and the leader of the opposition to a four-year term.

Regional and local government. Apart from Georgetown and New Amsterdam, which are municipalities, the country is divided for local-government purposes into six coastal and three interior divisions. The coastal divisions are subdivided into villages and country districts, with councils responsible to a local government board. The interior divisions comprise seven-eighths of the area of the country but have a population of only 43,000. They are directly administered by the central government. A number of "Amerindian districts" have been demarcated for the sole occupation of Amerindians, and local councils have been formed in some of them.

The political process. The right to vote belongs to all Guyanese citizens over 21 years of age and any Commonwealth citizen who has lived in Guyana for more than one year. Voting is carried out by secret ballot under a system of proportional representation. Votes are cast for lists of candidates compiled by the political parties, and seats in the National Assembly are then allocated proportionately among the lists. Elections must be held at least every five years.

The two major political parties

The two dominant political parties are supported by about 85 percent of the electorate. They are the People's Progressive Party (PPP), which is primarily supported by the East Indian community, and the People's National Congress (PNC), which is supported by the Afro-Guyanese. The small United Force Party is composed of the Portuguese and the wealthy and has attracted the Amerindian vote. The parties reflect the country's ethnic divisions and, in their struggle for power, tend to exacerbate racial distrust.

Justice and the armed forces. Guyana has two legal traditions, the British common law and the Roman–Dutch code, the latter of which is now largely relegated to matters of land tenure. The constitution is the supreme law of the land. The court structure consists of magistrates courts, the High Court, and the Court of Appeal. The independent judiciary is headed by the chancellor, who presides over the Court of Appeal. The chancellor and the chief justice, who heads the High Court, are appointed by the prime minister, and all other judges and magistrates are appointed by the Judicial Service Commission.

The Guyana Defense Force (GDF) is composed of a regular and a reserve army and is charged with the maintenance of law and order. There is no navy or air force. There is no conscription, and the army is of minimal political importance. The GDF is directly controlled by the prime minister acting as minister of defense.

The social milieu. *Administrative services.* Education is free and compulsory from six to 14 years of age. Primary and secondary instruction are separate, although the lack of accommodations requires that some secondary classes are held in primary schools. The government accepts charge of most schools and gives grants-in-aid to denominational schools, many of which are located in the interior. Because of the lack of educational facilities, there are many private primary and secondary schools in the towns. The government's educational intentions are also hampered by the difficulties of attendance enforcement; only about one-third of the primary students continue into the secondary level. Yet, in spite of such problems, Guyana has the relatively high literacy rate of 85 percent. There is a teachers' training college in Georgetown. The Queen's College, founded in 1844, is government maintained. A technical institute has made progress since 1945, and the Carnegie School of Home Economics has had a long and distinguished history. In 1963 the University of Guyana was established in Georgetown. Well-organized educational broadcasting aids the schools.

Health and welfare services

The standard of health is generally good, and the control of malaria and other formerly endemic diseases, such as whooping cough, measles, tuberculosis, and leprosy, is effective in populous areas. Low dietary standards are being gradually raised by education and public-health education. Medical facilities include almost 150 medical

centres, including rural maternal and child-care clinics. There are about 24 general hospitals, 12 hospitals on the sugar estates, and specialized units for tuberculosis, psychiatric illness, and leprosy, as well as mobile health units. In 1969 there was one doctor for every 3,800 inhabitants.

Public health has long been well organized, and food hygiene, malaria control, and drainage receive high priority. Housing and reconstruction are promoted by a special ministry. Community development, or self-help, programs encourage communal projects and have been successful in getting people of different ethnic origins to work together. There are systems of social security, including old age pensions, and public assistance.

Housing presents a critical problem. Most of the houses in Guyana are of poor construction and are crowded; few have adequate sanitation or electricity services. Most are constructed of wood, roofed with corrugated iron or wooden shingles, and raised on posts or concrete blocks. Housing on the plantations includes tenements constructed of old barracks, and there are many tenements in Georgetown. The government has launched ambitious housing schemes, but few units have actually been constructed.

