Balance beam. The balance beam is a wooden beam five metres (16 feet) long and ten centimetres (four inches) wide, which is raised 120 centimetres (about four feet) from the floor. The performer begins the exercise by mounting the beam either by a vault or a jump and executes movements that must include steps, running, jumps, turns, sitting and lying positions, and some held, or posed, positions. The duration of the exercise is from one minute 20 seconds to one minute 45 seconds.

Uneven parallel bars. These are of the same dimensions and construction as the men's parallel bars, except that the top bar is 2.30 metres (7.5 feet) above the floor whereas the lower bar is only 1.50 metres (4.9 feet) high. This apparatus is the latest to be developed, having been used first in the 1936 Olympic Games; it permits a great variety of movements, although hanging and swinging exercises predominate (such as hanging from the higher bar and swinging forward to the lower bar), interspersed with support and balance movements. The performer uses either of the bars or combines movements using both bars.

Vaulting horse. This is the same as the men's long horse, except that it is only 1.10 metres (3.6 feet) high and is placed sideways instead of lengthwise. Women also use the elastic board and perform vaults similar to those done by men, except that they are done over the width of the horse, rather than its length.

Floor exercises or calisthenics. The women's floor-exercise event is similar to the men's but it is performed to music and lasts from one to 1.5 minutes.

Scoring and judging. Although the scoring and judging of gymnastic competitions is solely subjective, there are detailed and comprehensive rules and regulations promulgated by the FIG that attempt to eliminate the factor of human judgment and provide guidelines for as objective an evaluation as is possible without the aid of mechanical measurements.

Evaluation and scoring of individual and all-around events

Four judges supervised by a superior judge evaluate and score each exercise on a one-tenth basis; *i.e.*, 8.8, 9.3, and so on, with 10.0 given for a perfect exercise. For the prescribed exercise, the entire ten points are confined to its execution. In the evaluation of the optional exercise, 3.4 points are allotted for the difficulty of the exercise, 2.6 points for the element of combination of the various movements, and 4.0 points for the execution of the exercise as a whole. All four judges evaluate and score each exercise independently. Then, in order to eliminate gross errors of judgment, the scorers delete the highest and the lowest marks of the four judges, and the two middle marks are averaged for the score of the exercise. For example, if the four judges' marks are 9.6, 9.2, 9.1, and 8.7, the 9.6 and 8.7 are deleted, and the 9.2 and 9.1 are averaged, giving the final score of 9.15. The average score of the prescribed exercise is added to that of the optional exercise to determine the final score of the competitor in the event and his standing as compared with the other competitors. To obtain the all-around score, the final scores of the six events (four in the case of women) are added, and the total comprises the score of the gymnast in the all-around competition.

The championships of the individual events are determined by a separate competition known as the "finals" wherein the gymnasts who have achieved the six highest scores in each event perform an additional optional exercise in that event, and the score of this final exercise is added to the gymnast's previous score to determine the standings of the six best competitors in each event.

Balance beam.
A front scale, with a vertical split of the legs, performed by Larisa Petrik (U.S.S.R.).

For Olympic champions, see ATHLETIC GAMES AND CONTESTS. For records of gymnastic world championships, see also SPORTING RECORD in the *Ready Reference and Index*.

Other forms of gymnastics. *Trampoline.* In trampoline tumbling, or rebound tumbling, the performer bounces upward from a resilient platform or bed and does acrobatics while in flight. It is performed on a table-height metal frame three by five metres (ten by 17 feet), with an elastic nylon webbing bed attached by a steel-spring suspension system. Competition consists of one compulsory and one voluntary routine, with judging similar to that in conventional competitive gymnastics. The sport has been especially popular in the United States. Annual world trampoline championships for men and women were instituted in 1964. For a list of champions, see also SPORTING RECORD in the *Ready Reference and Index*.

Moderne Gymnastics. A concept of women's gymnastics termed Moderne Gymnastics is an expression of very free movements. The floor exercises, done to music, permit more fluidity, dance, and ballet movements. The other events on this program are performed with hand apparatus, such as a *corde* (similar to a skipping rope), a hoop (rolling hoop), a ball, and a length of cloth ribbon. Another feature of this program is a team drill in which the entire team (six women) performs as a unit and is judged according to its execution, uniformity, difficulty of composition of the drill, harmony, and similar factors. Although the Moderne Gymnastics competition is recognized internationally by the Fédération Internationale de Gymnastique, and world championships in this program have been held biennially since 1963, it is not included in the Olympic program.

Gymnastic festivals and demonstrations. This form of gymnastics is popular mainly in European countries, where it is practiced by groups ranging from a few gymnasts to mass demonstrations of many thousands.

Gymnastic societies and gymnaestrada

The Sokols, gymnastic societies in Czechoslovakia, have promoted gymnastic festivals in which as many as 10,000 gymnasts participated simultaneously in a mass calisthenic drill. The Turnvereins of Germany and the gymnastic societies of Switzerland and the Scandinavian countries also participate in mass demonstrations, not only in calisthenic drills but also on apparatus.

The Fédération Internationale de Gymnastique recognizes the value of and encourages such noncompetitive aspects of gymnastics on national and international levels. For this purpose the FIG established in 1953 the international Gymnaestrada, sponsored quadrennially the year after each Olympiad, at which all member federations of the FIG are invited to demonstrate a noncompetitive gymnastic activity, preferably native to their country.

In addition to the internationally recognized programs of competitive events, local and national programs may include other activities such as tumbling, rope climbing, and exercises on the swinging rings. (J.F.H.)

WEIGHT LIFTING

Weight lifting is a competitive sport controlled by the International Weightlifting Federation, which is responsible for the technical rules governing the sport, the organization of annual world championships, continental championships, international tournaments and matches, recognition of world and Olympic records, and appointment of international referees. Weight lifting is included in the Olympic Games and all regular regional games.

History. Throughout his history, man has been interested in strength and trials of strength. For many prehistoric tribes the traditional test of manhood was to lift a special rock. Such stones, with centuries-old inscriptions giving the name of the athlete who first lifted them, can still be found in Greece. Manhood stones, or *clach cuid fir*, have been found in some ancient Scottish castles, indicating that this activity persisted through the Middle Ages. In Munich, a plaque above a stone in the courtyard of the Apothekerhof, weighing 364 pounds (165 kilograms), records that in the year 1490 Duke Christopher of Bavaria lifted and threw it. Stone-throwing competitions survive in West Germany and Switzerland, and rock lifting is still a popular rural activity in the Basque area of Spain.

Beginnings of modern weight lifting

Modern weight lifting began in the late 18th and 19th centuries, fostered by the feats of professional strongmen such as Eugene Sandow and Arthur Saxon of Germany, George Hackenschmidt of Russia, Louis Apollon of France, and others who performed in circuses and music halls. Their feats were copied by enthusiastic amateurs, mostly in western Europe. The first open world championships were held at the Café Monico, London, in 1891, and won by the Englishman Lawrence Levy. Two weight lifting competitions were included in the first revival of the Olympic Games, held in Athens in 1896. The winner of the one-hand lift competition was Launceston Elliot of Great Britain with 156½ pounds (71 kilograms); and the winner of the two-hand lift competition was Viggo Jensen of Denmark, with 244½ pounds (111 kilograms).

The one- and two-hand events were held again in 1904; then, in 1920, at the suggestion of the International Olympic Committee, the International Weightlifting Federation was formed to control the sport and, in particular, to formulate technical rules so that competitions in the Olympic Games could be held under universally accepted conditions. Since then, weight lifting has been included in the Olympic Games. The international federation originally included 14 member countries, but in the mid-1970s there were approximately 100 countries affiliated from all parts of the world. France and Germany were the leading nations until the 1930s, when Egypt became the leader. After World War II the United States was supreme until 1953. Since then, weight lifters of the Soviet Union have been world-team champions and have held most of the world records.

Principles of competitive weight lifting. *Equipment.* The weight used in modern weight lifting is a barbell, a steel bar, or rod, to which metal (cast-iron) disk weights are fastened at each end on a revolving sleeve. The range of weights is 25 kilograms (55 pounds), 15 kilograms (33 pounds), 10 kilograms (22 pounds), five kilograms (11 pounds), 2½ kilograms (5½ pounds), 1¼ kilograms (2¾ pounds). The lifts are performed on a wooden platform four metres (13 feet 1¼ inches) square. If a lifter steps off this platform during the course of a lift, that lift will not be passed.

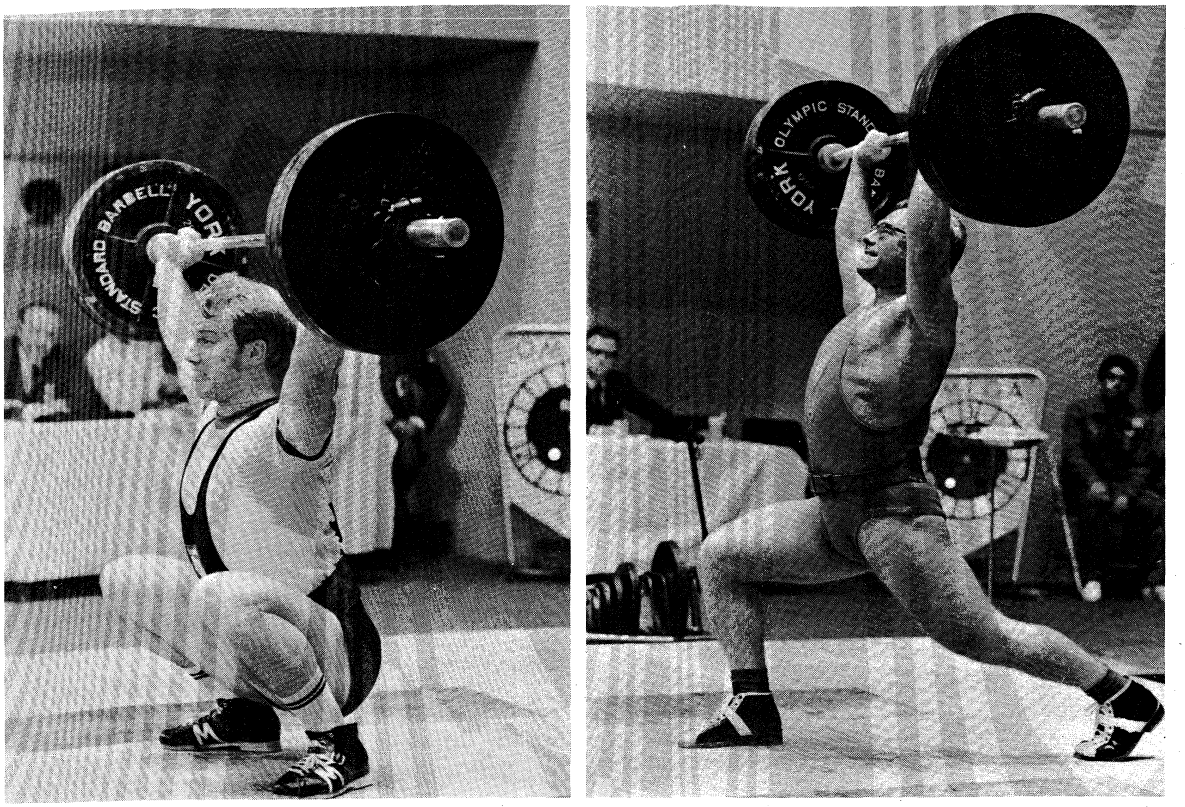
Weight categories. Originally there were five bodyweight categories for the contestants but others were added in 1947, 1951, and 1968, and there are now nine: flyweight 52 kilograms (114½ pounds); bantamweight 56 kilograms (123¼ pounds); featherweight 60 kilograms (132¼ pounds); lightweight 67.5 kilograms (148¾ pounds); middleweight 75 kilograms (165¼ pounds); light heavyweight 82.5 kilograms (181¾ pounds); middle heavyweight 90 kilograms (198¼ pounds); heavyweight 110 kilograms (242½ pounds); super heavyweight over 110 kilograms (over 242½ pounds).

The Olympic lifts. Originally, in International Weightlifting Federation competition five different lifts were used. These were reduced to three in 1928 and finally to two in 1972. The one eliminated in 1972 was the press (or clean and press), which is a two-part lift. The lifter first hefts the barbell to his shoulders in a single, clean movement. He may move his feet to do this. When he is standing erect, the chief referee gives him a signal to complete the lift, which he does by pressing the barbell in a steady, continuous movement to arm's length overhead, without any assistance from the legs.

The press, snatch, and clean and jerk

Only two lifts may now be called Olympic lifts, the snatch and the clean and jerk. In the snatch, the barbell is lifted from the floor to arm's length overhead in a single, continuous, explosive movement, with the lifter being permitted to move his feet or to squat under the barbell as he lifts it, after which he must recover to an erect position again.

The other remaining lift, the clean and jerk, is a two-part lift. After lifting the barbell to his shoulders, the lifter jerks it overhead to arm's length in his own time and



Weightlifting.
(Left) The snatch (squat style), performed by B.O. Johanson (Sweden). (Right) The jerk, performed by Gyozo Veres (Hungary).
Oscar State

without any restrictions on leg action. In both lifts, the lifter must finish with his feet in line, body erect, arms and legs extended, the barbell under control overhead, and he must wait for the referee's signal to lower the barbell back to the floor.

In the clean and the snatch, two main techniques are employed, either the split or the squat. In the split style the lifter lunges under the barbell, thrusting one foot forward and the other foot simultaneously backward to land in a fore-and-aft straddle position. This is also the invariable technique for lifting the barbell in the jerk. In the squat technique, the lifter bends both knees and drops vertically below the barbell into a low, squatting position with the trunk erect. The squat technique is more often used because it is mechanically superior to the split.

Judging of competition. The competition begins at the lowest weight specified by the lifter, and the weight of the barbell is then increased, as required, in multiples of 2½ kilograms (5½ pounds). Each lifter takes his turn as the barbell reaches the weight that he requires, but he is allowed only three attempts on each of the three lifts. The increase in weight from the first to the second attempt must be at least five kilograms (11 pounds) and from the second to the third attempt at least 2½ kilograms (5½ pounds). If a competitor fails a lift and makes another attempt, he may either take the same weight again or increase it, as he wishes. His best results on each of the three lifts are added to give a total. The lifter with the highest total is the winner. In case of a tie in totals, the lifter with the lighter body weight is the winner, and the rest are placed according to their totals. All lifters in official championships are weighed 1¼ hours before the competition begins. Two referees and a chief referee adjudicate the lifts and signal their decisions by means of a system of lights: a white light indicates a "Good Lift" and a red light "No Lift." A majority of two is equally decisive as a unanimous verdict.

For Olympic champions see ATHLETIC GAMES AND CONTESTS. For world weight lifting records see also SPORTING RECORD in the *Ready Reference and Index.*

Weight training. Weight training is distinguished from weight lifting in that it is not a competitive sport but a system of physical training using weights in the form of barbells and dumbbells and other specialized equipment such as pulley weights and leg machines. It is used extensively by track and field athletes, swimmers, football and soccer players, tennis players, and other sportsmen for whom basic strength is an important factor in their overall training program.

Weight lifting for strength and physical fitness

Other weight trainers use weights in a moderate program to obtain general physical fitness. There are also large numbers who train with weights to develop their physique in order to enter body-building contests. In the mid-1970s the medical profession was making increased use of weight training for physical rehabilitation after illness and injury. (O.S.)

Gymnosperm

Gymnosperms constitute one of the two major groups of seed-producing plants—the other group being the flowering plants, or angiosperms. Although they number only about 750 species, gymnosperms rank among the most familiar, important, and biologically interesting of all plants; they include such well-known species as pines, spruces, cedars, junipers, araucarias, and kauris. They are the major constituents of the vegetation in many parts of the world. Many species of gymnosperms are significant as timber trees, as ornamental plants, as food plants, as sources of essential oils and other products, and as medicinal plants. Gymnosperm forests of prehistoric times formed a large portion of the coal available today. Some gymnosperms are considered weeds, and a few are poisonous. Gymnosperms are of great biological interest because of their diversity of form and structure, their present and past distributions, and their well-preserved and rather complete fossil record.

The major groups of living gymnosperms are the coniferophytes, including conifers, taxads, and the ginkgo; the cycadophytes, including cycads; and the gnetophytes, including joint firs, gnetums, and *Welwitschia* (Figure 1).

ECONOMIC IMPORTANCE

Gymnosperms are among the most valuable timber trees. Outstanding in the Northern Hemisphere are pines, Douglas firs, cedars, and the redwood; in the Southern Hemisphere are kauris, podocarps, dacrydiums, and araucarias. Notable as sources of pulpwood for paper manufacture are hemlocks, spruces, firs, and pines. Gymnosperm wood is "softwood," structurally different from the wood ("hardwood") of angiospermous trees; despite that designation, a few gymnosperms produce wood that is harder and heavier than that of some angiosperms.

Ornamental gymnosperms

Gymnosperms rank high in value and popularity as ornamental plants. Pines, spruces, firs, Douglas firs, cedars, junipers, larches, arborvitaes, hemlocks, yews, podocarps, *Cunninghamia*, *Chamaecyparis*, araucarias, ginkgo, and cycads are well represented in cultivation. Some of these, particularly spruces, junipers, and *Chamaecyparis*, are notable for their many horticultural forms. Of those gymnosperms grown in greenhouses, cycads, araucarias, and kauris are perhaps the most common. Most gymnosperms grow to be too large for use as house plants, but juvenile forms of some, such as the araucarias, are popular. Some gymnosperms—*e.g.*, pines and junipers—are used in the Japanese art of tree dwarfing (bonsai).

Gymnosperms are of only local significance as food plants. Pine "nuts," the seeds of the pinyon, or nut, pines, are a minor article of commerce. Seeds of araucarias, ginkgo, gnetums, and *Torreya* are eaten locally by man. Of all the gymnosperms, however, the cycads have been most used as a food source, especially *Cycas*, *Encephalartos*, *Macrozamia*, and *Zamia*. They yield a starch, either from the seeds or from the stems, important particularly in areas of periodic famine or where the food supply is naturally limited. In the preparation of cycad starch, the seed kernels and the stem core are treated in various ways—often with water—to separate the starch from the fibrous matter and to remove a poison that is present in certain forms. Extraction of starch called Florida arrowroot from *Zamia* stems, a pioneer industry in Florida, continued until the mid-1920s. The only gymnosperm of importance as a flavouring is the common juniper, whose "berries" (*i.e.*, fleshy cones) contain an essential oil widely used to impart a distinctive flavour to gin and other alcoholic beverages.

Some gymnosperms are of prime benefit as sources of food and cover for wildlife. Pines, for example, furnish nutritious seeds for many birds and edible foliage and twigs for browsing mammals. Other gymnosperms of similar significance are spruces, hemlocks, firs, junipers, and joint firs. The seeds of some cycads are eaten by animals; *Encephalartos* seeds are taken in such quantity by baboons in southern Africa that the cycad is threatened with local extinction.

On the other hand, the leaves of pines, cypresses, junipers, yews, and cycads are dangerous to browsing livestock. Poisoning of stock by ingestion of cycads is especially common in parts of Australia, where cycad eradication on ranges has been attempted. Cycad seeds are poisonous to man. The use of cycad-seed and cycad-stem starch for food is, therefore, dangerous unless the poisonous substances are removed or made harmless by special treatment. In areas where cycads are used as food plants, they have been implicated in the high incidence of certain neurological disorders. The attractive seeds of yews, with their scarlet fleshy covering and hard toxic kernel, have caused death in man.

Oils and tannins

Certain gymnosperms, among them spruces, pines, junipers, firs, hemlocks, and arborvitaes, are the source of essential (volatile) oils much used industrially as scents in soaps, air fresheners, disinfectants, pharmaceuticals, cosmetics, and perfumes. These oils, obtained by distillation, are used primarily for their pleasing aromas but also, in certain cases, for their odour-fixative or antiseptic properties. Tannins, basic to the manufacture of leather from animal skins, are derived from many kinds of plants including, among the gymnosperms, hemlocks and spruces, which have a tannin-rich bark.

Natural resins, once much used commercially (especially for the manufacture of varnishes), are now of greatly reduced importance. The best known gymnospermous resin is kauri copal, from *Agathis australis* of New Zealand, obtained largely by digging pieces of resin from the ground in which they have become buried. Baltic amber, a "fossil" resin, was produced by a species of pine now extinct. Among the most important oleoresins (mixtures of resin and essential oil) are the turpentines, derived from pines. Distillation of the oleoresin yields oil of turpentine (the "turpentine" of commerce) and rosin, which have many industrial uses. The turpentine, or "naval stores," industry is well developed in the southeastern United States and in parts of Europe and Asia. Gymnosperms other than pines that yield turpentines include the balsam fir (source of Canada balsam), spruces, and the European larch.

Although many gymnosperms have local medicinal uses, the only ones of commercial importance are certain of the joint firs, the natural source of the alkaloid drug ephedrine, used to treat certain respiratory afflictions.

Extinct gymnosperms—the seed ferns, the cordaitaleans, and the early conifers—of Carboniferous times (280,000,000 to 345,000,000 years ago) contributed greatly to the formation of coal. The lush vegetation built up thick layers of peatlike material that, after deeper burial and compression over millions of years, became coal.

Although most gymnosperms are not considered to be weeds—plants growing where man does not want them—some may be so called under certain conditions. The value of some western United States rangelands has been lowered by invasion by pinyon pines and junipers, which have replaced more desirable forage vegetation. Pines and junipers have a marked tendency to invade abandoned fields, making the re-use of these lands for crops difficult. The aggressiveness of pines, in fact, may enable them to encroach upon vegetation that, for various reasons, is considered more valuable than pine-dominated vegetation.

Junipers are alternate hosts for the fungus that causes

Figure 1: *Diversity of form among gymnosperms.*

cedar-apple rust disease of apple trees and other members of the rose family. White pines (*Pinus*) of North America are seriously affected by the fungus that causes white-pine blister rust; gooseberries and related *Ribes* species are the alternate hosts.

Among the plants whose roots harbour nitrogen-fixing micro-organisms (*i.e.*, micro-organisms that can render atmospheric nitrogen usable by green plants) are the cycads. Although the significance of cycads in the nitrogen cycle is not known, in areas where these plants are abundant they have certainly played a role in the maintenance of the nitrogen supply in the soil.

The Christmas-tree industry is dependent upon various kinds of gymnospermous trees, including Douglas firs,

firs, pines, junipers, and spruces, harvested from natural stands or from plantations.

Conservation uses

In erosion control, gymnosperms—especially conifers—are valuable in both natural and planted vegetation. Pines, araucarias, podocarps, cryptomerias, and larches are much used for reforestation purposes. The role of forests, including those of gymnosperms, in the protection of watersheds is of the greatest importance. Junipers, spruces, Douglas firs, and *Callitris* are much planted in shelterbelts and windbreaks.

NATURAL HISTORY

Distribution and abundance. Gymnosperms are widely distributed, occurring on all continents except Antarctica. They are characteristic especially of temperate latitudes; most of those in the tropics occur in mountains rather than in lowlands. Eurasia has more gymnosperm species than any other continent—about 340. North America has about 150. Africa, South America, and Australia have about 50 species each. Approximately two-thirds of the species of gymnosperms are native in the Northern Hemisphere and about one-third in the Southern. Of the 67 genera, 35 are restricted to the Northern Hemisphere and 20 to the Southern. Three genera of cycads (*Cycas*, *Macrozamia*, and *Zamia*), the joint firs, the gnetums, and seven genera of conifers (*Agathis*, *Dacrydium*, *Juniperus*, *Papuacedrus*, *Phyllocladus*, *Pinus*, and *Podocarpus*) have ranges that cross the Equator. Thirty-nine genera of gymnosperms are restricted to the Old World, 11 to the New World; 17 occur in both.

The genus of gymnosperms that occupies the greatest area is *Juniperus*, the junipers, the range of which extends over much of the Northern Hemisphere from the Arctic to tropical mountains and into the Southern Hemisphere in East Africa. Other genera of wide distribution in North America and Eurasia are *Abies* (firs), *Larix* (larches), *Picea* (spruces), and *Pinus* (pines). The southern genus occupying the greatest area is *Podocarpus*, found from Mexico to southern South America and in Africa, Madagascar, southeastern Asia, Indonesia, Australia, New Zealand, and many South Pacific islands.

In contrast to these widely distributed genera are many of limited distribution—*e.g.*, *Sequoia*, confined to California and Oregon; *Sequoiadendron*, to California; *Microcycas*, to Cuba; *Saxegothaea*, to Chile and Patagonia; *Stangeria*, to southern Africa; *Bowenia*, to northeastern Australia; *Microcachrys*, to Tasmania; *Neocallitropsis*, to New Caledonia; and *Taiwania*, to Taiwan.

Gymnospermous trees reach more northerly latitudes than do angiospermous trees. On the fringes of the Arctic (*i.e.*, along the continental "tree line") in North America and Eurasia are only two kinds of trees, spruces and larches, both gymnospermous. Gymnosperms grow at almost the highest altitudes reached by vascular plants. A joint fir has been found at 5,350 metres (about 17,500 feet) in Kashmir.

Gymnosperms, especially the conifers, are dominant plants in vegetation in many parts of the world but mainly in the Northern Hemisphere. The coniferous forest of greatest extent is the so-called boreal forest in northern North America and northern Eurasia south of the Arctic. South of the boreal forest—in mountains of the north temperate zone—are also extensive forests of conifers, as in the Rocky Mountains, the Alps, and the Himalayas. Conifers are the dominant forest trees in many parts of the southeastern United States. Genera well represented in these Northern Hemisphere coniferous forests include *Picea*, *Pinus*, *Abies*, *Larix*, *Tsuga*, *Juniperus*, and *Cedrus*.

Gymnosperms of the Southern Hemisphere

In the Southern Hemisphere, forests dominated by conifers are of much less extent than in the Northern. Mention must be made of the kauri forests of New Zealand (*Agathis*) and the Parana "pine" forests of southern Brazil (*Araucaria*). Many of the Southern Hemisphere conifers grow in mixed forests with various hardwood trees. They may be major elements of such forests, as in certain Australian rain forests (*Araucaria*, *Agathis*, *Podo-*

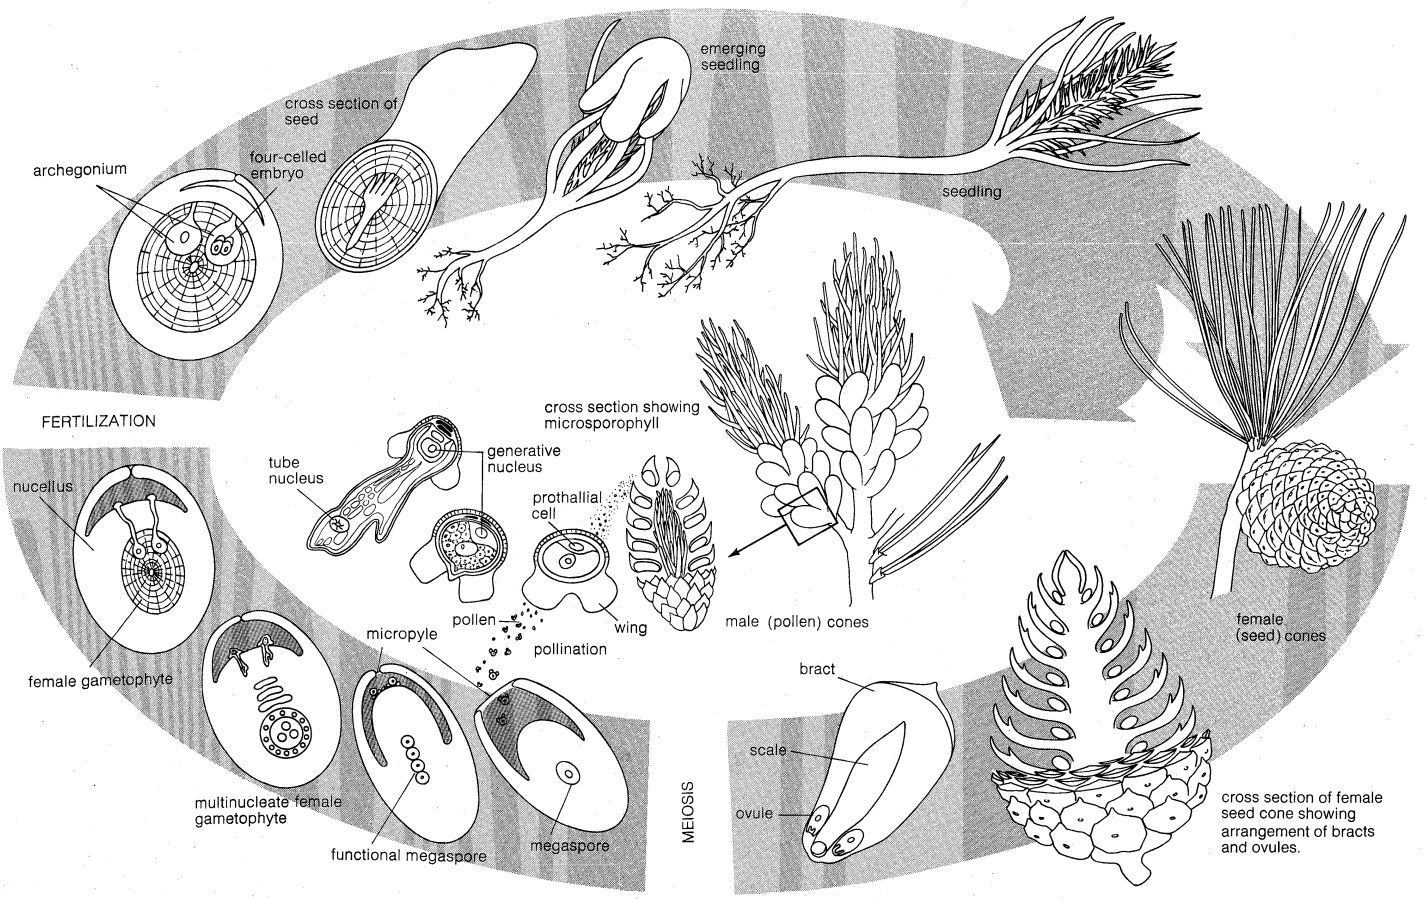

Figure 2: Life cycle of a representative gymnosperm (pine).

carpus) and in the Knysna Forest of South Africa (*Podocarpus*).

Gymnosperms other than conifers that may form a conspicuous feature of the landscape are cycads, as in parts of Australia and southern Africa, and the joint firs, which may be conspicuous in grasslands, as in parts of the southwestern United States.

It is of interest that gymnosperms are almost never dominant in vegetation as a result of superiority in numbers of species present but only in the size and conspicuousness of the plants; for example, in the boreal forest, which is dominated by relatively few species of pines, firs, spruces, and larches, the angiosperms (and frequently the thallophytes as well) are represented by many more species than are the gymnosperms.

Certain kinds of gymnosperms were more widely distributed in geologic times. Ginkgoes, for instance, once occurred in both the Eastern and the Western Hemispheres. The sole surviving species, *Ginkgo biloba*, or maidenhair tree of China, may well have been saved from extinction by being taken into cultivation by man. It is ironic that this survivor from ages past should be one of the most pollution-resistant trees for use in cities. Cycads, once distributed from the Arctic to the Antarctic, are now restricted to a few regions in the tropics and subtropics. As a group they seem to be on the way to extinction. The dawn redwood, *Metasequoia*, once grew in North America and Eurasia. It was abundant in North America from the Upper Cretaceous to the Miocene (from 26,000,000 to about 70,000,000 years ago). Indeed, the genus was first known from fossil remains. Not until the mid-1940s was the dawn redwood discovered to be still in existence, in a remote region of China, the surviving remnant of a once-widespread type.

Generalized life cycle. The life cycle of gymnosperms is typified by the pine (Figure 2). All gymnosperms exhibit an alternation of generations between an asexual phase—the sporophyte—and a sexual phase—the gametophyte. The sporophyte is the tree, with its roots, trunk, branches, leaves, and cones; it produces spores, which develop into gametophytes. The gametophytes—male and female—are microscopic and produce gametes, the egg and sperm. The fertilized egg then develops into a sporophyte.

Cone development

Pollen and seed strobili (cones) are produced on the same tree. In the pollen sacs (microsporangia) of the pollen cones, many cells, called microsporocytes, undergo meiotic cell division, which halves the chromosome number from diploid (24 in *Pinus*) to haploid (12). From each microsporocyte, four haploid microspores are produced. Each microspore ultimately develops into a pollen grain. A pollen grain, at time of shedding, is four-celled: it contains two degenerating prothallial cells, a generative cell, and a tube cell. Pollen grains are wind-borne and may be so abundant as to colour the soil surface yellow or to form a yellow scum on pools and ponds in the vicinity of pine trees. They are carried to the seed cones, where they sift down between the scales and come into contact with the ovules (immature seeds).

Each scale of the seed cones bears on its upper surface near the axis two ovules. Each ovule consists of a central portion, the megasporangium (nucellus), wrapped in a covering, the integument. At the tip of the ovule is an opening, the micropyle, facing the axis of the cone. A single megasporocyte develops within the megasporangium, enlarges, and undergoes meiotic cell division. All but one of the resulting haploid cells disintegrate. The remaining cell, the megaspore, then grows into the female gametophyte within the confines of the megasporangium. At maturity, this gametophyte is a small multicellular (probably 2,000 or more cells) structure that produces usually two to six archegonia at the end of the gametophyte nearest the micropyle. Each archegonium produces one egg.

Pollen grains that have been carried to the ovule adhere to the pollination drop, a drop of fluid exuding from the micropyle. The grains float through this drop or are drawn by its evaporation into a chamber between the integument and the megasporangium. There the grains germinate, each producing a pollen tube that grows through the megasporangium to an archegonium, where it discharges two non-motile sperm. The pollen tube with its sperm constitutes the male gametophyte.

Following fertilization of the egg, the embryo begins to grow. The ovule enlarges to become the seed; the seed coat develops from the integument. At the time of seed dispersal, the embryo consists of an axis bearing several seed leaves, or cotyledons (average of eight in *Pinus*). The lower end of the axis is the radicle, which gives rise to the primary root; the upper end is the plumule, which gives rise to the upper part of the stem and the first leaves of the seedling. The embryo is surrounded by nutritive tissue produced by the female gametophyte. Although usually more than one archegonium—each with its egg—is produced by the gametophyte and usually more than one egg is fertilized, normally only one embryo develops in the seed.

Pollination

The conifers rely on wind for pollination, but at least some cycads, some joint firs, and *Welwitschia* may be pollinated by insects. Agents of dispersal of gymnospermous seeds are several, especially wind and animals. Seeds that are dispersed by wind are mostly provided with wings, as in pines, larches, and kauris. Animal-dispersed seeds, sought by animals (especially birds and mammals) as a food source, include seeds of cycads, gnetums, yews, and podocarps, all of which have a fleshy edible covering. The seeds of bald cypresses are carried by water. Those of junipers are spread by animals, particularly birds, that feed on the berrylike cones.

FORM AND FUNCTION

Diversity in size and structure. Perhaps 60 percent of the gymnosperm species are trees; most of the remainder are shrubs. Some gnetums are vines with twining stems. Many cycads look like palms; others resemble ferns. Joint firs are densely branched shrubs; like many other plants of desert regions, they bear very small leaves. The most bizarre of gymnosperms—and of all plants—is *Welwitschia mirabilis* of southwestern Africa. The top of its turnip-shaped stem barely emerges from the soil, seldom more than 45 centimetres (about 1½ feet); frequently it is almost buried. From the exposed portion of the stem, which may reach 60 centimetres (two feet) in diameter, grow two leathery leaves, one on either side, that persist for the life of the plant, becoming as much as 300 centimetres (about 10 feet) long. As they age, the leaves rest on the ground, eventually splitting lengthwise into ribbons. Mature *Welwitschia* plants have been likened to giant octopuses sunning themselves on desert sands.

Probably the smallest gymnosperm is the Cuban cycad *Zamia pygmaea*, which grows only five to eight centimetres (about two to three inches) tall. The conifer *Dacrydium fonkii* of Chile is a shrub less than 30 centimetres (12 inches) tall. The world's bulkiest gymnosperms—and among the tallest and oldest plants—are the sequoias of California, the trunks of which may be nearly 12½ metres (almost 40 feet) in diameter at ground level. One, said to be the "largest living organism," is the General Sherman Sequoia, which contains more wood than any other single tree. The tallest gymnosperms are the redwoods of California, several of which have exceeded 112 metres (365 feet) high. The oldest gymnosperm—and the oldest trees—are bristlecone pines growing in California's White Mountains.

Most gymnosperms are evergreen plants, retaining their leaves for more than one year. Exceptions are the ginkgo and several conifers, including the larches, dawn redwood, and bald cypresses, which lose their leaves after a single growing season. Most gymnosperms have simple leaves; only the cycads have compound leaves—*i.e.*, leaves divided into leaflets.

Leaf diversity

In form, the leaves are highly varied. Those of cycads resemble the leaves of palms or ferns. The leaves of ginkgo are fan-shaped in outline and, unique among living gymnosperms, are dichotomously veined (*i.e.*, the veins fork equally and repeatedly). The leaves of gnetums, with their veins forming a network, are strikingly similar to those of many angiosperms. The leaves of

conifers show a wide range of form difficult to classify. Three main forms may be recognized: needlelike, scalelike, and broad. Needlelike leaves are long and narrow; they may be round, 3- or 4-angled, or flattened in cross section. Representative needle-leaved conifers are pines, spruces, firs, larches, hemlocks, cedars, and Douglas firs. Scalelike leaves are relatively small, flat, and more or less triangular in outline (at least at the tip); they often overlap like fish scales. Representative scale-leaved conifers are junipers, arborvitaes, sequoia, cypresses, and *Chamaecyparis*. The broad leaves of certain conifers are similar in outline to the leaves of some angiosperms; the flat blades may be up to 30 centimetres (12 inches) long and five centimetres (two inches) wide, with the margins curving out from the leaf base and meeting at the leaf tip. Such leaves are typically thick, even leathery, and may have one vein (the midrib) or several veins running more or less parallel to each other. Broad-leaved conifers include the kauris, araucarias, and podocarps.

The arrangement of the leaves may be spiral ("alternate"), opposite, or whorled (like the spokes of a wheel). In many cases crowding of the leaves or their small size obscures the arrangement. The leaves of some conifers are dimorphic; *i.e.*, of two distinct forms. In pines, for example, the primary leaves are small and papery, hardly leaflike; they constitute the overlapping scales easily seen in the terminal buds. In many pines the bases of these primary leaves remain on the branches behind the needles, or secondary leaves.

The joint firs and *Phyllocladus* are unique among gymnosperms in that their main photosynthetic organs are not leaves but stems. The leaves of the joint firs are rudimentary, whitish to brownish, opposite or whorled scales found at the joints of the green stems. In *Phyllocladus* the leaves are the minute scales found along the edges of the strikingly leaflike, flattened, green branchlets (cladodes).

Living gymnosperms produce pollen and seeds in separate conelike structures, or strobili. These two kinds of strobili may be borne on different plants, as in cycads, yews, ginkgo, joint firs, and *Welwitschia*, or on the same plant, as in most conifers.

The pollen (or "male") cones range in size from those of some junipers, about two millimetres (less than ⅛ inch) long, to those of some cycads, which may reach 80 centimetres (30 inches) in length and 20 centimetres (eight inches) in diameter. Each pollen cone consists of a number of scales (microsporophylls) spirally arranged on a central axis. Each scale bears on its under surface (*i.e.*, the surface toward the base of the cone) two or more microsporangia, or pollen sacs. The hanging pollen strobili of the ginkgo bear little resemblance to cones but look like the catkins of oaks.

Seed cone size

The seed (or "female") cones, especially those of conifers, are familiar objects. The largest cones of any plant, living or extinct, are the seed cones of certain cycads. Those of the Australian *Macrozamia denisonii* may be nearly 100 centimetres (40 inches) long and weigh 38 kilograms (about 84 pounds). The cones of the African *Encephalartos caffer* may weigh slightly more. Among the conifers, the largest cones are the seed cones of the sugar pine (*P. lambertiana*) of far western United States, which reach 50 centimetres (20 inches) in length. The smallest seed cones, those of certain junipers, are only four to five millimetres (3/16 inch) in diameter. The scales of conifer seed cones may be papery or woody and distinct, as in spruces and pines, or they may be fleshy and fused together, the cone being berrylike, as in junipers.

In some gymnosperms (including some conifers) the seeds are borne in fruitlike structures. Those of the ginkgo hang, either singly or in pairs, on long stalks, whereas those of yews, podocarps, *Torreya*, and *Cephalotaxus* occur singly among the leaves. In their commonly fleshy outer covering and hard, stonelike interior, these fruits bear a structural resemblance to plums.

The strobili of many living gymnosperms are simple in that the central axis bears only one kind of structure—sporophylls. Such is the case in the pollen cones of conifers, the pollen strobilus of the ginkgo, and both kinds of cones of cycads. In contrast, the seed cones of conifers such as pines are compound. The central axis bears two kinds of structures, (1) bracts and (2) scales, that morphologically are not sporophylls but are greatly modified lateral shoots. Each scale arises from the axil (upper angle) of a bract and bears one to many seeds on its upper surface (toward the apex of the cone). The pollen strobili and the seed strobili of joint firs, gnetums, and *Welwitschia* are also compound.

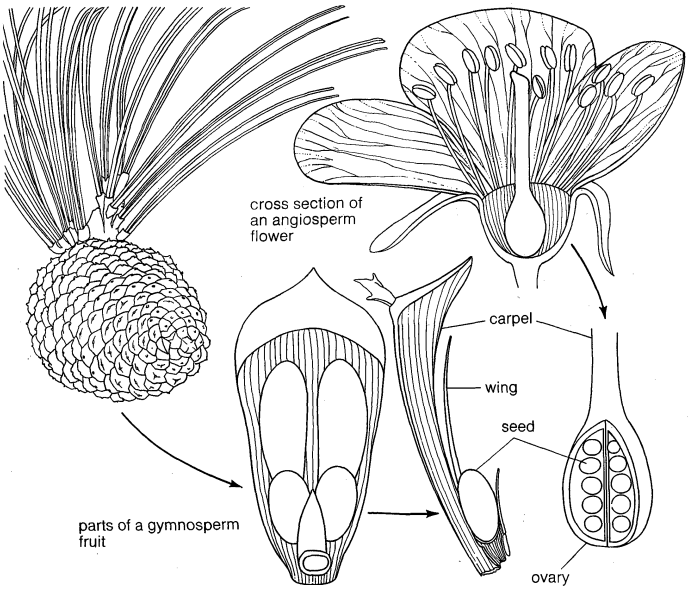

Figure 3: Comparison of gymnosperm cone and angiosperm flower; the seed and the carpel in gymnosperms and angiosperms.
From G. Simpson et al., *Life, An Introduction to Biology;* © 1965 by Harcourt Brace Jovanovich, Inc., reproduced with permission.

Distinguishing characteristics. The major distinguishing feature of the gymnosperms is their so-called naked seeds, which are borne, more or less exposed to the air, on the surface of cone scales or on stalks among the leaves (Figure 3). In contrast, the seeds of angiosperms are borne within fruit tissue that develops from the ovary and sometimes other parts of a flower. Pollen grains are carried to the ovules (immature seeds) and germinate there, extensions called pollen tubes penetrating the ovular tissues. The pollen grains of angiosperms, on the other hand, do not come into contact with the ovules but are carried to the receptive portion (stigma) of a flower, where they germinate; the pollen tubes grow through considerable tissue before they reach the ovary and finally penetrate ovular tissues.

Distinction between gymnosperms and angiosperms

Additional features that distinguish gymnosperms from angiosperms are: (1) the absence of vessels from the wood (except in Gneticae); (2) the lack of specialized cells called companion cells in the phloem; (3) the many-celled or many-nucleated (500 or more) female gametophyte; (4) the presence of archegonia in the female gametophytes (except in *Gnetum* and *Welwitschia*); and (5) the lack of double fertilization (unique to angiosperms). All gymnosperms are woody plants; many angiosperms are not.

Many plant morphologists would restrict the term flower to the reproductive structure of angiosperms, which typically consists of such parts as sepals, petals, stamens, and pistils. On the basis of this restriction, there are no flowers in gymnosperms.

EVOLUTION AND PALEONTOLOGY

The first seed plants (except for two genera of carboniferous lycopsids) were gymnosperms from the Late Devonian Period (about 345,000,000 years ago). It was not until the Lower Cretaceous—some 240,000,000 years later—that the first indisputable angiosperm fossils were laid down. The gymnosperms reached their greatest development during the Mesozoic, when they were the dominant plants in the world. During the Cretaceous,

however, they began to dwindle, and by the end of that period (65,000,000 years ago) their dominant position had been taken over by the angiosperms.

Many morphologists recognize three major groups among the gymnosperms. They are treated as the subdivisions Gneticae, Cycadicae, and Pinicae in this article.

The smallest of the subdivisions is the Gneticae, the gnetophytes, with three genera strikingly different from each other and from other gymnosperms: *Ephedra* (40 species), *Gnetum* (30 species), and *Welwitschia* (one species). The characteristics that unify the Gneticae are (1) the presence of vessels in the wood; (2) the compound strobili, both pollen and seed; (3) the presence of a "perianth," superficially corolla- or calyx-like, associated with the pollen-producing and seed-producing structures; and (4) the presence of two integuments, the inner one produced into a long, tubular micropyle. The Gneticae possess certain features that make them appear remarkably "angiosperm-like." Formerly, the group was even regarded by some morphologists as ancestral to the flowering plants. The Gneticae are isolated and have almost no fossil record. Essentially nothing is known about the origin and evolution of the group.

The remaining two subdivisions of the gymnosperms, the Cycadicae (cycadophytes) and the Pinicae (coniferophytes), are distinguished from each other largely on features of leaves, wood, and seeds. They represent lines that have been in existence since the Devonian (395,000,000 years ago) and that have left a rich fossil record. Whether the lines had a common origin is speculative. Both the Cycadicae and the Pinicae contain orders that have become extinct.

The cycadophytes are characterized generally by often unbranched trunks; by relatively soft and loose wood; by large, mostly compound leaves; and by radially symmetrical seeds. Three of the four orders are extinct. The oldest of these, Cycadofilicales, or seed ferns, ranged from the Devonian to the Jurassic (395,000,000 to 190,000,000 years ago), being most abundant in the Carboniferous. Typical seed ferns, appearing much like present-day tree ferns, had relatively slender stems and large, fernlike leaves that often were much divided. Their seeds were borne either on foliage leaves or on specially modified leaves (megasporophylls). Although seed ferns have many fernlike features, the origin of these plants from true ferns has not been demonstrated. Seed ferns and true ferns may well have arisen from a common ancestral group, one not exactly in either category. It is unsettled whether the seed ferns gave rise to the other orders of Cycadicae.