The 2,000-man Guyana Police Force (GPF) is an armed semi-military organization. It is charged with the maintenance of law and order, protection against fire, and civil defense.

Social conditions. In the sugar industry, price-rate wage systems prevail, and incentive schemes are particularly directed at improving the regularity of work. The sugar industry is by far the largest employer, but its labour force of 17,000 is being steadily diminished by mechanization. The bauxite industry is a relatively small employer, and rice milling is on a small scale except where connected with government irrigation schemes. The timber industry is the only other considerable employer.

Sugar and rice growing are seasonal occupations, so there has always been unemployment, underemployment, and casual labour. The rapid rise of population has aggravated the problem, which is being countered by efforts to make more drained land available and to introduce new local industries. Problematic inflation has given rise to labour unrest, and wages are not commensurate with the cost of living.

Social and economic divisions

The national social structure was inherited from the period of British colonial rule. The elite is composed of Europeans and those East Indians, Afro-Guyanese, and Portuguese of wealth, education, or the professions. The middle income group is not well defined, and social mobility tends to be related to occupation rather than to ethnic identity. The lower income group is composed of East Indian and Afro-Guyanese peasants, industrial workers, and artisans. The Amerindians remain apart from the country's main social stream. These social and economic groups are further complicated by the growing awareness of ethnic identity and the social stratification within each ethnic community.

Cultural life and institutions. Guyana is in the process of evolving a distinct national culture based on folk traditions and the contributions of the ethnic communities. Amerindian culture is important to music and dance; the landscape has long been central to painting and sculpture; and the literary arts reflect Guyana's history and its path to independence. The most impressive progress has been in the literary arts. Major writers include the original and sensitive Wilson Harris, the poet A.J. Seymour, and the novelist Edgar Mittelholzer.

Cultural institutions. Cultural institutions are concentrated in Georgetown. They include the Guyana Museum, which contains exhibits relating to industry, art, history, anthropology, and zoology, and the Guyana Zoo, with its collection of South American animals. Libraries include the Public Free Library, the Royal Agricultural and Commercial Society Library, and those of the British Council and the United States Information Service.

Press and broadcasting. Newspapers include three dailies, four Sunday papers, five weeklies, two fortnightlies, three monthlies, and three quarterlies. The *Guyana Graphic* of East Demerara is the major paper and is particularly influential among the Afro-Guyanese middle income group. The *Evening Post* is also published in East Demerara and is important among the trading community. The *Mirror* is the third daily. The weekly newspapers include *The New Nation*, an organ of the PNC; *The Sun*, an organ of the UFC; and the *Labor Advocate* of the Man-Power Citizens Association.

Radio services

There are two major radio broadcasting stations—Radio Demerara and the Guyana Broadcasting Service, which was purchased by the government in 1968. United Broadcasting also operates a broadcasting station. Programming includes school broadcasts, dramas, religious and ethnic programs, and sports. In 1968 television services were obtained from stations in Surinam, Trinidad, and Venezuela.

PROSPECTS FOR THE FUTURE

Guyana has had a relatively stable political life since achieving independence in 1966, and is seeking to establish its international position. The prospects of attracting foreign aid seem favourable, and finance for surveys, research, and prototype schemes is not difficult to acquire. The country's basic problems, however, remain much as they have been since the 19th century—diversification of the economy and development of natural resources. Agricultural development is necessarily slow, and it will probably remain true that Guyana's greatest asset is in the fertility of its coastal plain, of which only a small portion is now fully exploited. Successful forestry continues to be difficult, and future mining development will depend upon more intensive exploration with improved methods.

If political stability continues and a diminution in internal racial tensions can be achieved, the country could become an important settlement area for the overcrowded island populations of the surrounding Caribbean countries.