The second extinct order of the Cycadicae, the Caytoniales, was discovered in 1926. It lasted from the Triassic Period to the Lower Cretaceous Period (136,000,000 years ago). The plants had palmately compound leaves with three to six leaflets. Their ovules were clustered in pouches (cupules) that were paired along an axis. Similarities between the cupules, with their contained seeds, and the angiosperm carpel led to much speculation that the Caytoniales were actually primitive angiosperms, a view now discarded. The order is now regarded as a seed fern offshoot that left no descendants.

Cycadeoids and cycads

The third extinct order of the Cycadicae, the Bennettitales (cycadeoids), ranged from the Triassic to the end of the Lower Cretaceous. The Mesozoic Era was once often called the "Age of Cycads," but it has been demonstrated that much of the cycad-like foliage of that time belonged in reality to cycadeoids, cycad-like plants with either branched or unbranched stems and compound (or, rarely, simple) leaves. They were remarkable for the structure of their strobili, which contained either seed-producing or pollen-producing structures, or both, subtended by numerous leaflike bracts. When both kinds of structures were present, the pollen organs were arranged along the axis, and the ovules were clustered at the end of the axis. The occurrence of both kinds of structures on the same axis originated with the cycadeoids. The ovules were frequently long-stalked; among them were leafy tabs called interseminal scales. All in all the strobilus was superficially quite flowerlike. The hypothesis that these bisexual strobili were ancestral to the bisexual angiosperm flower, however, is now rejected. The origin of cycadeoids is problematical. Relationship to the seed ferns has been suggested but is not yet supported by conclusive evidence. The cycadeoids have no modern descendants.

The one surviving order of Cycadicae is the Cycadales (cycads), with nine genera and about 100 species. Palmlike or fernlike plants with pinnately compound leaves, they typically bear both their pollen and their seeds in cones on different individual plants. *Cycas* is exceptional in bearing the seeds on the margins of leaflike structures (megasporophylls) not grouped into cones. The oldest cycads are from the early Triassic. The present-day species are a remnant of a group that has been in existence for at least 200,000,000 years. The sperm of cycads are motile and are the largest known in vascular plants; as much as 300 microns long, they are barely visible to the unaided eye. The cycads possibly evolved from the seed ferns, but their origin is uncertain.

The final subdivision of the gymnosperms is the Pinicae (coniferophytes), which are characterized by branching stems, relatively dense wood, relatively small simple leaves, and bilaterally symmetrical seeds. One of the four orders, Cordaitales, is extinct. Ranging from the Devonian to the Permian (395,000,000 to 280,000,000 years ago), the cordaitaleans reached their greatest development in the Upper Carboniferous (about 300,000,000 years ago), when they formed great forests of tall, stately trees with a crown of branches near the summit of the trunk. The leaves were strap-shaped and had dichotomous (forking) veins. The pollen-bearing and seed-bearing structures, though separate, were constructed similarly. A slender axis bore two rows of bracts. In the axil of each bract was a budlike organ consisting of scalelike appendages spirally arranged on an axis. Those appendages that were terminal in each bud bore either pollen sacs or ovules. Little is known concerning the origin of the Cordaitales. They and the seed ferns may have arisen from the same stock. The Cordaitales are probably ancestral to the conifers and the ginkgo.

The ginkgo

The Ginkgoales, the second order of Pinicae, were once almost cosmopolitan in distribution. The sole living representative, *Ginkgo biloba*, is now widely planted as a street tree. It can well be called a "living fossil": leaves identical with those of modern ginkgoes have been found in Triassic deposits (200,000,000 years old). The oldest members of this order are from the Lower Permian. The Ginkgoales include branching trees with strap-shaped (fossil members only) or fan-shaped leaves that may be deeply divided. The veins of the leaves are dichotomous. The pollen strobili are catkin-like; the ovules are borne in groups of two to 10 (paired in the modern species) on long, branched, or almost unbranched axes. The sperm are motile. The origin of Ginkgoales is uncertain, but it may lie with some cordaitalean stock.

The third order of Pinicae, the Taxales (taxads), includes five living genera with about 20 species. Although frequently placed with the conifers, the Taxales have been a distinct group as far back as their fossil record goes—about to the Triassic. The best known living taxads are the yews. Members of the order have small, needlelike leaves. The pollen is produced in small cones. The ovules are solitary and terminal on short shoots. Each seed is arillate; *i.e.*, it arises from a juicy, cuplike structure. The origin of Taxales is unknown.

The final order of gymnosperms, the Coniferales (conifers), is the largest and most widespread at the present time. It contains almost 50 genera and about 570 species in six families. The fossil record of conifers extends back well into the Carboniferous. The Petrified Forest of Arizona represents the remains of a coniferous forest of Mesozoic times, with trees that may have resembled present-day araucarias. Conifers are trees or shrubs, with typically small, simple leaves. Both kinds of reproductive structures are borne in cones; the pollen cones are simple, and the seed cones are compound. The early conifers bear a close similarity to the Cordaitales and may have arisen from them.

CLASSIFICATION

Distinguishing taxonomic features. Traditionally the gymnosperms have been classified together in one large group (with rank of division, subdivision, or subclass, depending on the classification scheme used) equal in rank to the angiosperms. Such classification places great weight on one attribute of these plants—the naked seeds. In contrast, some classification schemes divide the gymnosperms into two to four groups, each equal in rank to the angiosperms. Such classification de-emphasizes the importance of the naked seeds but places great weight on the many basic differences among the various major kinds of gymnosperms.

Annotated classification. The classification adopted in this article—after Armen Takhtajan, a Soviet botanist—is no more "correct" than several others. The definitive classification of so large and diverse a group as the gymnosperms will perhaps never be achieved—mainly because each scheme presented depends upon individual and varying interpretations of data.

About 50 of the genera of gymnosperms have fewer than a dozen species; of these, 25 are monotypic (*i.e.*, having but one species). The two largest genera are *Podocarpus*, with about 80 species, and *Pinus*, with about 95. Groups marked with a dagger (†) are extinct and known only from fossils.

DIVISION PINOPHYTA (GYMNOSPERMAE) (gymnosperms)
Woody plants; low shrubs to tall trees. Ovules naked, not enclosed in an ovary; female gametophyte with 500 or more cells (or nuclei) and (except in *Gnetum* and *Welwitschia*) producing definite archegonia; wood without vessels (except in Gneticae); phloem without companion cells; double fertilization lacking.

Subdivision Cycadicae
Palmlike to fernlike plants. Leaves mostly compound. Living species with motile sperms; wood without vessels, relatively soft and loose; microstrobili, when present, simple; ovules with one integument; seeds radially symmetrical.

†*Order Cycadofilicales*

Extinct fernlike plants from the Devonian to the Jurassic. Leaves mostly relatively large, pinnately compound to decompound. Ovules borne separately along the margins or on the surface of pinnately compound megasporophylls, the latter commonly like the foliage leaves, not in strobili; microsporophylls pinnately compound, not in strobili.

†*Order Caytoniales*

Extinct plants from the Triassic to the Cretaceous. Leaves of 3–6 palmately arranged leaflets with netted venation; ovules borne in clusters within pouches on pinnately compound megasporophylls, these not in strobili; microsporophylls pinnately compound, not in strobili.

†*Order Bennettitales*

Extinct cycad-like plants from the Triassic to the Cretaceous. Leaves entire or pinnately compound; stomates of characteristic structure (syndetocheilic); ovules borne singly and terminally on simple megasporophylls, these in strobili, the cluster of megasporophylls sometimes subtended by microsporophylls; microsporophylls pinnately compound.

Order Cycadales

Palmlike or fernlike plants from the Triassic to the present. Dioecious; leaves pinnately or bipinnately compound; stomates of characteristic structure (haplocheilic); ovules borne on usually simple megasporophylls, these in strobili (except in *Cycas*); microsporophylls simple, in strobili. One modern family, Cycadaceae, with 9 genera.

Subdivision Pinicae
Plants with simple leaves, not like those of palms or ferns; living species without motile sperm (except in *Ginkgo*); wood without vessels, relatively dense; microstrobili simple; ovules with 1 integument; seeds bilaterally symmetrical.

Order Ginkgoales

Trees from the Permian to the present. Leaves strap-shaped or fan-shaped in general outline, with dichotomous venation; ovules 2–10, terminal on branched or almost unbranched axes; microstrobili catkin-like; sperm motile. One living species, *Ginkgo biloba*, the ginkgo or maidenhair tree, native to China, widely cultivated; many fossil representatives.

†*Order Cordaitales*

Extinct trees from the Devonian to the Permian. Leaves strap-shaped; strobili of two kinds, both simple, each kind bearing sterile appendages below and fertile appendages above.

Order Coniferales

Trees or shrubs from the Carboniferous to the present. Leaves needlelike, scalelike, or "broad"; microstrobili simple, conelike; megastrobili compound, often conelike. Six modern families: Pinaceae, with 10 genera; Taxodiaceae, 10; Cupressaceae, 19; Podocarpaceae, 7; Cephalotaxaceae, 1; and Araucariaceae, 2. Cosmopolitan.

Order Taxales

Trees or shrubs from the Triassic to the present. Leaves needlelike; microstrobili conelike; ovules solitary and terminal on short shoots, arillate. One modern family, Taxaceae, with 5 genera, in North America, Eurasia, Indonesia, and the Philippines.

Subdivision Gneticae
Plants with simple leaves, not like those of palms or ferns. Living species without motile sperm; wood with vessels; microstrobili compound; ovules with 2 integuments.

Order Ephedrales

Densely branched shrubs with jointed stems and minute scalelike leaves; strobili conelike. One family, Ephedraceae, with a single genus, *Ephedra*, of North and South America and Eurasia. *Ephedra* pollen from the Eocene, *Ephedra*-like pollen from the Permian; otherwise no fossils.

Order Welwitschiales

Plants with a large, turniplike, mostly subterranean stem and two thick, leathery, elongated leaves that persist for the life of the plant, becoming split lengthwise into ribbons; strobili conelike. One family, Welwitschiaceae, with a single species, *Welwitschia mirabilis*, of Angola and southwest Africa. *Welwitschia*-like pollen from the Permian; otherwise no fossils.

Order Gnetales

Woody vines or, less frequently, shrubs or trees. Leaves opposite, with netted venation, in aspect angiosperm-like; strobili not conelike. One family, Gnetaceae, with a single genus, *Gnetum*, of tropical South America, Africa, southeastern Eurasia, and Indonesia. No fossil record.

Not included in the above outline is the Pentoxylales, an order of Jurassic gymnosperms whose position is uncertain.

Critical appraisal. As an indication of the taxonomic instability of this rather diverse group of plants, taxonomic categories above the family level have long been and continue to be subjected to change. The yews (Taxales) in particular are problematically included by some authorities as a part of the order Coniferales. On the basis of the solitary position of the ovule and of the long, distinct fossil record, however, it seems best to give them separate and equal rank as an order.

Although most families of gymnosperms are well established taxonomically, a few present certain problems which have not yet been resolved. The family Cupressaceae, because of its diverse structure of cones (fleshy and dry) and its variety of foliage (scale and awl leaves), is difficult to sort out at the generic level. The Cupressaceae is frequently included as a subfamily in the pine family (Pinaceae), as is the Taxodiaceae. The family Podocarpaceae is equally diverse and presents a complex collection of plants which are not easily separable into genera. Although close to the conifers, the family Cephalotaxaceae eludes exact placement.

Gyroscope

A gyroscope consists of a rapidly spinning wheel set in a framework that permits it to tilt freely in any direction; that is, to rotate about any axis. The momentum of such a wheel causes it to retain its attitude when the framework is tilted; from this characteristic derive a number of extremely valuable applications. A properly mounted gyroscope on board a ship retains its original orientation while the ship rolls, and so can give an accurate measurement of the extent of the roll. Quite similarly the spin axis of a free gyroscope can be orientated to point to true north and will remain pointed in that direction regardless of changes in direction of the vehicle (except for the effects of the rotation of the Earth and the convergence of the meridians when steaming in an easterly or westerly direction; these will be discussed below).

Gyroscopes are used in such instruments as compasses and automatic pilots on board ships and aircraft, in the steering mechanisms of torpedoes, in antiroll equipment on large ships, and in inertial guidance systems.

HISTORY

A 19th-century French scientist, J.-B.-L. Foucault, is responsible for giving the name gyroscope to a wheel, or rotor, mounted in gimbal rings; that is, a set of rings that permit it to turn freely in any direction. Foucault's original experiment, conducted in Paris in 1852, was carried out with a pendulum rather than a rotor. He constructed a pendulum consisting of a very long wire suspending a heavy weight, then drew a line on the floor directly under the pendulum's arc. As spectators watched, the pendulum appeared to move slowly, until its arc was discernibly at variance with the line on the floor. What was actually happening was that the pendulum was remaining faithful to its original arc, with respect to space, but the Earth, and the floor of the exhibition hall, were moving under it due to the Earth's rotation. The phenomenon, startling in 1852, is still a feature of many science museums.

Foucault's experiment

Foucault later carried out a similar experiment using a rotor mounted with three supporting frames (Figure 1, left) and demonstrated that the spinning wheel maintained its original orientation in space regardless of the Earth's rotation. The word gyroscope he derived from the Greek *gyros*, "rotation," and *skopein*, "to view"; a method of "viewing" or demonstrating the rotation of the Earth.

The ability of a gyroscope to maintain its orientation as shown by Foucault suggested its use as a direction indicator, but it was not until 1910 that the first workable gyrocompass was installed, on board a German warship. In the year 1911 Elmer A. Sperry, in the United States, marketed a gyrocompass, and a little later one was produced in Britain. Few fundamental modifications have been made to these early types, and the basic design can still be recognized despite changes in outer appearance. Although it was designed to indicate direction on either land or sea, the gyrocompass has found its greatest application in marine navigation. The rotors of modern gyros are driven by a self-contained electric motor.

In 1909 Sperry built the first automatic pilot using the direction-keeping properties of a gyroscope to keep an aircraft on its course. The first automatic pilot for ships was produced by the Anschütz Company in Kiel, Germany, and installed in a Danish passenger ship in 1916.

A three-frame gyroscope (Figure 1, left) was used, also in 1916, in the design of the first artificial horizon for aircraft. This instrument indicates roll (side to side) and pitch (fore and aft) attitude to the pilot and is especially useful in the absence of a visible horizon.

One of the earliest uses of a gyroscope in a missile was to steer a torpedo on a straight course. The spin axis was aligned parallel to the longitudinal axis of the torpedo. Any angular error in the course was detected by the gyroscope and used to initiate rudder deflection to correct the error.

Early use in torpedoes

Conventional three-frame gyroscopes are used in ballistic missiles for automatic steering together with two-frame gyroscopes (Figure 1, right) to correct turn and pitch motion. Beginning in the 1930s German engineers were pioneers in this field and their knowledge was used in the design of guidance systems for the V-1 flying bomb, a pilotless aircraft, and the V-2 rocket, an early ballistic missile.

In 1915 the Sperry Company, employing a two-frame gyroscope, devised a gyrostabilizer to reduce the rolling of ships, thus minimizing damage to cargo, reducing stresses in the hull structure, and adding to the comfort of passengers. It was installed in about 40 ships, the most notable installation being a massive three–rotor gyrostabilizer in the 41,000-ton Italian liner "Conte di Savoia" in 1933. The roll-reducing action of this type of gyrostabilizer was quite effective and was independent of the speed of the ship. It had a number of disadvantages including its weight (over 600 tons), cost, and space requirements (each rotor was 13 feet in diameter and rotated 900 revolutions per minute), and it was not installed on later ships, in part because of the introduction by Japanese shipyards of an underwater fin-type ship stabilizer in 1925. At first manually controlled, the fins were later given automatic controls, using small gyroscopes.

The ability of a gyroscope to define a direction in space with a great degree of accuracy, used in conjunction with sophisticated control mechanisms, led to the development during World War II of stabilized gunsights, bombsights, and platforms to carry guns and radar antennas aboard ships.

Missiles and vehicles that depend on accurate navigation or on guidance or both are equipped with inertial navigation systems. Such a system requires a small platform, stabilized by gyroscopes to an extraordinary degree of precision. It was not until the 1950s that this type of platform was perfected, following work in the design of air-supported bearings and flotation gyroscopes (see below *Inertial navigation systems*).

From W. Burger and A. Corbet, *Ship Stabilizers, Their Design and Operation in Correcting the Rolling of Ships* (1966); Pergamon Press Limited

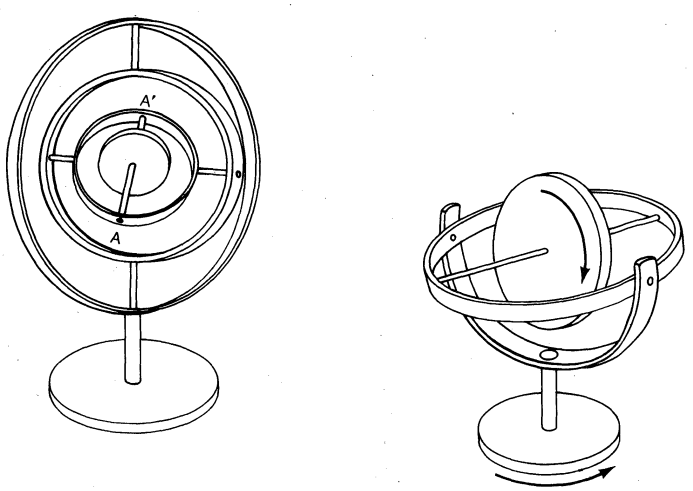

Figure 1: (Left) Three-frame gyroscope and (right) two-frame gyroscope.

BASIC OPERATING PRINCIPLES

Gyroscopic inertia and precession. If the base of a three-frame gyroscope model (Figure 1, left) is held in the hand with the rotor spinning and turned about any of the three axes, the rotor axle will continue to point in the original direction in space. This elemental property is known as gyroscopic inertia or rigidity in space. If the speed of the wheel decreases, the gyroscopic inertia gradually disappears; the rotor axle begins to wobble and ultimately takes up any convenient position. Rotors with a high speed and a concentration of mass toward the rim of the wheel display the strongest gyroscopic inertia. It is apparent, therefore, that gyroscopic inertia depends on the angular velocity and the moment of inertia of the rotor, or on its angular momentum. The rotor wheel is subject to the laws of rotational motion and inertia in that a freely rotating body will maintain a fixed direction in space, and the rotor tends to preserve its angular mo-

mentum, or spinning action, unless acted on by some external force.

The consequence of gyroscopic inertia is that to the observer on Earth the spin axis of a gyroscope makes an apparent movement over a period of time, although this apparent motion merely reflects the revolution of the Earth about its axis. There is one exception to this, that when the spin axis points toward the polar star, there is no movement of the spin axis with respect to the observer's surroundings, as the axis is parallel to the Earth's axis and points toward the celestial poles. This apparent movement is shown in Figure 2, in which, at position 1, the spin axis is parallel to the horizontal plane and the end of the spin axis, marked A, points due north. As the direction of the Earth's rotation is counterclockwise when seen from above the North Pole, the relative direction of the A-end will change through northeast, east, southeast, south (position 5), etc., and this clockwise movement will continue until, at the end of one period of rotation of the Earth (23 hours 56 minutes) the rotor and spin axis revert to their original position with respect to the observer on the Earth's surface. While this is taking place, the A-end is apparently tilting upward between positions 1 and 5 and tilting downward between positions 5 and 1. The change in azimuth (direction) of the spin axis is often referred to as "drifting"; sometimes "tilting" and "drifting" are collectively called "apparent wander."

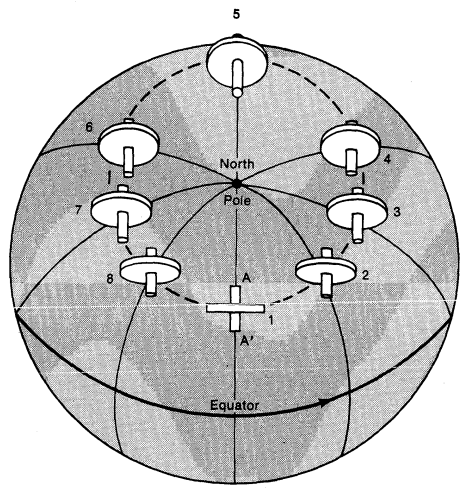

Figure 2: Apparent movement of the spin axis of a gyroscope (see text).
From W. Burger and A. Corbet, *Ship Stabilizers, Their Design and Operation in Correcting the Rolling of Ships* (1966); Pergamon Press Limited

Figure 2 is drawn for a gyroscope location in a latitude north of the Equator. A similar figure drawn for a latitude south of the Equator would reveal a counterclockwise drifting. In fact, the spin axis, whatever the place, would follow the movement across the heavens of a reference star at which it is pointing.

Precession. If, while the rotor of a model of a three-frame gyroscope (Figure 1) is spinning, a slight vertical downward or upward pressure is applied to the horizontal gimbal ring at A or A′, the rotor axle will move at right angles in a horizontal plane. But no movement will take place in the vertical plane; in fact, a definite resistance to motion is felt in this direction. Similarly if a sideways pressure is applied at the same point, the rotor axle will tilt upward or downward. This second property is called "precession." A precession or angular velocity in the horizontal plane is caused by the application of a couple—*i.e.*, parallel forces equal and opposite, in the vertical plane perpendicular to that of the rotor wheel. Precession is the tendency of the rotor's axis to move at right angles to any perpendicular force applied to it.

Determining the direction of precession

A convenient way to remember the direction in which precession takes place is to regard the force as though it acted at a single point on the rim of the wheel. This point will not move in response to the force; instead, a point 90° beyond in the direction of the wheel's rotation will move away.

To explain this strange anomaly—that cause and effect seem to operate in planes at right angles to one another—consider a particle m at the upper and lower rim of the rotor; *i.e.*, at those places where the vertical couple exerted on the axle has maximum effect (Figure 3). It will

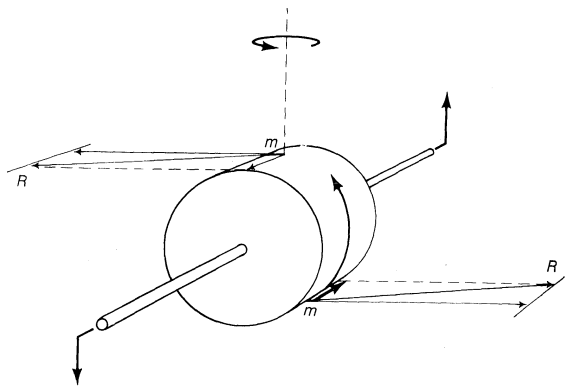

Figure 3: Precessional effect (see text).

then be apparent that the particle m is subject to two velocities, one relatively very large owing to the speed of the rotor, the other small as a result of the applied couple. The directions of the velocities are mutually at right angles, and the particle m will try to move in the direction of the resultant R of the two velocities; in other words, the rotor will acquire an angular velocity in the horizontal plane.

Sensing angular displacement. *Three-frame gyroscopes.* The unrestrained or "free" three-frame gyroscope has little practical use, because its spin axis is subject to tilting and drifting owing to the rotation of the Earth. In the controlled state, however, it is widely used. The term control of a gyroscope implies that the spin axis, by small continuous or intermittent applications of torque, is made to precess so that it points at—or, rather, oscillates around—a reference mark fixed in relation to coordinates on the Earth rather than in relation to space.

Controlled gyroscopes fall into three categories: north-seeking, directional, and gyrovertical.

The north-seeking gyro is used for marine gyrocompasses. In the settling (or normal) position the spin axis is kept horizontal and in the plane of a meridian.

The directional gyroscope is used in aircraft and is sometimes called a self-levelling free gyroscope corrected for drift. With its spin axis horizontal it has directional properties but does not automatically seek the meridian plane.

The gyrovertical has its spin axis vertical and is used to detect and measure angles of roll and pitch.

Those three types of three-frame gyroscopes are known as displacement gyroscopes because they can measure angular displacements between the framework in which they are mounted and a fixed reference direction—the rotor axis.

Two-frame gyroscopes. The following simulated experiments conducted on the two-frame gyro (Figure 1, right) illustrate the basis of important applications.

If, with the rotor spinning and the spin axis in the horizontal plane, the base is rotated uniformly in the horizontal plane, a definite resistance owing to gyroscopic inertia will be felt. At the same time, the spin axis will begin to precess in the vertical plane and will continue to do so until the axis is vertical and all gyroscopic inertia disappears.

If the experiment is then repeated as before, except that while the base is being turned in the horizontal plane, the precessional movement of the spin axis is stopped by the application of force to the end of the axle where it terminates in the gimbal ring, the resistance to the turning motion of the hand due to gyroscopic inertia will cease to exist. In effect, the precession process will have been reversed. A vertical downward force applied to the end of the rotor axle, then, introduces a torque (twisting force) that makes the base precess at the same rate and in

the same direction as the turning movement of the hand. The quicker the base is turned, the greater the force that must be exerted on the axle to stop the precession. Two important conclusions may be drawn from this experiment: (1) There is resistance to the turning motion of the base if, and only if, the spin axis precesses. (2) The force needed to stop the precession is directly proportional to the rate of turning of the base. This force can be exerted by a spring arrangement in which the gyroscope (Figure 4A) measures the rate of change of azimuth and is used in aircraft and ships as a "rate-of-turn indicator."

From W. Burger and A. Corbet, *Ship Stabilizers, Their Design and Operation in Correcting the Rolling of Ships* (1966); Pergamon Press Limited

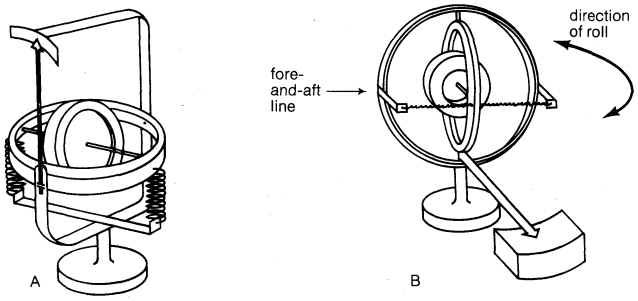

Figure 4: *Rate gyroscopes.*
(A) Velocity gyro for measuring rate of turn. (B) Velocity gyro for measuring rate of roll.

Rate-of-turn indicator

The greater the rate of turn of the vehicle—and base—the larger will be the force required to stop the precession in the vertical plane. Additional force results in more spring extension and greater angular displacement between the gimbal ring and the horizontal plane. The deflection of the instrument's pointer, when it is steady, therefore, gives an indication directly proportional to the rate of change of azimuth.

The gyroscope illustrated in Figure 4B is used on ships to measure the rate of roll; *i.e.*, the angular roll velocity. The spin axis is positioned at right angles to the fore-and-aft line and the rate of roll is measured about this line.

These gyroscopes are called velocity or rate gyroscopes as distinct from "displacement" gyroscopes. The sensitive or input axis of a rate gyroscope is at right angles to its spin axis, while with a displacement gyroscope the spin axis is directly equivalent to the sensitive or input axis. A north rate gyroscope combined with a north displacement gyroscope, therefore, have their spin axes at right angles to each other.

GYROSCOPIC DEVICES

Stabilizer for ships. The main components of a ship stabilizer are a set of fins and the gyroscopes. The fins protrude from the ship's hull and are so operated that the forward motion of the ship produces a tilt in one direction on one fin and in the opposite direction on the other fin. When properly controlled, therefore, these fins oppose the rolling motion. The gyroscopes sense the vertical angular displacement and the roll velocity and provide the proper control for the fins.

A block diagram of a stabilizer is shown in Figure 5. The installation is designed in accordance with the principle that the movement of the fins is a total function of the roll angle, the roll velocity, the roll acceleration, the amount of helm (rudder), and the natural list of the vessel. The "natural-list" unit operates if the vessel develops a permanent list. It generates a signal that makes it possible for the stabilizers to act about a mean position corresponding to the ship's permanent list, thus avoiding power waste in attempting to correct the list. Provision is made, however, to switch out this signal if desired; when this is done the stabilizer will operate to correct the list.

The roll-angle sensor is a vertical displacement gyroscope; the roll-velocity sensor, a rate gyroscope; and the accelerometer is an electrical device that measures the roll acceleration by determining the rate of change of movement of the roll velocity gyroscope. All the signals are combined and amplified to actuate a hydraulic relay unit, the output arm of which controls the action of a hydraulic pump that in turn controls the movement of the hydraulic fin-tilting mechanism.

Inertial navigation systems. Neither position nor velocity can be sensed directly by an inertial system. An acceleration (change of velocity), however, can be detected by an accelerometer and this can be used to determine the position of a ship, aircraft, or space vehicle. Basically this navigational system comprises three components: the platform, the gyroscopic frame, and the computer.

The platform. The accelerometers, mounted with their input axes mutually at right angles, are carried on a platform. Two accelerometers measure acceleration in the horizontal plane—the requirement for surface navigation. For space navigation an additional accelerometer measures acceleration in the vertical plane. Each of the acceleration signals can be converted into distance travelled by determining, first, the total change in velocity which, added to the known initial velocity, gives the vehicle velocity; and, second, the total change in position that, added to the known initial position, yields the present vehicle position. The platform on which the accelerometers are grouped must be stabilized; generally the stabilization is about the local vertical with the input axis of one accelerometer pointing north, one axis pointing east, and the third, when required, pointing vertically.

The gyroscopic frame. This component is responsible for the stabilization of the platform. Three rate gyroscopes are fitted in the frame with their three input axes mutually perpendicular. Two of the gyroscopes provide the horizontal alignment of the platform—an essential requirement to eliminate the influence of accelerations due to gravity—while the third is responsible for the north–south alignment.

The three components of the system

Pitch, roll, and yaw are detected by the three gyroscope input axes. The gimbal deflection of each of the gyroscopes is converted into a signal voltage that, when amplified, drives a servomotor which, via a gear train, rotates the frame back to its original position. Stabilization of the platform is achieved by coupling it to the gyroscopic frame.

Tilting and drifting due to the Earth's rotational movement (Figure 2) are also detected by the gyroscopic frame. If the platform is to be kept horizontal and north-south stabilized, torque signals must be applied to the roll and pitch servomotors to offset the precession caused by tilting, as well as to the azimuth servomotor to eliminate the precession caused by drifting.

The rate gyroscopes are not spring-restrained. Instead, "flotation gyroscopes" in which the precession is opposed by the viscous drag of a liquid are employed. The opposing torque is therefore proportional to the precession rate, instead of the precession displacement, as in a spring-restrained gyroscope.

The computer. This unit performs the necessary calculations. Specifically, it applies certain corrections to the

From W. Burger and A. Corbet, *Ship Stabilizers, Their Design and Operation in Correcting the Rolling of Ships* (1966); Pergamon Press Limited

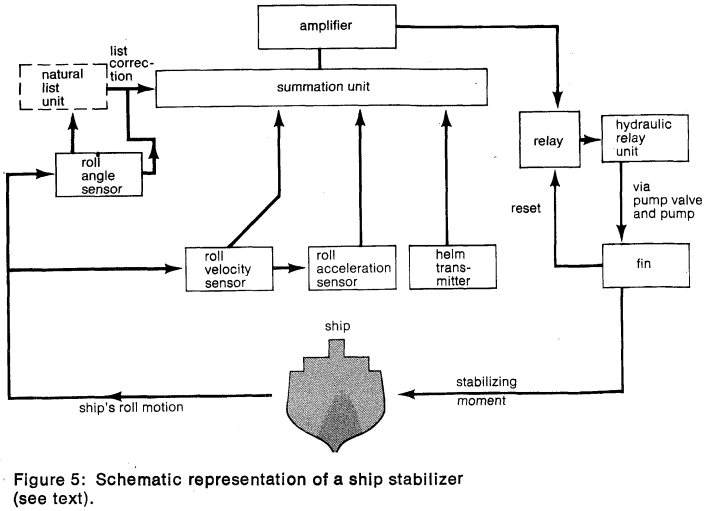

Figure 5: Schematic representation of a ship stabilizer (see text).

acceleration; integrates acceleration to velocity and velocity to distance; computes latitude and longitude; and converts geocentric latitudes into geographic latitudes. If the inertial system is used for inertial guidance in space navigation, then the computer also compares the vehicle's position with the destination or target position to provide steering commands and compares the vehicle's velocity vector (both direction and magnitude) with the programmed velocity vector to provide rocket steering and engine cutoff commands.

Stabilized platforms and gunsights. The inertial type of platform is extremely small and must be stabilized to an extraordinary degree of precision, but the method of stabilization used for gun platforms is essentially the same. The gyroscopes that detect platform displacement are not as accurate and expensive as the flotation type. The servomechanisms must be capable of exerting considerable torque and are often electrohydraulic in character.

The gyroscopic gunsight revolutionized aerial gunnery. The sight fitted on the gun contains a rate gyroscope capable of measuring angular velocities in two planes at right angles to each other. The gyroscope sight can be thought of as the three-frame gyroscope shown in Figure 1, left, constrained by horizontal and vertical springs to the inner and outer gimbal, respectively. Instead of a mechanical spring arrangement, variable-strength magnetic fields are used to constrain the rotor axle in azimuth and elevation. The field coils for producing the horizontal component of this magnetic field are coupled to the range finder. The current through the vertical field coils is adjusted so that the field depends on the drop of the projectiles due to gravity. The sensitivity of the gyroscope in the horizontal plane is a function of the sighting range; in the vertical it is a function of the gravity drop.

Use of magnetic fields

In operating this gunsight, often called a "predictor" sight, the gunner holds the image of a central dot over the target while the gun is automatically aimed by the gyroscope at the place where the target will be at the expiration of the time of flight of its projectile.

Aircraft instruments. The three primary gyroscopic instruments fitted to the flight panel are a rate-of-turn indicator, a directional gyroscope, and an artificial horizon. The rate-of-turn indicator was discussed above. Such gyroscopes may be driven by electric motors or by air jets.

Directional gyroscope. This instrument forms a standard reference for the pilot and navigator. It is a three-frame gyroscope with its spin axis in the horizontal plane. As soon as tilt develops, a switch is closed between the gyroscope housing and the vertical gimbal ring and a motor introduces a torque in the horizontal plane that causes the gyroscope to precess back toward the horizontal. The reduction of azimuth drift to its lowest practical limit is achieved by an adjustable "latitude" balance nut attached to one side of the inner gimbal ring. Random precessional errors (real wander) are always present because of wear of bearings, variation of temperature resulting in contractions and expansions, and mechanical imperfections. Owing to the convergence of the meridians at the poles, an apparent wander (drift) takes place when an aircraft changes its longitude, except when it is flying along the Equator.

Artificial horizon. The artificial horizon displays the rolling and pitching motion of the aircraft. It consists basically of a three-frame gyroscope with its spin axis vertical and automatic correcting devices to counteract the apparent motion of the spin axis around the celestial pole (the North Pole in celestial coordinates) and any other random precessions.

Other applications. The gyroscope principle has been utilized in many other applications, such as the gyrocompass and gyropilot, and in nonrotating gyroscope devices.

Gyrocompass. A compensated magnetic compass, free from external accelerations, indicates magnetic north, which varies from true north from place to place on the Earth's surface. A gyrocompass, however, when properly adjusted, can be made to indicate true north.

The marine gyrocompass is a three-frame gyroscope with its spin axis horizontal. To achieve the north-seeking and actual location (or meridian-settling) properties of a gyroscope, use is made of the tilting effect of the spin axis when it is not pointing true north. As soon as tilt develops, a pendulum type device introduces torques that precess the spin axis toward the meridian, causing it to describe a spiral with an ever-decreasing radius. When settled (stabilized) the spin axis is maintained in the meridian plane by a precession equal but opposite to the drift at the particular latitude.

Marine gyrocompasses

When there is no tilting effect the marine gyrocompass will lose its directional properties and become useless. This is the case at the poles and also when a vehicle moves due west with a speed equal to the surface speed of the Earth. Because the latter condition can easily exist in an aircraft in the middle and upper latitudes, it cannot be used for air navigation.

Aircraft gyrocompass. Aircraft gyrocompasses are based on automatically monitored directional gyroscopes in which the monitoring device senses the direction of the meridian and ensures that the gyroscope axis is maintained in this direction. The monitoring device consists of a magnetic sensing unit, called the flux valve, and allowance is made for variation in the direction of the Earth's magnetic field.

Gyropilot. The gyropilot—or automatic pilot, as it is usually called—consists basically of three devices, each of which detects disturbances of the aircraft in one plane and corrects for these disturbances by moving the appropriate control: the rudder control for azimuth and sudden change in heading (yaw) disturbances, aileron control for roll disturbance, and elevator control for pitch disturbance.

In the past some gyropilot designs have relied entirely on displacement sensors, but with this system accurate control is not possible. In the later designs rate detection forms the principal reference and displacement detection plays a secondary role. In such designs yaw disturbance is detected by a rate gyroscope and the change in heading is detected, to a lesser degree, by the associated gyrocompass. The two signals are added electronically and cause corrective rudder control to be applied to the rudder servomotor. The roll disturbance is detected by a roll rate gyroscope and to a lesser degree by a roll angle pendulum, which senses displacement. The aileron servo applies corrective action. Pitch disturbance is detected by a pitch rate gyroscope and to a lesser degree by a pitch pendulum. The elevator servo applies corrective action.

Ships' gyropilots primarily use displacement signals from the gyrocompass. Rate signals can be taken from a small generator geared to the displacement shaft of the gyrocompass.

Miscellaneous applications. Extensive use is made of two-frame gyroscopes to measure the rate of turn of a vehicle. Rate gyroscopes are also mounted on theodolites used for orientation of field artillery and other weapons and for surveying. Theodolites, mounted on gyrocompasses, are used in underground mine exploration, since magnetic compasses would be disturbed by metal deposits.

Use with theodolites and field artillery

Two-frame gyroscopes have been used successfully in the stabilization of ships, monorail cars, and two-wheel cars.

Vertical three-frame gyroscopes with pen recorder attachments often are used to analyze rolling and pitching movements of ships and rocking motions of trains.

Gyroscopes without rotors. The word gyroscope means "viewing the rotation," which implies that a rotating wheel is not a necessary part of a gyroscope. All instruments that are able to measure angular velocity relative to axes fixed in inertial space can be called gyroscopes. One example of such a gyroscope is the ring laser. In this instrument a laser beam (see LASER AND MASER) is split by means of mirrors into two beams that are sent in opposite directions around a closed circuit in the horizontal plane. The velocities of the two beams measured relative to the Earth will differ, since one beam travels in the direction of the Earth's rotation (drifting), while the other beam travels against the direction of this component. This leads to a displacement of the two signals with

respect to each other (phase shift), which can be measured when the two beams are recombined. The phase shift is proportional to the rate of turn. Thus, the ring laser measures the drifting due to the Earth's rotational motion and can therefore be classed as a rate gyroscope.

EFFECTS OF PRECESSION

The Earth as a gyroscope. The Earth itself belongs to the class of three-frame gyroscopes and owing to gyroscopic inertia it has maintained its axis in a (nearly) fixed direction. This characteristic, together with the facts that the Earth moves around the Sun in one year and that its axis is inclined to the plane of the ecliptic (the orbit around the Sun) at an angle of about 66½°, explains the changes of season.

The Earth can be thought of as a sphere that bulges toward the Equator. As a result of this equatorial bulge—coupled with the fact that the Earth's axis is not perpendicular to the plane of the ecliptic and the plane of the Moon's orbit—the forces exerted on the Earth by the Moon (and to a lesser degree by the Sun) in general do not pass through the centre of gravity of the Earth. This causes the Earth's axis to precess along a small ellipse with a period of 18⅔ years while at the same time the centre of the ellipse precesses along a circle with spherical radius of 23½° with a period of 26,000 years.

The former motion is called "nutation." The latter motion causes a precession of the equinoxes (the points on the ecliptic where day and night are of equal length), with a mean displacement of 50.26 angular seconds annually.

Satellites. Artificial satellites can be considered part of a spinning wheel and, provided they are not polar satellites (*i.e.*, those that have their orbital planes at right angles to the Equator), the equatorial bulge exerts a pull on the satellite. Since the direction of the pull falls outside the orbital plane, this results in a precessional movement of the satellite's orbit. This precession can be quite considerable; for example, a satellite at a height of 800 kilometres (500 miles) with an orbital inclination of 40° with the Equator and travelling eastward, precesses five degrees toward the west each day.

Moving vehicles. Precessional effects also are experienced in fast-moving motor cars and locomotives. Road and rail engineers must take these factors into account when working out banking angles for curves. Similar problems occur when large rotors, such as steam or gas-turbine rotors, are carried in moving vehicles. The pitching movement of such vehicles can generate precessional effects, resulting in a tendency to yaw.

Projectiles. Gun barrels are rifled to give the projectile a high rate of spin about its fore-and-aft axis. This imparts gyroscopic inertia to the projectile, preventing it from toppling over. Since wind resistance can produce precession, ballistic calculations must take this into account.

BIBLIOGRAPHY. W. BURGER and A.G. CORBET, *Marine Gyro-Compasses and Automatic Pilots*, 2 vol. (1963–64), of special interest to the mariner, but the first four chapters of vol. 1 give a comprehensive account of the basic principles of gyroscopes; *Ship Stabilizers* (1966), ch. 2 offers an interesting and simple approach to the principles of gyroscopes, ch. 3–4 deal with anti-roll devices in general and are easily understandable for the lay reader, while the remainder of the book throws light on the technical and engineering principles embodied in ship stabilizers. *Gyros* in the *Institution of Mechanical Engineers Proceedings*, vol. 179, pt. 3E (1964–65), includes a full account of the history and development of all types of gyroscopes and all instruments related to gyroscopes; most of it can be understood by the reader who does not have a technical background; R.H. PARVIN, *Inertial Navigation* (1962), a well-written book but requiring a fundamental knowledge of mathematics; K.I.T. RICHARDSON, *The Gyroscope Applied* (1954), one of the best books ever written about gyroscopes for the layman.

Haber, Fritz

The German physical chemist Fritz Haber was distinguished not only for his researches, which won him the Nobel Prize, but also for his services to industry and to his country. Haber and the research institute he directed contributed to a wide range of advances in physical chemistry. His most outstanding scientific achievement was his synthesis of ammonia virtually from air and water, which solved the urgent problem of meeting the world demand for nitrogen fertilizer.

EB Inc.

Haber.

Early life

He was born on December 9, 1868, in Breslau, Silesia (now Wrocław, Poland), the son of a prosperous chemical merchant. After the usual classical education of the *Gymnasium*, and student years in Berlin, Heidelberg, and Zürich, he entered his father's business, but his impatient spirit soon led to a break.

Deciding on an academic career, he first took up organic chemical research at the University of Jena, but its orthodox methods gave him little satisfaction. In later years he delighted in telling how chance brought him at the age of 25 to a junior post at the Technische Hochschule of Karlsruhe, where he immediately threw himself with tremendous zest into the teaching of physical chemistry (a subject in which he was essentially self-taught) and into research. His intensive early researches in electrochemistry and thermodynamics soon gained him the position of professor of physical chemistry (1898); his reputation was much enhanced by his timely book *The Theoretical Basis of Technical Electrochemistry* (1898) and especially by *The Thermodynamics of Technical Gas Reactions* (1905), a pioneering work that had considerable influence on teaching and research.

In the first decade of the 20th century the rapidly increasing demand for nitrogen fertilizer greatly exceeded the supply, which still came mainly from Chilean nitrate. The problem of utilizing atmospheric nitrogen for this purpose had become of worldwide concern. Haber developed a method for synthesizing ammonia from nitrogen and hydrogen. By 1909 he had established conditions for the large-scale synthesis of ammonia. The process was handed over to Carl Bosch of the Badische Anilin und Soda-Fabrik AG for industrial development, leading to the Haber–Bosch ammonia process. Haber was awarded the Nobel Prize for Chemistry in 1918.

Director of the Kaiser Wilhelm Institute

In 1911, at the age of 42, he was appointed director of the Kaiser Wilhelm Institute for Physical Chemistry in Berlin, a new research establishment that was to become even more famous than the school he had built up in Karlsruhe. With the outbreak of World War I in 1914, he immediately placed himself and his laboratory at the service of the government, his first concern being to organize the supply of essential war matériel. After the development of trench warfare he was made head of the chemical-warfare service, and his institute became a

major military establishment. He played a leading part in the development of poison gas as a weapon.

The war years were for Haber a period of intense effort motivated by his strong patriotism. He felt the outcome as a personal tragedy. When Germany was required to pay enormous reparations, Haber sought to find a way of extracting gold from seawater. Long efforts ended in 1926 with the conclusion that the gold content of seawater was far less than had been thought. The failure was a bitter disappointment to him, though it had positive results of much scientific value.

After the war Haber's institute became the world's leading centre of research in physical chemistry, with a large and distinguished international staff. All his life he had been an advocate of close relations between science and industry, and he now became a recognized authority in this field; he was active in promoting the national organization of research and in fostering friendly relations with foreign scientists. He was much attracted to Japan and in 1930 established the Japan Institute, with headquarters in Berlin and Tokyo, to promote mutual understanding and cultural interests. He enjoyed the high title of privy councillor (*Geheimer Regierungsrat*) and was an honorary fellow of leading chemical societies.

The breakup of Haber's institute began in 1933, when, with the rise of the Hitler regime and its anti-Semitic policy, this great German chemist became the "Jew Haber." He resigned in 1933 and accepted an invitation to work at Cambridge. After four months he left to spend the winter in Italy, but he suffered a heart attack on the way in Basel and died there on January 29, 1934.

Haber's first wife was Clara Immerwahr, with whom he had one son. In later life he married Charlotta Nathan, with whom he had a son and a daughter.

A striking feature of Haber's life and work was his versatility. He and the institutions he directed contributed in a fundamental way to nearly all the important branches of physical chemistry. In fact, his scientific life reflected the main developments of physical chemistry over a period of 40 years. Furthermore, Haber was strongly imbued with the conviction that the basic purpose of science was the betterment of mankind.

BIBLIOGRAPHY. A biography of Haber, as well as a survey of his scientific work, is J.E. COATES, "Haber Memorial Lecture," *J. Chem. Soc.*, pp. 1642–72 (1939). M. GORAN, *The Story of Fritz Haber* (1967), contains an exhaustive bibliography of writings by and relating to Haber. Of the many works by German authors about Haber, probably the best is ch. 10 of RICHARD WILLSTATTER, *Aus meinem Leben* (1949; Eng. trans., *From My Life*, 1965). Of Haber's own writings, apart from his scientific books and articles, two relate to his life and ideas: *Fünf Vorträge aus den Jahren 1920–1923* (1924); and *Aus Leben und Beruf; Aufsätze, Reden, Vorträge* (1927).

(J.E.Co.)

Habsburg, House of

Also known as the House of Austria, the Habsburgs were one of the greatest of the sovereign dynasties of Europe.

ORIGINS

The name Habsburg is derived from the castle of Habsburg, or Habichtsburg ("Hawk's Castle"), built in 1020 by Werner, bishop of Strasbourg, and his brother-in-law, Count Radbot, in the Aargau overlooking the Aar River, in what is now Switzerland. Radbot's grandfather, Guntram the Rich, the earliest traceable ancestor of the house, may perhaps be identified with a Count Guntram who rebelled against the German king Otto I in 950. Radbot's son Werner I (died 1096) bore the title count of Habsburg and was the grandfather of Albert III (died *c.* 1200), who was count of Zürich and landgrave of Upper Alsace. Rudolf II of Habsburg (died 1232) acquired Laufenburg and the "Waldstätte" (Schwyz, Uri, Unterwalden, and Lucerne), but on his death his sons Albert IV and Rudolf III partitioned the inheritance. Rudolf III's descendants, however, forming the House of Habsburg–Laufenburg, sold Laufenburg and other districts to Albert IV's descendants before dying out in 1408.

AUSTRIA AND THE RISE OF THE HABSBURGS IN GERMANY

Albert IV's son Rudolf IV of Habsburg was elected German king as Rudolf I in 1273. It was he who, in 1282, bestowed Austria and Styria on his two sons Albert (the future German king Albert I) and Rudolf (reckoned as Rudolf II of Austria). From this date the age-long identification of the Habsburgs with Austria begins (see AUSTRIA, HISTORY OF). The family's custom, however, was to vest the government of its hereditary domains not in individuals but in all male members of the family in common, and though Rudolf II renounced his share in 1283, difficulties arose again when King Albert I died (1308). After a system of condominium had been tried, Rudolf IV of Austria in 1364 made a compact with his younger brothers that acknowledged the principle of equal rights but secured de facto supremacy for the head of the house. Even so, after his death the brothers Albert III and Leopold III of Austria agreed on a partition (Treaty of Neuberg, 1379): Albert took Austria, Leopold took Styria, Carinthia, and Tirol.

King Albert I's son Rudolf III of Austria had been king of Bohemia from 1306 to 1307, and his brother Frederick I had been German king as Frederick III (in rivalry or conjointly with Louis IV the Bavarian) from 1314 to 1330. Albert V of Austria was in 1438 elected king of Hungary, German king (as Albert II), and king of Bohemia; his only surviving son, Ladislas Posthumus, was also king of Hungary from 1440 and of Bohemia from 1453. With Ladislas the male descendants of Albert III of Austria died out in 1457. Meanwhile the Styrian line descended from Leopold III had been subdivided into Inner Austrian and Tirolean branches.

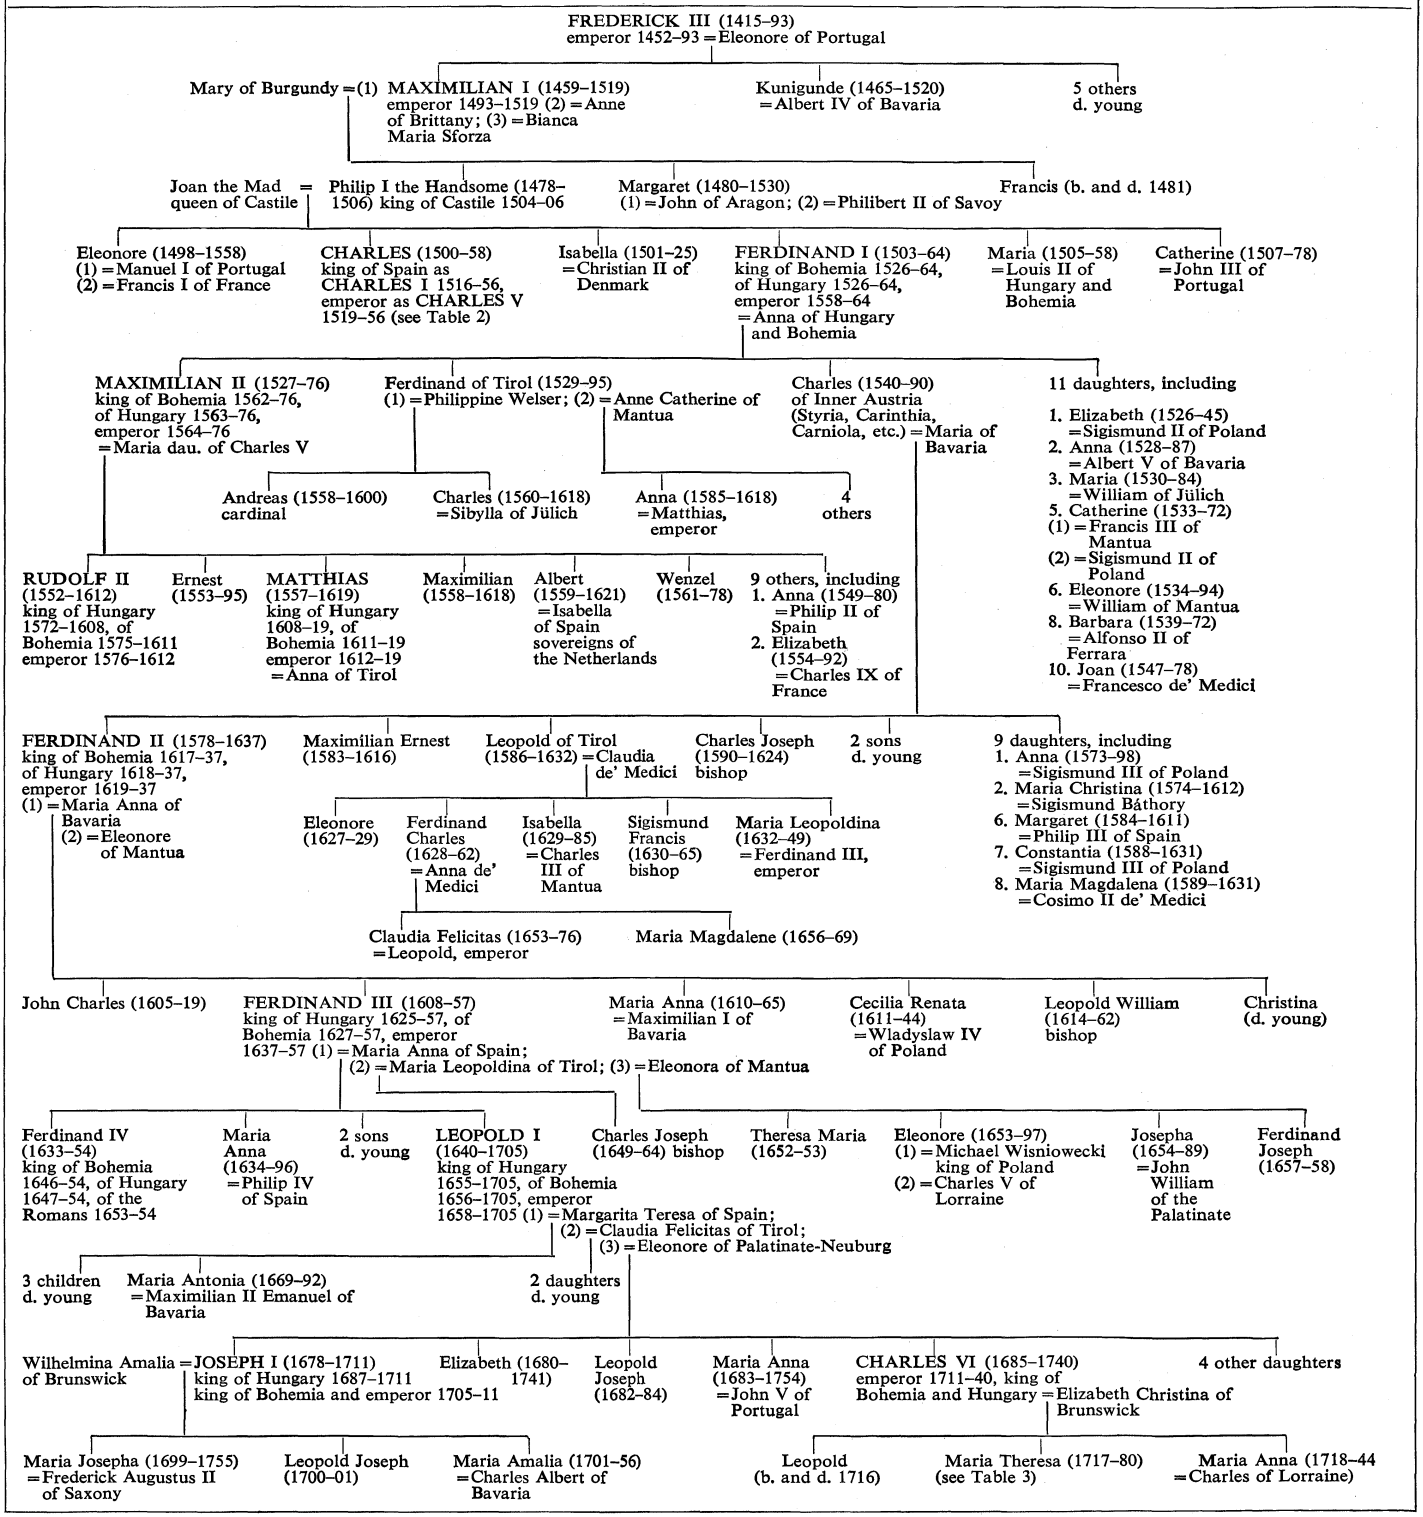
Frederick V, senior representative of the Inner Austrian line, was elected German king in 1440 and crowned Holy Roman emperor, as Frederick III, in 1452—the last such emperor to be crowned in Rome. A Habsburg having thus attained the Western world's most exalted secular dignity, a word may be said about the dynasty's major titles. The imperial title at this time was, for practical purposes, hardly more than a glorification of the title of German king; and the German kingship was, like the Bohemian and the Hungarian, elective. If Habsburg was to succeed Habsburg as emperor continuously from Frederick's death in 1493 to Charles VI's accession in 1711, the principal reason was that the hereditary lands of the Habsburgs, whether within the empire or outside it, formed an aggregate large enough and rich enough to enable the dynasty to impose its candidate on the other German electors (the Habsburgs themselves had an electoral vote only in so far as they were kings of Bohemia).

The emperor Frederick III

For the greater part of Frederick's reign it was scarcely foreseeable that his descendants would monopolize the imperial succession so long as they did. The Bohemian and Hungarian kingdoms were lost to the Habsburgs for nearly 70 years from the death of Ladislas Posthumus in 1457; the Swiss territories, lost in reality from 1315 onward (see SWITZERLAND, HISTORY OF), were finally renounced in 1474; and Frederick's control over the Austrian inheritance itself was long precarious, not only because of aggression from Hungary but also because of dissension between him and his Habsburg kinsmen. Yet Frederick, one of whose earliest acts in his capacity as emperor had been to ratify, in 1453, the Habsburgs' use of the unique title of "archduke of Austria" (first arrogated for them by Rudolf IV in 1358–59), may have had some prescient aspiration toward worldwide empire for the House of Austria: the motto *A.E.I.O.U.*, which he occasionally used, is generally interpreted as meaning *Austriae est imperare orbi universo* ("Austria is destined to rule the world"), or *Alles Erdreich ist Österreich untertan* ("The whole world is subject to Austria"). He lived long enough, in any case, to see his son Maximilian make the most momentous marriage in European history (see below); and three years before his death he also saw the Austrian hereditary lands reunited when Sigismund of Tirol abdicated in Maximilian's favour (1490).

Before explaining what the Habsburgs owed dynastically

Table 1: The Imperial Succession of the Habsburgs, 1493–1740



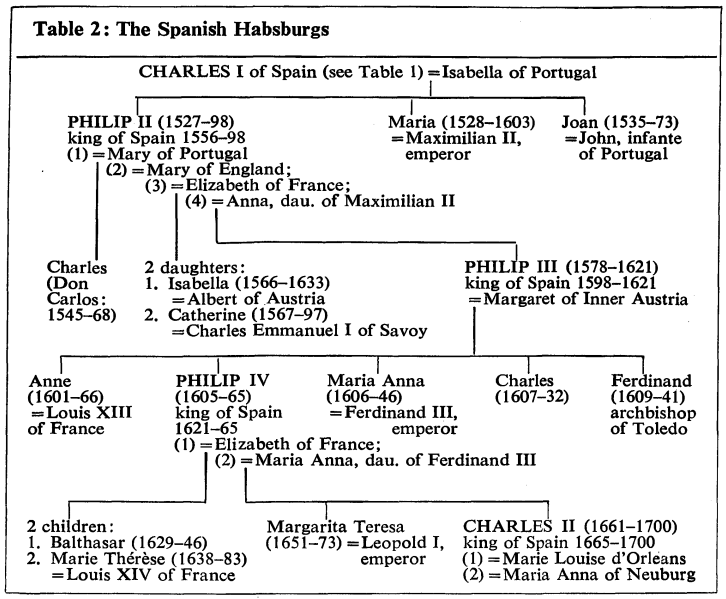
to Maximilian, mention can be made of a physical peculiarity characteristic of the House of Habsburg from the emperor Frederick III onward: his jaw and his lower lip were prominent, a feature supposed to have been inherited by him from his mother, the Mazovian princess Cymbarka. Later intermarriage reproduced the "Habsburg lip" more and more markedly, especially among the last Habsburg kings of Spain.

THE WORLD POWER OF THE HABSBURGS

Even before Frederick III's time the House of Habsburg had won much of its standing in Germany and in central Europe through marriages to heiresses. Frederick's son Maximilian carried this matrimonial policy to heights of unequalled brilliance. First he himself in 1477 married the heiress of Burgundy, Charles the Bold's daughter Mary, with the result that the House of Habsburg, in the person of their son Philip, inherited the greater part of Charles the Bold's widespread dominions: not the duchy of Burgundy itself, which the French seized, but Artois, the Netherlands, Luxembourg, and the County of Burgundy or Franche Comté. Secondly, though he failed after Mary's death in 1482 to secure Brittany also by a similar coup (France frustrated his proxy marriage to the

Maximilian: the Burgundian and Spanish marriages

Table 2: The Spanish Habsburgs



Breton heiress Anne), he procured Philip's marriage, in 1496, to Joan, prospective heiress of Castile and Aragon: thus securing for his family not only Spain, with Naples–Sicily and Sardinia, but also the immense dominions the Spaniards were about to conquer in America. Maximilian's matrimonial achievements were the occasion of the famous hexameter *Bella gerant alii, tu felix Austria nube* ("Let others wage wars: you fortunate Austria, marry").

Since Philip I of Castile died prematurely, his son was already ruler of the Burgundian heritage and of Spain when, in 1519, he succeeded Maximilian as ruler of the Habsburgs' Austrian territories. In the same year he was elected Holy Roman emperor as Charles V.

Charles V

The threat of force as well as an enormous expenditure in bribes was necessary to secure Charles's election. Besides the fact that many of the German princes were reluctant to saddle themselves with so mighty a sovereign, there was the opposition of France, which saw itself already half-encircled, from the northeast clockwise to the southwest, by Charles's possessions. Dating from Maximilian's Burgundian marriage, antagonism between the French kings and the Habsburgs was to persist, to the progressive detriment of the latter, until the middle of the 18th century, and until the second half of the 17th the other European powers would mostly sympathize with France. The Habsburgs in the 16th century were too formidable not to provoke envy and anxiety.

Charles V's responsibilities at the time of his becoming emperor were moreover too great for one man to assume, as he himself could acknowledge: they had to be divided. By the Treaty of Brussels (1522) he assigned the Habsburg-Austrian hereditary lands to his brother, the future emperor Ferdinand I. In 1521 Ferdinand had married Anna, daughter of Louis II of Hungary and Bohemia; and Louis II's untimely death in 1526, after his defeat by the Turks in the Battle of Mohács, prompted Ferdinand to stand as candidate for his succession, to which, despite rivals, he was elected.

The Habsburgs reached the zenith of their power before the end of the 16th century: the duchy of Milan, annexed by Charles V in 1535, was assigned by him to his son, the future Philip II of Spain, in 1540; Philip II conquered Portugal in 1580; and the Spanish dominions in America were ever expanding. There were, however, three faults in the power structure—two of them historical accidents, the third an effect of the Habsburg dynasty's own measures for self-preservation.

External and internal weaknesses in the 16th century

In the first place, the ascendancy of Charles V coincided with the outbreak of the Protestant Reformation in Germany, which was to spread turmoil for decades over Europe from the Netherlands to Hungary. As Charles, from his Spanish upbringing, was imbued with ideas of Catholic uniformity and as his successors, with the exception of the enigmatic Maximilian II, sought also to realize those ideas, religious resistance to the Habsburgs' authority came to aggravate or to camouflage political resistance. At the same time, the papacy, overawed though it was by the Spanish military presence in Italy, did not always subscribe to the Habsburg's special policy for Catholicism.

Secondly, Ferdinand's accession to Hungary meant that the Habsburgs had to bear the brunt of the Ottoman Turkish drive from the Balkans into central Europe, just as Habsburg Spain had to confront Turkish incursions into the western Mediterranean. The great victory of Lepanto (1571), won by a Habsburg bastard, did not end these troubles, which were exploited, against the dynasty, by Hungarian dissidents and, more covertly, by France.

The third flaw in the Habsburg edifice was latent in the 16th century. Mindful of what they had won by marriages, the Habsburgs sought to preclude rival dynasties from turning the tables on them by the same means: to keep their heritage in their own hands, they began to intermarry more and more frequently among themselves. The result, in a few generations, was a fatal inbreeding that brought the male line of Charles V to extinction.

By a series of abdications toward the end of his life Charles V transferred his Burgundian, Spanish, and Italian possessions to his son Philip II and his functions as emperor to his brother Ferdinand, who succeeded him formally as such after his death (1558). This division of the dynasty between imperial and Spanish lines was definitive: Ferdinand's male descendants were Holy Roman emperors until 1740 (for the emperors from Frederick III to Charles VI see Table 1), Philip's were kings of Spain until 1700 (see Table 2). The imperial line was inevitably concerned to maintain its position in Bohemia and to assert itself against the Turks in divided Hungary, because the loss of the two kingdoms would have meant the reduction of its possessions to what the Habsburgs had had hereditarily before Frederick III's time (the Austrian duchies and scattered holdings in Swabia and in Alsace)—a reduction that in turn would have compromised its chances of continuing to be elected to the German kingship. Philip II of Spain remained territorially the greatest sovereign in the Western world until his death in 1598; but the Revolt of the Netherlands (see LOW COUNTRIES, HISTORY OF), which he proved unable to subdue, was an irritation that his English and French enemies did their worst to inflame.

The imperial and the Spanish lines

Cooperation between imperial and Spanish Habsburgs in the 17th century failed to maintain the hegemony that the dynasty had enjoyed in the 16th. For the imperial

line, religious troubles in Germany and in central Europe went on even when the domestic conflict between the insane emperor Rudolf II and his brothers was over (1612); and the Bohemian insurrection of 1618 gave rise to that chain of wars involving the Austrian Habsburgs that, because it was prolonged until 1648, is known conventionally as the Thirty Years' War (*q.v.*). For the Spanish Habsburgs, their truce of 1609 with the Dutch ended in 1621, whereupon the renewed conflict in the Netherlands became merged with the struggles of their Austrian cousins. The Peace of Westphalia (1648) finally abolished Habsburg sovereignty over the northern Netherlands, severely restricted the emperor's authority over the other German princes, and transferred the Habsburg lands in Alsace to France; however the ordinance of 1627, whereby the Bohemian crown had been converted into a hereditary one for the Habsburgs, was permitted to stand.

The Thirty Years' War

France from the late 1620s had made the most of the Thirty Years' War to distress the Habsburgs of both lines, and peace with the imperial line did not prevent France from continuing its war against the Spanish until 1659, when by the Peace of the Pyrenees it obtained Gravelines, most of Artois, and part of Hainaut, together with some places south of Luxembourg.

The challenge of 17th-century France

The next 30 years saw the end of the Habsburg dynasty's claim to European hegemony in any real sense. The aggressions of Louis XIV of France, from 1667 onward, took territory after territory from the Spanish Habsburgs—large parts of Flanders, the rest of Artois, and other areas in the Netherlands, as well as the whole Franche Comté and, in 1684, the stronghold of Luxembourg—and demonstrated at the same time that the imperial Habsburgs, preoccupied as they were with the Turkish assault from Hungary, could not effectively defend the German frontier west of the Rhine. After being saved from the crisis of the Turkish siege of Vienna in 1683, the imperial Habsburgs did indeed obtain one dynastically significant success—the conversion, in 1687, of the Hungarian crown into an hereditary one for themselves—but by this time it was plain to Europe that the most formidable dynasty was no longer the Habsburg but the Bourbon. In the War of the Grand Alliance (1689–97) the rising powers that 100 years earlier had been Habsburg Spain's principal enemies and feeble France's most fluent encouragers, the Dutch and English, led those supporting the Habsburgs against Louis XIV.

Apart from the Bourbon ascendancy, there was a further reason for other powers to watch with jealous solicitude over the fate of Spain. The physical debility of Charles II of Spain was such that no male heir could be expected to be born to him, and the question of his succession was one of great concern to the European powers. Up to 1699 it was understood that his crowns would pass to the electoral prince of Bavaria, Joseph Ferdinand, son of his niece Maria Antonia, daughter of the emperor Leopold I; and this arrangement was generally acceptable because, by transferring the Spanish inheritance to the Bavarian House of Wittelsbach, it would not necessarily upset the balance of power between the imperial Habsburgs and Bourbon France. In 1699, however, when Joseph Ferdinand died, the moribund Charles II's next natural heirs were the descendants (1) of his half-sister, who had married Louis XIV of France, and (2) of his father's two sisters, of whom one had been Louis XIV's mother and the other the emperor Leopold I's. Critical tension developed: on the one hand neither the imperial Habsburgs nor their British and Dutch friends could consent to their Bourbon enemy's acquiring the whole Spanish inheritance; on the other neither Bourbon France nor its British and Dutch enemies wanted to see an imperial Habsburg reunite in one pair of hands most of what the emperor Charles V had had in 1519. Charles II in the meantime regarded any partition of his inheritance as a humiliation to Spain: dying in 1700, he named as his sole heir a Bourbon prince, Philip of Anjou, the second of Louis XIV's grandsons. The War of the Spanish Succession ensued.

The Spanish succession

THE HABSBURG SUCCESSION IN THE 18TH CENTURY

To allay British and Dutch misgivings, Leopold I and his elder son, the future emperor Joseph I, in 1703 renounced their own claims to Spain in favour of Joseph's brother Charles, so that he might found a second line of Spanish Habsburgs distinct from the imperial; but when Joseph I died, leaving only daughters, in 1711, and was succeeded by his brother as emperor (Charles VI) and as ruler of the Austrian, Bohemian, and Hungarian lands, the British and the Dutch lost interest in making him king of Spain and together began serious negotiations with France. Their Treaties of Utrecht (1713), which recognized the Bourbon accession to Spain and to Spanish America, virtually forced the hand of the reluctant Charles, who made peace with France by the Treaty of Rastatt in 1714: out of the whole inheritance of the Spanish Habsburgs, he had finally to content himself with the southern Netherlands and with the former Spanish possessions on the mainland of Italy, together with Mantua (annexed by him in 1708) and Sardinia. Sardinia, however, was exchanged by him in 1717 for Sicily, which the peacemakers of Utrecht had assigned to the House of Savoy. With characteristic obstinacy, Charles remained technically at war with Bourbon Spain until 1720, when an armistice was declared (formal recognition of the Bourbon accession came only in 1725).

Meanwhile the extinction of the Spanish Habsburgs' male line and the death of his brother Joseph left Charles, in 1711, as the last male Habsburg. He had therefore to consider what should happen after his death. No woman could rule the Holy Roman Empire, and furthermore the Habsburg succession in some of the hereditary lands was assured only to the male line. In order, therefore, to secure the indivisibility of his Habsburg inheritance he issued his famous Pragmatic Sanction of April 19, 1713, prescribing that, in the event of his dying sonless, the whole inheritance should pass (1) to a daughter of his, according to the rule of primogeniture, and thence to her descendants; next (2) if he himself left no daughter, to his late brother's daughters, under the same conditions; and finally (3) if his nieces' line was extinct, to the heirs of his paternal aunts. The attempt to win general recognition for his Pragmatic Sanction was Charles VI's main concern from 1716 onward (his baby son died in that year). By 1738, at the end of the War of the Polish Succession (in which he lost both Naples and Sicily to a Spanish Bourbon but got Parma and Piacenza for the Habsburgs in compensation), he seemed to have won his point: Saxony, Bavaria (grudgingly and with an express reservation), Spain, Russia, Prussia, Hanover-England, and finally France (with a reservation about third-party rights) had all, in one way or another, acknowledged the Pragmatic Sanction. His hopes were illusory: less than two months after his death, in 1740, his daughter Maria Theresa had to face a Prussian invasion of Silesia, which unleashed the War of the Austrian Succession. Bavaria then promptly challenged the Habsburg position in Germany; and France's support of Bavaria encouraged Saxony to follow suit and Spain to try to oust the Habsburgs from Lombardy. Great Britain came, late enough, to support Maria Theresa rather out of hostility toward France than out of loyalty to the Pragmatic Sanction.

The Pragmatic Sanction and the Austrian succession

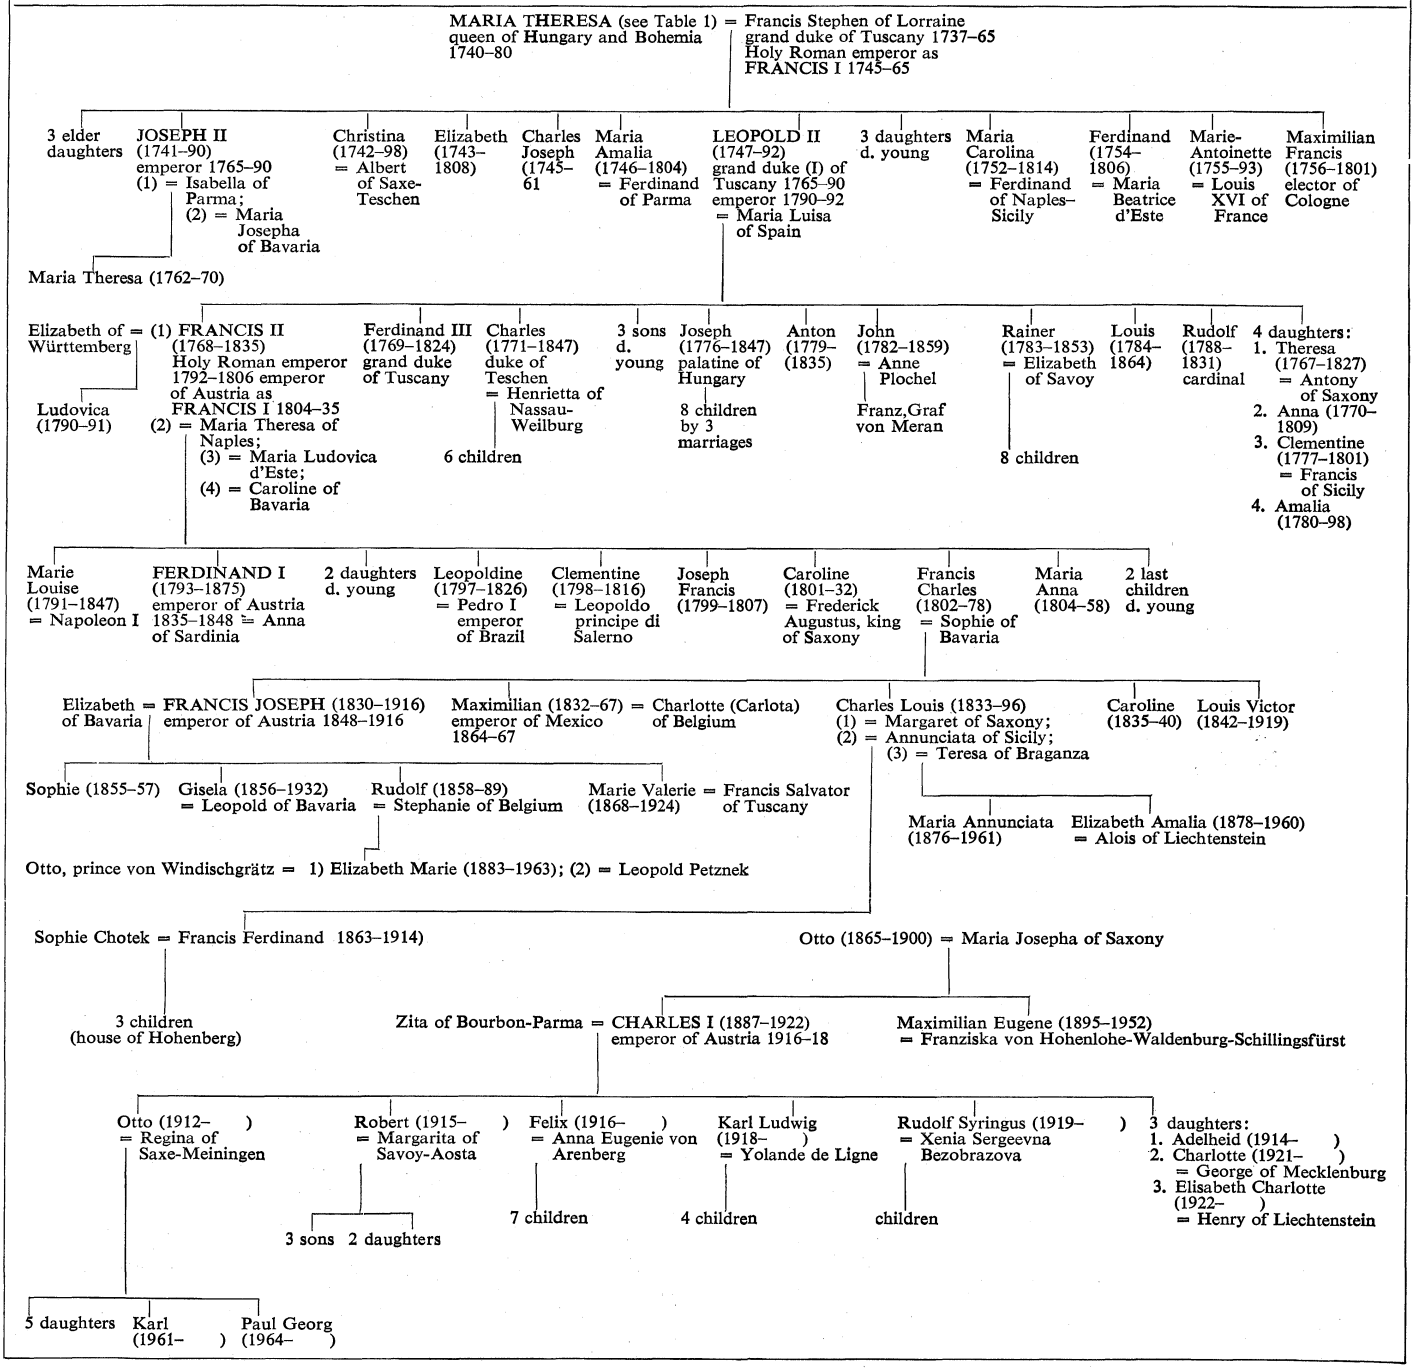
The challenge of Prussia

HABSBURG–LORRAINE

The War of the Austrian Succession cost Maria Theresa most of Silesia, part of Lombardy, and the duchies of Parma and Piacenza (Treaty of Aix-la-Chapelle, 1748) but left her in possession of the rest of her father's hereditary lands. Moreover, her husband, Francis Stephen of Lorraine, who in 1737 had become hereditary grand duke of Tuscany, was finally recognized as Holy Roman emperor, with the title of Francis I. He and his descendants, of the House of Habsburg–Lorraine (see Table 3 below), are the dynastic continuators of the original Habsburgs.

The peace of 1748 did not last long. Prussia was not

Table 3: The House of Habsburg–Lorraine in Austria



satiated by the seizure of Silesia from the Habsburgs, and they in turn were even more determined to recover Silesia than anxious to ensure the protection of their outlying possessions in the Netherlands against the continuing danger of French attack. The so-called Diplomatic Revolution, which preceded the Seven Years' War (*q.v.*) of 1756–63, was the product, basically, of these situations: finding that their former British friends were more interested in conciliating Prussia than in abetting Austro-Russian plans for destroying it, the Habsburgs played their part in the "reversal of alliances" by achieving a reconciliation with France, hitherto their longest-standing enemy. Though the new alliance and the consequent war brought no territorial profit to the Habsburg dynasty, an Austro-French entente was subsequently maintained until 1792: the marriage of the archduchess Marie-Antoinette to the future Louis XVI of France (1770) was intended to confirm it.

To secure their imperial status in Germany against Prussian enterprises, the Habsburgs exerted themselves to consolidate and to expand their central European bloc of territory. For this purpose Tuscany and the Netherlands were practically irrelevant. Tuscany in fact was kept separate from the ancient Habsburg inheritance: when the emperor Francis I died (1765), his eldest son, the emperor Joseph II, became coregent with his mother of the Austrian dominions, but Joseph's brother Leopold became grand duke of Tuscany; and similarly when Leopold succeeded to Joseph's titles (1790), his own second son succeeded to Tuscany as Ferdinand III. Thereafter the Tuscan branch of the Habsburgs remained distinct from the senior or imperial line.

The northeastward expansion of Habsburg central Europe, which came about in Joseph II's, time was a result not so much of Joseph's initiative as of external events: the First Partition of Poland (1772), which gave

him Galicia and Lodomeria, was a Russo-Prussian arrangement disgusting to his conscientious mother, who remembered Silesia; and his subsequent acquisition of Bukovina (1775), geopolitically logical though it was as bridging a gap between his Transylvanian and his new Galician lands, was a side effect of the Russo-Turkish Treaty of Küçük Kaynarca (1774).

Joseph II was considerably more interested in westward expansion, over Bavaria, which would have both strengthened his western frontier strategically and enhanced his status among the German princes politically. Prussia's forceful opposition. however, reduced his gains in the War of the Bavarian Succession to the Innviertel (1779) and frustrated his plan for ceding the Netherlands to the House of Wittelsbach in exchange for Bavaria five years later (1784).

The French Revolutionary and Napoleonic Wars (*q.v.*) brought a kaleidoscopic series of changes. Three were clearly significant for the future of the House of Habsburg: (1) the formal dissolution of the Holy Roman Empire in 1806, in anticipation of which Leopold II's successor Francis II had in 1804 begun to style himself "hereditary emperor of Austria," a title that, as Francis I, he could retain come what might; (2) the definitive renunciation of the southern Netherlands by the Habsburgs in 1797; and (3) the awakening of the spirit of nationalism in the modern sense.

The Austrian Empire

On Napoleon's downfall the Congress of Vienna (1814–15) inaugurated the Restoration, from which the battered House of Habsburg naturally benefitted. Francis I of Austria recovered Lombardy (lost in 1797), Venetia and Dalmatia (both of them acquired in 1797 but lost in 1809), and Tirol (lost also in 1809); Ferdinand III of Tuscany recovered his grand duchy; another Habsburg was recognized as sovereign duke of Modena, because his father, a brother of the Holy Roman emperors Joseph II and Leopold II, had in 1771 married the heiress of the House of Este; and Napoleon's Habsburg consort, Marie Louise, received the duchies of Parma and Piacenza for her lifetime (after which they were to revert to the Bourbons). The territory of Salzburg, which the Habsburgs had acquired in 1803 but lost to Bavaria in 1809, was finally restored to Austria in 1816. Though the Congress of Vienna did not restore Austrian rule over "Western Galicia" (the Habsburgs' share under the Third Partition of Poland in 1795, lost likewise in 1809), a small part of that area, namely the territory of Cracow, was annexed by Austria in 1846.

Nationalism against the dynasty

The history of the House of Habsburg for the century following the Congress of Vienna is inseparable from that of the Austrian Empire, a bastion of monarchical conservatism that the forces of nationalism—German, Italian, Hungarian, Slav, and Romanian—gradually eroded. The first territorial losses came in 1859, when Austria had to cede Lombardy to Sardinia–Piedmont, nucleus of the emergent kingdom of Italy, and could do nothing to prevent the same power from dispossessing the Habsburgs of Tuscany and of Modena. Next, the Seven Weeks' War of 1866, in which Prussia, exploiting German nationalism, was in alliance with Italy, forced Austria both to renounce its hopes of reviving its ancient hegemony in Germany and to cede Venetia. After this disaster the Habsburg emperor Francis Joseph took a step intended to consolidate his "multinational empire": in 1867, to conciliate Hungary, he granted to that kingdom equal status with the Austrian Empire in what was henceforth to be the Dual Monarchy of Austria–Hungary. The result, however, was that the Magyars, jealous of their unique parity with the Germans and of their superiority over the non-Magyar peoples of their kingdom, rejected any suggestion of conciliating the Slavs and the Romanians of the Dual Monarchy by similar measures. The ardent German nationalists of the Austrian Empire, as opposed to the Germans who were simply loyal to the Habsburgs, took the same attitude as did the Magyars.

Remote from Austria's national concerns but still wounding to the House of Habsburg was the fate of Francis Joseph's brother Maximilian: set up by the French as emperor of Mexico in 1864, he was executed by a Mexican firing squad in 1867. No less grievous to the dynasty and of more concern to Austria–Hungary was the suicide of the crown prince Rudolf in 1889, though his fitness for the imperial and royal succession was questionable; and the scandalous misconduct of certain archdukes and archduchesses, in the imperial and in the Tuscan lines alike, further impaired the Habsburgs' personal prestige. The assassination of Francis Joseph's Wittelsbach consort Elizabeth in 1898 was to be followed in less than two decades by an assassination of far greater consequence.

In 1878 Austro-Hungarian forces had "occupied" Bosnia–Hercegovina, which belonged to decadent Turkey. In 1908 that territory had been formally annexed to Austria–Hungary, in a manner that was outrageous not only to Serbia (which coveted Bosnia for itself) but also to Serbia's patron, Russia. Visiting the Bosnian capital, Sarajevo, in 1914, the archduke Francis Ferdinand, heir presumptive to the Dual Monarchy (and incidentally legatee, from 1875, of the rights of the House of Austria–Este to Modena), was shot to death by a nationalist Serb. A month later the First World War was beginning.

World War I and after

World War I led to the dismemberment of the Habsburg Empire. While Czechs, Slovaks, Poles, Romanians, Serbs, Croats, Slovenes, and Italians were all claiming their share of the spoil, nothing remained to Charles, the last emperor and king, but "German" Austria and Hungary proper. On November 11, 1918, he issued a proclamation recognizing Austria's right to determine the future form of the state and renouncing for himself any share in affairs of state, and on November 13 he issued a similar proclamation to Hungary. Even so, he did not abdicate his hereditary titles either for himself or for the Habsburg dynasty. Consequently the national assembly of the Austrian Republic passed the "Habsburg Law" of April 3, 1919, banishing all Habsburgs from Austrian territory unless they renounced all dynastic pretensions and loyally accepted the status of private citizens. In Hungary, however, the collapse of the republican regime at the end of 1919 raised strong royalist hopes of a Habsburg restoration, and after the conclusion of the Treaty of Trianon (June 1920) Charles twice tried to return (March and October 1921). Under pressure from the other European powers, especially those of the Little Entente (Czechoslovakia, Yugoslavia, and Romania), the Hungarian parliament on November 3, 1921, decreed the abrogation of Charles's sovereign rights and of the Pragmatic Sanction.

Habsburg property rights in Austria, forfeited under the law of 1919, were restored in 1935 but withdrawn again by the German chancellor Adolf Hitler in 1938. After World War II the Allied Control Council in Austria in January 1946 declared that it would support the Austrian government in measures to prevent any return of the Habsburgs, and the law of 1919 was written into the Austrian State Treaty of 1955. In June 1961 the Austrian government rejected an application by the archduke Otto, head of the House of Habsburg, to be allowed to return to Austria as a private citizen, but in 1963 the administrative court of Austria ruled that Otto's application was legal. Because of Socialist opposition to his return, however, he was not granted a visa until June 1966 after the People's Party had won a majority in that year's general election.

BIBLIOGRAPHY. For the English reader, the most comprehensive introduction to the subject remains ARCHDEACON WILLIAM COXE, *History of the House of Austria*, 3rd ed., 4 vol. (1847–53), a neglected work covering Habsburg history from 1218 to 1848; A. WANDRUSZKA, *Das Haus Habsburg* (1956, 2nd ed. 1959; Eng. trans., *The House of Habsburg*, 1964), covers 600 years more briefly but most authoritatively. Works in English on the Habsburgs in the 19th and 20th centuries vary in scope and in quality: C.A. MACARTNEY, *The Habsburg Empire, 1790–1918* (1968), provides a masterly survey by an expert; A.J.P. TAYLOR, *The Habsburg Monarchy, 1809–1918*, rev. ed. (1948, paperback 1964), is rather severely critical of

the dynasty's failings; E. CRANKSHAW, *The Fall of the House of Habsburg* (1963, paperback 1969), makes a brilliant and easily readable vindication of the last emperors; A.J. MAY, *The Habsburg Monarchy, 1867–1914* (1960), is fair and scholarly, with a good bibliography; Z.A.B. ZEMAN, *The Break-up of the Habsburg Empire 1914–1918* (1961), gives a just account of a subject usually misrepresented. For genealogical detail, see W. MERZ, *Die Habsburg* (1896), which contains 19 tables; and M. DUGAST-ROUILLE, *Les Maisons souveraines de l'Autriche* (1967), also well tabulated and with illustrations. For the physical heredity, see O. RUBBRECHT, *L'Origine du type familial de la maison de Habsbourg* (1910); W. STROHMAYER, *Die Vererbung des Habsburger Familientypus* (1937); and J. NADA, *Carlos, the Bewitched* (1963; U.S. title, *Carlos, the King Who Would Not Die*, 1963). For original research, the *Inventare* (1933–) of the Haus-, Hof- und Staatsarchiv in Vienna (known as the Austrian State Archives from 1945) are an indispensable guide.

(J.R.-S.)

Ḥadīth

Ḥadīth in Islām is the record of the traditions or sayings of the Prophet Muḥammad, revered and received as a major source of religious law and moral guidance, second only to the authority of the Qur'ān, or scripture of Islām. It might be defined as the biography of Muḥammad perpetuated by the long memory of his community for their exemplification and obedience. The development of Ḥadīth is a vital element during the first three centuries of Islāmic history, and its study provides a broad index to the mind and ethos of Islām.

NATURE AND ORIGINS

The term Ḥadīth derives from the Arabic root *ḥdth*, meaning "to happen," and so, "to tell a happening," "to report," "to have, or give, as news," or "to speak of." It means tradition seen as narrative and record. From it comes the Sunnah (that is, tradition taken as precedent and authority or directive), to which the faithful conform in submission to the sanction that Ḥadīth possesses and that legalists, on that ground, can enjoin. Tradition in Islām is thus both content and constraint, Ḥadīth as the biographical ground of law and Sunnah as the system of obligation derived from it. In and through Ḥadīth, Muḥammad may be said to have shaped and determined from the grave the behaviour patterns of the household of Islām by the posthumous leadership his personality exercised. There were, broadly, two factors operating to this end. One was the unique status of Muḥammad in the genesis of Islām; the other was the rapid geographical expansion of the new faith in the first two centuries of its history into various areas of cultural confrontation. Ḥadīth cannot be rightly assessed unless the measure of these two elements and their interaction is properly taken.

Sunnah

The experience of Muslims in the conquered territories of west and middle Asia and of North Africa was related to their earlier tradition. Islāmic tradition was firmly grounded in the sense of Muḥammad's personal destiny as the Prophet—the instrument of the Qur'ān and the apostle of God. The clue to tradition as an institution in Islām may be seen in the recital of the *Shahādah* or "witness" ("There is no god but God and Muḥammad is the apostle of God"), with its twin items as inseparable convictions—God and the messenger. Islāmic tradition follows from the primary phenomenon of the Qur'ān. Muḥammad had come through a variety of factors to the sense of prophetic vocation and to the assurance of finality within it. The Qur'ān, received by him in revelation-inspiration (*waḥy*), had never been a corporate activity but always solitary and personal. It had been accompanied by striking features of poetic eloquence and intensity and even of physical "signs," all of which contributed to the drama of its accumulation, recited as literature and acclaimed by disciples. Its sequences developed with the biographical movement of the Prophet's career of leadership, to which its contents gave form and occasion. Its 114 *sūrah*s, or chapters, synchronized with the events of 23 years of Muḥammad's life (from AD 609 to 632). It was thus inextricably bound up with his person and the agency of his vocation. Acknowledgment of the Qur'ān as scripture by the Islāmic community was inseparable from acknowledgment of Muḥammad as its appointed recipient. In that calling, Muḥammad had neither fellow nor partner, for God, according to the Qur'ān, spoke only to Muḥammad. When he died, therefore, in AD 632, the gap thus created in the emotions and the mental universe of Muslims was shatteringly wide. It was also permanent. That death had also terminated the revelation embodied in the Qur'ān. By the same stroke scriptural mediation had ended, as well as prophetic presence.

The Prophet's death was said to have coincided with the perfection of revelation. But the perfective closure of both the book and the Prophet's life, though in that sense triumphant, was also onerous, particularly in view of the new changing circumstances, both of space and time, in the gathering geographical expansion of Islām. In all the new pressures of historical circumstance, where was direction to be sought? Where, if not from the same source as the scriptural mouthpiece, who by virtue of that consummated status had become the revelatory instrument of the divine word and could therefore be taken as an everlasting index to the divine counsel? The instinct to and the growth of tradition making are thus integral elements in the very nature of Islām, Muḥammad, and the Qur'ān. Ongoing history and the extending dispersion of Muslim believers provided the occasion and spur for the compilation of Ḥadīth.

HISTORICAL DEVELOPMENT

The appeal of the ordered recollection of Muḥammad to the Islāmic mind did not become immediately formalized and sophisticated. On the contrary, there is evidence that the full development of Ḥadīth was slow and uneven. Time and distance had to play their role before memory became stylized and official.

Tradition in pre-Islāmic Arabia. The first generation had its own immediacy of Islāmic experience, both within the life span of the Prophet and in the first quarter century afterward. It had also the familiar patterns of tribal chronicle in song and saga. Pre-Islāmic poetry celebrated the glory of each tribe and their warriors. Such poetry was recited in honour of each tribe's ancestors. The vigour and élan of original Islām took up these postures and baptized them into Muslim lore. The proud history of which Muḥammad was the crux was, naturally, the ardent theme, first of chronicle, and then of history writing. Both needed and stimulated the cherishing of tradition. The lawyers, in turn, took their clues from the same source. While the Qur'ān was being received, there had been reluctance and misgiving about recording the words and acts of the Prophet, lest they be confused with the uniquely constituted contents of the scripture. But the very traditions that reveal Muḥammad disapproving of the practice of recording his words are evidence enough that the practice existed. With the Qur'ān complete and canonized, those considerations no longer obtained; and time and necessity turned the instinct for Ḥadīth into a process of gathering momentum.

Relation to early Arabic poetry

Developments of the 1st and 2nd centuries AH. Within the first century of the Prophet's death, tradition had come to be a central factor in the development of law and the shape of society. Association by Ḥadīth with Muḥammad's name and example became increasingly the ground of authority. The 2nd century brought the further elaboration of this relationship by increasing formalism in its processes. Traditions had to be sustained by an expert "science" of attestation able to satisfy rigorous formal criteria of their connection with the person of Muḥammad through his "companions," by an unbroken sequence of "reportage" (see below). This science became so meticulous that it is fair (even if also paradoxical) to suspect that the more complete and formally satisfactory the attestation claimed to be, the more likely it was that the tradition was of late and deliberate origin. The developed requirements of acceptability that the tradition boasted simply did not exist in the early, more haphazard and spontaneous days.