FANSHAWE, *The Vegetation of British Guiana* (1952). MICHAEL SWAN, *British Guiana* (1957), presents the only fairly recent general account of the country; his *Marches of El Dorado* (1958), is a lively account of travel in the interior savannas. L.F.S. BURNHAM, *A Destiny to Mould* (1970), is a recent history written by Guyana's Prime Minister. For statistics, see the *Guyana Quarterly Statistical Digest*. A vast quantity of information may also be found in the *Reports of the British Guiana Geological Survey*, the *Annual Colonial Reports*, *Agricultural Journal of British Guiana*, and their counterparts renamed for "Guyana" since independence in 1966.

(Ed.)

Gymnastic and Weightlifting Sports

Gymnastic sports involve physical exercise, specifically systematic and usually rhythmic exercises (calisthenics) and performances on rings, bars, and other apparatus to promote strength, suppleness, agility, coordination, and body control. They also include the lifting of weights to increase strength and improve physical fitness. This article deals principally with the organized, competitive sports, gymnastics and weight lifting, which in modern times have evolved from these activities.

While gymnastics and weight lifting have common characteristics, especially in their use in physical conditioning, there are distinct differences between them. Weight lifting, as a competitive sport, has been practiced only by men, and it is generally associated with the quality of bodily strength, whereas both men and women engage in the sport of gymnastics, which is well-known for developing suppleness, grace, and coordination. Further, competitive weight lifting is an objective matter because the results are determined by a specific measurement—*i.e.*, the number of pounds that are lifted—while the execution of gymnastic exercises is entirely subjective, for it is practiced without the aid of any mechanical measurements, and results depend entirely upon human judgment and interpretation.

GYMNASTICS

Some form of gymnastics—particularly calisthenics, or floor exercises—is practiced in connection with most other sports. Systematic exercises involving movements of the arms, legs, torso, and other parts of the body are employed for loosening up muscles prior to engaging in competition and also for long range physical conditioning before the start of such competitive team sports as football, baseball, and soccer.

The competitive aspect of gymnastics differs from that of physical conditioning, for it not only is a form of physical conditioning in itself but is the end result of such exercise. It consists of an infinite variety of movements on the various apparatus and on the floor, requiring individual ingenuity in their composition, skill in their performance, and harmony in their combination.

The countries that have been strongest in competitive gymnastics in recent years are Japan, the Soviet Union, the United States, East and West Germany, Switzerland, and Czechoslovakia. They all have instituted sound programs to develop gymnasts of international calibre, starting at the high school level. Other countries have followed suit, and now gymnastics as a competitive sport is practiced throughout the world.

History. The sport of gymnastics evolved from the rudimentary exercises performed as training for strenuous combative sports that took place during the public games of ancient Greece. At that time, the general term gymnastics included activities that have since developed as separate sports—for example, track and field athletics, fencing, wrestling, and boxing. During the ancient Olympic Games, a primitive form of modern gymnastics was developed, and the sport came into its own as a part of those games.

Origins in ancient games

With the termination of the ancient games, all sports fell into a decline. In the Middle Ages jousts and various field sports were popular, but the systematic training of the body that the Greeks had associated with gymnastics fell into neglect (see also ATHLETIC GAMES AND CONTESTS).

The modern development of gymnastics started in the 19th century, when there was a revival of interest in all sports; and gymnastics early came to be recognized as a systematized form of physical exercise, having not only recreational but therapeutic value and offering a means of developing a high degree of discipline of both mind and body.

Gymnastic societies were founded first in Germany (Turnvereins) and in the Bohemia of the Austro-Hungarian Empire (Sokols); these were followed in France and Switzerland (where a system of gymnastics performed in unison by groups was developed and is still practiced). Similar societies gradually spread throughout western Europe. Gymnastics was one of the first sports to recognize that its recreational and therapeutic advantages were as valuable to women as to men, and the European gymnastic societies provided children's classes, starting youngsters as early as the age of five.

The original impetus in the United States was in the 1880s with the advent of the great tide of immigrants from the European countries. They brought with them the ideas of their gymnastic societies and founded the societies wherever they settled. The younger generations carried the influence of these gymnastic societies into the athletic programs of their schools and colleges, where the sport gained recognition competitively on a large scale.