It is clear that many customs and usages native to non-Arab societies prior to their Islāmization found their way into Islām in the form of reputed or alleged traditions of Muḥammad, though always on the condition of their general compatibility with the Islāmic religion. Implicit in this sense in Muḥammad's personal example and genius, tradition inferred an elasticity and an embrace large enough to comprehend and anticipate all that Islām in its wide geographical experience was to become.

Qur'ānic commentary

Qur'ānic commentary, as it developed in the wake of these other factors of law and custom, also leaned heavily on traditional material, for the incidents of the Qur'ānic narrative and the occasions of revelation could best be understood by what tradition had to say in its reporting of them. Further, since the patterns of Qur'ānic commentary were largely hortatory, Ḥadīth was a ready mine of word and story calculated to exemplify and reinforce what exhortation commended. Except in rare and controversial cases (the so-called Ḥadīth Qudsī, or Holy Tradition), these traditional factors in Qur'ānic interpretation were only elucidatory, and the substance of tradition could in no way dispute or displace the essential, primary, authority of the Qur'ānic text. For the *obiter dicta* (incidental observations) of Muḥammad, though sacrosanct, did not have the hallmark of revelation that belonged solely to the Qur'ān. Among earliest developed examples of Ḥadīth are the narratives of the biographer Ibn Isḥāq (died AH 150 [AD 767]) and the compilation of laws by Mālik ibn Anas, known as al-Muwaṭṭa' (died AH 179 [AD 795]). But they preceded by less than half a century the success of the theory that made tradition indispensable to the valid development of Islāmic law.

3rd century AH and subsequent developments. The chief protagonist of the view correlating tradition and law was Muḥammad ash-Shāfi'ī (died AH 204 [AD 820]) who claimed for tradition a divine imprint as an extension of the revelation of the Qur'ān. It was in line with this conviction that the phrase "the Qur'ān and the Sunnah" became current to describe the fount of authority in Sunnī Islām (the major traditionalist sect). By this mandate and out of the needs and inventiveness of lawyers, the mass of tradition grew apace. When virtually no issues could be argued, still less settled, except by connection with cited acts and opinions of Muḥammad, the temptation to require or to imagine or to allege such traditions became irresistible. Supply approximated to demand, and the growth of both made more ingenious and pretentious the science of supporting attribution. The increasing volume and complexity of the material contained in Ḥadīth necessitated larger compilations and more detailed classification. These factors worked together to inspire a critical editorial activity that in the course of the 3rd century generated what have come to be regarded as the six canonical collections of Ḥadīth by Sunnī Muslims. The first two of them have acquired a status of great sanctity. Before noting these it is convenient to describe the editorial task and the editorial procedures that constitute the developed science of Ḥadīth criticism.

THE SCIENCE OF HADITH

Matn and *isnād*

The study of tradition distinguishes between the substance, or content, known as the "gist" (*matn*) of the matter, and the "leaning" (*isnād*) or chain of corroboration on which it hangs.

Form of Ḥadīth and criteria of authentication. That Muḥammad observed, "Seek knowledge, though it be in China" or "Beware of suspicion, for it is the falsest of falsehoods" reveals the *matn* or "the meat of the matter." The formula introducing such a Ḥadīth would speak in the first person: "It was related to me by A, on the authority of B, on the authority of C, on the authority of D, from E (here a companion of Muḥammad) that the Prophet said. . . ." This chain of names constituted the *isnād* on which the saying or event depended for its authenticity. The major emphases in editing and arguing from tradition always fell on the *isnād*, rather than on a critical attitude to the *matn* itself. The question was not, "Is this the sort of thing Muḥammad might credibly be imagined to have said or done?" but "Is the report that he said or did it well supported in respect of witnesses and transmitters?" The first question would have introduced too great a danger of subjective judgment or independence of mind, though it may be suspected that issues were in fact often decided by such critical appraisal in the form of decisions ostensibly relating only to *isnād*. The second question certainly allowed a theoretically objective and reasonably precise pattern of criteria.

If the adjacent names in the chain of transmission overlapped in life, there was certainty that they could have listened to one another. Their travels were also investigated to see if their paths could have really crossed. Biographies could be built up to show that they were honest men and spoke truly. Comparative study could be made of their reputations for veracity as acknowledged by their contemporaries or indicated by their traditions when compared. The frequency of currency through several sources was yet another element in the testing of traditions. Most important of all was the final link with the "companion," who in the first instance had the tradition from his or her contact with the Prophet.

Weight of traditions

Classifications. In all these ways, and others involving more minutiae, it was possible to establish categories of Ḥadīth quality. Traditions might be sound (*saḥīḥ*), good (*ḥasan*), or weak (*ḍā'īf*). Other terms, such as healthy (*ṣālih*) and infirm (*saqīm*), were also current. Each of the three classifications was liable to subdivisions, depending on refinements of assessment and, later, on their standing with the classic compilers. Distinctions were less rigorously seen if the traditions were cited not for legal definitions but merely for moral purposes. A *ḍā'īf* tradition, for example, might well be salutary for exhortation, even if lawyers were required to exclude or ignore it. Traditions also varied in strength according to whether one or more "companions" could be adduced, whether the *isnād* had parallels, whether they were continuous back to Muḥammad (*muttaṣil*), or intermitted (*mawqūf*). The subtleties in these and other questions were part of the active competence that attended the whole science.

The repute and authority of the canonical collections did much to stabilize the situation, but only because their emergence demonstrated that the zest for tradition had overreached itself. By the end of the 3rd century AH it was sorely necessary to solidify Ḥadīth into a stable corpus of material to which no new element could credibly be added and from which the extravagances of the process of development had been purged. The Ḥadīth tradition within the various traditions had by then become a permanent and disciplined element in the authority structure of Islām—the second great source of law and practice, complementary to the Qur'ān and available for analogical handling (*qiyās*) and for consensus (*ijtihād*) as further sources of legislation, arguing from the Qur'ān and the Sunnah as primary. Shī'ah tradition (see below) stands apart from this structure of authority.

THE COMPILATIONS

The most revered of all traditionalists was Muḥammad ibn Ismā'īl al-Bukhārī (AH 194–256 [AD 810–870]), whose *Kitāb al-Jāmi' aṣ-Ṣaḥīḥ* (*The Book of the Authentic Collection*) has a place that is unique in the awe and esteem of Muslims as a work of great historical import and of deep piety. While still a boy he made the pilgrimage to Mecca and gathered traditions in wide travels. According to tradition, he was inspired to his editorial task by a vision of Muḥammad pestered by flies while asleep—flies that he (al-Bukhārī) fanned away from the face of the Prophet. The flies represented the cloud of spurious traditions darkening the true image, and the fan was its tireless rescuer. Whatever the truth of this narrative, it captures the temper of al-Bukhārī's vocation. His *Ṣaḥīḥ* occupied 16 years of editorial pains and scrutiny. He included 7,397 traditions with full *isnād*. Allowing for repetitions, the net total was 2,762, gathered, it is said, from over 600,000 memorized items. He arranged the whole

into 97 books and 3,450 chapters or topics, repeating the traditions that bore on several themes.

Of comparable stature was the *Ṣaḥīḥ* of Muslim ibn al-Ḥajjāj (AH 202–261 [AD 817–875]), to which the compiler prefaced a discussion of the criteria of Ḥadīth. The material largely confirms his contemporaries, and all such traditions common to these two authorities are known as agreed (*muttafaq*). It became characteristic to give freer rein to prevailing or communal assent in matters of *isnād*.

There are four other classical collections of tradition, all belonging within the 3rd century AH, and interdependent in part. Abū Dā'ūd al-Sijistānī (AH 202–275 [AD 817–889]) produced his *Kitāb as-Sunan* ("Book of traditions"), containing 4,800 traditions relating to matters of jurisprudence (as the term *Sunan* indicates, in contradistinction to a *Jāmiʿ*, or collection embracing all fields). Abū ʿIsā Muḥammad at-Tirmidhī (died AH 279 [AD 892]) edited the *Jāmiʿaṣ-Ṣaḥīḥ*, adding notes on the distinctive interpretations of the schools of law (*madhāhib*). Abūʿ Abd ar-Raḥmān an-Nasā'ī (AH 216–303 [AD 830–915]) produced another *Kitāb as-Sunan* with special concern for the religious law relating to ritual acts. Abūʿ Abdallāh ibn Mājā (AH 210–273 [AD 824–886]), a pupil of Abū Dā'ūd, compiled another with the same title but tended to a readier tolerance of less than satisfactory traditions. Preferences shifted between these four, and some were slower of recognition than others. Nor did they oust the earlier collection of Mālik ibn Anas, which maintained, if intermittently, its wide appeal. But they formed the increasing reliance of generations of Muslims, within the unique eminence of the master "pair," and formed the sources of later popular editions, intended to conflate material for didactic purposes. One such was the work of Abū Muḥammad al-Baghawī (died AH 516 [AD 1122]) called *Maṣābīḥ as-Sunnah* ("The Lamps of the Sunnah"). Commentaries on all these classical *musannafāt*, or compilations, were many, and important in education and piety.

SECTARIAN VARIATIONS

Shīʿah differences

The Shīʿah tradition (distinguished from the Sunnī tradition by belief in the special role of the Prophet's cousin ʿAlī and his descendants) diverges sharply from a very early date, though the emphasis on the personality of Muḥammad was identical. The Shīʿah minority broke away from the (to be) dominant Sunnī stream of Islām for deep reasons of politics, emotion, and theology. There was the dispute about caliphal succession and the role of ʿAlī, cousin and son-in-law of Muḥammad and fourth caliph, and bitter cleavage because of the tragic fate of his two sons and especially of Ḥusayn in the massacre of Karbalāʿ, from which there ultimately evolved the theology of vicarious suffering epitomized in Shīʿah devotion and ritual. All these factors inevitably involved the business of tradition. The schism read the origins according to the divided loyalties, and there was little that was not potentially contentious, apart from obvious matters; *e.g.*, Muḥammad's intentions for ʿAlī and the caliphate. The issues were fought out in rivalry for the mind of the Prophet, the authority of which was the sole agreement in the very disputing of it. The Shīʿah thus rejected the Sunnah of the Sunnīs and developed their own corpus of tradition (though there is evidence that an-Nasā'ī, at least, among the classical compilers, had sympathy with aspects of their cause). They also questioned the Sunnī notions of *isnād* and of the community as a locus of authority and evolved their own system of submission to their *imāms* (Shīʿah leaders). This altered the whole role that tradition might play. The major Shīʿah compilations date from the 4th and 5th centuries and allow only traditions emanating from the house of ʿAlī. The first of them is that of Abū Jaʿfar Muḥammad al-Qulīnī (died AH 328 [AD 939]), *Kāfī fī ʿIlm ad-Dīn*, which might be translated: "All You Need About the Science of Religious Practice."

SIGNIFICANCE OF HADITH

To browse in the canonical collections of Ḥadīth is to be initiated into a fascinating world of faith, of behaviour and authority, a world of almost encyclopaedic inclusiveness. Provisions of law are the primary element, enlarging Qur'ānic legislation. They contain a whole array of moral, social, commercial, and personal matters, as well as the themes of eschatology. All reaches of public and private conduct may be found there, from the disposal of a date stone to the crisis of the deathbed, from the manner of ablution to the duties of forgiveness, from the physical routines of digestion to the description of the day of judgment. There is a Talmudic capacity for detail and scrupulousness in legal and ethical prescriptions and precepts. There are many delightful stories of integrity and right action like that of the purchaser of a plot of ground who subsequently unearthed in it a pot of gold, which he brought back to the former owner, protesting that it was not within his bargain. The vendor, likewise, refused to claim it since he had not known it was there when he sold his field. An arbitrator solved their dilemma of honesty by proposing the marriage of the son of one with the daughter of the other so that, after alms, the gold might be settled on the couple. Through and in tradition, Islām aligned itself authoritatively with all it found compatible in local usages and brought hospitably and masterfully within its purview the continuity of many cultures. There is wide evidence of the impact of Jewish and Christian elements, notably in the realm of eschatology, elaborating the stark and urgent Qur'ānic doctrine of the last judgment. But always the imprint of Islām is clear. Tradition is at once a mine and a kind of currency, the source and the circulation of the values it makes and preserves.

SIDDIQI, *Hādīth Literature: Its Origins, Development, Special Features, and Criticism* (1961), an Asian Muslim's presentation; J. SCHACHT, *Origins of Muhammadan Jurisprudence* (1950), a very able analysis of legal traditions.

(A.K.C.)

Hadrian

Hadrian was emperor of Rome from August 11, AD 117, until July 10, 138. An ardent admirer of Greek civilization and a creative artist in his own right, Hadrian was one of the most cultivated of all the Roman emperors. His complex personality still defies analysis. Capable of cruelty and deception, he combined a longing for peace with a taste for strict military discipline. He strengthened the frontier defenses of Britain but abandoned the eastern conquests of his predecessor, Trajan. His restless spirit drove him to so much travel that he was away from Rome more than he was in it. His homosexuality culminated in an infatuation that launched a new cult throughout the Roman Empire. Almost by accident, Hadrian provoked a rebellion among the Jews and earned their bitter, unceasing hatred. This passionate and erudite philhellene is a fitting symbol of the Greco-Roman world of the 2nd century.

Early life. The family of Hadrian came from the town of Italica, near Seville, in southern Spain. They were not, however, of native Spanish origin but rather of settler stock. Hadrian's forebears left Picenum in Italy for Spain about 250 years before his birth. Hadrian himself was probably born in Rome, as one of the ancient sources for his life explicitly states. Many modern biographers have assumed without good reason that Hadrian was born in Italica and have proceeded to postulate a powerful influence of Spanish sun and temperament upon the young man. In fact, there is nothing particularly Spanish about

Hadrian, bust in the Museo Archeologico Nazionale, Naples.
Anderson—Mansell

Hadrian. He bears the stamp of education in cosmopolitan Rome.

Hadrian, whose full Roman name was Publius Aelius Hadrianus, was born on January 24, 76. When his father died in 85, he was entrusted to the care of two men: one, a cousin of his father, was the future emperor Trajan, and the other was Acilius Attianus, who was later to serve as prefect of the emperor's Praetorian Guard early in Hadrian's own reign. In the year 90, Hadrian visited the home of his ancestors in Spain probably for the first time. At Italica he received some kind of military training and also developed a fondness for hunting that stayed with him for the rest of his life. It would seem, however, that Hadrian did not much care for the small-town provincial life of Italica. He remained there for only a few years, and his subsequent relations with the place were not cordial. When he returned to Spain as emperor, he avoided Italica altogether.

Rise to power. Trajan was consul in 91, and his ward moved into several junior posts of importance. Hadrian began to follow the traditional career of a Roman Senator, which meant advancement through a conventional series of posts, and held the post of military tribune with three Roman legions in succession. In about 95 he served with the Legio II Adjutrix in the province of Upper Moesia, on the Danube River, whence he transferred in the next year to the adjacent province of Lower Moesia (with the Fifth Macedonica). Toward the end of 97 Hadrian was chosen to go west to Gaul to convey congratulations to Trajan, whom the aged emperor Nerva had just adopted and thereby designated his successor. Trajan's ward now belonged to the governing circles of the empire. Inevitably, hostility and envy awaited him in that society. In 98 Julius Servianus, his brother-in-law, attempted to prevent him from being the first to inform Trajan of Nerva's death; Servianus wanted the distinction for himself, but his plan failed. Thereafter, the two men were probably never on cordial terms, for Servianus posed a constant threat to Hadrian's position.

Plotina's protégé

The greatest single political figure behind the emperor Trajan was the man who masterminded his elevation, Lucius Licinius Sura. Hadrian was fortunate to enjoy this man's favour, and, as long as Sura was alive, Hadrian's career advanced briskly. Trajan's wife, Plotina, seems also to have been close to Sura and a partisan of Hadrian. For a time Servianus could do no harm. Through Plotina's favour, Hadrian married Trajan's grand-niece, Vibia Sabina, in 100. In the following year Hadrian held the senatorial office of quaestor and in 102 served as Trajan's companion in the Emperor's first war in the kingdom of Dacia on the Danube. In 105 Hadrian rose to the office of tribune of the plebs and, exceptionally, advanced to the praetorship in the very next year. No less exceptional than the speed of promotion was the fact that Hadrian served as praetor while in the field with the Emperor during his second war in Dacia. In 107 he had a brief tenure as governor of the Danubian province of Lower Pannonia. Then, in 108, Hadrian reached the coveted pinnacle of a Senator's career, the consulate. In the preceding year Licinius Sura had held that office for the third time, an honour vouchsafed to very few. Sura's influence must have been significant for Hadrian. It was a cruel blow when death removed so powerful a patron at an unknown date in the years immediately following Hadrian's consulate.

The career of Hadrian appears to have stopped for nearly ten years. Other promising young Romans suffered a similar retardation at about the same time. It would appear that a new political influence, opposed to Sura, Plotina, and Hadrian, dominated Trajan's court after Sura's death. It may be conjectured that Servianus played some role. Only one fact illuminates this otherwise obscure period of Hadrian's life: he held the post of archon at Athens in 112, and a surviving inscription commemorating this office was set up in the Theatre of Dionysus. Hadrian's tenure of that high Athenian office is a portent of the philhellenism that characterized his reign, and it suggests that in a time of political inactivity Hadrian devoted himself to the nation and culture of his beloved Greeks. Somehow, however, Hadrian's star rose again; and he returned to favour before the Emperor died.

One source says that Hadrian was an officer under Trajan during the Parthian wars at the end of his reign. In 117, when Trajan began his journey westward, Hadrian was left in charge of the crucial army in Syria. Friends of Hadrian, whose careers had been held up, can also be discovered in sensitive commands at the same time, probably because Plotina and her associates had regained Trajan's confidence. On August 9 Hadrian learned that Trajan had adopted him; this was the sign of succession. On the 11th, it was reported that Trajan had died on the way to Rome, whereupon the army proclaimed Hadrian emperor. The close sequence of events has always provoked suspicion of a conspiracy on Plotina's part, but the truth will never be known. Certainly, it was Trajan who had taken the fateful step of entrusting the army of Syria to Hadrian. That, at least, was not a decision made in his name by a woman and her friends.

Policies as emperor. Hadrian wrote to the Senate requesting honours for his adoptive father and ratification of the army's proclamation; all this was granted. The new emperor began a slow return to Italy. He had to make sure of the crucial provincial commands; it was also expedient to have some dissidents rounded up at home before his return and (he would be able to argue) on someone else's orders. Trajan's conquests in Armenia and Mesopotamia were quickly abandoned. The relinquishment of these territories was almost inevitable, and the process may already have begun under Trajan himself. Rome could not have managed those remote regions. Hadrian would have been pleased to recall the advice of the first Roman emperor, Caesar Augustus, not to extend the boundaries of the empire. He soon came to look upon his reign as a new Augustan age. In 123 he began to style himself Hadrianus Augustus, deliberately evoking the memory of his great predecessor; he announced a golden age on his coinage. The peace he so much cherished was a latter-day Augustan peace, and he bequeathed to posterity a public statement of his exploits that imitated the one left by Augustus.

His admiration of Augustus

Acilius Attianus, as prefect of the Praetorian Guard, directed affairs in Rome before Hadrian's return. He ordered the summary executions of four senators of exalted, consular rank: Cornelius Palma, Publilius Celsus, Avidius Nigrinus, and Lusius Quietus, all (it would seem) threats to the security of Hadrian. This bloody prelude to the new regime was unsettling, and Hadrian affirmed it was contrary to his will; he laid the blame on Attianus, just as he often blamed instructions of the dead Trajan for other unpopular acts. When Hadrian reached Rome in the summer of 118, his position was reasonably stable. He courted popular sentiment by public largesse, gladi-

atorial displays, and a formal cancellation of debts to the state. Attianus, however, was replaced; he had served his purpose. Attianus' colleague in the prefecture, Sulpicius Similis, was also dismissed. Hadrian installed as prefects the distinguished Marcius Turbo, a general to whom the Emperor owed much, and Septicius Clarus, the patron of Suetonius the biographer. Before many years had passed, both of these men had fallen into disgrace. Hadrian was mercurial or possibly just shrewdly calculating in dispensing favours.

The new emperor remained at Rome for three years. In 121 he set forth on a tour of the empire, west and east, with a view to inspecting troops and examining frontier defenses. He went to Gaul and Germany, thence to Britain in 122. From there he moved on to Spain and spent the winter in Tarraco, where he made arrangements for coping with an uprising in Mauretania (Morocco). It is not known whether he went himself to North Africa at this time. He next passed eastward, approaching Asia Minor (Anatolia) by the Aegean after an overland trip through the Balkans. He quickly negotiated some problems with the Parthians and then visited northwest Asia Minor. Returning to the west coast in 124, he sailed to Athens and finally reached Rome again in 125. This prolonged absence from the capital of the empire had its administrative justifications. There had been disturbances in some provinces, and the Parthians had to be dealt with; there was a general need for imperial supervision. Nevertheless, another motive impelled the emperor in his journeys, namely, an insatiable curiosity about everything and everybody. The Christian writer Tertullian called him rightly *omnium curiositatum explorator*, an explorer of everything interesting. That curiosity was bred of a keen intellect and an anguished spirit. These together drove him inexorably, and by a roundabout path, to the Greek East. After he left Spain early in 123, he never saw the western provinces again.

Hadrian spent another three years in Rome, but in 128 he set forth for the second time as emperor. After a visit to North Africa, he went to Athens, and from there he sailed to Asia Minor; he penetrated far eastward into Syria and Arabia. Crossing over into Egypt, he explored the Nile; then, for the third time, he went to Athens. It is not certain whether Hadrian returned to Rome in 132 or a little later; he was certainly there in May of 134, but by then a revolt in Judaea forced him abroad still another time. He went to Palestine, not as a tourist but as a commander. That journey was Hadrian's last.

Hadrian's wall

The Emperor's travels show the man better than anything else, and some of his most memorable achievements are associated with them. In northern Britain he initiated the construction of the tremendous frontier wall that bears his name from Wallsend-on-Tyne to Bowness-on-Solway. At Lambaesis, in Algeria, his rigorous inspection of the troops and his severe standards of discipline can be seen in a long inscription preserving an address he made to the soldiers in 128. In Athens, the city he loved so well, the Emperor's benefactions were numerous. At the Athenians' request, he had their laws professionally redrafted, and he brought to completion the massive temple of Olympian Zeus that the Peisistratid tyrants had begun over five centuries before. He created a federation of Greeks, based at Athens, that gave equal representation to all Greek cities. This was the Panhellenion, which thereafter played a conspicuous part in the history of Roman Greece. At the shrine of Delphi, Hadrian gave his support to a building renaissance that ushered in a new era of vitality. The impact of all this, on Hadrian personally, cannot be exaggerated. Like Augustus before him, he was initiated into the Greek mystery religion at Eleusis, and, after the temple of Olympian Zeus was dedicated, he assumed the title Olympius.

The irrational element in Hadrian was important. He was an adept in astrology, like many intelligent Romans of the time. He was also an aesthete who ascended Mt. Etna, in Sicily, and Jabal al-Ḥamrā', near Syrian Antioch, simply to watch the sunrise. He had a lively sense of the past, preferring older writers to more recent ones, favouring archaism for its own sake. He revolutionized style in the empire by wearing a beard and setting a precedent for generations of emperors. The philosophic aura of the beard may have pleased Hadrian, but at the same time there is reason to think that he was concealing a facial blemish. Hadrian did not like blemishes; he adored beauty.

In the town of Bithynium-Claudiopolis (modern Bolu) in northwest Asia Minor, Hadrian encountered a languid youth, born about 110, by the name of Antinoüs. Captivated by him, Hadrian made Antinoüs his companion. When, as they journeyed together along the Nile in 130, the boy fell into the river and drowned, Hadrian was desolate and wept openly. In antiquity a report circulated and was widely believed that Antinoüs had cast himself deliberately into the river as a part of some sacred sacrifice. Although Hadrian himself denied this, the sober 3rd-century historian, Dio Cassius, thought it was the truth. The religious character, if such there was, of the relation between Hadrian and the boy is totally elusive. The emotional involvement is, however, quite clear. Seeing Hadrian's grief, the Greek world strove to provide suitable consolation for the bereaved and honour for the deceased. Cults of Antinoüs sprang up all over the East and then spread to the West. Statues of the boy became a common sight; his unheroic shape introduced a new and important element into the art of the Roman Empire. In Egypt the city of Antinoöpolis commemorated his death.

Artistic achievements. The artistic temperament of Hadrian manifested itself in his poetry, his architectural designs, his very style of life. Four complete poems of his composition survive; they illustrate an exceptional technical mastery of versification. Although the manner of expression is often artificial and the subjects are slight, Hadrian's control of difficult metres and poetic vocabulary is impressive. His most famous verses are no exception: these are the lines addressed to his soul and reportedly uttered as he lay dying. In architecture, the Emperor had a notorious quarrel with a leading contemporary architect, Apollodorus of Damascus, whom it is even alleged Hadrian had put to death. It is easy to believe at the least that the Emperor was confident of his talents and not likely to tolerate criticism. His ultimate artistic achievement was undoubtedly the villa he created for himself at Tivoli, outside Rome. Here the Emperor surrounded himself with elegant evocations of his travels; by landscaping and superior reproductions, he re-created the sights he most loved and thereby managed in his last years to experience the satisfactions of travel without ever leaving the shores of Italy.

As a creative artist himself, Hadrian was not the best of patrons. The authoritarianism displayed in the case of Apollodorus was probably not unique, and it is clear that Latin literature did not progress during his reign. The greatest Hadrianic authors, Suetonius the biographer, Juvenal the satirist, and Tacitus the historian, were all, in a sense, only survivors of the Trajanic age. All three had begun writing before Hadrian's accession and finished their work relatively early during his reign. They had no immediate literary heirs. Suetonius, although elevated to the important literary post of *ab epistulis* in the court during Hadrian's first years, was summarily dismissed about 122. An ancient source alleges excessive familiarity with Hadrian's wife, Sabina; but that would not have been something to worry the Emperor. More probably there had been a literary quarrel. The fortunes of two eminent orators, Dionysius of Miletus and Favorinus of Arelate (in Gaul), are instructive. The former Hadrian openly favoured and advanced; he then tried to overthrow him. Favorinus is found living in exile toward the end of Hadrian's reign. The Emperor's tastes dominated the world. His penchant for archaic authors and styles is mirrored in the tastes of the entire century throughout the Greek East and the Latin West. It is difficult to ascertain whether Hadrian was in this respect more a symptom or a cause. He was probably something of both.

In the city of Rome itself, during his brief sojourns there, Hadrian left his memorial in several imposing buildings. Designs for the Temple of Rome and Venus

provoked the conflict with Apollodorus. He completely rebuilt the Pantheon, which had been destroyed by fire in the reign of his predecessor. The original structure had been Augustan; therefore, a rebuilding by a man who viewed himself as a new Augustus was no accident. His own great tomb (the modern Castel Sant'Angelo) was likewise inspired by an Augustan precedent, the Julio–Claudian mausoleum, at Rome.

Last years. When Hadrian left Rome in 134 for his final journey abroad, it was to resolve a problem of serious proportions in Judaea. The troubles had already started when he was in the last stages of his previous journey. Under the leadership of Bar Kokhba (known also as Bar Koziba), the Jews were in open revolt. What had moved them is not altogether clear. Rabbinical literature alludes to a Hadrianic persecution that caused fear and apostasy. The probable explanation of this kind of reference is a universal ban on circumcision that Hadrian issued in, it seems, the early 130s. The Emperor had an abhorrence of physical mutilation and even went so far as to declare that castration was no less a crime than murder. It was in the same spirit that he denounced and forbade circumcision, which he viewed as mutilation. There is no reason to imagine that Hadrian intended by his measure to punish or provoke the Jews. His concern was ultimately humane, and he had perhaps no notion of how important the rite of circumcision was to Jewry. The uprising came swiftly and understandably. Hadrian's visit to Athens in 131–132 and his residence at Rome until the summer of 134 suggest a reluctance to deal personally with the disturbance in Judaea. He first placed an able general, Sextus Julius Severus, in charge of the problem. In the year after Hadrian's arrival in the Near East, the revolt was over. Recent discoveries have shown that several measures hitherto connected with the close of the revolt and often cited as indications of imperial severity have to be dated at least six years earlier and, very probably, well before that. Already by 129 a second garrisoning legion had been stationed in Judaea and the area transformed into a province of high rank with a former consul as governor. This disposition was clearly neither a cause nor an effect of the uprising and may well have been envisaged by Trajan. Likewise, the establishment of a Roman colony at Jerusalem under the name of Aelia Capitolina must be detached from the context of the rebellion. Hadrian meted out no savage punishments in 135.

The Jewish revolt

In 134 Hadrian's aged rival, Julius Servianus, held the consular office for the third time. This was a great but empty honour, for the man was too old. He and others may, however, have seen in his young grandson, Pedanius Fuscus, a successor to Hadrian. In 136 both Servianus and Fuscus were executed. The Emperor had realized that it was time to face the issue of succession, and he wanted it resolved in his own way. With Fuscus eliminated, Hadrian adopted the profligate Lucius Ceionius Commodus, aged about 36. The extravagant life of Ceionius, now renamed Lucius Aelius Caesar, portended a disastrous reign. Fortunately, he died two years later, and Hadrian, close to death himself, had to choose again. This time he picked an 18-year-old boy named Annius Verus, the future emperor Marcus Aurelius.

In 138 Hadrian arranged for the succession to pass to the young Verus in due course. His arrangements were clever. An estimable and mature senator, Antoninus, was adopted by Hadrian and designated to succeed him. The Emperor, however, required that Antoninus adopt both the young Verus and the eight-year-old son of the recently deceased Ceionius. Thus, the family of his first choice was remembered, whereas an early succession for the older boy seemed assured. No one expected that Antoninus would last very long. Hadrian's scheme of imposing a double adoption upon his immediate successor looks like another imitation of the first emperor, Augustus, who had made a similar demand of Tiberius. By an irony of fate, Hadrian's expectations about the future were confounded. Antoninus, like Tiberius, lived far longer than anyone would have though possible. He did not die until 161.

On July 10, 138, Hadrian died at the seaside resort of Baiae. Death came to him slowly and painfully. He wrote a letter in which he said how terrible it was to long for death and yet be unable to find it. His reign concluded two years after a double execution; it had begun with a quadruple one. The dead man was not widely mourned. Few loved him, though many feared him. He was someone to propitiate like a god, wrote a person who knew him, but he was not one to evoke affection. Since the Senate was not inclined to raise him formally to the rank of a god after his death, Antoninus had to work hard to secure a vote of deification. His exertions won him the name Pius.

Assessment. Yet Rome had reason to be grateful to Hadrian. His buildings were not his only lasting bequest. In the realm of law he had effected profound and enduring reform. The circle of the Emperor's advisers henceforth regularly included professional jurists; the praetor's edict, according to which magistrates had administered justice by varying and sometimes novel procedures, was revised and given a permanent form. The work of revision had been brilliantly carried out by the jurist Salvius Julianus under instructions from Hadrian. The humanitarianism that went so badly astray in the case of circumcision had in other areas, such as the treatment of slaves, a beneficent effect upon society. Hadrian's legal pronouncements do him credit. Whatever his weaknesses, he was no snob. One can easily believe the ancient testimony that reports his liking of the plebs.

A man of many moods and inordinate sensitivity, Hadrian was unpredictable. A friend could suddenly become an enemy; a 20-year-old Eastern youth could become a god. Hadrian seemed unable to rest physically and intellectually, even at the end when he craved to be released. Although his wife Sabina was accorded full public honour, her marriage to Hadrian was generally accounted a failure, and scandalmongers claimed that he had poisoned her when she died in 136. The Emperor composed his autobiography so as to leave posterity with his own version of the mysteries and paradoxes of his career, but posterity knew more than Hadrian wished to be known. Historians were able to counter his own statements. A definitive biography does not and cannot exist. Only the enigma and the tragedy remain.

BIBLIOGRAPHY. Ancient evidence for Hadrian and his reign may be found in the life of Hadrian in the *Historia Augusta;* CASSIUS DIO, *Roman History*, bk. 69 (surviving only in Byzantine epitomes); life of Hadrian in AURELIUS VICTOR, *On the Caesars;* and the life of Hadrian in the anonymous *Epitome De Caesaribus.* There are two modern biographies of Hadrian in English, neither of which is wholly reliable: B.W. HENDERSON, *The Life and Principate of the Emperor Hadrian, A.D. 76–138* (1923); and S. PEROWNE, *Hadrian* (1960). The article "Hadrian" in the *Oxford Classical Dictionary*, 2nd ed., pp. 484–486 (1970), contains many errors. The fictional evocation, M. YOURCENAR, *Mémoires d'Hadrien* (1951; Eng. trans., *Memoirs of Hadrian*, 1954), is, however, remarkably successful.

(G.W.Bo.)

Haeckel, Ernst

Ernst Heinrich Haeckel, a zoologist and an enthusiastic proponent of Darwin's theory of evolution—"more Darwinist than Darwin himself"—became embroiled in controversy as he popularized the theory of descent. The concept of evolution afforded him a means of constructing a family tree for all living things. The theory of descent was the basis for his monist philosophy, in which he envisioned all of nature as a unity, while rejecting design and a Creator. It was Haeckel who gave the then-recurrent recapitulation theory its fullest expression as the "fundamental biogenetic law." Freely originating new terms as he needed them, he declared that ontogeny (the embryology and development of the individual) briefly, and sometimes necessarily incompletely, recapitulated, or repeated, phylogeny (the developmental history of the species or race). From the evidence of embryology, paleontology, and comparative anatomy he undertook to depict an entire evolutionary scheme and to trace the descent of man.

Haeckel, *c.* 1870.
The Bettmann Archive

Born at Potsdam on February 16, 1834, he was the younger son of Carl and Charlotte Sethe Haeckel and grew up at Merseburg, where his father, a lawyer, was a government official. While attending the *Gymnasium* (secondary school), he read books on nature and travel and particularly enjoyed Goethe's works and Darwin's account of his voyage aboard the "Beagle." The youth collected and classified plants for his own herbarium.

After a rheumatic attack prevented him from beginning the study of botany at the University of Jena and sent him home to his parents, it was decided that he would enter medicine. He studied at Würzburg and at the University of Berlin, where his professor, the physiologist and anatomist Johannes Müller, took him on a summer expedition to observe small sea creatures off the coast of Heligoland in the North Sea.

Education

Such experiences in marine biology strongly attracted Haeckel toward zoology, but dutifully he took his medical degree, as his family wished, at Berlin in 1857. His father then agreed to his travelling to Italy, where he painted and even considered art as a career. At Messina he studied the one-celled protozoan group Radiolaria, which are strikingly crystalline in form; not surprisingly, Haeckel later maintained that the simplest organic life had originated spontaneously from inorganic matter by a sort of crystallization.

Darwin's influence

The turning point in Haeckel's thinking was his reading of Charles Darwin's 1859 work, *On the Origin of Species by Means of Natural Selection*. Meanwhile, he completed a dissertation in zoology in 1861 at Jena and became *Privatdozent*, or lecturer. In 1862 he was appointed extraordinary professor of zoology, and that year, when he published his monograph on the Radiolaria, he expressed in it his agreement with Darwin's theory of evolution; from that time he was a proponent of Darwinism and soon was lecturing to scientific and lay audiences on the descent theory, incurring both admiration and opposition. Haeckel believed the theory was implicit in Goethe's writings. Darwin had described evolution through the natural selection of accumulated favourable variations that in time formed new species; to Haeckel, however, this was only a beginning, with consequences to be pursued further. In 1865 he was appointed full professor and he remained at Jena until his retirement in 1909.

Haeckel's views on evolution

Haeckel saw evolution as the basis for a unified explanation of all nature and the rationale of a philosophical approach that denied final causes and the teleology of the church. His *Generelle Morphologie der Organismen* (1866; "General Morphology of Organisms") presented many of his evolutionary ideas, but the scientific community was little interested. He set forth his ideas in popular writings, all of which were widely read, though deplored by many of Haeckel's scientific colleagues.

Enthusiastically attempting to explain both inorganic and organic nature under the same physical laws, Haeckel portrayed the lowest creatures as mere protoplasm without nuclei; he speculated that they had arisen spontaneously through combinations of carbon, oxygen, nitrogen, hydrogen, and sulphur. In those days of great interest in protoplasm it was believed for awhile that certain deep-sea dredgings had brought up such structureless organisms; when scientists found this to be in error, Haeckel continued to insist, throughout the years, that "monera" existed. From them he traced one-celled forms with nuclei and three kingdoms—animal, vegetable, and the neutral, borderline "protista." His artistic leanings toward ideal symmetries led him to outline numerous geneological trees, sometimes to supply missing links or branches; and he reconstructed the human ancestral tree, to show man's descent from the lower animals.

Haeckel tended to speculate and for some years pondered over the problem of heredity. Interestingly, though it was only on a theoretical basis, he suggested as early as 1866 that the cell nucleus was concerned with inheritance. He had long been thinking of "vital molecular movement" when, in 1876, he attempted to place heredity on a molecular basis in a work entitled *Die Perigenesis der Plastidule* ("The Generation of Waves in the Small Vital Particles"). Here again, he traced a branching scheme, this time to illustrate the mechanism of heredity and to show the influence of outer conditions on the inherited undulatory motion he attributed to the "plastidules," the term he adopted for the molecules making up protoplasm.

Though his concepts of recapitulation were in error, Haeckel brought attention to important biological questions. His gastraea theory, tracing all multicellular animals to a hypothetical two-layered ancestor (which he even drew in section), stimulated both discussion and investigation. His propensities to systematization along evolutionary lines led to his valuable contributions to the knowledge of such invertebrates as medusae, radiolarians, siphonophores, and calcareous sponges.

Haeckel was the teacher of noted zoologists and a member of learned societies. He was not one to change his ideas and was often involved in controversy. While extending his arguments into the theological, political, and social fields, he attracted disciples, yet alienated friends. Building the collections around his own, Haeckel founded both the Phyletic Museum in Jena and the Ernst Haeckel Haus; the latter contains his books and archives and in it many mementos of his life and work are preserved. Haeckel died at Jena on August 9, 1919.

BIBLIOGRAPHY. Biographical references are GEORG USCHMANN'S article on Haeckel in the *Dictionary of Scientific Biography*, vol. 6, pp. 6–11 (1972), with bibliography; and his *Geschichte der Zoologie und der zoologischen Anstalten in Jena 1779–1919* (1959), describing Haeckel's career and influence at Jena, with a comprehensive list of source material. WILHELM BOLSCHE, *Ernst Haeckel: Ein Lebensbild* (1900; Eng. trans., *Haeckel: His Life and Work*, 1906); JOHANNES HEMLEBEN, *Ernst Haeckel, in Selbstzeugnissen und Bilddokumenten* (1964); PETER KELMM, *Ernst Haeckel, der Ketzer von Jena* (1966); and GERHARD HEBERER (ed.), *Der gerechtfertigte Haeckel* (1968), provide further data on his life and writings. Discussions of Haeckel's thought may be found in DANIEL GASMAN, *The Scientific Origins of National Socialism: Social Darwinism in Ernst Haeckel and the German Monist League* (1971), which describes Haeckel's influence on German social and political thought under National Socialism; and P. SMIT, "Ernst Haeckel and His 'Generelle Morphologie': An Evaluation," *Janus*, 54:236–252 (1967), which reviews his work and the impact of his theories. ERIK NORDENSKIOLD in *Biologins Historia*, 3 vol. (1920–24; Eng. trans., *The History of Biology*, 1928); and EMANUEL RADL in *Geschichte der biologischen Theorien seit dem Ende des siebzehnten Jahrhunderts*, 2 vol. (1905–09; Eng. trans., *The History of Biological Theories*, 1930), present general introductions to Haeckel. SIR GAVIN DE BEER in *Embryos and Ancestors* (1954), discusses the recapitulation theory.

(G.Ro.)

Hague, The

The Hague (Dutch 's-Gravenhage, usually abbreviated Den Haag; French La Haye) is the seat of the government of The Netherlands and the capital of the province of South Holland. The third largest city in the country with a population in 1971 of 537,643, The Hague lies on a sandy plain about four miles from the North Sea. Its fine parks, its nearness to the beach and the sea, and its easy connections with the principal cities of the country make the city a convenient capital, a pleasant residential area, and a popular centre of international conferences.

History. The city's name recalls the hunting lodge and principal residency of the counts of Holland, located in a woodland area called Haghe, or "hedge" (whence 's-Gravenhage, "the counts' private dominion"). Count William II built a castle there in 1248, around which several buildings—including the famous Knight's Hall (1280)—came to be clustered. Together they form the Binnenhof ("inner courtyard") in the very heart of the city. Originally this group of buildings was surrounded by a double canal. Around 1350 an artificial lake, the Hofvijver, was dug on the north side and still forms one of the many attractions of the city. On the west side is the Buitenhof ("outer courtyard"), where once stood the workshops and stables of the court. The main gateway of the courtyard, *gevangenpoort* ("prison gate"), once used as a prison, formed the entrance. These courtyards, together with areas north and east of it, formed a complex under the Count's immediate rule and jurisdiction. He rented part of the ground to the nobles who formed his council and to high court dignitaries, who built their mansions there, giving rise to a spacious and well-laid-out distinctive district, still seen today in the Plaats, Kneuterdijk, Voorhout, and Vijverberg.

In the 14th century the counts connected the Binnenhof with the Dutch waterways by means of an entrance canal known as the Spui.

Growth of the village west of the court

West of the court area, a small settlement of farmers and craftsmen grew up to service the court, gradually forming a village, the boundaries of which were officially determined in 1370. A flourishing wool industry grew up within the village, the rapid growth of which was reflected in the construction in 1399 of the Great Church of St. James or St. Jacobs to replace the wooden parish church. The village became the centre of a larger rural district known as the Haagambacht. The governing body (Magistraat) resided in the Town Hall opposite the Great Church. Until 1795 the court area and the village comprised two separate sections, each with its separate administration and jurisdiction.

In 1436 the earldom of Holland passed into the possession of the dukes of Burgundy. They charged a *stadhouder* (lord lieutenant) with the government of the earldom, assisted by a court composed of professional lawyers. These were mostly foreigners who, in establishing themselves in the surrounding court area, proved of great financial and cultural importance for The Hague; it was probably through their influence that a new Flemish Renaissance Town Hall (Stadhuis) was built in 1565.

Because of its open location, the borough suffered much in the beginning of the Dutch war of liberation from Spain (1568–1648). But in 1585, when much of the danger had passed, the States-General, the governing body of the seven United Provinces of the Netherlands, along with other bodies of the central government, established themselves in the Binnenhof. The government of the province of Holland also returned, and *stadhouder* Prince Maurice of Orange took up residence here. It was at his instance that in 1616 The Hague was defended by a web of canals that remained the city's borders to the mid-19th century.

In the 17th century, when the Dutch Republic played a leading role in Europe, The Hague became an international city, a centre of diplomacy, and a refuge for persecuted minorities such as the French Protestants and the Portuguese Jews. A mixture of nationalities lived within the city, and all of them helped to fashion its social and cultural life.

After 1630 there was an important expansion both in the court area and in the newly constructed Prinsegracht region in the village. Many beautiful houses were built in the new French-Italian style by the architects Jacob van Campen and Pieter Post. The finest surviving examples of their work are the Noordeinde Palace (now the International Institute of Social Studies) and the Mauritshuis (now the Royal Art Gallery) on the Plein.

Canals and small harbours were constructed around the Spui, encouraging small trades and industries. The first Protestant New Church, established in 1654, contains the

Charles E. Rotkin—Photography for Industry

The old castle in the heart of The Hague. The Ridderzaal or Knights' Hall stands in the middle of the Binnenhof or Inner Court. The Binnenhof is surrounded by the Buitenhof or Outer Court of buildings. The Hofvijver pond lies to the north.

tombs of the Dutch statesmen Jacob and Johan de Witt and of the philosopher Spinoza.

Building continued in the 18th century under such capable architects as the French refugee Daniel Marot and Pieter de Swart. The medieval houses of the nobles, already partly replaced by 17th-century patrician mansions, were then reconstructed in the French style.

By about 1780 The Hague's silver and porcelain were famous. Printing and publishing prospered, and many books proscribed abroad were produced in the city.

Decline under French rule

During French rule (1795–1813), The Hague declined into a poor provincial town, but with liberation from the French it once again became the residence of the monarch and the administrative centre, now of the kingdom of The Netherlands. Immediate revival, however, was impeded by a lack of money and the narrow-mindedness of the city magistrates. It was not until after 1850, when the revenues from the Dutch East Indies started to pour in, that any real signs of improvement were seen. The Willemspark (a residential quarter, or "villa park," dominated by greenery and influenced by the architecture of London squares of the period) was then constructed, and the city started to expand outside its borders of 1616. Cheap housing was constructed for a rapidly growing middle class. Netherlanders repatriating from the Dutch East Indies showed preference for living in The Hague, thus giving the population a markedly "Indonesian" aspect still found today.

After 1870, prosperity increased, and a more progressive city administration provided modern public facilities. Many new shops were built in addition to better housing areas. Between 1880 and 1890, the population jumped from under 114,000 to 200,000. The arts flourished, and The Hague school of landscape painters became world famous. As a result of the Hague Peace Conferences held in The Hague in 1899 and 1907, The Hague became a permanent centre of international law. The American steel magnate Andrew Carnegie endowed the Peace Palace, completed in 1913.

The 20th century saw real growth and progress: industry increased, harbours were constructed, and oil and insurance companies set up their head offices in the city. Large office buildings were designed by architects such as H.P. Berlage (1856–1934), who also designed the Haggs Gemeentemuseum, the municipal museum.

During World War II the city suffered heavily from the German occupation, but afterward there was a remarkable tide of reconstruction and expansion.

Among the more interesting structures of the postwar period are the unusual United States Embassy designed by Marcel Breuer (1961) and The Netherlands Congress Centre designed by J.J.P. Oud (1969).

The contemporary city. *Physical layout and boundaries.* The Hague is situated along the shore of the North Sea: 4° east of Greenwich, at 52° north latitude and about 15 feet above sea level. Its northern climate is tempered by a branch of the Gulf Stream, resulting in an average temperature of 50° F—several degrees higher than elsewhere at the same latitude. The Hague is protected from the sea by a row of wide dunes broken only by the Scheveningen fishing harbour and the beach promenade about 2 miles long. To the south of the city is Westland, the vegetable garden of western Europe, and, to the east, the polders of The Netherlands low-middle region, where the land often lies below sea level. It is in this polder land that Zoetermeer, 10 miles east, has become a satellite town expected to grow in the next decade from a quiet township of about 20,000 inhabitants to a town accommodating about 100,000. North of The Hague is the municipality of Wassenaar, one of the richest municipalities in The Netherlands and the residence of cabinet ministers, ambassadors, and wealthier businessmen. In the direction of Haarlem, less than seven miles from The Hague centre, begins the bulb-growing area where the crocuses, daffodils, hyacinths, and tulips attract hundreds of thousands of visitors every spring.