Development as an organized sport. Internationally, gymnastics is governed by the Fédération Internationale de Gymnastique (FIG), which was founded in 1881 to formalize international competitions. FIG, which has a membership of more than 60 countries, each of which has its own national governing body, or federation, is administered by an executive committee (Comité Directeur) and by men's and women's technical committees that promulgate the rules and regulations governing competitions. The committees also prescribe international standards for the various apparatus to be used, the types of exercises to be performed, and the conduct of the competitions.

Modern competitive gymnastics has developed from two major systems. In Sweden a system of free exercises on the ground arose in the mid-19th century to develop perfect rhythm of movement. This system was introduced in England in 1879 and in the United States in about 1889; and for the next 20 years the relative merits of Swedish (rhythmic) gymnastics and the German gymnastic system (apparatus work of a formal nature, stressing muscular development) were debated intensively by both the educational authorities and adherents of the sport. A solution was found by the Fédération Internationale de Gymnastique in the 1920s, in blending the rhythmic, fluent movements of the Swedish system with the precision and developmental emphasis of the German system.

Major systems of gymnastics

Although the Swedish system is still popular in the country of its origin, the combined version has been adopted by national authorities elsewhere. Current trends, however, are to lean more and more to the aesthetic and fluent movements, rather than to movements of strength and the holding of static positions.

Competitions in gymnastics are conducted at all levels, from local school and gymnastic societies to national championships, international meets, world championships, and the Olympic Games. The Fédération Internationale de Gymnastique, which is recognized as the international authority by the International Olympic Committee and, as such, has jurisdiction over the gymnastic competitions of the Olympic Games, also conducts the world championships in gymnastics every fourth year (two years after each staging of Olympic Games).

Principles of competitive gymnastics. There is constant evolution of the sport. The innovation of movements—never seen before in gymnastic competitions—by gymnasts of international repute tends to popularize such movements in international competitions. Such innovations have a considerable influence on the competitive sport because they encourage originality and a greater expansion of the types of exercises that can be performed on the various apparatus and on the floor. For instance, a movement on the horizontal bar by Josef Stalder of Switzerland never seen previously in international competition has since been known as the "Stalder Shoot"; a vault on the vaulting horse by Haruhiro Yamashita of Japan in the 1964 Olympic Games in Tokyo has ever since been known as the "Yamashita"; and as another example, a movement on the parallel bars in the 1966 Fédération Internationale de Gymnastique World Championships in Dortmund, West Germany, by Sergey Diomidov of the Soviet Union, gave rise to its being included in the nomenclature of movements on the parallel bars as a "Diomidov."

Innovative aspects of the sport

As a competitive sport, gymnastics is akin to diving and figure skating, for it is a demonstration sport, and the effectiveness of the competitor is assessed solely by the judgment of officials who have a knowledge of the technical rules and regulations governing the competition. In other words, these demonstration sports are competitions in which there is no physical contact with an opponent to guide an official, such as a touch of the foil that occurs in fencing, a knockdown in boxing, an advantage in wrestling—and where there is no mechanical measurement to evaluate the effort of the competitor, such as timing a race, measuring the height or distance of a jump or throw, or weighing the number of pounds lifted.

Men's events and apparatus. The men's competition in international gymnastics consists of seven events: the horizontal bar, parallel bars, side or pommelled horse, long or vaulting horse, stationary rings, floor exercises, or calisthenics, and the all-around event consisting of the combined scores in the first six events. (International rules require that a gymnast perform in all events similar to the decathlon event in track and field.)

Each competitor performs two exercises in each event. One is a prescribed exercise that all competitors must perform, and it is composed by the governing body of the sport (for international competitions, the FIG). Its performance is judged solely on its execution—*i.e.*, the form of the gymnast, the fluency of his performance, the correctness of the execution, and the beauty of combining the component parts of the exercise.

Prescribed and optional exercises

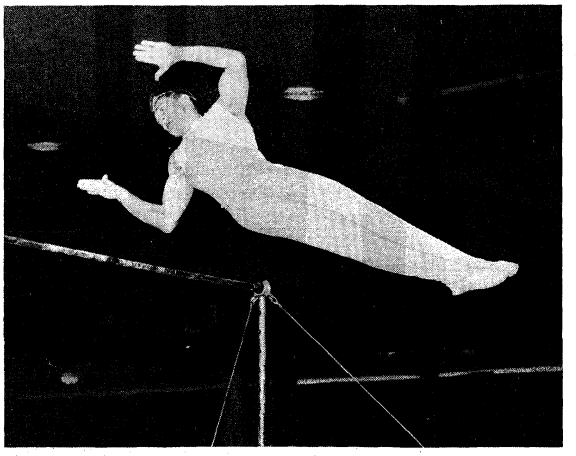
In addition, an optional exercise, composed by the gymnast himself, must also be performed. The element of difficulty of the component movements of the exercise enters into the evaluation of the optional exercise. Besides difficulty, other elements evaluated are originality, beauty of combining the various movements, and the fluency and perfection of execution. There is a minimum of 11 parts, or skills, required for a complete optional exercise.

The requirements of the events and the apparatus used for the men's competition are described below.

Horizontal bar. The horizontal bar is a polished steel bar, 28 millimetres (about 1.1 inches) in diameter, 2.35 to 2.50 metres (7.7 to 8.2 feet) long, and 2.40 to 2.50 metres (7.9 to 8.2 feet) high from the floor, supported at the ends by steel poles that are held upright by guy wires. Only movements of swinging and vaulting, without pause, are permitted. Such exercises as upstarts, or kips, back and front (*i.e.*, moving with an impetus from a hanging position in which the hips are bent and the stretched legs and feet are stretched over the head, to a support position with the head above the feet and the body either in front or back of the bar); uprises (in which the gymnast swings himself from a hang to a support position above the bar); giant circles forward and backward (rotating around the bar from a handstand position with the arms fully extended), with changes from one grip to another; vaulting over the bar, releasing the grip and regrasping the bar; movements requiring turns and changes of body position and the releasing and regrasping of the bar; and finishes, or dismounts, with straddles over the bar, or forward and backward somersaults from the bar are performed on this apparatus.

Parallel bars. The parallel bars consist of two bars made of wood, oval in form and 42 to 48 centimetres (17 to 19 inches) apart, 3.50 metres (11.5 feet) long, and 1.60 to 1.70 metres (5.2 to 5.6 feet) high. The requirements for this apparatus are movements combining swings, vaults, strength, and balances, although swings and vaults must predominate. There may not be more than three balances (such as handstands) in an exercise (a sequence of at least 11 different movements or tricks), and there must be at least one movement of strength (such as a handstand that is pressed into by strength, rather than swung up into). Movements below the bars and the release and regrasping of the bars are also required.

Side, or pommelled, horse. This apparatus is a leather-covered form 1.60 metres (5.2 feet) long, 35 to 37 centimetres (14 to 15 inches) wide, and raised 1.08 metres (3.5 feet) from the floor (measured to its top) by a support in its centre. Curved wooden pommels, 12 centimetres (five inches) high, are inserted in the top of the horse 40 to 45 centimetres (16 to 18 inches) apart in the centre, or "saddle" of the horse. The gymnast supports himself on the pommels and performs movements of the trunk and legs without stops, such as single or double leg circles and crosses of the legs (scissors) with turns and changes of the grasp to the forward (neck) part of the horse, the centre (saddle), and the rear (croup). It is necessary to vary the movements and also to perform them both to the left (clockwise) and to the right (counterclockwise).