Demography and economic life. In 1971 The Hague's population was 537,643, and that of its metropolitan area was 710,528. This included a large number of older people: nearly 41 percent of the population were above 45 years of age. In religion, 29.3 percent were Roman Catholic, 33.5 percent Protestant, and 5.6 percent other; 31.6 percent reported no religious affiliation.

There is little heavy industry in The Hague. Most of the city's 26,000 business firms are engaged in trade, banking, insurance, or services. The hosting of international conferences is big business in The Hague. The Netherlands Congress Centre, which is able to accommodate 9,000 conference delegates a day, was completed in 1969. In the same year there were over a half million overnight stays in the hotels by over 187,000 guests. Several large oil firms have their international headquarters in the city.

Political and governmental institutions. The Hague is the seat of The Netherlands government and Parliament. This means that practically all of the ministerial departments are established here.

Most of them are in or very close to the historic city centre, but a few are in the suburbs, such as Rijswijk (Ministry of Culture, Recreation, and Social Works) and Leidschendam (Ministry of Social Affairs). Many of the political parties also have their headquarters in The Hague. And because The Hague is the city of the government, it also accommodates many government and semi-government institutions such as industrial organizations, waterways departments, and advisory councils.

The Hague is also the capital of South Holland, one of the 11 provinces into which The Netherlands is divided, and the seat of the High Council of The Netherlands and of the Supreme Court of The Netherlands. It also houses the International Court of Justice, the Institute of Social Studies, and 61 embassies.

Transportation services. The Hague is situated in the heart of the city belt or agglomeration known as the Randstad Holland, or Rim-City Holland. It is less than an hour's drive (35 miles) to Amsterdam and the international Schiphol Airport, while Rotterdam, with its own Zestienhoven Airport, is less than a half hour (10 miles) away. The Hague has direct train connections with the German Ruhr area via Rotterdam, while Brussels is reached by electric train in two hours and Paris in five hours. From The Hague to the Belgian border by road takes about an hour and a half, as does the trip to the German frontier.

Since 1968 there has been ferry service from Scheveningen to the English coastal town of Great Yarmouth, while from the nearby Hook of Holland there is a fine boat service to the English steamer harbour of Harwich.

Cultural life. The Hague's 14 museums comprise a wide range of collections. The Mauritshuis Royal Art Gallery has a remarkable collection of the works of the Dutch masters: Rembrandt, Vermeer, Jan Steen, and others. The Haags Gemeentemuseum has the largest collection of paintings by Piet Mondrian in the world as well as extensive collections of modern art, old handicrafts, musical instruments, and prints.

Other notable museums are The Netherlands Costume Museum, the Mesdag Museum, the Mesdag Panorama, the Coin and Medal Cabinet, and the Postal Museum. In addition, about 25 galleries display various aspects of modern art.

Art and music

The Hague has two art academies: the Koninklijke Akademie van Beeldende Kunsten (Royal Academy for the Plastic Arts) and the Vrije Akademie (the Free Academy). The Koninklijk Conservatorium voor Muziek (Royal Conservatory of Music) graduates dozens of musicians annually. Musical life in The Hague is largely dominated and determined by the resident orchestra, The Hague Philharmonic, whose main auditorium since 1969 has been The Netherlands Congress Centre. Theatre life is centred mainly in the Koninklijke Schouwburg (Royal Theatre) for which de Haagse Comedie (the Hague Comedy Group) is the resident company. The avant-garde section of this company has been giving performances since 1969 in the HOT (Haags Ontmoetingscentrum voor Toneel), a converted church in the centre of the city. A third local company, the Nieuwe Komedie, specializes in modern plays.

The city also houses the Netherlands Dance Theatre, specializing in modern ballet and well known throughout Europe.

Recreation. Of The Hague's 16,140 acres, 1,820 consist of parks, woods, dunes, large gardens, playing fields, and sports grounds—an average of over 144 square feet of green for every citizen, more than any other large city in western Netherlands.

There are 16 large parks and a beach about five miles long, which at low tide is dozens of yards wide and provides pleasure and recreation for hundreds of thousands every year. The city has 773 acres of sports fields; several swimming pools; three sports halls; 16 tennis parks; one racecourse (Duindigt); and the largest camping park in western Europe, with 8,500 camping places.

BIBLIOGRAPHY. JACOB DE RIEMER, *Beschrijving van 's-Gravenhage*, 2 vol. (1730–39), is the most reliable of a number of early descriptions of The Hague and its history; H.E. VAN GELDER, *Zeven eeuwen Den Haag* (1937), a modern general view of the history of The Hague, published at the town's 700th anniversary; C. DE WIT, *Den Haag vroeger en nu* (1968), is the most recent general view of the history of The Hague, more condensed than that by Van Gelder but with more emphasis on the foundation of the initial Castle and its first development; *Haagsch Jaarboekje* (1889–1899); and its successor, *Die Haghe* (annual), published by the association Die Haghe, contains a large number of good articles on a variety of subjects; *Statistical Yearbook* (annual), offers a wealth of data; *The Hague, Swinging Between Tranquility, Dynamic Action and the Arts* and *The Hague, the Arts*, both published by the Public Relations Department City of the Hague, offer general information about The Hague.

(M.v.H./Ja.B.)

Hahn, Otto

The discovery of nuclear fission, at the end of 1938, by the German chemist Otto Hahn, working with the radiochemist Fritz Strassmann, was one of the most pregnant events of modern times. Hahn, the senior of the two, was awarded the 1944 Nobel Prize for Chemistry in recognition of this discovery. Already highly respected for his previous work, he was widely known as a brilliant experimentalist.

Landesbildstelle Berlin

Hahn.

Hahn was born on March 8, 1879, in Frankfurt-am-Main, the son of a glazier. Although his parents wanted him to become an architect, he eventually decided to study chemistry at the University of Marburg. Life at home was simple and abstemious, but at Marburg Hahn developed a taste for beer and cigars, and his student days were not without romantic episodes. He worked hard at chemistry, though he was inclined to absent himself from physics and mathematics lectures in favour of art and philosophy, and he obtained his doctorate in 1901. After a year of military service, he returned to the university as chemistry lecture assistant, hoping to find a post in industry later on.

In 1904 he went to London, primarily to learn English, and worked at University College with Sir William Ramsay, who was interested in radioactivity. While working on a crude radium preparation that Ramsay had given to him to purify, Hahn showed that a new radioactive substance, which he called radiothorium, was present. Fired by this early success and encouraged by Ramsay, who thought highly of him, he decided to continue with research on radioactivity rather than go into industry. With Ramsay's support he obtained a post at the University of Berlin. Before taking it up, he decided to spend several months in Montreal with Ernest Rutherford (later Lord Rutherford of Nelson) to obtain further experience of radioactivity. Shortly after returning to Germany in 1906, Hahn was joined by Lise Meitner, an Austrian physicist, and five years later they moved to the new Kaiser Wilhelm Institute for Chemistry. There Hahn became head of a small but independent department of radiochemistry.

Early work on radioactivity

Feeling that his future was more secure, Hahn married Edith Junghans, the daughter of the chairman of Stettin City Council, in 1913; but World War I broke out the next year, and Hahn was posted to a regiment. In 1915 he became a chemical warfare specialist, serving on all the European fronts.

After the war, Hahn and Miss Meitner announced the discovery of a new radioactive element, protactinium. Since nearly all of the natural radioactive elements had then been discovered, he devoted the next 12 years to studies on the application of radioactive methods to chemical problems.

In 1934 Hahn became keenly interested in the work of the Italian physicist Enrico Fermi, who found that when the heaviest natural element, uranium, is bombarded by neutral subatomic particles called neutrons, several radioactive products are formed. Fermi supposed these products to be artificial elements similar to uranium. Hahn and Miss Meitner, assisted by the young Strassmann, obtained results that at first seemed in accord with Fermi's interpretation but which became increasingly difficult to understand. Miss Meitner fled from Germany in July 1938 to escape the persecution of Jews by the Nazis, but Hahn and Strassmann continued the work. By the end of 1938, they obtained conclusive evidence, contrary to previous expectation, that one of the products from uranium was a radioactive form of the much lighter element barium, indicating that the uranium atom had split into two lighter atoms. Hahn sent an account of the work to Lise Meitner, who, in cooperation with her nephew Otto Frisch, formulated a plausible explanation of the process, to which they gave the name nuclear fission.

Discovery of nuclear fission

The tremendous implications of this discovery were realized by scientists before the outbreak of World War II, and a group was formed in Germany to study possible military developments. Much to Hahn's relief, he was allowed to continue with his own researches. After the war, he and other German nuclear scientists were taken to England, where he was profoundly affected by the announcement of the explosion of the atomic bomb at Hiroshima in 1945. Although now aged 66, he was still a vigorous man; a lifelong mountaineer, he maintained physical fitness during the enforced stay in England by a daily run.

On his return to Germany he was elected president of the former Kaiser Wilhelm Society, renamed the Max Planck Society for the Advancement of Science; and became a respected public figure; a spokesman for science; and a friend of Theodor Heuss, the first president of the Federal Republic of Germany. He campaigned against further development and testing of nuclear weapons. Honours came to him from all sides; in 1966 he, Meitner, and Strassmann shared the prestigious Enrico Fermi Award. This period of his life was saddened, however, by the loss of his only son Hanno and his daughter-in-law, who were killed in an automobile accident in 1960. His wife never recovered from the shock. Hahn died in Göttingen on July 28, 1968, after a fall; his wife survived him by only two weeks.

BIBLIOGRAPHY. OTTO HAHN, *Mein Leben* (1968; Eng. trans., *My Life*, 1970), provides information on personal experiences and views. His scientific work and views to 1945

are treated in *Vom Radiothor zur Uranspaltung* (1962; Eng. trans., *A Scientific Autobiography*, 1966), including three of Hahn's scientific papers on nuclear fission. R. SPENCE, "Otto Hahn," *Biogr. Mem. Fellows R. Soc.*, 16:279–313 (1970), describes Hahn's life and work and gives a complete list of his publications.

(R.Sp.)

Haiti

Haiti (République d'Haïti) is a republic in the West Indies, situated in the western part of the Caribbean island of Hispaniola. With an area of 10,714 square miles (27,750 square kilometres), it occupies slightly more than one third of the island. Since much of its territory consists of two peninsulas, it has a coastline that is long in proportion to its size—amounting to 672 miles. It is bounded to the east by the Dominican Republic (which occupies the remainder of the island), to the north by the Atlantic Ocean, and to the west and south by the Caribbean Sea. Its population numbers approximately 4,250,000. The capital is Port-au-Prince.

Haiti, which won its independence from France in 1804, was the first country in the Americas, after the United States, to win freedom from colonial rule. From 1957 to 1971 its president was François Duvalier, popularly known as Papa Doc; Duvalier established a personal style of government. The great majority of the people are Negro; about 5 percent, however, consists of a mulatto minority who form an élite that has played a leading role in Haiti's history; many members of this élite are now living abroad. The official language is French, but a Creole patois is more generally spoken. Coffee is the principal export, and the United States is Haiti's principal trading partner.

Strategically, Haiti commands the Windward Passage, a 50-mile-wide corridor running between the northwest extremity of Haiti and the eastern extremity of Cuba, which is situated midway on the sea-lane between New York and the Panama Canal. Important air routes between North and South America pass across Haiti, but without stopping there. (For coverage of associated physical features, see ATLANTIC OCEAN; CARIBBEAN SEA; for historical aspects see HAITI, HISTORY OF.)

The landscape. *Relief.* Haitian territory consists essentially of two peninsulas, both of which project westwards —the northwestern peninsula and the southern peninsula. They are separated by the Golfe de la Gonâve, and are joined together by the alluvial plain of Artibonite, which covers about 310 square miles, as well as by the Plateau Central, which covers 840 square miles. The backbones of the two peninsulas are formed by mountain ranges of white calcareous (chalky) rock. The northern peninsula trends from northwest to southeast, while the southern peninsula trends east to west. The mountains of the southern peninsula are higher, reaching an altitude of 8,772 feet about 15 miles west of the Dominican frontier. Short rivers flow rapidly down to the sandy shore, carving gullies in the hillslopes, and forming small coastal plains on which local administrative and trade centres have been established. Viewed from the sea, therefore, the prospect consists of succeeding valleys and hills. Most valleys are quite small, as are the towns located in them. The principal exceptions to this general pattern are the Plaine du Nord (the Northern Plain), which extends over almost 150 square miles, and the two plains—Cul-de-Sac (140 square miles) and Léogâne (40 square miles)—which unite in the region of the capital, Port-au-Prince. The plain of Cul-de-Sac extends into the interior along an east-west rift that divides the island into two distinct parts and which is subject to frequent but minor earthquakes. Two lakes, the Étang Saumâtre (literally "brackish pond"), with an area of 65 square miles, and the Étang de Miragoâne, with an area of about 10 square miles, are also situated in this rift near the Dominican frontier.

The principal mountain ranges are the Massif du Nord on the northern peninsula, the Massif du Sud (Massif de la Hotte) on the southern peninsula, the Massif de la Selle in the southeast, and the Chaîne des Montagnes Noires in the central part of the country. The principal river is the Artibonite, which rises in the mountains of the Dominican Republic and flows westward for about 174 miles to drain into the Golfe de la Gonâve. To the north of the Artibonite is the country's second river, L'Estere, which is about 28 miles long; both rivers are partly navigable.

Offshore islands

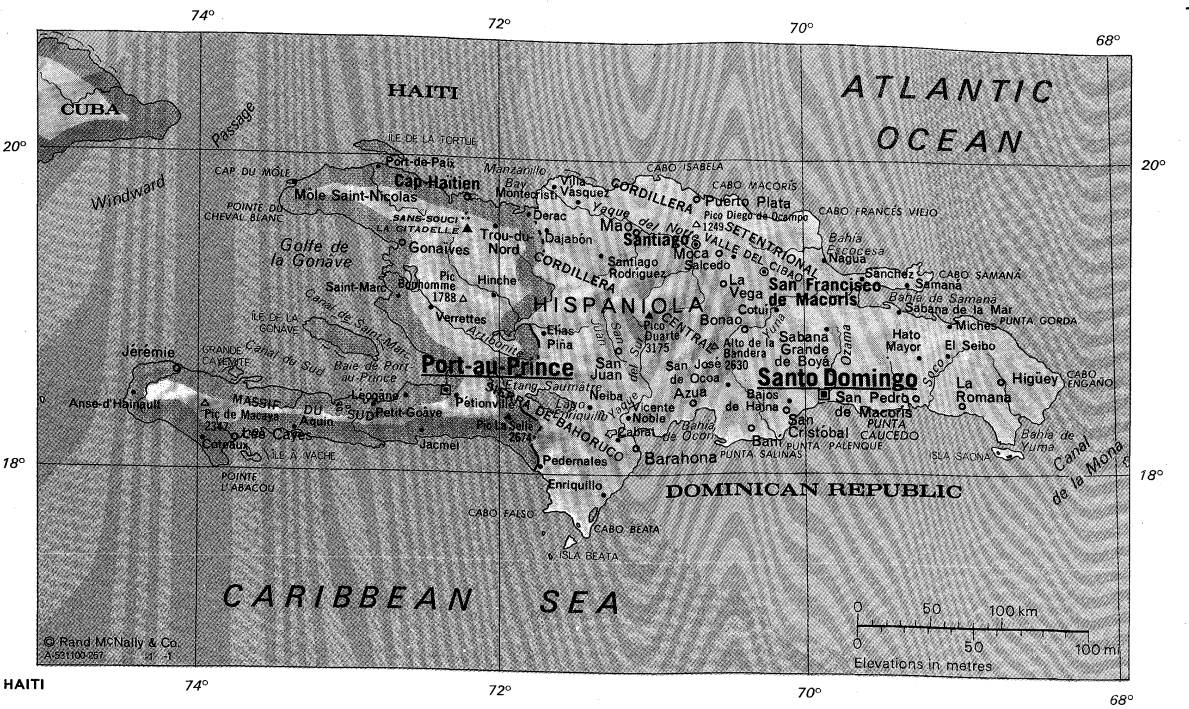
Haiti has several offshore islands, the largest of which is the island of La Gonâve, about 40 miles long and with an area of 254 square miles; it lies about 40 miles northwest of Port-au-Prince. Off the northern coast lies the small island of Tortuga ("Turtle Island")—once the haunt of French buccaneers who, in the 17th century, first colonized the western part of Hispaniola; it has an area of 69 square miles. Other small islands are Grande Cayemite, situated off the northern coast of the southern peninsula, and Île à Vache, which lies off the southern coast.

Climate. Haiti lies near the northern limit of the tropical zone. The climate is modified by the proximity of the sea as well as by the mountainous terrain. Temperatures vary little throughout the year; they remain constantly high near sea level, but are lower at the higher altitudes inland. Average temperatures range from 75° F (24° C) in January and February to 83° F (28 °C) in July and August. Port-au-Prince, at sea level, has an average annual temperature of 80° F (27° C). Inland, frosts occur from time to time at high altitudes, such as Pic la Selle (8,793 feet). There is considerable variation in the amount of rainfall experienced at different locations, as the mountain ranges intercept low-flying clouds blown by the northeast trade winds in winter, and by eastern and southeastern winds in summer. Seasonal rainfall is highest in the south from May to November, and in the north from December to April. The average annual rainfall varies greatly in different locations: at Môle Saint-Nicolas in the northwest it is only about 20 inches, while some highland areas receive over 100 inches. Hurricanes occasionally strike the island, travelling from south to north; they may occur between the months of August and November.

Vegetation and animal life. Timber was once so abundant that mahogany and guayacan (a certain type of lignum vitae, the hardwood) were exported in quantity. The demand for cultivable land created by an increasing population, however, led to deforestation, so that today only a few pine forests survive at the higher altitudes. Stands of mahogany, rosewood, and cedar may still nevertheless be found. An alpine type of vegetation occurs at altitudes of more than 4,800 feet, where the climate is misty, cold, and damp. Elsewhere, many tropical and semi-tropical plants occur, with coconut palms and trees bearing such tropical fruits as avocados, mangoes, limes, and oranges growing wild. Mangrove swamps are often found bordering tidal mud flats on the coast.

So far as is known, animal life never included poisonous snakes or mammals large enough to be dangerous to man. There are a number of rodents, and insects abound. Reptile life includes crocodiles, iguana, and lizards. There are over 200 species of birds, including ducks and guinea hens, and—on the lakes—flamingos. There are about 270 species of fish in the coastal waters, including tarpon, kingfish, barracuda, and red snapper.

Traditional regions. Five traditional regions may be recognized; they correspond closely to the five *départements* into which the country has been divided—the North, the Northwest, the Artibonite, the West and the South. The North—in reality located in the northeast—is a well-watered plain, suitable for the cultivation of tropical crops, including sisal in its northeastern corner, which receives somewhat less rainfall than the remainder. The Northwest is, on the contrary, an arid area that becomes desert in its southern half; the island of Gonâve may be grouped with this arid region. In the centre of the country the region of the Artibonite River basin includes both a lowland area and the Central Plateau; rainfall is not abundant, but the Artibonite River itself, which flows at the rate of almost 3,000 cubic feet per second, offers possibilities of hydroelectric development. The West (in effect the southeast), where the cap-



MAP INDEX

Cities and towns

Physical features and points of interest

ital is located, is where geographic contrasts are the most noticeable; here the people of the plains depend for their subsistence on the waters that flow down from the Massif de la Selle. The South (in effect the southwest) consists of fertile valleys tucked between mountain ranges that render transport unusually difficult; in addition the region is exposed to hurricanes from the south.

Human settlement. Human settlement almost everywhere has modified the natural landscape. The countryside is settled not by villages but by scattered extended-family settlements, which take the form of small groups of dwellings sheltered from passers-by and from the winds by groves of banana and coffee trees. The small wooden-frame houses thus protected vary in design according to the region, but are everywhere enclosed within a compound of four mud-daubed wattle walls. The roof is either thatched or—when the inhabitants are prosperous—is made of corrugated-iron sheets. Some peasants achieve considerable wealth, but seldom use it to further improve their housing; the furniture inside most houses remains restricted to necessities, with tools such as hoes and machetes taking pride of place. Wealth is invested in land and cattle, as well as in lavish entertainment that all who can are expected to provide free for all. The traveller in the countryside often meets small groups of men engaged in collective work to the sound of drums and other instruments; files of women bringing produce to market are also a common sight. On Saturday night dance drums can be heard everywhere.

Family settlements

Urban growth has played a lesser part than rural population growth in changing the Haitian landscape. About 420,000 people live in Port-au-Prince, and a further 30,000 in its suburbs, but after this the principal towns are Cap-Haïtien (population 44,000), Gonaïves (29,000), Les Cayes (23,000), Jérémie (17,000), and Port-de-Paix (14,000)—fewer than 600,000 town dwellers all told. Thus out of a population of nearly 4,250,000, only about 13.6 percent is urban. The official urban figure of 18 percent includes residents of about 100 commune (local administrative district) headquarters, most of whom are farmers. Town growth, moreover, is virtually restricted to Port-au-Prince, with its Pétionville suburb, and Cap-Haïtien.

Port-au-Prince was founded in 1749. It was laid out on a gridiron plan in an almost unbelievably beautiful setting of green and red mountains that fall abruptly down to the blue waters of the Golfe de la Gonâve. The city centre has uninterrupted rows of stone houses, and several buildings that have arcades. The streets are straight and still broad enough for the existing traffic. The poorest inhabitants—constituting more than half the city's population—live in wooden frame houses that cover the hills to the north and the low ground to the south. Density reaches a peak of 284 to the acre around the Catholic cathedral.

The route to the mountains is via the Champ de Mars, the old colonial drilling ground and promenade, now turned into public gardens; it is dominated by the national palace—Haiti's White House. Relatively well-kept houses stand to the north and south of it; they are occupied by skilled manual workers or junior office employees whose children, on Sundays, crowd the streets dressed in school uniforms. Farther east are residential areas standing on slopes that become progressively steeper and are covered with thick garden vegetation from which royal palm trees emerge with dignity. The density in this area is 40 persons per acre, or even less, as houses grow fewer in number but larger in size and modern in style. Stupendous views of Baie de Port-au-Prince are seen from these slopes, particularly at sunset.

Cap-Haïtien

Cap-Haïtien has virtually remained within the limits of its gridiron plan established in the French colonial era. It differs in appearance from the capital city because fear of fires once made its governor decide that all its houses should be built of stone. Today it remains an old-fashioned agglomeration of storied and balconied stone houses.

People and population. Haiti's population was about 3,000,000 in 1950, was estimated at about 4,000,000 in 1962, but was found to have increased to only 4,244,000 at the 1971 census.

The official language is French, but workers and peasants speak Creole—a language in which many West African elements are discernible, although its vocabulary is of predominantly French origin. The bulk of population originated in the 480,000 slaves who won their freedom in a struggle that ended with Haiti's independence in 1804. Most of the Africans brought to the island before the middle of the 18th century came from the Dahomeyan town of Ouidah, in West Africa, but later on the French slave traders mostly called at Loango in the Congo. Mulattoes, who often had enjoyed the privilege of some education, also formed part of the new nation, together with a few Europeans. Since 1804 small waves of immigration have taken place—the immigrants consisting mostly of traders and mechanics, together with a few teachers and priests; they came at first from the British Isles and later from the United States, forming a part of the same repatriation movement that elsewhere gave birth to Liberia. A concordat with the pope, signed in 1860, gave Haiti an all-French clergy and helped to attract more French-speaking residents, some of whom came from France, some from Guadeloupe, and some from Martinique. Members of these three foreign communities today hardly number more than 1,000 and almost all of them are of mixed foreign and Haitian parentage. Arab traders came in the latter years of the 19th century, followed by a few Germans and Italians. The U.S. occupation, which lasted from 1915 to 1934, led to the establishment of a number of enterprises, both public and private, manned by personnel who, in contrast to earlier immigrants, migrated with their families.

Almost all Haitians are baptized as Roman Catholics, and the clergy has always consisted of ordinary priests rather than missionaries. Protocols with the pope, signed in 1966, enabled the president to appoint an archbishop, two bishops, and three auxiliary bishops of Haitian descent. There are about 160 Haitian priests and the three bishoprics still held by the French are likely to have Haitian incumbents before long. British Methodists introduced Protestantism as early as 1816, but no mass conversion movement was launched before the advent of American revivalist missionaries in the 1940s. Even so, Protestants remain few, and to place their numbers at 10 percent would seem an exaggeration, although they stand high in prestige in both rural and urban communities.

The realities of religion in Haiti, however, require a look in another direction. As the country was left without a regular clergy until as late as 1860, the peasants built up Voodoo (*vaudou*), a syncretic cult in which the Catholic god rules over an African pantheon—a far cry indeed from the voodoo of New Orleans.

The national economy. Although Haiti, like its neighbour the Dominican Republic, has a diversity of resources unknown to other West Indian islands, these resources are too limited in quantity for commercial exploitation.

Table 1: Town Growth in Haiti

	1950 census	1971 census
Port-au-Prince	134,600	420,000
Suburbs	30,000	30,000
Cap-Haïtien	24,200	44,000
Gonaïves	13,600	29,000
Les Cayes	11,600	23,000
Jérémie	11,000	17,000
Port-de-Paix	6,400	14,000

Known mineral resources are restricted to alluvial gold (discovered on the Haitian-Dominican borders as early as the 16th century), copper, bauxite (discovered comparatively recently), and small quantities of silver, lignite, and manganese.

Population pressure on the land

Vegetation and other biological resources are unusually varied in species, but have suffered as a result of overpopulation, which even at times led hungry peasants to uproot coffee trees in order to plant quick-growing foodstuffs instead. Soil erosion has resulted from such actions, and soil conservation by terracing has only occurred sporadically in recent decades. Educational work is needed before improved methods of cattle-breeding and fishing can be introduced.

Prospects for the use of hydroelectric power are limited almost everywhere except in the Artibonite River Valley, which has a potential for large-scale development.

More than 85 percent of the economically active population is employed in agriculture and fishing. Coffee, by far the most important commercial crop, is cultivated on the slopes of almost all mountains, in the shade of fruit and other trees. Haitian coffee is of an excellent mild type, but production varies considerably from year to year. Sugarcane is grown on all the plains, but depends for success on irrigation. Most of the crop is processed at a mill located near Port-au-Prince. The northeast is favourable for the cultivation of sisal (about 27,000 metric tons were produced in 1969), and the Artibonite Valley for rice, the yearly crop amounting to about 45,000 tons. Cacao, tobacco, and cotton are also grown. Aromatic plants, such as lime, vetiver (the khuskhus plant, from the roots of which an oil is derived), neroli (sour orange, used for making perfumes), and amyris (a tropical shrub from which a sweet oil is obtained), are grown in the south and are processed for their essential oils.

Table 2: Haitian Production
(in 000 of metric tons)

year	coffee	sugar
1960	25.5	60
1961	43.5	71
1962	35.4	69
1964	33.0	61
1965	34.5	65
1966	27.9	68
1968	27.9	67
1969	27.9	59
1970	28.8	66

Source: *United Nations Statistical Year Book*, 1971.

Crops grown for local consumption include maize (the staple food), manioc, several kinds of peas and beans, and all tropical fruits but especially mangoes. Bananas are mostly of the plantain species, and are eaten as a vegetable rather than as a fruit. Palm trees disappear at about 3,600 feet above sea level, and vegetables and fruits characteristic of temperate climates may be grown. Out of the total agricultural production, farmers use about three-quarters for their own consumption, export about 20 percent, and process about 5 percent.

Mining has so far yielded disappointing results. The production of bauxite was 446,000 tons in 1968. The

output of copper, which was 5,000 tons in 1964 fell to 1,800 tons in 1969, and silver production fell from 92,000 to 17,000 troy ounces during the same period. Alluvial gold, collected by Indians at the time of Columbus, still yields about 8,000 troy ounces a year.

Manufacturing. The oldest and largest industrial plant in Haiti is the Port-au-Prince sugar mill, but two others were opened more recently. Total production averages 66,000 tons, but can increase when higher international quotas permit. A cement factory has a yearly capacity of 60,000 tons, but in 1967 had an output of only 35,000 tons. There are two cotton mills, two soap factories, and a tannery, as well as some small plants producing pharmaceutical and plastic articles, paint, and aerated water.

Fuel-driven generating plants supplied about 80,215,000 kilowatts of electricity in 1968, 90 percent of which went to Port-au-Prince.

Financial services. The state operates a central bank that issues notes and coins in gourdes, the national currency, maintained at a fixed value of U.S. 20 cents (5 gourdes = $1 U.S., 12 gourdes = £1 sterling on December 1, 1970) ever since the time of the American occupation, which ended in 1934. There are state banks for development and for rural credit and three private ones —the Banque Commerciale d'Haïti, the Royal Bank of Canada, and the Banque Populaire Colombo-Haïtienne.

Foreign trade. More than one-half of the foreign trade is conducted with the United States, which took 60 percent of exports and supplied 52 percent of imports in 1967–68. Other buyers of Haitian products are France, Italy, and Japan, while Japan and France also supply goods. Coffee, the largest export item, accounts for about 41 percent of all exports. Sisal represents about 5 percent of exports; other exports are sugar, bauxite, copper, and handicrafts. Imports include cotton goods, foodstuffs, machinery, mineral oils, and motor vehicles.

Table 3: Haitian Foreign Trade
(in $000,000 U.S.)

year	imports	exports	year	imports	exports
1938	8	7	1963	39	41
1948	31	30	1964	41	40
1953	44	38	1965	36	37
1958	43	39	1967	36	34
1960	36	33	1968	38	36
1962	46	43	1970	53	40

Source: *UN Statistical Year Book*, 1969, 1971.

The economy, as is often the case in developing countries, is governed by an oligopoly of foreign merchants who maintain the state through export taxes and custom duties, the burden of which ultimately falls on the peasantry. Out of a revenue of about 140,200,000 gourdes for the fiscal year 1968–69, the government spent about 25.5 percent on defense and police, about 11.7 percent on education, about 13.6 percent on health, and about 8.1 percent on debt redemption.

Trade unions. Trade unions have been recognized since 1946, but they never had more than 7,000 paying members and their numbers declined from 56 in 1954 to 48 in 1964. Employers maintain a chamber of commerce in Port-au-Prince.

Transportation. Transport problems result from the the mountainous character of two-thirds of the country; rivers usually have to be crossed close to the seashore, where their flow is broader and deeper than farther inland. All travelling on land was on horseback until as late as 1915. Since that time about 2,000 miles of roads have been built, but they deteriorate rapidly in the rainy season. There are about 14,700 motor cars in the country. Three short railway lines, radiating from the capital, have a combined length of 187 miles, and are used to carry sugarcane and other produce. The indented coastline, however, has innumerable tiny ports that have been visited by small craft since the days of buccaneers and freebooters. Small sailboats and power boats still call there regularly, and several hundred foreign vessels visit the two main ports of Port-au-Prince and Cap-Haïtien each year.

Difficulty of travel

An airport, accommodating jet aircraft, is situated close to Port-au-Prince; there are frequent flights to and from New York, either directly or via Santo Domingo, San Juan, or Miami.

Administration and social conditions. Since 1804, Haiti has had 20 different constitutions and 41 heads of state, including two emperors and one king. Today, under the 1964 constitution, the president is elected for life. He appoints the members of his Cabinet—all styled secretaries of state—and usually directs one to two or more of the 19 departments into which his administration is divided. There is a unicameral National Assembly of 58 members, and an advisory role is played by a Resources and Development Council and a Budget Bureau. The national territory is divided into five *départements.* The *départements*, each of which has a capital, are further subdivided into communes, of which there are about 100, each one consisting of a centre called a *bourg*, which enjoys municipal authority, and five to six *sections rurales* (rural districts), each supervised by a local resident appointed by the central police authority.

All Haiti's constitutions have provided for universal suffrage, which, since 1950, has also included women, but, as almost all rural citizens are illiterate, the results of elections are always subject to discussion. The only organized party is the "Single Party for Revolutionary and Governmental Action," founded by President Duvalier. In rural areas the peasants are prompt to react when their *chefs de section* (district leaders) exceed their power, but opposition at the national level is expressed only by political groups remaining abroad.

Political activity

Justice. Justice is rendered according to the French tradition. Codes inspired by those of Napoleon were issued in 1825 together with a more peculiar Rural Code that governs the conduct of country life. There is a justice of the peace in every commune, as well as primary courts at departmental capitals, four Courts of Appeal, and a Supreme Court in Port-au-Prince. All judges are appointed by the head of state; the higher ones are appointed for terms of ten years.

The armed forces. The armed forces are divided into four services. These are, firstly, the army proper, consisting of about 1,000 men with 100 officers; the presidential guard, which is composed of 250 men and 15 officers; the air force, consisting of 140 men and 30 officers; and the coast guard, consisting of 250 sailors and 40 officers, manning eight patrol vessels. Since 1961 there has also been a militia, the National Security Volunteers, numbering about 10,000 men and women; they are popularly known as Tontons Macoutes—a name that literally means "uncles knapsacks" and derives from a folk-tale ogre.

Education. The educational tradition also is French. Public schools are free and attendance is compulsory at the primary level, but funds are lacking for the proper implementation of the law, except in Port-au-Prince, which has about as many children at school as there are throughout the rest of the country. There are about 300,000 in school altogether, of which 20,000 are in secondary school and the remainder in primary school. There is a university at Port-au-Prince with an enrollment of about 1,500.

Health and welfare. There are about 350 doctors—approximately one doctor for 13,420 people. In the towns there are 11 hospitals and 12 outpatient clinics, while in the countryside there are about 150 rural clinics and 17 sanatoriums. The United States Agency for International Development (AID) formerly conducted malaria-eradication campaigns and distributed surplus food, but the agency left Haiti in 1966. Yaws was practically eradicated by mass treatment performed with international assistance in the 1950s. No reliable data are available on health conditions but the infant mortality rate is estimated at 170 per 1,000 live births, and an alleged life expectancy of 40 years was mentioned as an objection to a 1966 law providing a pension at 65, on the basis of contributions of 3 percent of earnings over a 20-year period.

Table 4: School Population in Haiti, 1968

level	teachers	pupils
First level (primary, elementary)	6,778	275,192
Second level–general (secondary school, high school, middle school)	1,286	23,047
Vocational (trade and technical, teacher training)	383	5,892
Third level (university, teachers' college, higher professional school)	226	1,313

Regular welfare services are in an embryonic stage. They would, in any case, hardly fit the peculiar needs of the country. But 209 cooperatives may be mentioned as fostering mutual help along lines that are not without roots in Haitian tradition.

Housing. Housing is simple but adequate in the countryside, but is quite unsatisfactory in towns because of overcrowding, despite the fact that five presidents in succession have built model estates out of their private funds. A number of privately built residences in Port-au-Prince offer interesting examples of the use of cement and wrought iron in modern tropical architecture.

Police services. There are 600 policemen in the capital city, and about 2,000 more in the rest of the country, including about 500 people who, as mentioned earlier, act as part-time *chefs de section.*

Wages and cost of living. Wages are low and are hard to control by legislation; an attempt to establish a fixed minimum wage a number of years ago was virtually disregarded. Prices in recent times have risen more rapidly than in the past. Between 1963 and 1969 the cost of living rose by about 20 percent except for rents, which were "frozen" by the government, which forbade further increases.

Social and economic divisions. In sharp contrast to the rest of Latin America, Haiti never had a landed aristocracy. Thus power was for a long time held by an élite of professionals and of merchants of old standing. The contact between them and the illiterate masses was maintained through the army, which, until 1915, was an administrative as well as a military body, thus providing an opportunity for social as well as political mobility. After 1915 social and economic development resulted in the growth of two intermediate social groups. One of them, most conservative in outlook, associated itself with élite employers, but the other consisted of skilled manual and junior office workers who held entirely different views. The tension between these two groups grew more bitter than tension between the élite and the illiterates had ever been. In 1946 the majority, consisting of the poorer people, brought to power Dumarsais Estimé, who was defeated in 1950 by a reaction led by Gen. Paul Magloire; in 1957, however, the majority, most of whom are black rather than mulatto, won again with François Duvalier, who remained in power until his death in 1971. This resulted in a mass emigration of the élite and of many others associated with previous governments.

Tensions between élite and peasants

Cultural life and institutions. Haitian arts and literature have traditionally been under strong French influence, in spirit as well as in language, although the author Georges Sylvain (1865–1925) marked a new departure when he wrote fables in Creole under the title *Cric-Crac* (a traditional password and response exchanged between storyteller and audience at the beginning of a tale) as early as 1901. An interest in local folk culture became apparent in the late 1920s with the publication of a periodical, *La Revue Indigène,* and of *Ainsi Parla l'Oncle,* an essay by the internationally renowned scholar Jean Price-Mars (1876–1970). Another Haitian author, Jacques Roumain (1907–44), first won world fame writing French novels on popular Haitian subjects and on folk tradition, subsequently exercising a powerful influence in theatrical dancing and in painting as well as in literature. The works of Haitian folk painters are hung in many museums and private collections abroad.

Port-au-Prince has museums of history and ethnology, a national library, and a library of Haitiana kept in a Catholic school. Seven dailies and about 35 other periodicals are published. Three dailies are of old standing—the official *Le Moniteur* gazette, with a circulation of 4,000 and *Le Nouvelliste* and *Le Matin,* each of which has a circulation of 3,000. Public libraries are maintained at departmental headquarters.

The capital city has 14 radio stations; a television station was opened in 1965. In 1967 the television station was temporarily closed because of financial problems.

Table 5: Haiti, Area and Population

	area		population	
	sq mi	sq km	1950 census	1971 census*
Départements†				
L'Artibonite	2,625	6,800	567,000	756,000
Nord	1,583	4,100	539,000	698,000
Nord-Ouest	1,062	2,750	168,000	212,000
Ouest	3,050	7,900	1,083,000	1,611,000
Sud	2,394	6,200	740,000	967,000
Total Haiti	10,714	27,750	3,097,000	4,244,000

*Preliminary figures. †Statutory provision has been made for the creation of four new *départements:* Centre, Grand Anse, Nord Est, and Sud Est. No administrative action has yet been taken to create them.
Source: Official government figures.

Prospects for the future. Economically Haiti faces difficulties because the growth in gross domestic product is virtually absorbed by the rate of population increase. In the earlier 1960s there was a small improvement in living standards, but by the later 1960s further population growth had offset economic advancements. The best hope for a more rapid improvement in living standards resides in an irrigation project in the Artibonite River valley, which might enable some 22,000 farmers to settle on 80,000 acres there.

BIBLIOGRAPHY. Official statistical data appears in the *Bulletin trimestriel de statistiqué* (quarterly); and, occasionally, in *Guide économique de la République d'Haïti.* The results of the 1950 census were published in *Recensement général de la République d'Haïti* (1950). Only summary results of the census of 1971 are so far available. General information may be found in S. RODMAN, *Haiti: The Black Republic* (1954); and S. SIMMONDS, *Economic and Commercial Conditions in Hayti* (1956). For their relation to world events, see K. IRVINE, *The Rise of the Colored Races* (1970). Opposite views on recent developments were presented by H. COURLANDER and R. BASTIEN, *Religion and Politics in Haiti* (1966); B. DIEDERICH and A. BURT, *Papa Doc* (1969); and F. DUVALIER, *Mémoires d'un leader du Tiers-Monde* (1969). Changes in the social structure were studied by S. and J. COMHAIRE-SYLVAIN, "Urban Stratification in Haiti," in *Social and Economic Studies, University of the West Indies, Jamaica,* vol. 8 (1959); and the emergence of a new art school by S. RODMAN, *Renaissance in Haiti* (1949). Haitian folk culture was described in a general way by H. COURLANDER, *The Drum and the Hoe* (1960). The results of extensive field work were incorporated in A. METRAUX *et al., Making a Living in the Marbial Valley, Haiti* (1951); and in R.A. HALL *et al., Haitian Creole* (1953).

(E.Sy.)

Haiti, History of

Christopher Columbus discovered the island that now includes Haiti and the Dominican Republic on December 6, 1492, and named it La Isla Española. By the end of the 16th century, most of the island's original Arawak Indian population had disappeared—worked to death or slaughtered outright by the Spaniards or killed by disease. Spanish settlement was thin and restricted mainly to the eastern end of the island; French pirates, based in the Cayman Islands, had an almost unimpeded run of the western end. The pirates began to establish plantations there; in 1664 they founded Port-de-Paix in the northwest, and the French West India Company took possession (see DOMINICAN REPUBLIC, HISTORY OF THE).

Arrival of the French

The French colonial regime (to 1804). In 1697, by the Treaty of Ryswick, the western third of the island was formally ceded to France by Spain and was renamed Saint-Domingue.

Prosperity under the French. The 18th century saw a great increase in Saint-Domingue's population. It became the most prosperous New World colony, exporting sugar, coffee, cocoa, indigo, and cotton cultivated by African slave labour; most of the land and slaves were owned by a handful of families. By 1789 nearly two-thirds of France's foreign investments were based on Saint-Domingue, and in a good year its trade needed more than 700 oceangoing vessels carrying more than 80,000 seamen.

Abolition of slavery. Saint-Domingue had a population in 1789 of 556,000; of this, 500,000 were slaves, 32,000 were whites, and 24,000 were free blacks. On August 24, 1791, stimulated by the French Revolution (begun 1789), the slaves rose in rebellion. In order to maintain the island as a French possession, slavery was abolished by a decree of February 4, 1794. In 1795, by the Treaty of Basel, Spain ceded the rest of the island to France, but war in Europe precluded the actual transfer of possession.

Moves toward independence. In May 1801 Toussaint-Louverture (*q.v.*), a former slave, was declared governor general, but he would not take the final step of declaring the colony independent. Later that year Napoleon sent his brother-in-law, Gen. Charles Leclerc, with an experienced force, including several mulatto officers in exile from Saint-Domingue, to restore the old regime. After several months' resistance, Toussaint came to terms with the French expedition, early in 1802. But the French broke the arrangement and imprisoned him (he died on April 7, 1803).

In the face of a rumour that Napoleon intended to restore slavery in Saint-Domingue as he had done in other French possessions, Jean-Jacques Dessalines and Henry Christophe led a black army against the French in 1802. The French commander and a large part of his army were defeated, and on November 9, 1803, the remnant of the French expedition, under Gen. Jean-Baptiste Rochambeau, surrendered. Under the armistice signed on November 18, the French withdrew, but they maintained a presence in the eastern part of the island until 1809.

Haiti (1804–1957). On January 1, 1804, the whole island was declared independent under its original Arawak name of Haiti.

Independent Haiti (1804–1915). The war with France had utterly laid waste the country and destroyed the economy. In October 1804 Dessalines assumed the title of Emperor Jacques I; on October 17, 1806, he was killed while trying to put down a mulatto revolt and Henry Christophe took control of his kingdom. Civil war broke out between the blacks under Christophe (later Henry I) in the north and mulattoes under Alexandre Sabès Pétion, based at Port-au-Prince in the south. In 1808, with British help, Spanish rule was restored in the eastern part of the island (Santo Domingo).

Christophe managed to improve the country's economy, but he had to force peasants to work on the plantations. He built a spectacular palace, Sans Souci, where he held an equally spectacular court; he also built an imposing fortress, the Citadelle Laferrière, in the hills to the south of Cap-Haïtien—where, with mutinous soldiers almost at his door, he committed suicide in 1820.

Jean-Pierre Boyer, who had succeeded to the presidency of the mulatto south on Pétion's death in 1818, became president of the whole country after Christophe's death. In 1822 he invaded and conquered Santo Domingo, which had declared itself independent from Spain the previous year and was now engaged in fighting the Spaniards and in internal quarrels. Boyer abolished slavery and confiscated church property in Santo Domingo; it was not until 1844 that the Haitians were expelled from Santo Domingo by a popular uprising.

Haitian independence was recognized by France in 1825, in return for an indemnity of nearly 100,000,000 francs, to be paid at an annual rate until 1887. Britain recognized the state in 1833, the United States in 1862, after the secession of the Southern slave states, which had objected to recognition.

Boyer was overthrown in 1843. Between then and 1915 a succession of 20 rulers followed, 16 of whom were overthrown by revolutions or were assassinated. The 1890s saw an increase in U.S. attempts to gain military and commercial privileges in Haiti. In 1905 the U.S. took Haiti's customs into receivership, and before World War I, U.S. business interests had gained a secure financial foothold and valuable concessions.

U.S. involvement

U.S. occupation (1915–34). From 1915 to 1934, Haiti was occupied by U.S. Marines. The U.S. claimed legal justification on the grounds of humanitarian intervention and under the Monroe Doctrine. Many Haitians believed that the Marines had really come to protect U.S. investments in the country and to establish a base to protect the approaches to the Panama Canal. Haiti signed a treaty with the U.S.—originally for ten years, but eventually it lasted until 1934—establishing U.S. financial and political domination. In 1918, in an election supervised by the Marines, a new constitution was introduced under which, for the first time, foreigners were permitted to own land in Haiti.

One effect of the Marine occupation was the nominal re-establishment of the mulatto elite in control of the government. Many Haitians resented the occupation, which they believed excluded them from public office and subjected them daily to racist indignities at the hands of the Marines. The Marines revived an old law of Christophe's time, which enabled them to employ forced labour on the roads. This resulted in a revolt of *cacos* (guerrillas), which was suppressed. The program of public works undertaken by the Marines in health clinics, sewage, and roads hardly satisfied the Haitians, who felt that these efforts barely scratched the surface and left little tangible result.

In October 1930 a national assembly, the first since 1918, was elected. Controlled by nationalists, it in turn elected as president Sténio Joseph Vincent. In August 1934 the U.S. president, Franklin D. Roosevelt, withdrew the Marines; but direct U.S. fiscal control continued until 1941; and indirect control continued until 1947.

Presidential regimes (1934–57). In 1935 a plebiscite extended Vincent's term to 1941 and amended the constitution so that future presidents would be elected by popular vote.

In October 1937, troops and police from the Dominican Republic (formerly Santo Domingo), with popular support, massacred thousands of Haitian labourers living near the border. The following year the Dominican government agreed to pay $3,400,000 in compensation to relatives of those slain, but only part was actually paid. The enmity between the two countries had long historical roots, going back to the events of the 19th century. The Dominicans, with their Spanish culture and greater admixture of European blood, looked with disfavour and a certain amount of fear upon the black Haitian labourer with his "inferior" African culture and lower standard of living, which enabled him to work for far less. Haitian labour was, however, necessary to the Dominican economy.

In 1946 Haitian workers and students held strikes and violent demonstrations in opposition to the president, Élie Lescot, who had succeeded Vincent in 1941 and had altered the constitution to enable himself to serve a further term. Three military officers seized power, and under their supervision Dumarsais Estimé was elected president. In 1950 Estimé in turn sought to extend his term, and the same three officers again took control. That October one of them, Col. Paul E. Magloire, was elected president in a plebiscite. Magloire in turn sought to remain in power unconstitutionally, but in December 1956 the army forced him to resign.

Haiti since 1957. In September 1957, after a period of considerable unrest and the rise and fall of several provisional presidents, François Duvalier (called "Papa Doc") —a black physician, formerly employed on a U.S. medical-aid scheme and a student of vodun (voodoo, an animist religion of African origin, with Christian influ-

Rise of Duvalier

ence)—was elected president in a plebiscite. Duvalier promised to end domination by the wealthy mulatto elite and to put political and economic power into the hands of the black masses. Violence continued, however, and in July 1958 there was an unsuccessful attempt to overthrow Duvalier. He organized an extralegal gang of violent adherents—the Tontons Macoutes—who terrorized the population. Duvalier, by then firmly in control, had himself elected president for life.

Relations with the Dominican Republic. In April 1952 an agreement was signed between Haiti and the Dominican Republic, regulating the movement of Haitian labour. In the late 1950s an uneasy alliance came into existence between Duvalier and Rafael Trujillo, the Dominican leader, to protect themselves against the common threat of uprisings similar to the successful overthrow of the Cuban government in 1959. In the 1960s, with a more liberal government in power in the Dominican Republic, Duvalier sealed off the border, razed a zone contingent to it, and prohibited entry on pain of summary execution; he aimed to keep infiltrators out of Haiti and to prevent Haitians from leaving.

The people. Haiti in the 1970s was a country in which 95 percent of the people were black, the remainder mulatto. The official language was French, but over three-quarters of the population spoke a Creole patois; near the Dominican border a Spanish patois was also spoken. The official religion was Roman Catholicism, but Duvalier claimed to be an authority on vodun, which the majority of the rural population practiced.

The economy. The economy was predominantly agricultural. The land was mostly cultivated in small overworked plots, with primitive tools, resulting in a low level of productivity. Production was mainly for local sale and subsistence. Coffee accounted for 75 percent of exports, the other main commodities being sugar and sisal. The second major source of income was tourism, with about 100,000 annual visitors. The country had considerable untapped resources, including abundant timber, fishing, and such minerals as gold, silver, copper, bauxite, and tin. A plan was announced for the Artibonite Valley, which would irrigate 100,000 acres and also provide electricity. Industry was mainly concerned with processing coffee, sugarcane, sisal, and edible oils; but there was also some production of soap, cement, and cotton fabrics and some light manufacturing for the U.S. market. The late 1960s saw a general economic decline, due partly to the ending of aid and investment from abroad and to a drop in tourism because of an uncertain political situation.

Economic decline in the 1960s

Education. Education was free where available in Haiti, but by 1970 only a small number of children attended schools. Secondary education was limited and provided mainly by the Roman Catholic Church. About 1 percent of the gross national product was spent on education. In 1968 there were 313 urban primary schools, 508 country schools, 16 professional schools, and 15 schools of higher education. There was also a university in Port-au-Prince. The majority of professional people—doctors, dentists, writers, academics, and journalists—had left the country, most going to Africa.

Government and administration. In April 1961 the two houses of the legislature were amalgamated into one. Although the constitution required elections every six years, by the early 1970s none had been held since April 1961. All assembly deputies were members of the one official party, and the assembly was completely subordinate to Duvalier, who ruled by decree. The constitution in effect in the early 1970s was mainly the result of the 1950 military coup, but it had been amended in 1964 to enable Duvalier to be made president for life.

Duvalier's rule. Haiti under Duvalier was, in effect, a police state ruled as a dictatorship. The militia was founded originally because Duvalier mistrusted the army and thus built an armed force of supporters with rudimentary military training. The militia still existed in the early 1970s, although Duvalier had by then strengthened his control over the army. The Tontons Macoutes, Duvalier's private police force, became less brutal and arbitrary, because its earlier conduct had disturbed tourists.

Several attempts to overthrow Duvalier by force were unsuccessful, and in 1968 his enemies tried unsuccessfully to invade Haiti from outside the country. In 1969 Duvalier began to show increasing signs of ill health. His death in 1971 left Haiti's future even more uncertain than before.

BIBLIOGRAPHY

General: J.G. LEYBURN, *The Haitian People* (1941, reprinted 1966 with new introduction by S. MINTZ), an overall survey of the growth of Haiti including a very good sociological and historical analysis of the development of Haitian culture and institutions, based on the thesis that Haitian society is and always has been deeply divided between two castes, a small mulatto elite and the black peasant masses, and a supplementary bibliography dealing with the period since 1941.

Historical background: C.L.R. JAMES, *The Black Jacobins: Toussaint L'Ouverture and the San Domingo Revolution*, 2nd ed. with new appendix (1963), generally accepted as the most revealing analysis of the historical forces, social and economic, that led to the establishment of the independent state of Haiti and of the part played in this movement by Toussaint, Dessalines, and Christophe.

Sociological and cultural background: H. COURLANDER and R. BASTIEN, *Religion and Politics in Haiti* (1966); H. COURLANDER, *The Drum and the Hoe* (1960), an evocative study of the culture of the Haitian peasant as revealed in his daily life in the fields and in the village; M.J. HERSKOVITS, *Life in a Haitian Valley* (1937, reprinted 1964), a penetrating, detailed study of a Haitian peasant community at Mirebalais.

Politics: B. DIEDERICH and A. BURT, *Papa Doc: Haiti and Its Dictator, Francois Duvalier* (1969; U.S. title, *Papa Doc: The Truth About Haiti Today*, 1969), a recent and up-to-date account, sometimes superficial in conception and often clumsy in execution, of the rise of Duvalier and his consolidation of power; L.F. MANIGAT, *Haiti of the Sixties: Object of International Concern* (1964), a penetrating analysis of the present regime and the historical and political background from which it came.

(C.L.R.J.)

Ḥājj ʿUmar, al-

A century ago, ʿUmar Tal founded the empire of the Masina, in the western Sudan (in the modern Republic of Mali). But this black conqueror was hardly a man of his time. He lived, fought, and died more like a 7th-century warrior. He was a mystic, and his life resembled those of the early followers of the Prophet Muḥammad, who fought in the name of God and converted by fire and the sword. Senegalese poets, singing of ʿUmar's life, have compared it with the Prophet's. Some have glorified him and lauded his victories, citing the thousands he killed and the thousands he sold into slavery as proof of the divine character of his mission, but others to this day hate him for having shed Muslim blood.

ʿUmar Tal was born about 1797 in the village of Halvar in Fouta Toro in the upper valley of the Sénégal River and was a member of the Tukulor tribe. His father was an educated Muslim who instructed students in the Qur'ān, and ʿUmar, a mystic, perfected his studies in Arabic and the Qur'ān with scholars of a Moorish tribe who initiated him into the Tijānīyah brotherhood.

Pilgrimage to Mecca

At the age of 23, ʿUmar set out on the pilgrimage to Mecca. He was already well-known for his piety and erudition and was received with honour in the countries through which he travelled. Muhammad Bello, emir of Sokoto in Nigeria, offered him his daughter Maryam in marriage. Enriched by this princely alliance, he had become an important personage when he reached Mecca about 1827. He visited the tomb of the Prophet in Medina, returned to Mecca, and then settled for a while in Cairo. On a visit to Jerusalem he succeeded in curing a son of Ibrahim Pasha, the viceroy of Egypt. In Mecca, finally, he was designated caliph for black Africa by the head of the Tijānīya brotherhood.

Armed with his prestige as a scholar, mystic, and miracle worker, ʿUmar returned to the interior of Africa in 1833. Trained for political leadership by his father-in-law, Muhammad Bello, the emir of Sokoto, with whom he again spent several years, and his position strengthened by the title of caliph, ʿUmar now decided to obey

the voice of God and to convert the pagan Africans to Islām.

By now he was not only looked upon as a miracle worker but had also acquired a bodyguard of followers and of devoted Hausa slaves.

Upon the death of Bello, he left for his native country, hoping to conquer the Fouta with the help of the French, in exchange for a trade treaty, an agreement the French declined because of ʿUmar's growing strength. ʿUmar realized that faith without force would be ineffective and made careful preparations for his task. In northeast Guinea, where he first established himself, he wrote down his teachings in a book called *Kitāb rimāḥ ḥizb ar-raḥīm* ("Book of the Spears of the Party of God"). Deriving his inspiration from Ṣūfism—a mystic Islāmic doctrine—he defined the Tijānī "way" as the best one for saving one's soul and for approaching God. He recommended meditation, self-denial, and blind obedience to the sheikh. He gained many followers in Guinea, but, when, in 1845, he went to preach in his own country, he met with little success.

Military achievements

Having built up an army ʿUmar decided to use force. In March 1854 he issued an order for a *jihād* to sweep away the pagans and bring back the Muslims who had strayed from the fold. Starting out with about 10,000 men who lived off the land, he spread terror in order to force the pagan chieftains to submit. In 1855 he defeated the Bambara pagans of Mali, adding to his empire. He forcibly converted them, yet these conversions proved to be ineffectual. To defend his authority ʿUmar had 300 hostages executed, but revolt broke out again as soon as his armies were removed.

After an unsuccessful attack on a French fort that had refused to supply him weapons, ʿUmar again set off toward the east, but he had great difficulty subsisting in a land already ravaged. His men deserted, and his companions began to doubt his mission.

Having been unable to decisively conquer his adversaries, ʿUmar was to spend the next ten years trying to contain his empire. Repressing new revolts, he was led eastward by the resistance he stirred up. In 1860 he signed a treaty with the French general Louis Faidherbe, governor of Senegal, accepting the Sénégal River as a common boundary.

ʿUmar perennially had to defend his conquests and foil hostile coalitions without giving up the principle of the *jihād*. This proved difficult, however, when he was confronted by the Fulani people of the Masina, who were Muslims, followers of the Qādirīyah brotherhood. When ʿUmar attacked the Fulani, he no longer represented the "wrath of God"—he was a conqueror. His mission turned into a fratricidal war, and ʿUmar inspired in his adversaries a hatred that has survived to this day.

Both armies prayed to the same God before the battle. ʿUmar, recognizing the danger to his divine mission, proposed a duel with Aḥmadu III, the leader of the Fulani army. But the latter refused the judgment of God. ʿUmar won the battle, and Aḥmadu was captured and beheaded.

In 1863 ʿUmar took possession of the city of Timbuktu, but, defeated by the nomadic Tuaregs, he had to beat a retreat. In a subsequent battle, attacked by the Tuaregs, the Moors, and the Fulani, his army was destroyed. He withdrew to the city of Hamdalahi, where he was besieged. He escaped and took refuge in a cave, but on February 12, 1864, he was killed when the cave was blown up with gunpowder.

Al-Ḥājj ʿUmar Tal's empire lasted for 50 years, from 1848 to 1897, when it was annexed by the French. Few of the Mali people still remember it, except the descendants of the Tijānī initiates or the Fulani and Bambaras, who suffered the conqueror's cruelties. In order to enhance his own position, General Faidherbe described ʿUmar in his reports as the symbol of resistance to French penetration, at the same time recognizing his virtues and his courage. In fact, ʿUmar was not anxious to oppose the French. He had sought their neutrality and had hoped to buy arms from them, but they had other sources and feared his power. The mosque of Dinguiraye in Guinea is all that remains of ʿUmar's empire.

BIBLIOGRAPHY. There is no study in English that deals specifically with the life and work of al-Ḥājj ʿUmar. Additional information may be found in J. SPENCER TRIMINGHAM, *A History of Islam in West Africa* (1962); and J.D. HARGREAVES, *Prelude to the Partition of West Africa* (1963). A complete bibliography on Senegal, Masina, and the life of al-Ḥājj ʿUmar is included in YVES-J. SAINT-MARTIN, *L'Empire Toucouleur 1848–1897* (1970), an indispensable work. The *Kitāb rimāḥ ḥizb ar-raḥīm* (written 1845, published in Arabic 1927), is ʿUmar's most famous work, in which he explains his doctrine.

(J.C.F.)

Hakluyt, Richard

The geographer Richard Hakluyt persistently and imaginatively encouraged the continuation of exploration and colonization of the New World. At a time when England was on the brink of becoming a colonial nation, Hakluyt's lectures, publications, and advice proved to be as politically influential as Queen Elizabeth's closest counsellors in promoting the undertaking of overseas expansion. His immense knowledge and editorial skill set him apart from all other geographers of his time, and his three-volume work, *The principall Navigations, Voiages and Discoveries of the English Nation . . .*, provides almost everything known about the early English voyages to North America.

He was born in or near London about 1552, the third son of Richard Hakluyt. The Hakluyt family was of some standing in the Welsh Marches and held property at Eaton. His father died in 1557, leaving his family to the care of a cousin, another Richard Hakluyt, a lawyer who had many friends among prominent city merchants, geographers, and explorers of the day. Because of these connections, and his own expertise in overseas trade and economics, he was well placed to assist the future geographer in his life work.

Young Richard, with the help of various scholarships, was educated at Westminster School and Christ Church, Oxford, entering in 1570 and taking his M.A. degree in 1577. His interest in geography and travel had been aroused on a visit to the Middle Temple, one of the four English legal societies, while in his early teens. As he writes in the "Epistle dedicatorie" to *The principall Navigations*, his cousin spoke to him of recent discoveries and of the new opportunities for trade, and showed him "certeine bookes of Cosmographie, with an universall Mappe." His imagination thus stirred, the schoolboy had thereupon resolved to "prosecute that knowledge and kinde of literature" at the university. Some time before 1580 he took holy orders, and, though he never shirked his religious duties, he spent considerable time reading whatever accounts he could find about contemporary voyages and discoveries.

Public lectures

Hakluyt also gave public lectures—he is regarded as the first professor of modern geography at Oxford—and was the first to display

> both the olde imperfectly composed, and the new lately reformed Mappes, Globes, Spheares, and other instruments of this Art for demonstration in the common schooles.

He made a point also of becoming acquainted with the most important sea captains, merchants, and sailors of England. This was the time when English attention was fixed on finding the northeast and northwest passages to the Orient, and on Francis Drake's circumnavigation of the world. Hakluyt was concerned with the activities of Sir Humphrey Gilbert and Martin Frobisher, who were both searching for a passage to the East; was consulting Abraham Ortelius, compiler of the world's first atlas, and Gerardus Mercator, the Flemish map maker, on cosmographical problems; and was gaining approval for future overseas exploration from such politically prominent men as Lord Burghley, Sir Francis Walsingham, and Sir Robert Cecil. He thus embarked upon his career as a "publicist and a counsellor for present and future national enterprises across the ocean." His policy, constantly expounded, was the exploration of temperate North America in conjunction with the search for the Northwest Passage, the establishment of England's claim to possession based on the discovery of North America

by John and Sebastian Cabot, and the foundation of a "plantation" to foster national trade and national well-being. These views are first set out in the preface he wrote to John Florio's translation of an account of Jacques Cartier's voyage to Canada, which he induced Florio to undertake, and are further developed in his first important work, *Divers voyages touching the discouerie of America* (1582). In this he also pleaded for the establishment of a lectureship in navigation. In 1583 Walsingham, then one of the most important secretaries of state, sent Hakluyt to Paris as chaplain to Sir Edward Stafford, the English ambassador there. He served in Paris also as a kind of intelligence officer, collecting information on the fur trade of Canada and on overseas enterprises from French and exiled Portuguese pilots. In support of Walter Raleigh's colonizing project in Virginia, he prepared a report, known briefly as *The Discourse on the Western Planting* (written in 1584), which set out very forcefully the political and economic benefits from such a colony and the necessity for state financial support of the project. This was presented to Queen Elizabeth I, who rewarded Hakluyt with a prebend (ecclesiastical post) at Bristol Cathedral but took no steps to help Raleigh. *The Discourse*, a secret report, was not printed until 1877. In Paris Hakluyt also edited an edition of the *De Orke Novo* of Pietro Martire so that his countrymen might have knowledge of the early successes and failures of the Spaniards in the New World.

Hakluyt returned to London in 1588. The outbreak of war with Spain put an end to the effectiveness of overseas propaganda and the opportunity for further exploration so he began work on a project that he had had in mind for some time. This was *The principall Navigations, Voiages and Discoveries of the English Nation . . .*, which, by its scholarship and comprehensiveness, transcended all geographical literature to date; the first edition, in one volume, appeared in 1589. About this time he married Douglas Cavendish, a relative of Thomas Cavendish, the circumnavigator, and was appointed to the parish of Wetheringsett in Suffolk. Until after the death of his wife in 1597, little is heard of any geographical work, but he then completed the greatly enlarged second edition of the *Voyages*, which appeared in three volumes between 1598 and 1600. Shortly before its completion, he was granted by the Queen the next vacant prebend at Westminster so that he might be at hand to advise on colonial affairs. He gave information to the newly formed East India Company and continued his interest in the North American colonizing project; he was one of the chief promoters of the petition to the crown for patents to colonize Virginia in 1606 and at one point contemplated a voyage to the colony. Nor did his belief in the possibility of Arctic passages to the East fade, for he was also a charter member of the Northwest Passage Company of 1612. In 1613 appeared the *Pilgrimage* of Samuel Purchas, another clergyman fascinated with the new discoveries of the age; in spirit, it was a continuation of Hakluyt's own work, and the two editors probably became acquainted. Purchas procured some of Hakluyt's manuscripts after his death and used them in *Hakluytus Posthumus or Purchas his Pilgrimes* of 1625. Hakluyt died on November 23, 1616, and was buried in Westminster Abbey.

Major work

Works by Hakluyt in addition to those mentioned above include translations of Antonio Galvano's *Discoveries of the World . . .* (1601), and of Hernando de Soto's account of Florida, under the title *Virginia richly valued by the description of . . . Florida . . .* (1609). But it is the *Voyages* that remain his memorial. This, the prose epic of the English nation, is more than a documentary history of exploration and adventure; with tales of daring it mingles historical, diplomatic, and economic papers to establish British right to sovereignty at sea and to a place in overseas settlement. Its overriding purpose was to stimulate, guide, and encourage an undertaking of incalculable national import. Hakluyt was not blind to the profits arising from foreign trade. It has been asserted that the income of the East India Company was increased by £20,000 through a study of Hakluyt's *Voyages*.

BIBLIOGRAPHY. *The principall Navigations . . .* were reprinted with additional matter as *Hakluyt's Collection of the Early Voyages, Travels, and Discoveries of the English Nation*, new ed., 5 vol. (1809–12), and for the Hakluyt Society with a preface by WALTER RALEIGH, 12 vol. (1903–05). *The Divers voyages* was edited by the Hakluyt Society (1850). The best text of *The Discourse on the Western Planting* is in E.G.R. TAYLOR (see below). Many narratives from Hakluyt's collection have been republished by the Hakluyt Society (founded 1846). For his life, the dedications to the two early editions of *The principall Navigations* should be consulted. See also G.B. PARKS, *Richard Hakluyt and the English Voyages*, 2nd ed. (1961); E.G.R. TAYLOR, *The Original Writings and Correspondence of the Two Richard Hakluyts*, Hakluyt Society, 2nd series, vol. 76–77 (1935); J.A. WILLIAMSON, "Richard Hakluyt," in *Richard Hakluyt and His Successors*, Hakluyt Society, 2nd series, vol. 93 (1946); D.B. QUINN and R.A. SKELTON, "Introduction" (on character, production, and sources) in the facsimile edition of *The principall Navigations . . .*, 2 vol., pp. ix–lx (1965); D.B. QUINN, "Richard Hakluyt, Editor," study accompanying facsimile edition of Richard Hakluyt's *Divers voyages*, 1582 (1967); and T. GIRTIN, "Mr. Hakluyt, Scholar at Oxford," *Geogrl. J.*, 119:208–212 (1953).

(G.R.C.)

Hale, Sir Matthew

One of the greatest scholars of the history of English common law, Sir Matthew Hale first gained renown for his fair-minded conduct during the often violent political fluctuations in England's Civil War (1642–51) and his prominent role as counsel in the political trials of royalist defendants. His reputation for integrity and sagacity grew steadily throughout his career, and even though he was a judge under Oliver Cromwell, Charles II upon his restoration raised him to high office and eventually made him lord chief justice.

By courtesy of the National Portrait Gallery, London

Hale, oil painting after John Michael Wright (1623–1700). In the National Portrait Gallery, London.

Hale was born at Alderley, Gloucestershire, on November 1, 1609, the son of Robert Hale, a barrister. Orphaned at the age of five, he was educated according to Puritan principles under the direction of his guardian, until he enrolled at Magdalen College, Oxford, in 1626, with the intention of taking holy orders. He soon changed his mind and began to devote most of his time to sports, especially fencing, and to gambling and other diversions; at one time he considered enlisting as a soldier in the service of Frederick Henry, prince of Orange. A consultation with an eminent lawyer on family business so impressed him that he chose the law as his profession. In 1628 he was admitted to Lincoln's Inn, one of London's four legal schools and societies. He studied 16 hours a day, and under the guidance of such friends as John Selden, one of the leading jurists and scholars of his age, extended his studies to include Roman law, English history, mathematics, and natural philosophy. Called to the bar in 1637, he soon had a flourishing practice.

Hale remained aloof from the Long Parliament's oppo-

Role in the Civil War

sition in the 1640s to King Charles and avoided taking sides during the Civil War between the King and Parliament. Nevertheless he defended many royalists, most notably Archbishop William Laud, who had persecuted Puritan churchmen; and he probably advised the Earl of Strafford, who was impeached by the House of Commons on charges of high treason, and later Charles I during his trial. In spite of his support of the royalists, in 1649 he took the oath of fidelity to the republican Commonwealth and, later in 1654, was persuaded by his royalist friends to accept a judgeship from Oliver Cromwell, now lord protector. In 1651 and 1652, he was active in the law-reform movement and contributed much to the work of the committee that advised Parliament on far-reaching improvements in the law and legal system of the time. On Cromwell's death he refused to continue as judge and was returned to Parliament as member for Oxford. He took a prominent part in the proceedings of the Convention Parliament, called after the dissolution of the Long Parliament, and in promoting the restoration of Charles II.

In 1660 Hale was appointed chief baron of the Exchequer, the court principally concerned with matters of crown revenue, and in the same year he was knighted. Between 1666 and 1672 he spent much time on the statutory tribunal that resolved disputes between owners and tenants of property destroyed in the Great Fire of London in 1666. In 1671 he became chief justice of the King's Bench, an office he relinquished in 1676 when his health began to fail. He died on Christmas day of the same year, at Alderley.

Hale's work on the Bench—in an age when these attributes were not a matter of course even among judges—was characterized by singular personal integrity and judicial impartiality. Moreover, he acted with scrupulous fairness towards prisoners. The one point on which he was criticized by later writers was his belief in witchcraft, and he once permitted the execution of two women accused as witches. Hale was tolerant in religious matters and on numerous occasions mitigated the rigours of the law against dissenters from the Church of England. Throughout his life he retained his Puritan sympathies and numbered among his intimate friends prominent nonconformists. But, evenhanded also in his friendships, he maintained close ties with Anglican bishops as well.

Lord Chancellor Nottingham (the other outstanding legal figure of Hale's generation) wrote of him that

> as great a lawyer as he was, he would never suffer the strictness of the law to prevail against conscience; as great a chancellor as he was, he would make use of all the niceties and subtleties of law when it tended to support right and equity.

Writings

But Hale is principally remembered not as a judge but as a jurist. He was a prodigious searcher of legal records and formed an extensive collection of manuscripts and transcripts. The bulk of this collection is now deposited in the library of Lincoln's Inn. On the basis of these manuscripts and transcripts he wrote numerous books and treatises, though he published little of his own legal work during his lifetime; some of his treatises were printed posthumously, others still remain unpublished. The published work by which he is perhaps best known is his *History of the Pleas of the Crown* (the House of Commons directed in 1680 that it should be printed, though it was not published till 1736). This work remains one of the principal authorities on the common law of criminal offenses. But he also wrote widely on topics of constitutional and civil law, as his editorial talent enabled him to analyze and rearrange the jumbled collection of 17th-century and earlier law materials. When Sir William Blackstone wrote his classic *Commentaries on the Laws of England* (1765–69), he found that he could not do better than adopt Hale's "Analysis of the Civil Part of the Law."

Hale's literary talent was enhanced by his considerable critical faculty. He was both an historian and critic of the law, and his writings take stature from his talents as historian and critic. His place is undoubtedly among the principal figures in the history of English common law.

BIBLIOGRAPHY. The principal authority for Hale's life is GILBERT BURNET, *Life and Death of Sir Matthew Hale* (1682). Fuller accounts are given in SIR JOHN WILLIAMS, *Memoirs of the Life, Character and Writings of Sir Matthew Hale* (1835); and in LORD CAMPBELL, *The Lives of the Chief Justices of England*, ch. 16–18 (1849). A balanced outline of Hale's career and work is SIR WILLIAM HOLDSWORTH, *A History of English Law*, 2nd ed., vol. 6, pp. 574–595 (1924); and a modern study of Hale's political philosophy is J.G.A. POCOCK, *The Ancient Constitution and the Feudal Law*, ch. 7 (1957). The biographical account by J.M. RIGG in the *Dictionary of National Biography*, vol. 24, pp. 18–24, is of merit, and contains a catalogue of Hale's writings, both published and unpublished.

(D.E.C.Y.)

Ḥallāj, al-

Abū al-Mughīth al-Ḥusayn ibn Manṣūr al-Ḥallāj was a celebrated but controversial representative of Islāmic mysticism (Ṣūfism). Because he represented in his person and works the experiences, causes, and aspirations of many Muslims, arousing admiration in some and repression on the part of others, the drama of his life and death has been considered a reference point in Islāmic history.

Early life and education

He was born around AD 858 in the southern Iranian community of Ṭūr in the province of Fars. According to tradition, his grandfather was a Zoroastrian and a descendant of Abū Ayyūb, a companion of Muḥammad. At an early age al-Ḥallāj went to live in the city of Wāsiṭ, an important Iraqi centre for textiles, trade, and Arab culture. His father had become a Muslim and may have supported the family by carding wool.

Al-Ḥallāj was attracted to an ascetic way of life at an early age. Not merely satisfied with having learned the Qur'ān (the Islāmic scripture) by heart, he was motivated to understand its deeper and inner meanings. During his adolescence (*c.* 874–894), at a time when Islāmic mysticism was in its formative period, he began to withdraw from the world and to seek the company of individuals who were able to instruct him in the Ṣūfī way. His teachers, Sahl at-Tustarī, ʿAmr ibn ʿUthmān al-Makkī, and Abū al-Qāsim al-Junayd, were highly respected among the masters of Ṣūfism. Studying first under Sahl at-Tustarī, who lived a quiet and solitary life in the city of Tustar in Khuzistan, al-Ḥallāj later became a disciple of al-Makkī of Basra. During this period he married the daughter of the Ṣūfī Abū Yaʿqūb al-Aqṭaʿ. He concluded his instruction in the mystical way under al-Junayd of Baghdad, a brilliant intellect, under whom al-Makkī had likewise studied.

During the next period of his life (*c.* 895–910), al-Ḥallāj undertook extensive travels, preaching, teaching, and writing. He made a pilgrimage to Mecca, where he followed a strict discipline for a year. Returning to such regions as Fars, Khuzistan, and Khorāsān, he preached and wrote about the way to an intimate relationship with God. In the course of his journeys he attracted a large number of disciples, some of whom accompanied him on a second pilgrimage to Mecca. Afterward, he returned to his family in Baghdad and then set out by sea for a mission to a territory hitherto not penetrated by Islām—India and Turkistan. Following a third pilgrimage to Mecca, he again returned to Baghdad (*c.* 908).

Factors leading to his arrest

The milieu in which al-Ḥallāj preached and wrote was filled with social, economic, political, and religious tensions—all factors that contributed to his later arrest. His thought and activity had been provocative and had been interpreted in various ways, some of which left him highly suspect in the eyes of civil and religious authorities. The Ṣūfī movement, in general, had aroused considerable opposition, and its thought and practice had yet to be coordinated with developments in jurisprudence, theology, and philosophy.

Al-Ḥallāj's propensity for travel and his willingness to share the profundity of his mystical experiences with all who would listen were considered breaches of discipline by his Ṣūfī masters. His travel for missionary purposes was suggestive of the subversive activity of the Qarmaṭians, a 9th-century movement with Ismāʿīlī affiliations that was founded by Hamdān Qarmaṭ in Iraq, whose

acts of terrorism and whose missionaries were undermining the authority of the central government. Through his wife's family, he was suspected of having connections with the destructive Zanj rebellion in southern Mesopotamia that was carried out by oppressed Negro slaves inspired and led by outside dissidents. The alleged involvement of al-Ḥallāj in an attempt at political and moral reform upon his return to Baghdad was an immediate factor in his arrest, and it did nothing to improve his image in the eyes of the political leaders.

Al-Ḥallāj has been identified as an "intoxicated" Ṣūfī in contradistinction to a "sober" one. The former are those who, in the moment of ecstasy, are so overcome by the presence of the Divine that awareness of personal identity is lost and who experience a merging with Ultimate Reality. In that exalted state, the Ṣūfī is given to use extravagant language. Not long before his arrest al-Ḥallāj is said to have uttered the statement, "Anā al-ḥaqq" ("I am the Truth"—*i.e.*, God), which provided cause for the accusation that he had claimed to be divine. Such a statement was highly inappropriate in the view of most Muslims. Furthermore, this was the kind of theosophical (divine wisdom) idea that was associated with the Qarmaṭians and the supporters of the Zanj slaves. There was no consensus about al-Ḥallāj, however. The long, drawn-out trial proceedings were marked by indecision.

Death and influence

After his arrest in Sūs (*c.* 911–922) and a lengthy period of confinement in Baghdad, al-Ḥallāj was eventually crucified and brutally tortured to deatn on March 26, 922. A large crowd witnessed his execution. He is remembered to have endured gruesome torture calmly and courageously and to have uttered words of forgiveness for his accusers. In a sense, the Islāmic community (*ummah*) had put itself on trial, for al-Ḥallāj left behind revered writings and supporters who courageously affirmed his teachings and his experience. In subsequent Islāmic history, therefore, the life and thought of al-Ḥallāj has been a subject seldom ignored.

BIBLIOGRAPHY. LOUIS MASSIGNON, *Passion d'al-Ḥallāj*, 2 vol. (1922; Eng. trans., *The Passion of al-Ḥallāj*, 3 vol., 1974), the definitive work on al-Ḥallāj, but not strictly a biography; *Encyclopaedia of Islam*, new ed., vol. 3 (1971), contains a comprehensive survey of the life, thought, and times of al-Ḥallāj.

(J.W.F.)

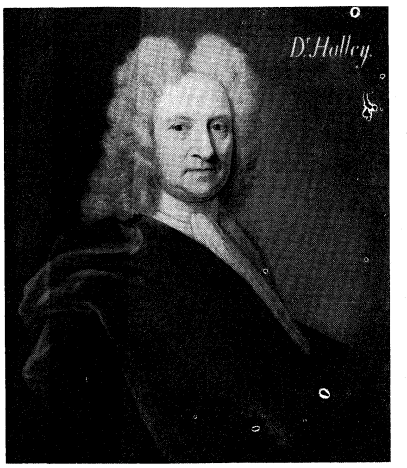
Halley, Edmond

Edmond Halley, English astronomer and mathematician, is best known for his role in the publication of Newton's *Philosophiae Naturalis Principia Mathematica* and for accurately calculating the orbit of the comet that bears his name.

Born on November 8, 1656, Halley began his education at St. Paul's School, London. Halley had the good fortune to live through a period of scientific revolution that established the basis of modern thought. He was four years old when the monarchy was restored under Charles II; two years later the new monarch granted a charter to the informal organization of natural philosophers originally called the "invisible college," which then became known officially as the Royal Society of London. He entered Queen's College, Oxford, in 1673 and there was introduced, by letter, to John Flamsteed, who was appointed astronomer royal in 1676. On one or two occasions, Halley visited the Royal Greenwich Observatory, where Flamsteed did his work, and there was encouraged to study astronomy.

Observations in the Southern Hemisphere

Influenced by Flamsteed's project of using the telescope to compile an accurate catalog of northern stars, Halley proposed to do the same for the Southern Hemisphere. With financial assistance from his father and, from King Charles II, an introduction to the East India Company, he sailed in November 1676 in a ship of that company (having left Oxford without his degree) for the island of St. Helena, the southernmost territory under British rule, in the South Atlantic. Bad weather frustrated his full expectations. But, when he embarked for home in January 1678, he had recorded the celestial longitudes and latitudes of 341 stars, observed a transit of Mercury across the Sun's disk, made numerous pendulum observations, and noticed that some stars apparently had become fainter since their observation in antiquity. Halley's star catalog, published late in 1678, was the first such work to be published containing telescopically determined locations of southern stars, and it established his reputation as an astronomer. In 1678 he was elected a fellow of the Royal Society and, with the intercession of the King, was granted the M.A. degree from Oxford University.



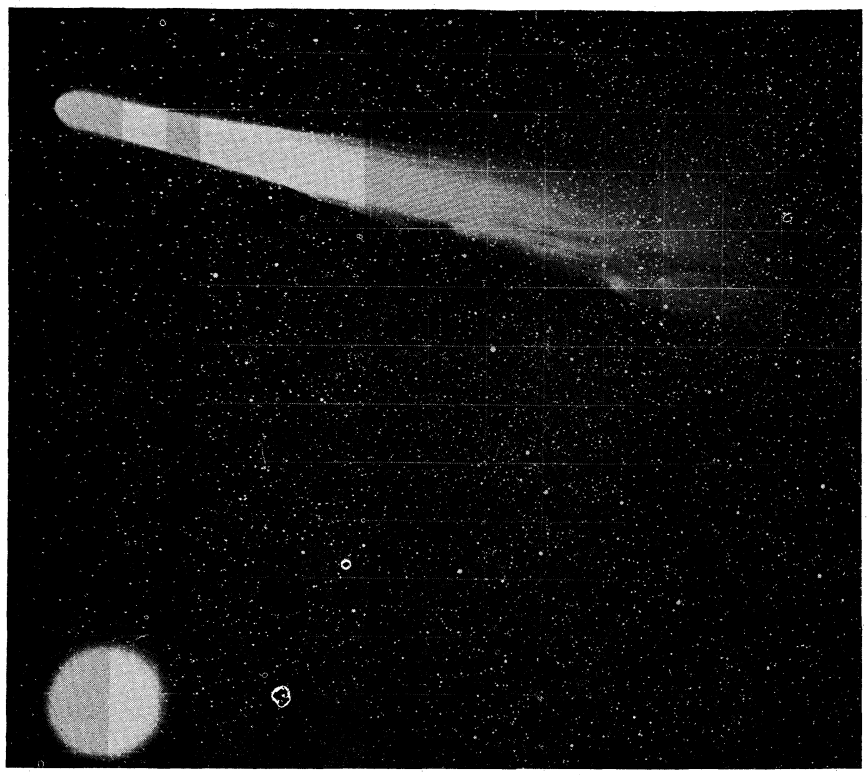
Halley, oil painting by R. Phillips, *c.* 1720. In the National Portrait Gallery, London.
By courtesy of the National Portrait Gallery, London

In 1684 Halley made his first visit to Sir Isaac Newton in Cambridge, an event that led to his prominent role in the development of the theory of gravitation. Halley was the youngest of a trio of Royal Society members in London that included Robert Hooke, the inventor and microscopist, and Sir Christopher Wren, the famous architect, both of whom, with Newton at Cambridge, were attempting to find a mechanical explanation for planetary motion. Their problem was to determine what forces would keep a planet in forward motion around the Sun without either flying off into space or falling into the Sun. Since these men were dependent upon their scientific stature for both livelihood and sense of achievement, each had a personal interest in being the first to find a solution. This desire for priority, a propelling motive in science, was the cause of much lively discussion and competition between them.

Halley and Newton

Although Hooke and Halley had calculated that the force keeping the planets in orbit decreased as the inverse of the square of the distances between them, they were not able to deduce from this hypothesis a theoretical orbit that would match the observed planetary motions, despite the incentive of a prize offered by Wren. Halley then visited Newton, who told him he had already solved the problem—the orbit would be an ellipse—but that he had mislaid his calculations to prove it. Encouraged by Halley, Newton then expanded his studies on celestial mechanics into one of the greatest masterpieces produced by the mind of man, the *Principia*. The Royal Society decided that "Mr. Halley undertake the business of looking after it, and printing it at his own charge," which he proceeded to do. He consulted with Newton, tactfully subdued a priority dispute between Newton and Hooke, edited the text of the *Principia*, wrote laudatory verse in Latin for the preface to honour its author, corrected the proofs, and saw it through the press in 1687.

Halley had the ability to reduce large amounts of data to a meaningful order. In 1686 his map of the world, showing the distribution of prevailing winds over the oceans, was the first meteorological chart to be published. His mortality tables for the city of Breslau, published in 1693, comprised one of the first attempts to relate mortality and age in a population; as such, it influenced the future development of actuarial tables in life insurance. Under instructions from the Admiralty, he commanded the war sloop "Paramour Pink" in 1698–1700 on the first



Halley's Comet, with the planet Venus at the lower left.
Camera Press—Publix

sea voyage undertaken for purely scientific purposes, this one to observe variations in compass readings in the South Atlantic and to determine accurate latitudes and longitudes of his ports of call. In 1701 he published the first magnetic charts of the Atlantic and Pacific areas, showing curved lines that indicated positions in the oceans having the same variation of the compass. Such charts, compiled from all available observations augmented with many of his own made on sea voyages, were of great practical value in navigation and were used for many years after his death. Notwithstanding opposition from Flamsteed, Halley in 1704 was appointed Savilian professor of geometry at Oxford, where he continued to investigate the reckoning of accurate longitude at sea.

Halley's comet

Continuing his pioneering work in observational astronomy, Halley published in 1705 *A Synopsis of the Astronomy of Comets*, in which he described the parabolic orbits of 24 comets that had been observed from 1337 to 1698. He showed that the three historic comets of 1531, 1607, and 1682 were so similar in characteristics that they must have been successive returns of the same visitant—now known as Halley's comet—and accurately predicted its return in 1758.

In 1716 he devised a method for observing transits of Venus across the disk of the Sun, predicted for 1761 and 1769, in order to determine accurately, by solar parallax, the distance of the Earth from the Sun. In 1718 he published data to show that stars actually move in space. In 1720 Halley succeeded Flamsteed as astronomer royal at Greenwich, where he made observations, such as timing the transits of the Moon across the meridian, that he hoped would eventually be useful in determining longitude at sea.

Halley was an outstanding 17th-century virtuoso who, in the early days of the Royal Society, examined many different scientific questions. His concern with practical applications of science, such as problems of navigation, reflects the influence on the Royal Society of Francis Bacon, who held that science should be for the "relief of man's estate." Though wide ranging in his interests, Halley displayed a high degree of professional competence that foreshadowed scientific specialization. His wise assessment of Newton's work and his persistence in guiding it to completion earned for him an important place in the emergence of Western thought. He died at Greenwich on January 14, 1742.

BIBLIOGRAPHY. All that is now known of Halley's life is contained in a collection of contemporary materials by EUGENE FAIRFIELD MACPIKE, *Correspondence and Papers of Edmond Halley* (1932) and *Hevelius, Flamsteed and Halley: Three Contemporary Astronomers and Their Mutual Relations* (1937); and in the biographies by C.A. RONAN, *Edmond Halley: Genius in Eclipse* (1969); and A. ARMITAGE, *Edmond Halley* (1966).

(O.J.E.)

Hallucinogen

Psychopharmacological agents are drugs that act predominantly on psychological processes, such as perception, thinking, feeling, and acting. They are divided into two main classes: the psychotherapeutic drugs, which may be tranquillizers, antidepressants, or anti-anxiety agents, and the psychotomimetic drugs, which produce such psychotic reactions as depression, mania, or schizophrenia in normal subjects. Those that reproduce schizophrenic reactions are termed hallucinogens.

Characteristically hallucinogens produce changes in perception, which vary from sensory illusion to outright hallucinations. Illusions are mere distortions of what is sensed, while hallucinations are objects sensed where there are, in fact, none to be sensed. The human response to these perceptual changes depends upon a large number of factors that include personality, education, dose, reason for taking the drug, and previous experience. The experience may mimic psychosis (and is then termed psychotomimetic); under different circumstances, it may produce a quasi-mystical or "psychedelic" experience, which has been defined as one that enriches the mind and enlarges the vision.

Influence on psychiatry

The hallucinogens have also influenced the development of a new, more biologically oriented psychiatry, in which there is a renewed interest in experience and in the role perception plays in producing symptoms and behavioural changes in the schizophrenic. Doctors and nurses who have experienced model psychoses have found themselves able to communicate more effectively with patients, and the millions of young people who have experienced transient model psychoses have helped to make schizophrenia

less mysterious. Recent hypotheses concerning the role of biochemical factors in the development of schizophrenia have arisen from studies with d-lysergic acid diethylamide (LSD). It is possible that ancient man used his experience with natural hallucinogens to create his religions. Mescaline, an active ingredient of the peyote cactus, *Lophophora williamsii*, is used as a sacrament by the Native American Church of North America. Lysergic acid amide, much less potent a hallucinogen than LSD, is present in many varieties of morning glory plants and is used extensively in magical ointments and potions.

A number of the naturally occurring hallucinogens are indole derivatives, including N,N-dimethyltryptamine (DMT), bufotenine, psilocybin, harmine, ibogaine, and lysergic acid amide. All of these compounds have been used in one way or another by primitive peoples for their hallucinogenic qualities. Two other naturally occurring hallucinogens, mescaline and tetrahydrocannabinol (the active ingredient of marijuana), are not indole derivatives, but the former at least has some structural resemblance to indole. Lysergic acid diethylamide (LSD) is a synthetic derivative of the naturally occurring lysergic acid, and diethyltryptamine (DET) is a synthetic compound that closely resembles DMT. Many drugs used primarily for their other pharmacological effects, particularly the anticholinesterase agents, also are hallucinogenic.

Sites and nature of action. It is clear that hallucinogens must interfere with normal chemical reactions in the central nervous system, chiefly in the brain. But there is no generally accepted theory that explains how they do so. The hypotheses currently being investigated derive from the structure and function of the brain as an organ for receiving, processing, and transmitting information. The main transmitting elements of the brain are the nerve cells, or neurons, that are separated from one another by small gaps called synapses. When an impulse is transmitted along the neurons, it cannot directly jump these gaps, but substances called "transmitters" are believed to do so.

Transmitter substances

These so-called neurohormone transmitters are of three main types: (1) sympathomimetic amines derived from tyrosine, such as dopamine, epinephrine (adrenalin), norepinephrine (noradrenalin), and perhaps isoproterenol (isopropylnoradrenalin); (2) indoles, such as serotonin, derived from tryptophan; and (3) acetylcholine and similar compounds. The last two groups are believed to be closely related to substances found in the parasympathetic nervous system. It is generally supposed that the hallucinogens exert their major effect by interfering in some way with the action of the transmitters. The best evidence for this point of view arises from the remarkable similarity in structure between the main classes of hallucinogens and the three classes of neurohormone transmitters. Mescaline is similar in structure to the sympathomimetic amines. (The amphetamines, similar structurally, are euphorients and, in large quantities or over long periods of time, they are capable of producing psychoses.) The large number of indole hallucinogens are similar in structure to serotonin and could be imagined to interfere with its role as a transmitter. Finally, substances like atropine, which interfere with the transmitter action of acetylcholine, are also potent hallucinogens.

The resemblance between the hallucinogens and the transmitters could have any one or more of a number of effects. Thus, it has been proposed that the hallucinogens could act: (1) by causing anatomical changes in neurons; (2) by interfering directly in chemical reactions within the cell; (3) by altering blood-flow relationships in the brain; (4) by affecting the blood-brain barrier (and allowing nontoxic substances in the blood to penetrate into the brain where they become toxic); and (5) by displacing in the synapses the transmitters they resemble. (The hallucinogens could also be interfering with chemical reactions outside the brain; chemicals normally present in low concentration might then build up to the point where they would penetrate into the brain and cause abnormal changes.)

It now seems likely that psychological response to the hallucinogens may yield sooner to investigation than physiological response. Because of the dramatic nature of the perceptual changes brought about by hallucinogens, it is obvious that these changes must play a major role in shaping the psychological response. John Conolly in 1830 defined psychosis as a disease of perception combined with an inability to judge that the perceptual changes involved are unreal. In a sense, this definition is appropriate today, for it takes into account the factors known to shape personality (*e.g.*, inheritance, training, education, culture). In a similar way, a subject responding to a hallucinogen will observe certain perceptual changes (usually visual; less often auditory); however, his final experience will be influenced not only by the nature of the change but also by his judgment of it.

Biological disposition. Hallucinogens are readily absorbed by all the usual routes of administration, but the most common methods are by ingestion or inhalation. As a rule, administration by injection accelerates the response.

Metabolic transformation

The metabolism of mescaline and LSD has been studied most thoroughly. Whereas some mescaline is excreted unchanged in the urine, it is mainly oxidized. In rabbits a chief excretion product is 3,4,5,-trimethoxyphenylacetic acid. In humans some 3,4-dihydroxy-5-methoxyphenylacetic acid is excreted. With LSD most of the drug is degraded and excreted within several hours, although small quantities may be present for as long as 12 hours. Only about 1 percent is found in the brain. One of the metabolic derivatives is 2-oxy-LSD, which is psychologically inactive.

DMT and DET are metabolized very quickly in the body; ten minutes after injection they are no longer present. These compounds are mainly degraded in the body into two inactive derivatives, indole-3-acetic acid and a 6-hydroxy substance. After psilocybin is injected into rats, the highest concentration is reached in 30 minutes, after which it decreases rapidly. In 24 hours 94% is excreted, two-thirds of it in the urine. About 25% is excreted unchanged; 15% is converted to 4-hydroxyindoleacetic acid; 10% is demethylated and deaminated (with the rest unaccounted for). The parasympathomimetic hallucinogens also are excreted very quickly; up to 95% is excreted in urine within two hours. Again, very little is found in the brain after one hour (less than 0.1% of the dose).

All the hallucinogens are relatively nontoxic, in the sense that there is a wide range between the mean dose required to produce the specific psychological reaction and the dose that is lethal for one-half the animals tested (LD_{50}). In rats LD_{50} for mescaline given intraperitoneally is 370 mg per kg, whereas the active dose is about 10 mg per kg. No deaths in humans have yet been attributed to mescaline (or any of the hallucinogens), so the LD_{50} in man cannot be determined.

Members of the Native American Church of North America have taken peyote weekly for many years with no evidence of physical harm. LD_{50} for LSD was 46, 16.5, and 0.3 mg per kg for mice, rats, and rabbits respectively. Comparable values are not known for higher mammals. In chronic trials using about 100 μg per day for autistic children over periods of up to 1½ years, LSD has been nontoxic. Psilocybin at a dose of 250 mg per kg given intravenously proved fatal to a number of mice.