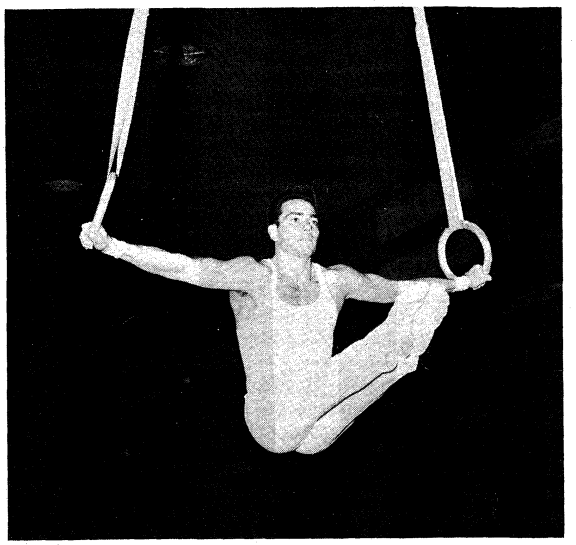


Horizontal bar.
A full turn (pirouette) at the end of a backward swing (releasing grasp), performed by Bruno Klaus (U.S.).
John Nicolas

Long or vaulting horse. This is the same device that is used for the side horse, except that the pommels are withdrawn and the horse is placed lengthwise, so that the part nearest to the gymnast's stand is the croup, and the neck is farthest away from him. The height of the horse is raised to 1.35 metres (4.4 feet). An elastic board, or springboard, is placed in front of the croup end of the horse.

The gymnast runs toward the horse, rebounds off the elastic board and, supporting his hands on the horse, vaults over it. A variety of vaults is performed, such as vaulting over with straddled legs, with the legs together and bent into a squatting position, or with the legs straight and the hips bent, Handsprings, cartwheels, and other vaults are performed over the horse. The hands may be placed on either the croup or the neck end of the horse, but the space for the support of the hands is limited and encroaching beyond this space incurs a penalty on the scoring of the vault. Each vault is evaluated by a table as to its difficulty.

Stationary rings. The stationary rings are made of wood, 28 millimetres (1.1 inches) in thickness and 18 centimetres (seven inches) in diameter (inside). They are suspended by straps at a height of 5.50 metres (18 feet) from the floor, with the rings themselves hanging 2.40 to 2.50 metres (7.9 to 8.2 feet) above the floor. The exercises must be performed with the rings in a stationary position (without a swinging or pendulum movement of the rings), and they must combine swinging movements of the body, strength and holding of positions. There must be at least two handstands in each exercise, one of which must be pressed into by strength with the body held above the rings. In the other, the athlete swings up into the handstand from a hanging position below the rings. At least one other example of strength must be exhibited, such as a cross (holding the body vertical with the arms fully stretched sideways), or a lever (hanging with straight arms with the body stretched horizontally, parallel to the floor, either in front of the arms or in a dislocated hang; *i.e.*, hanging in an inverted position with the head nearest the floor and then lowering the body backward, stretching it in a horizontal position). Combined with such required move-



Rings.
A cross hang, with legs in "L" position, performed by Abie Grossfeld (U.S.).
John Nicolas

ments may be either forward or backward upstarts, forward or backward uprises, straight or inverted hangs, and circles of the body, either forward or backward.

Floor exercises, or calisthenics. No apparatus is used in the floor exercises, or calisthenic event. The exercise is done on the floor, which may be covered by canvas or felt, in an area 12 by 12 metres (39 by 39 feet), and it must be at least 50 seconds and not more than 70 seconds in duration. The type of exercise required is a series of combined movements that demonstrate flexibility (tumbling movements such as handsprings, cartwheels, somersaults in the air), jumps, strength, holding of poses, balances, and other tricks. The exercise must be performed with rhythm and harmony, and the gymnast must move in different directions and utilize a major portion of the allotted area.

The exercise usually starts and finishes with a series of tumbling movements, such as a cartwheel with a half a turn (a roundoff) and continues with handsprings and somersaults backward or forward in the air. In between the start and finish, balances are held on one leg (scales), handstands are pressed into by strength, and exercises resembling ballet and tumbling movements and jumps are interposed.

Competition for women

Women's events and apparatus. Generally the basic requirements for the women's competition are the same as those for the men as regards the prescribed and optional exercises and their evaluation. The women's events are performed on the balance beam, the uneven parallel bars, and the vaulting horse; women's floor exercises, like the men's, are performed without apparatus.