On the basis of studies on subjects who frequently took drugs obtained from illegal sources, it was concluded that LSD, especially, produced chromosomal aberrations in leucocytes and was responsible for congenital defects in offspring of the users; however, every study recorded by mid-1970, which used pure LSD on known subjects and was carried out with controls, failed to show chromosomal changes. Other findings suggest that the incidence of congenital abnormality among the offspring of subjects given LSD is not greater than it is in the general population.

Reactions to the hallucinogens can occur, however, which, from a psychiatric point of view, can be more dangerous than any toxic reaction. These are of two

kinds: a marked prolongation of the psychotic reaction (which may occasionally last many months) and a transient or prolonged reappearance of the psychotomimetic reaction some months after the last experience. During recurrences, serious accidents, including suicide, can occur. There is a fair amount of evidence that these reactions occur mainly in subjects who are ill before they take hallucinogens, but there is little doubt that the psychosis can be greatly aggravated by these drugs.

Dangerous reactions

In general, prolonged reactions or recurrences are best dealt with in two ways, either by personal contact with experienced friends or trained professionals who can reassure the subject, or by use of psychotropic drugs, especially tranquillizers. If parasympathomimetic drugs are consumed, tranquillizers must be used with caution, however. Massive doses of vitamin B_3 (nicotinic acid and nicotinamide) are used on a large scale by youthful drug users to terminate psychotomimetic reactions (called freak outs, bad trips, etc.).

The principal hallucinogens. *Mescaline.* Chemically mescaline is 3,4,5-trimethoxyphenethylamine, a colourless, alkaline oil, soluble in water and alcohol. The sulfate and chloride salt are white crystalline powders, very soluble in water. The three adjacent oxygen functions on the benzene ring seem vital for the hallucinogenic activity. The drug is usually prepared from peyote cactus by extraction and purification, but it can be synthesized. When given by mouth the usual dose begins to produce an effect in 1½ to 3 hours, reaches a maximum at about 8 hours, and then abates in approximately 12 hours. The prolonged action of mescaline compared to other hallucinogens may be an advantage for psychedelic therapy. A disadvantage of the drug is that a large dose is required, which often produces nausea and vomiting.

Lysergic acid diethylamide. Lysergic acid diethylamide can exist as four stereoisomers, but only the dextro form is active psychologically. Active LSD is prepared from lysergic acid, the main source of which is grain (usually rye) infected with the fungus ergot. The pure fungus in culture can also be used to synthesize lysergic acid, however. Impure, black-market LSD may contain small or large quantities of ergot alkaloids, which are psychologically inert but physiologically active and perhaps capable of modifying the LSD experience.

The usual dose given by mouth begins to act in one to two hours, reaches its maximum effect in two to four hours, and is usually gone in about six to eight hours. Usually, all LSD effects are terminated by one normal period of sleep. LSD is preferred in psychedelic therapy because the reaction is initiated more predictably, is easier to control, and disappears more regularly than is the case with other hallucinogens. All hallucinogens suffer from the disadvantage that, once the reaction has started, it must proceed through the usual time sequence unless terminated by administration of tranquillizers or massive doses of vitamins.

Cohoba. Cohoba was a narcotic snuff used by natives of Haiti and of Central and South America for many centuries. It was snuffed as deeply as possible into the lungs using bifurcated tubes, although among some tribes individuals blew snuff into one anothers' nostrils using single tubes.

Cohoba was prepared from parts of the tree *Piptadenia peregrina* and contained bufotenine, DMT, and other indole derivatives. Bufotenine is also found in fly agaric mushrooms used as a hallucinogen by natives in northeast Siberia. And it is also present in the skin of certain toad species.

Bufotenine is a weak hallucinogen, active chiefly by intravenous injection. Since it is a powerful vasoconstrictor, the dose must be small. DMT is a much more powerful hallucinogen, and it too must be given by injection (or sniffed). The reaction begins in about five minutes and is over in about an hour. Diethyltryptamine (DET), a related synthetic, begins to act in about 15 minutes, and the experience continues for about 3 hours. The hallucinogenic properties of DMT are particularly important because the substance has been found in the body fluids of schizophrenics, but not yet in normal subjects. DMT could be formed by abnormal transmethylation of normal tryptophan metabolites.

Psilocybin. Chemically, psilocybin is O-phosphoryl-4-hydroxy-N,N-dimethyltryptamine; it is the psychoactive ingredient in the hallucinogenic mushroom *Psilocybe.* Removal of the phosphate group leaves the substance psilocin. The mushroom has been used in the southern United States, Mexico, and Central America—not regularly, as is the case with peyote by the Native American Church of North America, but on special occasions and to serve special needs.

Psilocybin and psilocin produce identical hallucinogenic experiences that are indistinguishable from those produced by mescaline and LSD. In addition, these hallucinogens are cross tolerant—that is, when tolerance is developed to any one of them, increased dosage of any of the others is needed to invoke a response. In contrast, however, DMT is not cross tolerant with the major plant hallucinogens.

Psilocybin is usually taken sublingually. The reaction appears in about half an hour, reaches its maximum in an hour, and is usually gone in about four hours. Psilocybin is thus somewhere between DMT and LSD in its duration of effect. It may be given parenterally, when of course it reacts much more quickly.

Ibogaine. This drug is an indole present in the woody plant *Tabernanthe iboga.* It was used in West Africa and the Congo in small doses as a stimulant and in large doses as a narcotic. Natives chewed the root of the plant. It has been studied largely in animals, where it is shown to be a stimulant.

Harmine. Harmine is also an indole found in the plant *Banisteriopsis caapi.* It was used by natives in the area drained by the tributaries of the upper Amazon. The drug was extracted from small pieces of wood by boiling with water for from 2 to 24 hours. As was usually the case with native hallucinogens, harmine was used for religious purposes or as a medicine. In experimental studies, harmine has produced the same kind of experience as LSD or mescaline.

Marijuana. Δ^1-Tetrahydrocannabinol, found mainly in the resin of unripened fruit and adjacent leaves of the hemp plant *Cannabis sativa,* is one of the oldest known and most widespread hallucinogens. It is native to Central Asia but is grown around the world. The more tropical the area in which it is grown the more active is the material. The drug is used in a variety of ways and under many different names throughout the world. In the Middle East and North Africa resin from the plant, called hashish or kif, is ingested. In Western countries the plant is dried and incorporated into cigarettes for smoking. In this form it is called marijuana or any of a number of colloquial names.

In one of the best studies of the effects of the drug, 250 to 400 milligrams of resinous extract of powdered *Cannabis sativa* were given to ten normal subjects. The experience began suddenly, within the first hour, and was comparable to that induced by LSD; characteristic perceptual changes occurred, including illusions and visual hallucinations when the eyes were closed. Temporal disorientation was marked in all subjects, as were distortions of the body image. There were disorders in thought content (delusions) and thought processes (*e.g.*, blocking, slowing, inability to grasp meanings, loss of memory). The moods induced were chiefly euphoria and a sense of detachment, although in some cases anxiety and depression were felt. Physical changes included suffusion of conjunctiva of the eye after one to two hours, increase in pulse rate, moderate coldness of the extremities, and nausea after three hours.

As with all hallucinogens, the effect of marijuana depends upon the potency of the preparation, the mode of administration, the degree of experience of the user, and other factors. Pure tetrahydrocannabinol is the most potent form of the drug. Generally, marijuana is not addictive in a narcotic sense, but many subjects come to depend on it, and marijuana psychoses have been reported.

Drugs with hallucinogenic properties. Cholinesterase inhibitors are not necessarily hallucinogenic; but several hallucinogens have strong cholinesterase-blocking activity, and most of the hallucinogens already described have moderate to weak anticholinesterase activity. Known anticholinesterase drugs may have undetected hallucinogenic properties. Thus, physostigmine (also known as eserine), found in Calabar beans, is not a hallucinogen, but this may be due to its intense activity, which limits the dose. In an analogous way, adrenalin is such a powerful vasopressor that its psychological properties cannot be readily studied. Prostigmin is normally not hallucinogenic, but it has sometimes produced psychotic episodes in patients treated for myasthenia gravis.

The belladonna alkaloids are the best known parasympatholytic hallucinogens. The chief members of the family, atropine and scopolamine, are found in deadly nightshade, black henbane, and Jimsonweed; they have been used as poisons and hallucinogens since the dawn of history. In modern times they have found a variety of pharmacological uses in anesthesia, opthalmology, and the management of respiratory and other diseases.

Sufficient atropine has been absorbed from instillations in the eye to produce hallucinations, especially in children. Atropine psychoses are infrequent now but were fairly common at one time. A person admitted to the hospital in a psychotic state with fever and widely dilated pupils often turned out to have smoked excessive quantities of anti-asthma cigarettes, which contained belladonna alkaloids.

An interesting hallucinogen in larger doses is benactyzine, which was originally introduced as an antidepressant. The hallucinogenic dose is about 20 times the antidepressant dose; the effect produced is similar to that of LSD or mescaline.

A series of piperidyl compounds are potent hallucinogens, but the psychological experience tends to be more of a delirium than that induced by the other hallucinogens. They are typical anticholinergic chemicals and produce large pupils, dry mouth, flushed skin, and slight hypertension.

Metabolites with hallucinogenic properties. The amines dopamine, norepinephrine (noradrenalin), and epinephrine (adrenalin) are readily oxidized in the body to dopachrome, noradrenochrome, and adrenochrome. They may be further changed to adrenolutins, yellow fluorescent compounds that have been identified in the body but have not been isolated from tissues or body fluids. These are potentially very important as intermediates in schizophrenic pathology—*i.e.*, they could provide the link between vitamin B_3 dependency and schizophrenia.

Only synthetic preparations of adrenochrome and adrenolutin have been studied for hallucinogenic properties. The experience they induce resembles that of LSD. In low doses there are minor perceptual changes, alterations in thought, and depression. There have been no instances of euphoria. The experience has always been psychotomimetic. In large doses they produce LSD-like perceptual changes. Activity depends upon the mode of administration.

Halogen Elements and Their Compounds

Fluorine (chemical symbol F), chlorine (Cl), bromine (Br), iodine (I), and astatine (At) are the members of the family of halogen elements, and they constitute Group VIIa of the periodic table (see Figure). They were given the name halogen from the Greek roots *hal-*, "salt," and *gen*, "to produce," because they all produce sodium salts of similar properties, of which sodium chloride, table salt, is the best known. Because of their great reactivity, the free halogen elements are not found in nature. In combined form, fluorine is the most abundant of the halogens in the earth's crust. The percentages of the halogens in the igneous rocks of the Earth's crust are 0.06 fluorine, 0.031 chlorine, 0.00016 bromine, and 0.00003 iodine. Astatine does not occur normally on Earth because it consists only of short-lived radioactive isotopes (forms of the element that differ in mass).

The halogen elements show great resemblances to one another in their general chemical behaviour and in the properties of their compounds with other elements. There is, however, a progressive change in properties from fluorine through chlorine, bromine, and iodine to astatine—the difference between two successive elements being most pronounced with fluorine and chlorine. Fluorine is the most reactive of the halogens and, in fact, of all elements, and it has certain other properties that set it apart (see below *General properties*).

Chlorine is the best known of the halogen elements. The free element is widely used as a water purification agent, and it is employed in a number of chemical processes. Sodium chloride, of course, is one of the most familiar of chemical compounds. Fluorides are known chiefly for the controversy over their addition to water to prevent tooth decay, but organic fluorides are also used as refrigerants and lubricants. Iodine is most familiar as an antiseptic, and bromine is used chiefly to prepare a gasoline additive (ethylene dibromide) that prevents deposits of lead in engines.

History

Rock salt (common salt, sodium chloride) has been known for several thousand years; it is the main constituent of the salts dissolved in seawater, from which it was obtained in ancient Egypt by evaporation. In 1648 the German chemist Johann Rudolf Glauber obtained a strong acid, which he called spirit of salt, by heating moist salt in a charcoal furnace and condensing the fumes in a receiver. Later he obtained the same product, now known to be hydrochloric acid, by heating salt with sulfuric acid.

In 1774 the Swedish chemist Carl Wilhelm Scheele treated powdered black oxide of manganese with hydrochloric acid and obtained a greenish-yellowish gas, which he failed to recognize as an element. The true nature of the gas as an element was recognized in 1810 by the British chemist Sir Humphry Davy, who later called it chlorine.

In 1811 the French chemist Bernard Courtois obtained a violet vapour by heating seaweed ashes with sulfuric acid. This vapour condensed to a black crystalline substance, which he called "substance X." In 1813 Davy, who was passing through Paris on his way to Italy, recognized substance X as an element analogous to chlorine; he suggested the name iodine.

Discovery of bromine

Bromine was discovered in 1826 by the French chemist Antoine-Jérôme Balard in the residues from the manufacture of sea salt at Montpellier. He liberated the ele-

ment by passage of chlorine through aqueous solution of the residues, which contained magnesium bromide. Distillation of the material with manganese dioxide and sulfuric acid produced red vapours, which were condensed to a dark liquid. The similarity of this procedure to that for making chlorine suggested to Balard that he had obtained a new element similar to chlorine. (The German chemist Justus von Liebig appears to have obtained the element before Balard, but he wrongly considered it to be iodine chloride.)

The fluorine-containing mineral fluorspar (fluorite) was described in 1529 by Georg Bauer, the German physician and mineralogist better known as Agricola. It appears likely that crude hydrofluoric acid was first prepared by an unknown English glassworker in 1720. In 1771 Scheele obtained hydrofluoric acid in an impure state by heating fluorspar with concentrated sulfuric acid in a glass retort, which was greatly corroded by the product; as a result, vessels made of metal were used in subsequent experiments with the substance. The nearly anhydrous acid was prepared in 1809, and two years later the French physicist André-Marie Ampère suggested that it was a compound of hydrogen with an unknown element, analogous to chlorine, for which he suggested the name fluorine. Fluorspar was then recognized to be calcium fluoride.

The isolation of fluorine was for a long time one of the chief unsolved problems in inorganic chemistry, and it was not until the year 1886 that the French chemist Henri Moissan prepared the element by electrolyzing a solution of potassium hydrogen fluoride in hydrogen fluoride. The difficulty in handling the element and its toxic properties contributed to the slow progress in fluorine chemistry. Indeed, up to the time of World War II the element appeared to be a laboratory curiosity. Then, however, the use of uranium(VI) fluoride in the separation of uranium isotopes and the development of organic fluorine compounds of industrial importance made fluorine an industrial chemical of considerable use. Astatine was prepared for the first time in 1940 by bombarding bismuth with alpha particles.

Comparative chemistry of the halogen compounds

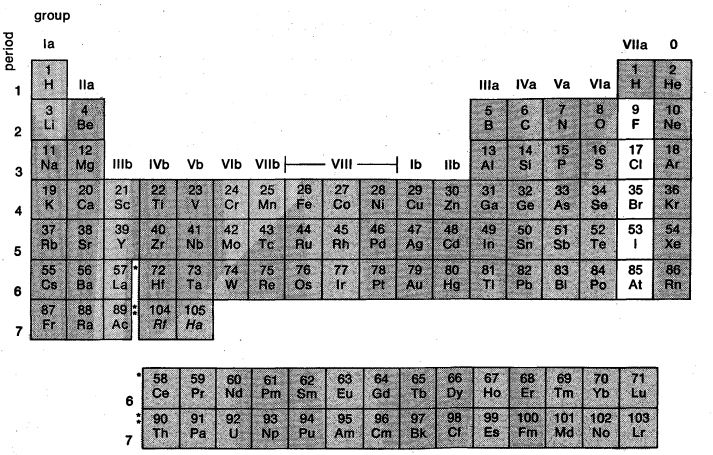
GENERAL PROPERTIES

Oxidizing property. Probably the most important generalization that can be made about the halogen elements is that they are all oxidizing agents; *i.e.*, they raise the oxidation state, or oxidation number, of other elements —a property that used to be equated with combination with oxygen but that is now interpreted in terms of transfer of electrons from one atom to another. In oxidizing another element, a halogen is itself reduced—*i.e.*, its oxidation number is reduced from 0, the typical state for a free element, to −1. In this state the halogens combine with other elements to form compounds known as halides—namely, fluorides, chlorides, bromides, iodides, and astatides. Many of the halides may be considered to be salts of the respective hydrogen halides, which are colourless gases at room temperature and atmospheric pressure and which are known to exhibit acidic properties. Indeed the general term salt is derived from rock salt, or table salt (sodium chloride). The tendency of the halogen elements to form saltlike compounds increases in the following order: astatine, iodine, bromine, chlorine, and fluorine.

Halides

This order is also that of increasing oxidizing properties of the free halogen elements. Fluorides are usually more stable than the corresponding chlorides, bromides, or iodides. (Often astatine is omitted from general discussions of the halogens because it is less well known than the other elements.) Conversely, of the halogen elements, fluorine is prepared in the free state with the greatest difficulty and iodine with the least. As a class, the halogen elements are nonmetals, but astatine shows certain properties resembling those of the metals.

Electronic structure. The chemical behaviour of the halogen elements can be discussed most conveniently in terms of their position in the periodic table of the elements (see Figure) In the periodic table the halogens



Halogen elements in the periodic table.

comprise Group VIIa, the group immediately preceding the noble gases. It is characteristic of the atoms of the halogen elements that each carries seven electrons in its outermost orbitals (an orbital is the space suitable for electrons). The seven outermost electrons of an atom of a halogen element are in two different kinds of orbitals, designated *s* (with two electrons) and *p* (with five). Potentially, a halogen atom could hold one more electron (in a *p* orbital), which would give the electrons the same arrangement (configuration) as that of the noble gas next to it in the periodic table, the noble gases all having exceptionally stable configurations of electrons in their atoms. It is in acquiring such an electron that an atom of a halogen element acts as an oxidizing agent (or is itself reduced). In the process, the atom acquires an electrical charge (in this case a negative one) and becomes a charged particle or ion. Halogen elements exist in their salts as halide ions, which are relatively large ions, colourless and extremely stable.

At room temperature and atmospheric pressure the halogen elements in their free states exist as diatomic molecules—molecules composed of two atoms each. In molecular fluorine the atoms are held together by a bond made from the union of a *p* orbital from each atom, such a bond being classed as a sigma bond. Beginning with chlorine, however, the halogen atoms are able to make use of different orbitals, called *d* orbitals—an option that is not open to the fluorine atoms. By forming partial bonds with their *d* orbitals, chlorine and the other halogens (with the exception of fluorine) form diatomic molecules held in part by multiple bonds (called pi bonds), which are stronger than single bonds, such as those that hold together the atoms in a fluorine molecule.

Diatomic halogen molecules

RELATIVE REACTIVITY

The great reactivity of fluorine largely stems from the relatively low energy of the fluorine–fluorine bond (37.7 kilocalories per mole, a standard measure for bond energies). The chlorine–chlorine bond is considerably stronger (57 kilocalories per mole) because of its partial multiple-bond character.

Fluorine and chlorine are gases at room temperature. Bromine is a reddish-brown liquid at room temperature, and is—apart from mercury—the only element that is liquid at 20° C (68° F) and atmospheric pressure. Iodine forms dark-violet crystals under these conditions. In the solid state the halogen elements form molecular lattices —extended weblike structures including a great many separate units. The lattice energies increase with increasing size of the molecules. The principal properties of the halogen elements are noted in Table 1.

The energy released in the formation of an ion from a free atom and an electron (brought up from an infinite distance) is called the electron affinity. The electron affinities for the halogen elements are all high and show only slight differences from one another. It is known, however, that the oxidizing properties (ability to take up an electron) increase from astatine to fluorine, and this

Electron affinities

increase is reflected in the position of the respective oxidation–reduction systems in the electromotive series (a standard arrangement of oxidation–reduction systems in water in order of oxidizing strength).

The fluoride ion is extremely stable toward oxidation; the iodide ion is a mild reducing agent. This difference between the ions is caused by two factors: (1) a decreasing tendency for the halide ion to act as an electron-pair donor (a so-called Lewis base) in the series fluoride, chloride, bromide, iodide, and astatide, leading to a decrease in stability of the hydrated form of the ion (*i.e.*, the free ion surrounded by water molecules) in the same order; and (2) a decrease in electron pair acceptor (Lewis acid) properties of the free halogens in the reverse order, namely, astatine, iodine, bromine, chlorine, and fluorine.

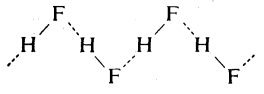
Within a molecule in which atoms are held together by a shared electron pair—*i.e.*, by a covalent or nonionic bond—the tendency of an atom to attract the shared electrons may be expressed by an electronegativity value. Fluorine has the greatest electronegativity value (is the most electronegative) of all elements (not just the halogens), and there is a decrease in electronegativity within the family of the halogen elements from fluorine through chlorine, bromine, and iodine to astatine.

Fluorine replaces any other halide ion from its compounds, as shown in the following equations (in which atoms of the elements are represented by their chemical symbols; number of atoms of a given kind in a molecule are indicated by subscripts; and positive and negative charges on ions are indicated by superscript plus and minus signs; as is customary in chemical equations the reactants are written to the left and the products to the right; the double arrows indicate that both the forward reaction and the reverse reaction occur).

$$F_2 + 2Cl^- \rightleftharpoons 2F^- + Cl_2$$
$$F_2 + 2Br^- \rightleftharpoons 2F^- + Br_2$$
$$F_2 + 2I^- \rightleftharpoons 2F^- + I_2$$
$$F_2 + 2At^- \rightleftharpoons 2F^- + At_2.$$

Chlorine, however, replaces only bromide, iodide, and astatide ions, and bromine only iodide and astatide ions. Free fluorine, chlorine, bromine, and iodine are expected to replace astatide ions.

The halogen elements all form compounds with hydrogen—the hydrogen halides. The energy of the hydrogen–halogen bond increases strongly from iodide to fluoride. Hydrogen fluoride in the crystalline state consists of infinite zigzag chains, as shown in the diagram



in which H represents the hydrogen atoms and (as before) F the fluorine atoms; the solid lines represent covalent bonds between the hydrogen and fluorine atoms within the molecules, and the dotted lines represent secondary bonds, called hydrogen bonds. The hydrogen bonds between hydrogen fluoride molecules are considerably weaker (seven kilocalories per mole) than those within the molecules (135 kilocalories per mole), yet they are retained to a great extent in the liquid state. Similar hydrogen bonding exists in the other hydrogen halides, but it is considerably weaker. The large difference in hydrogen bonding between hydrogen fluoride and the other hydrogen halides accounts for the relatively high melting and boiling points of hydrogen fluoride as compared

Table 2: Comparison of Properties of Hydrogen Halides

hydrogen halide	formula	melting point (°C)	boiling point (°C)	homolytic dissociation energy (kcal/mol)	heterolytic dissociation energy (kcal/mol)	dipole moment (D)	H–X distance (angstrom)	K_a* in water at 20° C

*K_a = acid dissociation constant.

to those of hydrogen chloride and the other hydrogen halides. The hydrogen–halogen bond energies also decrease considerably in going from hydrogen fluoride to hydrogen iodide. These and other properties of the hydrogen halides are compared in Table 2.

Hydrogen halides as acids

In aqueous solution the hydrogen halides are acids, as reflected in their common names; such as hydrofluoric acid for hydrogen fluoride, and so on. The acidity increases dramatically from hydrofluoric acid to hydrochloric acid. Further increases occur with the other hydrogen halides, and hydriodic acid is not only the most acidic of the hydrogen halides but one of the most acidic substances known in aqueous solution. On the other hand, the oxidizing properties of the hydrogen halides decrease markedly from hydrogen fluoride to hydrogen iodide (thereby accounting for the extreme reactivity of hydrofluoric acid toward certain substances).

The ionization potentials of the halogens are generally high, but they fall markedly with atomic number. Fluorine is the only halogen that does not form compounds with positive oxidation states—*i.e.*, states in which it has lost, rather than gained, electrons. This property is related to the inability of the fluorine atom to use *d* orbitals in bonding (see above), an inability not shared by the other halogen elements. Iodine forms an appreciable number of compounds in which a unipositive iodine ion is stabilized by coordination (surrounding with other groups); for example, with the coal-tar base, pyridine. The same situation has also been found with astatine.

Whereas fluorine exhibits only the single oxidation state of −1, the principal oxidation states of chlorine, bromine, and iodine are −1, +1, +3, +5, and +7. The oxo acids are compounds in which halogen atoms are joined to oxygen atoms and show large positive oxidation numbers. The oxo acids are all powerful oxidizing agents, being reduced to the corresponding aqueous hydrogen halides—the oxidation numbers passing from +5 or +7 to −1 in the process. The oxidizing properties of the oxo acids, however, fall with increasing oxidation number of the halogen because the coordination number increases with increasing oxidation number and the ion is stabilized by the coordination.

All the molecules and ions in which halogen atoms employ four electron pairs in bonding are basically tetrahedral in shape—as is, for example, the perchlorate ion $(ClO_4)^-$. Those employing five electron pairs are square pyramidal in structure, such as iodine(V) fluoride (IF_5)—the roman numeral in the name being used to indicate the oxidation number of the element it follows. Those with six electron pairs are octahedral; *e.g.*, the paraperiodate ion, $(IO_6)^{5-}$. The unique binary compound iodine(VII) fluoride (IF_7) is believed to have a pentagonal bipyramidal arrangement of fluorine atoms.

The maximum coordination number of chlorine(VII) toward oxygen is 4 (*i.e.*, the chlorine atom is surrounded by four oxygen atoms) in the perchlorate ion, $(ClO_4)^-$, whereas that of iodine(VII) is 6 in the paraperiodate ion, $(IO_6)^{5-}$. Analagous behaviour is found in the elements preceding the respective halogen in the periodic table, sulfur and tellurium.

Individual halogen group elements and their compounds

FLUORINE

Occurrence and distribution. The fluorine-containing mineral fluorspar has been used for centuries as a flux (cleansing agent) in various metallurgical processes. The name fluorspar is derived from the Latin *fluere,* "to flow." The mineral subsequently proved to be a source of the element, which was named fluorine accordingly. The colourless, transparent crystals of fluorspar exhibit a bluish tinge when illuminated, and this property is accordingly known as fluorescence.

Fluorspar —source of fluorine

Fluorine is found in nature only in the form of its chemical compounds, except for trace amounts of the free element in fluorspar that has been subjected to the action of radiation from radium. The principal fluorine-containing minerals are: (1) fluorspar (fluorite, CaF_2), deposits of which occur in Illinois, Kentucky, Derbyshire, southern Germany, the south of France, and the Soviet Union; (2) cryolite (Na_3AlF_6), chiefly from Greenland; (3) fluoroapatite ($Ca_5[PO_4]_3[F,Cl]$), widely distributed and containing variable amounts of fluorine and chlorine; (4) topaz $Al_2SiO_4[F,OH]_2$), the gemstone; and (5) lepidolite, a mica as well as a component of animal bones and teeth.

Production and use. Fluorspar is the most important source of fluorine. In the manufacture of hydrogen fluoride, powdered fluorspar is distilled with concentrated sulfuric acid in a lead or cast-iron apparatus. The hydrogen fluoride is obtained in a fairly anhydrous state by fractional distillation in copper or steel vessels and stored in steel cylinders. The usual impurities in commercial hydrogen fluoride are sulfurous and sulfuric acids as well as fluorosilicic acid, arising from the presence of silica in the fluorspar. Traces of moisture may be removed by electrolysis with platinum electrodes.

The preparation of the free element is carried out by electrolytic procedures in the absence of water. Generally these take the form of electrolysis of a melt of potassium fluoride–hydrogen fluoride (in a ratio of 1 to 2.5–5) at temperatures between 30° and 70° C (86° and 158° F), 80° and 120° C (176° and 248° F), or at 250° C (482° F). During the process the hydrogen fluoride content of the electrolyte is decreased and the melting point rises; it is therefore necessary to add hydrogen fluoride. In the high-temperature cell the electrolyte is replaced when the melting point reaches over 300° C (572° F). Fluorine can be safely stored under pressure in cylinders of stainless steel if the valves of the cylinders are free from traces of organic matter.

The element is used for the preparation of various fluorides, such as chlorine trifluoride, sulfur(VI) fluoride, or cobalt(III) fluoride. The cobalt compound and certain other metal fluorides are important fluorinating agents for organic compounds. With appropriate precautions, the element itself may be used for the fluorination of organic compounds. Fluorine derivatives of hydrocarbons (compounds of carbon and hydrogen) are useful as refrigerants and as lubricants. The element is also used for the preparation of uranium(VI) fluoride, which is important in the process of separation of uranium-235 from natural uranium. Its outstanding oxidizing properties make elemental fluorine of possible interest as an oxidizer in rocket propulsion. Hydrogen fluoride and boron(III) fluoride are produced commercially because they are good catalysts for the alkylation reactions used to prepare organic compounds of many kinds. The addition of sodium fluoride to drinking water to reduce the incidence of dental caries in children is a matter of some controversy.

Uses in fluorination

Chemical properties. At room temperature fluorine is a pale-yellow gas with an irritating odour. Inhalation of

the gas is dangerous except in very low concentration. There is only one stable isotope of the element—fluorine-19.

Because fluorine is the most electronegative of the elements, atomic groupings rich in fluorine are negatively charged. Methyl iodide (CH_3I) and trifluoroiodomethane (CF_3I) have different properties for that reason. The charge distributions in these molecules are shown in the following formulas, in which the Greek symbol δ (delta) indicates a partial charge:

$$\overset{\delta+\delta-}{CH_3I} \qquad \overset{\delta-\delta+}{CF_3I}.$$

The ionization potential of fluorine is very high (402 kilocalories per gram atom), giving a standard heat formation for fluoride ion of 420 kilocalories per mole.

The small size of the fluorine atom makes it possible to pack a relatively large number of fluorine atoms or fluoride ions around a given coordination centre—*i.e.*, around a central atom. Fluorine is the most powerfully oxidizing element. No other substance, therefore, is able to reduce the fluoride ion to the free element, and for this reason the element is not found in the free state in nature. Furthermore, all chemical methods have failed to produce the element, success having been achieved only by the use of electrolytic methods. The high oxidizing properties of fluorine allow the element to produce the highest oxidation numbers possible in other elements, and many higher fluorides of elements are known for which there are no other corresponding halides—*e.g.*, silver(II) fluoride, cobalt(III) fluoride, rhenium(VII) fluoride, bromine(V) fluoride, and iodine(VII) fluoride.

Fluorine reacts with nearly all other elements at room temperature. Some metals, such as nickel, are quickly covered by a fluoride layer, which prevents further attack of the metal by the element. When dry, certain metals, such as mild steel, copper, aluminum, or Monel metal, are not attacked by fluorine to any extent at ordinary temperatures. For work with fluorine at temperatures up to 600° C (1,100° F) Monel metal is suitable; sintered alumina is resistant up to 700° C (1,300° F). When lubricants are required, fluorocarbon oils are most suitable.

Fluorine reacts violently with organic matter (such as rubber, wood, and cloth), and controlled fluorination of organic compounds by the action of elemental fluorine is not possible unless special precautions are taken.

Principal compounds. Because fluorine has a high electron affinity, it forms many ionic compounds. In contrast to aluminum(III) chloride, which is covalent, aluminum(III) fluoride is composed of an ionic lattice. In general, a metal–fluorine bond is considerably stronger than the corresponding metal–chlorine bond. This strength is one reason why a fluoride compound is dissociated to a smaller extent than the corresponding chloride in a given solvent, the other reason being the "hard" properties (small polarizability) of the fluoride ion.

Small size of the fluorine ion

Because of the small size of the fluoride ion—nearly the same as that of the oxide ion—and the resulting tendency to acquire a high coordination number, hexafluorides of nonmetals—sulfur(VI) fluoride—or of metals—molybdenum(VI) fluoride and uranium(VI) fluoride—are readily formed. They are rather inert and volatile compounds, which form molecular lattices in the solid state. Three heptafluorides are known; namely, technetium (VII) fluoride, rhenium(VII) fluoride, and iodine(VII) fluoride. In certain complex fluorides even higher coordination numbers are found; for example, potassium octafluorotantalate(V) (K_3TaF_8).

The tendency of fluorine to form unique compounds with various metals in their highest possible coordination numbers (caused by its great oxidizing ability) is further assisted by the small size of the fluorine atom (and the fluoride ion). Bismuth(V) fluoride, for example, is the only known compound of bismuth with all the bismuth atoms in the +5 oxidation state; and cobalt(III) fluoride, a very useful fluorinating agent, is the only binary halide of cobalt in the +3 state. Cesium hexafluorocobaltate (IV) (Cs_2CoF_6) is readily formed by oxidizing cesium tetrachlorocobaltate(II) (Cs_2CoCl_4) with elemental fluorine at 300° C (572° F). Potassium hexafluoronickelate(IV) (K_2NiF_6) may be obtained in a similar fashion. Although silver(II) fluoride is the only known binary halide of silver(II), it may be oxidized further with fluorine in the presence of a fluoride able to form complexes. Thus in the presence of a potassium salt, silver(II) fluoride gives the compound potassium tetrafluoroargentate(III) ($KAgF_4$). Further examples are the fluoro complexes of the general composition Cs_3MF_7, in which $M = Pr^{4+}$ (praseodymium), Nd^{4+} (neodymium), Tb^{4+} (terbium), and Dy^{4+} (dysprosium). Fluorine reacts even with the relatively inert noble gas xenon to give the compounds xenon(II) fluoride, xenon(IV) fluoride, and xenon(VI) fluoride.

The high electronegativity of fluorine suggests that boron(III) fluoride should behave as a stronger Lewis acid (electron-pair acceptor) than boron(III) chloride. In fact, however, the fluoride acts as a weaker Lewis acid than the chloride, and this fact has been attributed to pi bonding between boron and the fluorine atoms. On coordination of boron(III) fluoride with a fourth fluoride ion, the tetrafluoroborate ion, $(BF_4)^-$, is formed, in which pi bonding is virtually impossible; and, indeed, in this complex ion the boron–fluorine distances are considerably greater than the simple trifluoride.

The "hard" fluoride ion is a fairly strong ligand (coordinating substance) toward similarly "hard" metal ions, whereas it acts as a weaker ligand toward "soft" metal ions, such as mercury(I) ion. In octahedral complexes, fluorine atoms exert a stronger ligand field (coordination effect) than any other halogen atoms.

Hydrogen fluoride. Pure hydrogen fluoride is prepared in the laboratory by heating dry potassium hydrogen fluoride in a copper or platinum vessel. In the liquid state hydrogen fluoride molecules are associated through hydrogen bonds. The pure liquid is almost a nonconductor of electricity; it dissolves many substances to yield conducting solutions. It has a high dielectric constant—*i.e.*, an ability to separate electric charges—and hence acts as a dissociating medium for ionic compounds. Precipitation reactions, such as that shown below between thallium fluoride (TlF) and potassium perchlorate ($KClO_4$), may be carried out in anhydrous hydrogen fluoride:

$$TlF + KClO_4 \rightleftharpoons TlClO_4 + KF.$$

Alcohols, ethers, ketones, and acids give conducting solutions containing fluoride ions; methyl alcohol, for example, reacts according to the following equation:

$$CH_3OH + HF \rightleftharpoons (CH_3OH_2)^+ + F^-.$$

Acetic acid is protonated (takes up a hydrogen ion) in the solvent, and thus acts as a base in it:

$$CH_3COOH + HF \rightleftharpoons (CH_3COOH_2)^+ + F^-.$$

In concentrated solution there is found the $(HF_2)^-$ ion, which is also a constituent of potassium hydrogen fluoride (KHF_2).

Most inorganic chlorides, bromides, and iodides are converted into the respective fluorides by reaction with hydrogen fluoride; for example, titanium chloride ($TiCl_4$) reacts according to the following equation:

$$TiCl_4 + 4HF \rightarrow TiF_4 + 4HCl.$$

These last reactions go to completion because the other hydrogen halides are more volatile than hydrogen fluoride, and they are nearly insoluble in the latter.

Hydrogen fluoride is used as a solvent for the reaction of fluorine with various organic compounds, and some of them may be electrolyzed in this solvent to give fluorocarbons. Hydrogen fluoride is much used as a catalyst in organic chemistry. Butadiene, isoprene, and styrene, for example, polymerize (*i.e.*, individual molecules join together to form long chains, or polymers) rapidly when treated with hydrogen fluoride to give useful products. One of the main industrial uses of hydrogen fluoride is as a catalyst for the alkylation (addition of alkyl groups) of aromatic compounds by alcohols, olefins, alkyl halides, esters, and ethers. Hydrogen fluoride has also been used extensively for the low-temperature alkylation of

Hydrogen fluoride as a solvent

paraffinic hydrocarbons, particularly for the production of branched-chain compounds for aviation gasoline.

Hydrogen fluoride reacts with silica glass to give silicon(IV) fluoride (SiF_4). Silica and aqueous hydrofluoric acid yield fluorosilicic acid (H_2SiF_6). Etchings made on glass with hydrogen fluoride gas are opaque; those made with the aqueous solution are transparent.

The binary fluorides may be formally considered to be salts of hydrofluoric acid. They fall into two main groups: (1) those of metals, which have ionic lattices and are characterized by low volatility and low solubility; and (2) those of the nonmetals and the transition elements (metals in the centre of the periodic table), which are volatile and frequently hydrolyzed by water and decomposed by organic solvents. Within a group of ionic fluorides, such as the alkali metal fluorides, certain properties vary in a regular manner. The lattice energy, and hence the melting point, decreases as the size of the cation (positive ion) increases; thus, cesium fluoride has a relatively low melting point. Because the free energies of solvation (a measure of ease of solubility) of the ions decrease less rapidly than the lattice energies, the solubility is higher for cesium fluoride than for rubidium fluoride. These properties of the fluorides of the alkali metals are summarized in Table 3.

Table 3: Properties of the Fluorides of the Alkali Metals

fluoride	formula	radius of cation (angstrom)	melting point (°C)	solubility at 20° C (g/100 ml water)
Sodium	NaF	0.97	988	4.22
Potassium	KF	1.33	846	49.6
Rubidium	RbF	1.47	775	130
Cesium	CsF	1.67	682	very soluble

In a series of fluorides of nonmetals in any single group in the periodic table the size–volatility relationship is the reverse of that for compounds of the alkali metals, as shown in Table 4. Intermolecular attractions (van der Waals forces) increase and volatility decreases with increasing molecular weight.

Table 4: Properties of the Fluorides of Carbon Group Elements

fluoride	formula	melting point (°C)	boiling point (°C)
Carbon	CF_4	−184	−128
Silicon	SiF_4	−97	−65
Germanium	GeF_4	—	−15 (4 atm)
Tin	SnF_4	sublimes at 700	

In gaseous fluorides the observed bond lengths are usually shorter than expected. The carbon–carbon distance in ethane, for instance, is 1.54 angstroms (one angstrom unit equals 10^{-10} metre) and the fluorine–fluorine distance in molecular fluorine is 1.42 angstroms, whereas the observed carbon–fluorine distance in carbon(IV) fluoride is only 1.36 angstroms. Similarly, the nitrogen–nitrogen and phosphorus–phosphorus distances in hydrazine and white phosphorus, respectively, are 1.48 and 2.21 angstroms, but the bond length in nitrogen(III) fluoride is about 1.40 and that in phosphorus(III) fluoride is 1.54 angstroms.

Halogen fluorides. Fluorine forms several binary compounds with the other halogens, in which the other, more electropositive, halogen may be in the oxidation state of +1, +3, +5, or +7; whereas the fluorine atom always has the oxidation number −1. The known compounds of this family are shown in Table 5.

Table 5: Halogen Fluorides

F_2	—	—	—
ClF	ClF_3	ClF_5	—
BrF	BrF_3	BrF_5	—
IF*	IF_3	IF_5	IF_7

*Unstable.

No fluoride of astatine has been reported, but astatine(V) fluoride and astatine(VII) fluoride are thought to be capable of existence.

Halogen fluorides are made by direct combination of the halogen elements under suitable conditions. Increases in temperature favour the formation of higher fluorides, those with higher oxidation number. There is a gradual change in properties from fluorine through chlorine(I) fluoride and bromine(I) fluoride to iodine(I) fluoride, the last being unstable. On the other hand, iodine forms a heptafluoride, one of the very few known binary compounds with a coordination number of 7. Bonding in halogen fluorides is covalent. The structure of iodine(VII) fluoride has not yet been confirmed, but there are indications that the molecule has a pentagonal bipyramidal shape. The trifluorides have T-shaped molecules, and the pentafluorides appear to have square pyramidal structures.

Halogen fluorides as fluorinating agents

All halogen fluorides are strong fluorinating agents, their reactivity increasing in order from the iodine to the chlorine compounds and also with increasing number of fluorine atoms in the molecule. Bromine(III) fluoride, for example, reacts explosively with water, wood, and rubber, and with incandescence even with asbestos and most organic solvents. Most metals, including many noble metals—such as gold—are converted into their highest fluorides upon reaction with halogen fluorides. With molybdenum, for example, the reaction is as follows:

$$Mo + 2BrF_3 \rightarrow MoF_6 + Br_2.$$

Gold(III) fluoride has been obtained by the thermal decomposition of the adduct formed from the metal and bromine(III) fluoride, as shown in the following equations:

$$Au + 2BrF_3 \rightleftharpoons BrF_2AuF_4 + \tfrac{1}{2}Br_2$$

$$BrF_2AuF_4 \rightleftharpoons BrF_3 + AuF_3.$$

Pure liquid bromine(III) fluoride is pale yellow in colour and may be used as an ionizing solvent for fluorides and as a reaction medium for the preparation of numerous complex fluorides. A self-ionization equilibrium has been assumed to exist in the pure liquid, as follows:

$$2BrF_3 \rightleftharpoons (BrF_2)^+ + (BrF_4)^-.$$

It has been suggested that fluoride bridging is a characteristic structural feature in the liquid. Compounds have been isolated that contain the planar tetrafluorobromate(III) ions $(BrF_4)^-$. One example—with silver fluoride—is:

$$AgF + BrF_3 \rightleftharpoons Ag^+ + (BrF_4)^-.$$

Hydrogen fluoride yields fluoride ions in bromine(III) fluoride solution, and—like alkali metal fluorides and silver fluoride—it must be considered as a base in this solvent.

Lewis acids such as antimony(V) fluoride (SbF_5) give adducts with bromine(III) fluoride, which ionize to form difluorobromine(III) ions, $(BrF_2)^+$, as shown below:

$$BrF_3 + SbF_5 \rightleftharpoons (BrF_2)^+(SbF_6)^-.$$

Reactions of the acid–base type yield complex fluorides; for example:

$$Ag^+(BrF_4)^- + (BrF_2)^+(SbF_6)^- \rightleftharpoons Ag^+(SbF_6)^- + 2BrF_3.$$

Chlorine(III) fluoride behaves in an analogous manner. Iodine(V) fluoride gives hexafluoroiodate(V) with alkali metal fluorides such as potassium fluoride:

$$KF + IF_5 \rightarrow K^+(IF_6)^-.$$

Oxides. As stated above, fluorine is the only halogen element that occurs solely in the −1 oxidation state. Thus, no oxo acid of fluorine is stable, and the hypofluo-

rites, such as the compound pentafluorosulfur hypofluorite (F_5SOF), are covalent and cannot be considered as salts of a hypofluorous acid. Binary oxides of fluorine, however, do exist, and this fact is not in conflict with the above statement since oxygen has a lower electronegativity than fluorine and assumes the positive oxidation state in the compounds. Oxygen difluoride (OF_2) is obtained by passing fluorine into a fairly concentrated solution of alkali hydroxide, as shown below:

$$2F_2 + 2OH^- \rightarrow 2F^- + OF_2 + H_2O.$$

The colourless gas oxygen difluoride has strong oxidizing properties, and it is decomposed by alkali hydroxide:

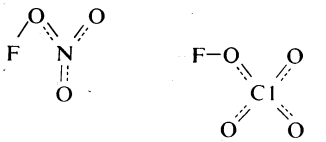
$$OF_2 + 2OH^- \rightleftharpoons 2F^- + O_2 + H_2O.$$

The highly unstable dioxygen difluoride (O_2F_2) is obtained in an electric-discharge tube cooled in liquid air. Reaction of dioxygen difluoride with antimony(V) fluoride gives a stable dioxygenyl compound [$O_2^+(SbF_6)^-$]. By admitting different ratios of oxygen and fluorine to an electric discharge, a number of unstable compounds can be obtained with molecular formulas, as follows: trioxygen difluoride (O_3F_2), tetraoxygen difluoride (O_4F_2), pentaoxygen difluoride (O_5F_2), and hexaoxygen difluoride (O_6F_2).

The compound known as fluorine nitrate (FNO_3) is prepared by the action of fluorine on concentrated nitric acid:

$$HNO_3 + F_2 \rightleftharpoons FNO_3 + HF.$$

The compound is a powerful oxidizing agent and, like the closely related compound fluorine perchlorate ($FClO_4$), is considered to be derivative of oxygen difluoride. These compounds are thought to be as follows:



in which the dotted lines indicate partial double-bond character.

Analysis. The accurate quantitative determination of the amount of fluorine in compounds is difficult. Free fluorine may be detected by its oxidizing action on chlorides such as sodium chloride, as shown:

$$F_2 + 2NaCl \rightleftharpoons 2NaF + Cl_2.$$

Qualitative tests for fluorine

The chlorine evolved may be determined by measurement of the volume of gas produced. The principal qualitative tests for the presence of fluorine are: (1) liberation of hydrogen fluoride by the action of sulfuric acid, (2) formation of a precipitate of calcium fluoride upon addition of a calcium chloride solution, and (3) decoloration of a yellow solution prepared from titanium(IV) oxide and hydrogen peroxide in sulfuric acid. Quantitative methods for analyzing fluorine are: (1) precipitation of calcium fluoride in the presence of sodium carbonate and treatment of the precipitate with acetic acid; (2) precipitation of lead chlorofluoride by addition of sodium chloride and lead nitrate; and (3) titration (determination of concentration of a dissolved substance) with thorium nitrate [$Th(NO_3)_4$] solution using sodium alizarin sulfonate as indicator, according to the equation

$$Th(NO_3)_4 + 4KF \rightleftharpoons ThF_4 + 4KNO_3.$$

CHLORINE

Occurrence and distribution. When Sir Humphry Davy in 1810 recognized the elementary nature of the yellowish-green gas that had first been obtained by Scheele in 1774, he suggested the name chlorine from the Greek *chloros*, meaning "yellowish-green." Apart from very small amounts of free chlorine in volcanic gases, chlorine is found only in the form of chemical compounds. It constitutes 0.031 percent of the Earth's crust. The most common compound of chlorine is sodium chloride, which is found in nature as crystalline rock salt, often discoloured by impurities. Sodium chloride is also present in seawater, which has an average concentration of about 3 percent of that salt. Certain landlocked seas, such as the Dead Sea, contain up to 7.2 percent of dissolved salt. Besides sodium chloride, other metal halides, such as magnesium chloride, magnesium bromide, and—in small amount—certain sulfates, are contained in seawater. Small quantities of sodium chloride are present in blood and in milk. Other chlorine-containing minerals are sylvite (potassium chloride, KCl), bischofite ($MgCl_2 \cdot 6H_2O$), carnallite ($KCl \cdot MgCl_2 \cdot 6H_2O$), and kainite ($KCl \cdot MgSO_4 \cdot 3H_2O$). Free hydrochloric acid is present in the stomach.

Present-day salt deposits must have been formed by evaporation of prehistoric seas, the salts with the least solubility in water crystallizing first, followed by those with greater solubility. Because potassium chloride is more soluble in water than sodium chloride, certain rock salt deposits—such as those at Stassfurt, East Germany—were covered by a layer of potassium chloride. In order to gain access to the sodium chloride, the potassium salt, important as a fertilizer, is removed first.

Mining of rock salt deposits

Production and use. Rock salt deposits are usually mined; occasionally water is pumped down and brine, containing about 25 percent sodium chloride, is brought to the surface. When the brine is evaporated, impurities separate first and can be removed. In warm climates salt is obtained by evaporation of shallow seawater by the sun, to give bay salt.

Chlorine is produced on a large scale by any of a number of different methods:

1. By electrolysis of a concentrated solution of sodium chloride in water. Hydrogen is evolved at the cathode and chlorine at the anode. At the same time, an alkali metal hydroxide is produced in the electrolyte, and hence this process is often referred to as chlorine-alkali-electrolysis.

The chemical reactions occurring at each electrode and the overall cell process are given in the equations below:

cathode process: $2H_2O + 2e^- \rightarrow 2OH^- + H_2$
(cathode of iron)
anode process: $2Cl^- \rightarrow Cl_2 + 2e^-$
(anode of graphite)
cell process: $2H_2O + 2Cl^- \rightarrow 2OH^- + H_2 + Cl_2$

in which the symbol e^- represents a single electron. In the reaction vessel free chlorine and hydroxide ions must not come in contact with each other because chlorine would be consumed according to the reaction:

$$Cl_2 + 2OH^- \rightarrow (ClO)^- + Cl^- + H_2O.$$

To accomplish the separation of chlorine gas and the hydroxide ion, a porous wall is inserted between the electrodes (diaphragm process), or the iron cathode is replaced by a cathode consisting of liquid mercury (mercury cathode process) which avoids the production of hydroxide ions at the electrode. Instead, free sodium is discharged at the cathode, and this metal is readily dissolved in the mercury forming an amalgam, as follows:

$$2Na^+ + 2e^- \rightleftharpoons 2Na(amalgam).$$

The amalgam is allowed to react with water outside the cell:

$$2Na(amalgam) + 2H_2O \rightarrow 2Na^+ + 2OH^- + H_2.$$

The overall process is equivalent to the cell process given above.

2. By electrolysis of fused sodium chloride, which also produces metallic sodium; chlorine is again evolved at the anode.

3. By electrolysis of fused magnesium chloride, in which chlorine is formed as a by-product in the manufacture of metallic magnesium.

4. By oxidation of hydrogen chloride. In this process gaseous hydrogen chloride mixed with air or oxygen is passed over pumice in contact with cupric chloride as a catalyst, as shown in the following equation:

$$4HCl + O_2 \xrightarrow{\text{catalyst}} 2H_2O + 2Cl_2.$$

The equilibrium constant for this reaction decreases with increase of temperature; *i.e.*, the reaction proceeds less extensively at higher temperatures. In practice, however, a temperature of 400° C (750° F) is required to achieve a reasonable rate of conversion.

5. Of historical interest is the process in which a mixture of almost any solid chloride and manganese dioxide (MnO_2) yields chlorine when heated with concentrated sulfuric acid (H_2SO_4). The reaction occurs, as follows:

$$2NaCl + 3H_2SO_4 + MnO_2 \rightarrow MnSO_4 + 2NaHSO_4 + 2H_2O + Cl_2.$$

In the laboratory chlorine is frequently prepared by the oxidation of concentrated hydrochloric acid with permanganate or dichromate salts:

$$2MnO_4^- + 10Cl^- + 16H^+ \rightarrow 2Mn^{2+} + 5Cl_2 + 8H_2O$$

$$Cr_2O_7^{2-} + 6Cl^- + 14H^+ \rightarrow 2Cr^{3+} + 3Cl_2 + 7H_2O.$$

Laboratory preparations of chlorine

Similarly, chlorine may be prepared on a small scale by addition of any dilute acid to bleaching powder, a mixture of dry calcium salts, including the hydroxide, chloride, and hypochlorite.

Chlorine is marketed in steel cylinders in the liquid state under pressure. The total world production of chlorine was estimated at 17,000,000 tons in 1968, and more than 7,000,000 tons are produced annually in the United States. American production has shown an annual rate of increase of about 8 percent per annum since the early 1950s.

Most of the chlorine produced is used for chemical processes involving the introduction of chlorine into organic compounds, yielding carbon tetrachloride (used as a solvent, a fire extinguisher, and a dry-cleaning agent) and glycols (used as antifreeze), and other organic compounds for the manufacture of plastics (polyvinyl chloride) and synthetic rubber. Sulfur chloride, made by the action of chlorine on carbon disulfide or by combining sulfur and chlorine, is used in the vulcanization of rubber and as a chlorinating agent in organic synthesis. Chlorine and carbon monoxide form carbonyl chloride, or phosgene, which has been employed as a war gas and is used in metallurgy to transform certain oxides into chlorides. Much chlorine is used to sterilize water and wastes; and the substance is employed either directly or indirectly as a bleaching agent for paper or textiles. Chlorine is applied in the manufacture of hydrochloric acid, the extraction of titanium with formation of titanium(IV) chloride, the removal of tin from old tinplate, and in the production of antiknock materials for gasolines, such as tetraethyl lead. Anhydrous aluminum chloride is made by the reaction of chlorine with scrap aluminum or with aluminum oxide and carbon. Chlorine is also used to prepare silicon(IV) chloride and methyl chloride, which are employed in the synthesis of silicon materials. Chlorine enters directly, or indirectly as an intermediate, into many organic syntheses of industrial importance.

Physical and chemical properties. Chlorine is a greenish-yellow gas at room temperature and atmospheric pressure. It is considerably heavier than air. It has a choking smell, and inhalation causes suffocation, constriction of the chest, tightness in the throat, and—after severe exposure—edema (filling with fluid) of the lungs. As little as 2.5 milligrams per litre in the atmosphere causes death within a few minutes, but less than 0.0001 percent by volume may be tolerated. Chlorine was the first gas used in chemical warfare in World War I. The gas is easily liquefied by cooling or by pressures of a few atmospheres at ordinary temperature.

Toxicity of chlorine

Chlorine has a high electronegativity and a high electron affinity, the latter being even slightly higher than that of fluorine. The affinity of chlorine for hydrogen is so great that the reaction proceeds with explosive violence in light, as in the following equation:

$$H_2 + Cl_2 \xrightarrow{h\nu} 2HCl.$$

In the presence of charcoal, the combination of chlorine and hydrogen takes place rapidly (but without explosion) in the dark. A jet of hydrogen will burn in chlorine with a silvery flame. Its high affinity for hydrogen allows chlorine to react with many compounds containing hydrogen. Chlorine reacts with hydrocarbons, for example, substituting chlorine atoms for the hydrogen atoms successively. If the hydrocarbon is saturated, however, chlorine atoms readily add to the double or triple bond.

Chlorine reacts with many elements of both metals and nonmetals to give chlorides. Only toward carbon, nitrogen, and oxygen is it fairly inert. The products of reaction with chlorine usually are chlorides with high oxidation numbers, such as iron(III) chloride ($FeCl_3$), tin(IV) chloride ($SnCl_4$), or antimony(V) chloride ($SbCl_5$), but it should be noted that the chloride of highest oxidation number of a particular element is frequently in a lower oxidation state than the fluoride of highest oxidation number. Thus, vanadium forms a pentafluoride, whereas the pentachloride is unknown, and sulfur gives a hexafluoride but no hexachloride. With sulfur, even the tetrachloride is unstable.

Chlorine displaces the less electronegative halogens from compounds. The displacement of bromides, for example, occurs according to the following equation:

$$2Br^- + Cl_2 \rightleftharpoons Br_2 + 2Cl^-.$$

Furthermore, it converts several oxides into chlorides. An example is the conversion of iron(III) oxide to the corresponding chloride:

$$2Fe_2O_3 + 6Cl_2 \rightleftharpoons 4FeCl_3 + 3O_2.$$

With carbon monoxide chlorine gives carbonyl chloride; and with sulfur dioxide, sulfuryl chloride:

$$CO + Cl_2 \rightleftharpoons COCl_2$$

$$SO_2 + Cl_2 \rightleftharpoons SO_2Cl_2.$$

Chlorine water

Chlorine is moderately soluble in water, yielding chlorine water, and from this solution a solid hydrate of ideal composition $Cl_2 \cdot 7.66H_2O$ is obtained. This hydrate is characterized by a structure that is more open than that of ice; the unit cell contains 46 molecules of water and six cavities suitable for the chlorine molecules. When the hydrate stands, disproportionation takes place—that is, one chlorine atom in the molecule is oxidized and the other is reduced. At the same time, the solution becomes acidic, as shown in the following equation:

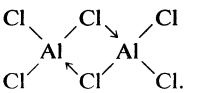
$$\overset{0}{Cl_2} + H_2O \rightleftharpoons \overset{+1}{HClO} + \overset{-1}{HCl}$$

in which the oxidation numbers are written above the atomic symbols. Chlorine water loses its efficiency as an oxidizing agent on standing, because hypochlorous acid gradually decomposes. The reaction of chlorine with alkaline solutions yields salts of oxo acids (see below).

The ionization potential of chlorine is high. Although ions in positive oxidation states are not very stable, high oxidation numbers are stabilized by coordination, mainly with oxygen and fluorine. In such compounds bonding is predominantly covalent, and chlorine is capable of exhibiting the oxidation numbers +1, +3, +4, +5, +6, and +7.

Principal compounds. The nonvolatile chlorides of the alkali and alkaline-earth metals are essentially ionic. The volatile chlorides of the nonmetals, such as boron, carbon, silicon, and sulfur, however, are covalently bonded molecular liquids at room temperature. Carbon tetrachloride is not miscible with water, but silicon(IV) chloride is readily decomposed with water (hydrolyzed).

Between the ionic and covalent extremes are the chlorides of such metals as aluminum, iron, titanium, or gold. In the chlorides of aluminum, iron(III), titanium(III), vanadium(III), chromium(III), and gold(III), a coordination number of 4 is found, and chloride bridges are present, as in the following formulation:



These chlorides are hydrolyzed by water.

The chlorides of silver and lead(II) are scarcely soluble in water. The solubility is increased in the presence of

excess chloride ions because of the formation of complex ions, namely dichloroargentate(I), $(AgCl_2)^-$, and tetrachloroplumbate(II), $(PbCl_4)^{2-}$. The increased solubility of mercury(I) chloride in the presence of chloride ions is due to disproportionation to metallic mercury and trichloromercurate(II) $[(HgCl_3)^-]$.

Preparation of anhydrous chlorides

The following methods are utilized for the preparation of anhydrous chlorides: (1) direct union of the element with chlorine, as with titanium (Ti) in:

$$Ti + 2Cl_2 \rightarrow TiCl_4;$$

(2) reaction of the element or its oxide with hydrogen chloride, as with zinc (Zn):

$$Zn + 2HCl \rightleftharpoons ZnCl_2 + H_2,$$

or magnesium oxide (MgO),

$$MgO + 2HCl \rightleftharpoons MgCl_2 + H_2O;$$

(3) chlorination with certain chlorides as in the reaction of chromic anhydride (Cr_2O_3) with carbon tetrachloride (CCl_4):

$$Cr_2O_3 + 3CCl_4 \rightleftharpoons 2CrCl_3 + 3COCl_2;$$

(4) dehydration of the hydrated chloride with hydrogen chloride or thionyl chloride as with the hydrated cobalt chloride $[Co(OH_2)_6]Cl_2$:

$$[Co(OH_2)_6]Cl_2 + 6SOCl_2 \rightleftharpoons CoCl_2 + 6SO_2 + 12HCl.$$

The chloride ion has an electronic configuration consisting of a complex octet, and hence it can act as a Lewis base (donor of an electron pair). The ion is strongly hydrated by water, which acts as a Lewis acid, and in this way the ion is stabilized. Because of its Lewis-base properties, the chloride ion is known to act as a ligand in complex compounds. The coordination numbers in such chloro complexes are usually 4 or 6; *e.g.*, tetrachloroaluminate(III) $[(AlCl_4)^-]$, hexachlorophosphate(V) $[(PCl_6)^-]$, and hexachlorotitanate(IV) $[(TiCl_6)^{2-}]$. It should be noted that several transition metal ions, such as cobalt(II), form only tetrahedral chloro complexes.

Lower chlorides of transition metal elements that have a very high heat of atomization are known only as metal clusters. Thus the dichlorides of molybdenum and tungsten, represented by M, contain a group formulated as $(M_6Cl_8)^{4+}$, in which the chlorine atoms are placed at the apices of an octahedron with the chlorine atoms lying above the centres of the eight triangular faces, thereby forming three-way bridges between the metal atoms. This structure is similar to those of certain cluster compounds of niobium and tantalum, with formulas $(Nb_6Cl_{12})^{2+}$ and $(Ta_6Cl_{12})^{2+}$, respectively, and it appears that formation of such groups of metal atoms with halogen bridges between them may be a recurring feature for these metals in their low oxidation states.

Hydrogen chloride. Hydrogen chloride is formed chiefly by three reactions: (1) reaction of the elements: $H_2 + Cl_2 \rightarrow 2HCl$; (2) hydrolysis of a covalent chloride such as thionyl chloride:

$$SOCl_2 + 2H_2O \rightarrow H_2SO_3 + 2HCl;$$

(3) reaction of an ionic chloride, such as sodium chloride, with sulfuric acid:

$$NaCl + H_2SO_4 \rightleftharpoons NaHSO_4 + HCl.$$

Hydrogen chloride is a colourless gas with a strong irritating odour. It dissolves rapidly and extensively in water, giving a strongly acidic solution, which is known as hydrochloric acid:

$$H_2O + HCl \rightleftharpoons (H_3O)^+ + Cl^-.$$

The concentrated hydrochloric acid contains about 40 percent hydrogen chloride. Many metals are dissolved in the acid giving the respective metal chloride and hydrogen, as may be seen in the equation for zinc (Zn):

$$Zn + 2HCl \rightleftharpoons ZnCl_2 + H_2.$$

This type of reaction is used for the preparation of hydrogen on a laboratory scale.

Anhydrous hydrogen chloride is less reactive. Only a few reactive metals, such as sodium (Na), react with the gas at room temperature:

$$2Na + 2HCl \rightarrow 2NaCl + H_2.$$

At higher temperatures reaction takes place with less reactive metals; in the case of a metal exhibiting several oxidation states, the lower chloride is formed preferably, as with tin (Sn) and iron (Fe):

$$Sn + 2HCl \rightarrow H_2 + SnCl_2$$

$$Fe + 2HCl \rightarrow H_2 + FeCl_2.$$

Liquid hydrogen chloride

Liquid hydrogen chloride may be used as a nonaqueous solvent. It dissolves tetraalkylammonium chloride to give a conducting (ionic) solution, in which the anionic species is an ion formulated as $(HCl_2)^-$. Hydrogen bonding in this ion is considerably weaker than in the related ion $(HF_2)^-$. Covalent chlorides, such as boron(III) chloride, behave as acids in liquid hydrogen chloride in that they are capable of accepting a chloride ion; in doing so they may be considered to be neutralized by chlorine ion donors, such as tetraalkylammonium hydrogen dichloride, which in effect are bases, the reaction being:

$$(R_4N)(HCl_2) + BCl_3 \rightleftharpoons (R_4N)(BCl_4) + HCl$$

base acid salt solvent.

Hydrochloric acid is used for the surface treatment of metals (the removal of oxide layers), for the manufacture of various chlorides, and for the preparation of dye substances. Hydrogen chloride is used for the preparation of various solvents, as well as vinyl chloride and other intermediates used in the preparation of plastics and synthetic rubber.

Oxo acids. Chlorine forms oxo acids with oxidation states of +1, +3, +5, and +7 and with coordination numbers 1, 2, 3, and 4, respectively. The names and formulas of these acids and the corresponding salts are given in Table 6. The acids are formed by reaction of chlorine with water and hydroxide ions under appropriate conditions.

Table 6: Oxo Acids of Chlorine

name	oxidation number	formula	corresponding oxide	name of the salt	anion
Hypochlorous acid	+1	$HClO$	Cl_2O	hypochlorite or chlorate(I)	$(ClO)^-$
Chlorous acid	+3	$HClO_2$	—	chlorite or chlorate(III)	$(ClO_2)^-$
Chloric acid	+5	$HClO_3$	—	chlorate or chlorate(V)	$(ClO_3)^-$
Perchloric acid	+7	$HClO_4$	Cl_2O_7	perchlorate or chlorate(VII)	$(ClO_4)^-$

Hypochlorous acid ($HClO$) exists only in aqueous solution. It is made by shaking precipitated mercuric oxide (HgO) in water with chlorine:

$$2Cl_2 + 2HgO + H_2O \rightleftharpoons HgO \cdot HgCl_2 + 2HClO.$$

It is also formed slowly in aqueous solutions of chlorine:

$$Cl_2 + H_2O \rightarrow HClO + HCl.$$

Hypochlorous acid is in equilibrium with its anhydride, dichlorine monoxide (Cl_2O):

$$2HClO \rightleftharpoons Cl_2O + H_2O.$$

Under the influence of light, or on heating, the acid disproportionates as in the following equation:

$$\overset{+1}{3HClO} \rightleftharpoons \overset{+5}{HClO_3} + \overset{-1}{2HCl}.$$

Hypochlorous acid is a weak acid (only slightly dissociated into ions) in water (acid dissociation constant about 10^{-8}) and a strong oxidizing agent. It is used as a bleaching agent and for the production of chlorohydrins and glycols. Chlorohydrins are formed as in the following equation:

$$HClO + CH_2 = CH_2 \rightarrow CH_2ClCH_2OH.$$

The salts of hypochlorous acid, the hypochlorites or chlorates(I), may be obtained (1) by the action of chlorine on solutions of alkali carbonate at a temperature below +40° C (104° F):

$$Cl_2 + Na_2CO_3 \rightarrow NaOCl + NaCl + CO_2;$$

(2) by passing chlorine into alkaline solutions at room temperature:

$$Cl_2 + 2OH^- \rightarrow (ClO)^- + Cl^- + H_2O;$$

or (3) by electrolysis of concentrated alkali chloride solutions in slightly alkaline medium at a high current density.

Chlorous acid

Chlorous acid ($HClO_2$) is known only in aqueous solution, in which form it is a stronger acid than hypochlorous acid (dissociation constant about 10^{-2}). The salts, called chlorites or chlorates(III), are much more stable than the free acid. The sodium salt exists in the anhydrous state as well as in the form of a trihydrate. The hydrate is white in colour and releases chlorine dioxide (ClO_2) under the influence of light; it is decomposed into sodium chloride and oxygen on heating at 200° C (392° F), according to the following equations:

$$3NaClO_2 \rightarrow 2NaClO_3 + NaCl$$

$$NaClO_2 \rightarrow NaCl + O_2.$$

Chlorites are best made by the reaction of chlorine dioxide (ClO_2) with peroxides:

$$Na_2O_2 + 2ClO_2 \rightarrow 2NaClO_2 + O_2,$$

or by disproportionation of ClO_2 in alkaline solution:

$$\overset{+4}{2ClO_2} + 2NaOH \rightleftharpoons \overset{+5}{NaClO_3} + \overset{+7}{NaClO_2} + H_2O.$$

Chlorites of some of the heavy metals may explode in the presence of certain organic materials. In alkaline solution chlorites are fairly stable, whereas in acidic solution they are converted to the free acid, which decomposes rather rapidly:

$$4HClO_2 \rightarrow 2ClO_2 + (ClO_3)^- + Cl^- + 2H^+ + H_2O.$$

Chlorites are used as bleaching agents for cellulose, oils, starch, sugar, wool, and other materials.

Chloric acid ($HClO_3$) is soluble in water, in which it acts as a fairly strong acid. The chlorate ion, $(ClO_3)^-$, is pyramidal in structure. The acid is a strong oxidizing agent, which dissolves even copper metal.

Potassium chlorate ($KClO_3$) forms white crystals, melting at 356° C (673° F), which are moderately soluble in water. When the dry crystals are heated, oxygen is released, particularly in the presence of manganese dioxide, as shown below:

$$2KClO_3 \rightleftharpoons KCl + O_2 + KClO_4.$$

Sodium chlorate ($NaClO_3$), with a melting point of 255° C (491° F), absorbs water (*i.e.*, is hygroscopic) and is soluble in water. Chlorates may explode in the presence of sulfur, phosphorus, and certain organic materials. Chlorates are produced by the action of chlorine on solutions containing hydroxide ions, as follows:

$$3Cl_2 + 6OH^- \rightleftharpoons (ClO_3)^- + 5Cl^- + 3H_2O$$

$$2HOCl + (ClO)^- \rightleftharpoons (ClO_3)^- + 2Cl^- + 2H^+.$$

Electrolysis of a hot potassium chloride solution, preferably at platinum or graphite electrodes, gives crystalline potassium chlorate on cooling. Chlorates are used to destroy weeds and in the production of chlorine dioxide, as well as in the manufacture of explosives and matches. Small amounts are used in drug products, such as mouthwash.

Perchloric acid ($HClO_4$) is the most stable oxo acid of chlorine. It contains chlorine with oxidation number +7. In the perchlorate ion, the chlorine atom is surrounded tetrahedrally by four oxygen ligands. There is a certain amount of pi bonding involved in the chlorine–oxygen bonds. The perchlorate ion has little tendency to serve as a ligand in complexes, and thus perchlorates are widely used as electrolytes in studies of complex formation in solution. The free acid is obtained by vacuum distillation of aqueous solutions. It is a colourless liquid, solidifying at −112° C (−170° F). It is commercially available as a 72 percent aqueous solution. It is miscible with water in all proportions and acts as one of the strongest acids in water. The crystalline mono- and dihydrates are known to be fully ionized in the solid state, having the formulas $(H_3O)^+(ClO_4)^-$ and

$$(H_2O{-}H{-}OH_2)^+(ClO_4)^-.$$

Perchlorates

Perchlorates are formed by heating chlorates under controlled conditions:

$$4(ClO_3)^- \xrightarrow{480°} 3(ClO_4)^- + Cl^-$$

Electrolytic oxidation of a cooled chlorate solution at a high current density also yields perchlorates. Any chlorate remaining in the electrolyte may be decomposed by hydrochloric acid, which does not react with the perchlorate ion. Perchlorate salts are converted to the free acid by reaction with fluorosilicic acid or with hydrochloric acid:

$$2NaClO_4 + H_2SiF_6 \rightleftharpoons Na_2SiF_6 + 2HClO_4$$

$$NaClO_4 + HCl \rightleftharpoons NaCl + HClO_4.$$

Alternatively, the free acid may be obtained by anodic oxidation of hydrochloric acid, followed by vacuum distillation. Sodium perchlorate is readily soluble in water, whereas the potassium, rubidium, and cesium salts are only sparingly soluble. Magnesium perchlorate forms white, hexagonal crystals, melting at 146° C (295° F); it is an excellent drying agent. Applications of perchlorates are in fireworks and explosives, and they are also employed as oxidizing agents in rockets.

Oxides. Chlorine forms binary oxides in which it has oxidation states of +1, +4, +5, and +7, as shown in Table 7.

Table 7: Oxides of Chlorine

name	oxidation number	oxide
Dichlorine monoxide	+1	Cl_2O
Chlorine dioxide	+4	ClO_2
Dichlorine hexoxide	+6	Cl_2O_6
Dichlorine heptoxide	+7	Cl_2O_7

Dichlorine monoxide (Cl_2O) is the anhydride (compound formed with loss of water) of hypochlorous acid, as shown in the following equilibrium:

$$Cl_2O + H_2O \rightleftharpoons 2HClO.$$

It is formed from chlorine and mercuric oxide:

$$2Cl_2 + HgO \rightleftharpoons HgCl_2 + Cl_2O.$$

Chlorine dioxide (ClO_2) is an orange-yellow gas at room temperature. It is made from sodium chlorate, sulfur dioxide, and sulfuric acid, according to the following equation:

$$2NaClO_3 + SO_2 + H_2SO_4 \rightarrow 2ClO_2 + 2NaHSO_4.$$

A second method of preparation involves treating silver chlorate at 90° C (194° F) with dry chlorine and condensing the resulting dioxide by cooling:

$$2AgClO_3 + Cl_2 \rightarrow 2AgCl + 2ClO_2 + O_2.$$

The chlorine dioxide molecule contains an odd number of electrons and thus is unstable. It decomposes by the following equation:

$$ClO_2 \rightarrow \tfrac{1}{2}Cl_2 + 2O_2.$$

It may be stored only when diluted by an inert gas. It is used for the preparation of chlorites and also as a bleaching agent, *e.g.*, for flour or cellulose.

Dichlorine hexoxide (Cl_2O_6) is a red liquid at room temperature. It is readily decomposed. The chief method

of preparation is the action of ozone (O_3) on chlorine dioxide:

$$2ClO_2 + 2O_3 \rightarrow Cl_2O_6 + 2O_2.$$

The substance appears to be in equilibrium with its monomeric form:

$$Cl_2O_6 \rightleftharpoons 2ClO_3.$$

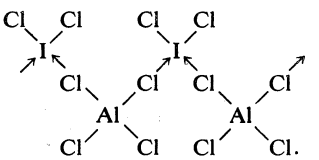
It is thermally unstable, decomposing to chlorine dioxide and oxygen.

Dichlorine heptoxide, (Cl_2O_7; boiling point −92° C [−134° F]) is the anhydride of perchloric acid. It is made by dehydrating perchloric acid with phosphorous pentoxide and distilling the product. The colourless liquid has strong oxidizing properties.

Halogen chlorides. The chlorine fluorides, in which the chlorine atoms exhibit positive oxidation numbers, have already been described. In its compounds with the other, less electronegative halogen elements, chlorine has the oxidation number −1. Of these, the iodine and bromine chlorides are chlorinating agents.

The iodine chlorides

Bromine(I) chloride is unstable, but iodine forms two stable chlorides, namely, iodine(I) chloride (ICl) and iodine(III) chloride (ICl_3). These compounds are obtained by direct union of the elements, and, when excess chlorine is used, the trichloride is obtained, in the form of yellow crystals. On addition of chloride ions the trichloride is connected to the planar ion, $(ICl_4)^-$. The trichloride also reacts with Lewis acids, such as aluminum(III) chloride ($AlCl_3$) or antimony(V) chloride ($SbCl_5$), to give crystalline compounds that contain chlorine bridges and are formulated as in the following example:



Iodine(I) chloride forms dark-brown crystals, which have an irritating smell and which melt on gentle warming. The compound may be prepared by heating iodine (III) chloride with the appropriate amount of iodine. Molten iodine(I) chloride behaves as an ionizing solvent for chlorides. By treatment with it, various elements are converted into their chlorides. The chloride ion reacts with iodine(I) chloride to give a polyhalide ion—namely, the $(ICl_2)^-$ ion—in which the atoms are arranged in a nearly linear manner. Other polyhalide anions containing chlorine have also been found in aqueous solutions.

Analysis. Free chlorine may be recognized by its smell, its colour, and its characteristic reaction with mercury to produce white mercury(II) chloride. Tests for chloride ions are:

1. The formation of a white precipitate of silver chloride on addition of silver nitrate in dilute nitric acid. (This precipitate is soluble in the presence of ammonia.)
2. The formation of chromyl chloride, a red gas, by heating a solid sample with potassium dichromate and concentrated sulfuric acid. When chromyl chloride is passed into water, a yellow chromate solution forms (bromides and iodides do not form analogous compounds).
3. The evolution of free chlorine by heating the sample with manganese dioxide and concentrated sulfuric acid.

The following methods are available for the quantitative determination of free chlorine:

Quantitative determination of chlorine

1. The chlorine-containing gas is shaken with an aqueous solution of potassium iodide, and the resulting iodine is determined by titration.
2. Chlorine is reduced in alkaline solution by an alkali arsenite. Back-titration of excess arsenite is carried out with potassium bromate.
3. In the presence of an alkali hydroxide, chlorine is reduced to the chloride ion by hydrogen peroxide, and the excess alkali hydroxide is back-titrated with acid.
4. With sulfur dioxide or sodium thiosulfate, chlorine is reduced to chloride, and the latter is analyzed as silver chloride (see below).
5. Colorimetric measurements are carried out in the presence of *o*-toluidine in hydrochloric acid.

For the determination of chloride ions, one of the following methods may be recommended: (1) gravimetric analysis (analysis by weight of a given product) as silver chloride; (2) titration of neutral chloride solution with silver nitrate in the presence of potassium chromate; and (3) potentiometric titration (measurement of voltage changes) with silver nitrate, a process that can be carried out in the presence of bromide and iodide ions.

Most insoluble chlorides can be melted with soda, and the resulting melt is then usually soluble in water. Organic compounds containing chlorine are heated with alkali peroxide, and the product is dissolved in water.

BROMINE

Occurrence and distribution. Because of the bad odour of the element, the French Academy of Science suggested the name bromine, from the Greek word *bromos*, meaning "bad smell," or "stench." Bromine occurs only in compounds and is considerably less abundant than chlorine. Apart from silver bromide (bromyrite), which is found in Mexico and Chile, the element is mainly found in seawater or in salt deposits. The bromide content of seawater is about 0.07 grams per litre, but the Dead Sea contains much more—up to five grams per litre. Natural salt deposits are the main source of bromine and its compounds in the United States. In Germany it is available as a by-product of the manufacture of potassium.

Production and use. Bromine is produced on a large scale from seawater by treatment with chlorine in the presence of sulfuric acid, according to the following equation:

Bromine from seawater

$$2Br^- + Cl_2 \rightleftharpoons Br_2 + 2Cl^-.$$

The product of the reaction is a dilute solution of bromine, from which the element is removed by blowing air through it. The free bromine is then mixed with sulfur dioxide, and the mixed gases are passed up a tower down which water is trickling. The following reaction takes place in the tower:

$$SO_2 + Br_2 + 2H_2O \rightarrow 2HBr + H_2SO_4,$$

resulting in a mixture of acids that is much richer in bromide ion than seawater. Treatment with chlorine again liberates bromine, which is freed from chlorine and purified by passage over moist iron filings. In Germany most bromine produced comes from the mother liquor obtained in the production of potassium salts. This mother liquor, which contains mainly magnesium bromide, is treated with chlorine in a continuous process to release the bromine.

Commercial bromine generally contains up to 0.3 percent chlorine. It is usually stored in glass bottles or, in the United States, in barrels coated with lead or Monel metal. In 1969, 392,000,000 pounds of bromine were produced, most of it in the United States.

Much of the bromine produced is converted to ethylene dibromide ($C_2H_4Br_2$), which is added to gasoline with tetraethyl lead to prevent deposition of lead in the engine. Bromine is also used for the preparation of silver bromide, which is employed in photography, and in the production of catalysts, such as aluminum bromide, as well as of organic dyestuffs and various other organic compounds.

Physical and chemical properties. Free bromine is a reddish-brown liquid with an appreciable vapour pressure at room temperature. Both liquid bromine and the vapour are highly toxic and produce painful burns on the skin. Like the other halogens, bromine exists as diatomic molecules in all aggregation states.

About 3.41 grams of bromine dissolve in 100 millilitres of water at room temperature. The solution is known as bromine water. Like chlorine water, it is a good oxidizing agent, and it is more useful because it does not decompose so readily. It liberates free iodine from iodide-containing solutions and sulfur from hydrogen sulfide. Sulfurous acid is oxidized by bromine water to sulfuric acid.

Bromine water

In the sunlight bromine water decomposes, with release of oxygen, as in the following equation:

$$H_2O + Br_2 \rightarrow 2HBr + \tfrac{1}{2}O_2.$$

From bromine water a hydrate can be isolated that contains 172 water molecules and 20 cavities capable of accommodating the bromine molecules. Bromine dissolves in aqueous alkali hydroxide solutions, giving bromides, hypobromites, or bromates, depending on the temperature. Bromine is readily extracted from water by organic solvents such as carbon tetrachloride, chloroform, or carbon disulfide, in which it is very soluble. In the organic solvents it gives an orange solution.

The electron affinity of bromine is high and similar to that of chlorine. It is, however, a less powerful oxidizing agent, chiefly because of the weaker hydration of the bromide ion as compared with the chloride ion. Similarly, a metal–bromine bond is weaker than the corresponding metal–chlorine bond, and this difference is reflected in the chemical reactivity of bromine, which lies between that of chlorine and that of iodine.

Bromine combines violently with the alkali metals and with phosphorus, arsenic, and antimony but less violently with certain other metals. Bromine displaces hydrogen from saturated hydrocarbons and adds to unsaturated hydrocarbons, though not as readily as chlorine does.

The ionization potential of bromine is high, and compounds containing bromine in positive oxidation numbers are stabilized by appropriate ligands, mainly oxygen and fluorine. Compounds with the oxidation numbers +1, +3, +4, +5, and +7 are known; they all contain covalent bonds.

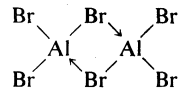
Principal compounds. The bromides of the alkali and alkaline-earth metals form ionic crystals in the solid state. The bromides of boron, carbon, silicon, germanium, and hydrogen, however, form molecular lattices in the solid state; such compounds are volatile.

The tendency to promote high oxidation numbers decreases in passing from fluorine to chlorine, and it does so even further in proceeding to bromine. Thus, for vanadium the highest fluoride is the pentafluoride (VF_5), the highest chloride is the tetrachloride (VCl_4), and the highest bromide is the tribromide (VBr_3). Similarly, sulfur gives a hexafluoride, (SF_6), a tetrachloride (SCl_4), and a monobromide (S_2Br_2) as the highest respective halides.

Properties of bromides

The bromide ion is considerably larger than the chloride ion, and this may account for the differences in structure of the solid phosphorus(V) chloride and bromide. Both compounds have an ionic lattice, which consists of tetrahedral tetrahalophosphorus $(PX_4)^+$, but the chloride contains octahedral hexachlorophosphate(V) anions, $(PCl_6)^-$, and the bromide, uncomplexed bromide ions (Br^-).

Aluminum bromide is similar in structure and properties to aluminum chloride in that it consists of dimeric, or double, molecules held together by bromide bridges, as in the following formulation:



Bromides of transition-metal elements are usually deeper in colour and have somewhat lower volatility than the corresponding chlorides. Their general chemical properties resemble those of the chlorides fairly closely, but they are more easily oxidized. The structures of some of the lower bromides are analogous to the chloride cluster compounds. Examples are the compounds formulated as $ReBr_3$, $MoBr_2$, WBr_2, Nb_6Br_{14}, and Ta_6Br_{14}.

Because the bromide ion is a weaker ligand toward hard metal ions than the chloride ion, complex bromides are in general less stable than the corresponding complex chlorides. Tetrachlorocobaltate, for example, is stable in dimethylsulfoxide solution, but tetrabromocobaltate is unstable in this solvent. The stability of the latter is increased, however, by decreasing coordinating properties of the solvent molecules, and thus it is easily formed in nitromethane or in acetonitrile.

Hydrogen bromide. Hydrogen bromide may be obtained by any of four principal methods:

1. By direct reaction of the elements, as in the following equation:

$$H_2 + Br_2 \rightleftharpoons 2HBr.$$

The reaction is much slower than that between chlorine and hydrogen, and it must be initiated by heat. It also proceeds by means of a chain mechanism involving atomic hydrogen and atomic bromine.

2. By hydrolysis of covalent bromides; *e.g.*, as with phosphorus(III) bromide (PBr_3):

$$PBr_3 + 3H_2O \rightleftharpoons H_3PO_3 + 3HBr.$$

When bromine is dropped onto red phosphorus in the presence of water, phosphorus(III) bromide is formed and—on contact with the water—immediately hydrolyzed.

3. By adding bromine to benzene containing aluminum powder, which acts as a catalyst for the following reaction:

$$C_6H_6 + Br_2 \xrightarrow{Al} C_6H_5Br + HBr.$$

4. By the action of phosphoric acid on a bromide, such as potassium bromide (KBr), as follows:

$$KBr + H_3PO_4 \rightarrow KH_2PO_4 + HBr.$$

If sulfuric acid is substituted for the phosphoric acid, the product is contaminated by free bromine, because the bromide ion is readily oxidized by sulfuric acid.

Hydrogen bromide is a colourless gas, similar in properties to hydrogen chloride. It is very soluble in water (193 grams of hydrogen bromide can be dissolved in 100 grams of water at 25° C), producing hydrobromic acid. This acid is even stronger than hydrochloric acid. Hydrobromic acid is easily oxidized when exposed to light, however, and turns brown because of the bromine liberated.

Hydrobromic acid

Hydrobromic acid may be prepared directly by hydrolysis of sulfur bromide, made by dissolving sulfur in excess liquid bromine:

$$S_2Br_2 + 5Br_2 + 8H_2O \rightleftharpoons 12HBr + 2H_2SO_4.$$

A constant boiling mixture containing about 47 percent hydrogen bromide is obtained by distillation.

Liquid hydrogen bromide has moderately good properties as a nonaqueous solvent. A solution of tetraalkylammonium bromide conducts electric current and contains anions formulated as $(HBr_2)^-$. Hydrogen bonding in this ion is similar to that in the corresponding chloro ion. Neutralization reactions occur with acidic bromides, such as boron(III) bromide. Hydrogen bromide is soluble in liquid hydrogen chloride, with which it appears to react according to the equation

$$(HCl_2)^- + HBr \rightleftharpoons HCl + (HClBr)^-.$$

Hydrogen bromide is used as a sedative and in the preparation of the various bromides. Ionic bromides may be obtained by the action of hydrobromic acid on appropriate metal hydroxide or carbonate. Silver bromide is scarcely soluble in water. The salt is used—together with silver iodide—in the production of photographic films.

Oxo acids and oxides. Hypobromous acid (HBrO) is known only in solution, which is obtained by the action of bromine water on mercury(II) oxide (HgO), as in the following equation:

$$2Br_2 + HgO + H_2O \rightleftharpoons HgBr_2 + 2HBrO.$$

Salts of the acid, the hypobromites, or bromates(I), are formed by the action of bromine on alkali hydroxide solution. They may be crystallized from the alkaline solution, as follows:

$$Br_2 + 2OH^- \rightleftharpoons (BrO)^- + Br^- + H_2O.$$

Hypobromites have oxidizing properties and are used as bleaching agents.

Bromic acid ($HBrO_3$) is prepared from barium bromate and dilute sulfuric acid, as follows:

$$Ba(BrO_3)_2 + H_2SO_4 \rightleftharpoons 2HBrO_3 + BaSO_4.$$

The salts of bromic acid, the bromates, or bromates(V), may be obtained by disproportionation of a hypobromite salt:

$$3NaBrO \rightleftharpoons NaBrO_3 + 2NaBr.$$

They also result when bromine is passed into a hot alkali hydroxide solution:

$$3Br_2 + 6NaOH \rightleftharpoons NaBrO_3 + 5NaBr + 3H_2O.$$

Bromic acid and bromates are much stronger oxidizing agents than the corresponding compounds of chlorine.

Perbromic acid

Perbromic acid ($HBrO_4$) may be obtained in various ways. The initial synthesis involved a radioactive-decay process in which the decay of selenium-83 incorporated in a selenate produced perbromate. Other modes of preparation involve oxidation of bromate solutions by xenon difluoride or by fluorine. Aqueous perbromic acid is a strong monobasic acid (releasing one hydrogen ion), which oxidizes inorganic substances, such as iodide ion and bromide ion, only slowly at room temperature. Neutralization of perbromic acid results in the formation of stable alkali metal perbromates. The perbromate ion is tetrahedral in the solid state, and it remains so in neutral and acidic solutions, thus resembling the perchlorate ion rather than the periodate ion.

All oxides of bromine are unstable. Dibromine monoxide (Br_2O) is prepared in analogy to the chloro compound. Tribromine octoxide (Br_3O_8) is obtained by the action of ozone on bromine at low pressure, and bromine dioxide (BrO_2) is prepared from the elements in a glow discharge at low temperature.

Halogen bromide. Bromine reacts with iodine to give iodine monobromide, as in the following equation:

$$\tfrac{1}{2}I_2 + \tfrac{1}{2}Br_2 \rightleftharpoons IBr.$$

The product forms dark-brown crystals at room temperature. Iodine bromide is less reactive than bromine but more reactive than iodine. It melts at 40° C (104° F), and in the liquid state it reacts with various elements to give the respective bromides. With bromide ions it forms a polyhalide ion, formulated as $(IBr_2)^-$. Like other trihalide ions, it is almost linear.

Analysis. A sensitive test for bromine is the reaction with fluorescein to give a deep red colour caused by bromination of the organic molecule, or by its reaction with fuchsine dyes in the presence of sulfurous acid, to give a deep blue colour. A more common test involves heating of the sample with dilute sulfuric acid in the presence of potassium dichromate; the bromine is then extracted with chloroform, and, upon addition of potassium iodide, the pink colour of iodine appears. The presence of bromine may also be recognized by the evolution of hydrogen bromide containing some brown bromine vapour when a solid sample is treated with concentrated sulfuric acid. Alternatively, chlorine may be added to an aqueous solution of a sample containing bromide, with development of a brown colour (free bromine).

For the quantitative determination of bromine the following methods are recommended:

1. Free bromine is titrated with sodium thiosulfate in the presence of potassium iodide:

$$Br_2 + 2(S_2O_3)^{2-} \rightleftharpoons (S_4O_6)^{2-} + 2Br^-.$$

2. Bromides may be determined either gravimetrically (by weight analysis) or by titration with silver nitrate:

$$Br^- + Ag^+ \rightleftharpoons AgBr.$$

3. In the presence of chloride and iodide, the potentiometric method may be used (as with chlorine).

4. In the absence of iodide, bromide may be oxidized to bromine, which is then determined in the distillate. Alternatively, bromide may be oxidized to bromate by hypochlorous acid. The excess of the oxidizing agent is destroyed by sodium formate, and iodine is liberated by addition of potassium iodide and acid, the free iodine being titrated by thiosulfate.

5. For the determination of bromine in an organic compound, the latter is oxidized by nitric acid, and the bromine is determined as silver bromide.

IODINE

Occurrence and distribution. Because of its violet-coloured vapours, the element was given the name iodine from the Greek word *ioeides*, "violet coloured." Iodine occurs to a small extent in seawater and is formed in seaweeds, oysters, and cod livers. Sodium iodate ($NaIO_3$) is contained in crude Chile saltpetre (sodium nitrate, $NaNO_3$). The human body contains iodine in the compound thyroxine, which is produced in the thyroid gland. It occurs in small quantities in much animal and vegetable matter.

Production and use. Iodine is produced commercially either from Chile saltpetre or from iodine-containing brines. In the former process, the salt is dissolved in hot water and the saltpetre allowed to crystallize on cooling. The mother liquor is used for further extractions until the extracts contain up to nine grams of iodine per litre. Sodium hydrogen sulfite is then added in order to reduce all iodate to iodide, and the solution is nearly neutralized with sodium carbonate. Fresh mother liquor is then added until all iodide is oxidized by the iodate to free iodine, according to the equation:

Iodine from brines

$$2NaIO_3 + 5NaHSO_3 \rightleftharpoons 3NaHSO_4 + 2Na_2SO_4 + H_2O + I_2.$$

The solid, containing up to 80 percent iodine, is collected, washed with water, and pressed into cheeselike blocks. These are heated to distill off both iodine and water.

Natural brines, or brines extracted from oil wells containing up to 150 milligrams of iodine per litre, are found in Java, California, and northern Italy. Impurities, such as clay, sand, and oil, are removed by filtration, and the solution is passed through a stream of sulfur dioxide and then through a number of containers containing bundles of copper wire. The copper(I) iodide that forms is removed by filtration, washed with water, dried, and finely ground. The product is heated with potassium carbonate to give potassium iodide, which is then oxidized to the free element with dichromate and sulfuric acid:

$$Cu_2I_2 + K_2CO_3 \rightleftharpoons 2KI + Cu_2O + CO_2$$

$$6KI + Na_2Cr_2O_7 + 7H_2SO_4 \rightleftharpoons 3I_2 + Cr_2(SO_4)_3 + Na_2SO_4 + 3K_2SO_4 + 7H_2O.$$

In an alternate process, chlorine is used as the oxidizing agent:

$$2KI + Cl_2 \rightleftharpoons 2KCl + I_2.$$

Iodine from seaweed

For a long time, iodine has been recovered on a commercial scale from seaweed. This is dried and burnt; the ash is leached with water; sodium sulfate and sodium chloride are removed by crystallization; and the remaining solution is concentrated by evaporation of water. The final solution, which contains 30 to 100 grams of iodine per litre, is treated with sulfuric acid in order to decompose any sulfite, and sulfide and manganese dioxide are added to release iodine, which is vapourized and purified by sublimation. Alternatively, addition of cupric sulfate gives cuprous iodide.

Iodine is widely used as a disinfectant and antiseptic, frequently in a solution of alcohol and water containing potassium iodide. Several compounds of iodine, such as iodoform (CHI_3), also serve as antiseptics.

Because iodine is converted to thyroxine in the thyroid gland, a small amount of iodine is essential for the body. In many places drinking water contains sufficient iodine for this purpose. In the absence of iodine in the water supply, however, goitre is prevalent, and a small quantity of iodine is frequently added to table salt in order to ensure against iodine deficiency.

Iodine and its compounds are used extensively in analytical chemistry, many analytical procedures being based on the release or uptake of iodine and its subse-

quent titration with sodium thiosulfate (iodometry). Unsaturation of fats (that is, the number of double bonds between carbon atoms) is determined by addition of free iodine (iodine number). Iodine compounds are also employed as catalysts in certain classes of organic reactions. Iodine, silver iodide, and potassium iodide are used in photography. Silver iodide is also used to seed clouds to induce rain. Iodine has been introduced into metallurgical processes for the production of certain transition metals in a high state of purity, among them titanium, zirconium, thorium, chromium, and cobalt. Electronic equipment, such as scintillation counters or neutron detectors, contain single-crystal prisms consisting of alkali metal iodides.

The annual production rate of iodine has increased from 96 tons in 1950 to 431 tons in 1955. The world's largest producer of crude iodine is Japan.

Solid iodine

Physical and chemical properties. Iodine is solid at room temperature, dark coloured, and with a glittering crystalline appearance. The molecular lattice contains discrete diatomic molecules, which are also present in the molten and the gaseous states. Above 700° C (1,300° F) dissociation into iodine atoms becomes appreciable.

Iodine has a moderate vapour pressure at room temperature and in an open vessel slowly sublimes (sublimation is vaporization of a solid—comparable to distillation of a liquid). For this reason, iodine is best weighed in a stoppered bottle; for the preparation of an aqueous solution the bottle may contain a solution of potassium iodide, which considerably decreases the vapour pressure of iodine, a complex (triiodide) being readily formed.

Molten iodine may be used as a nonaqueous solvent for iodides. The electrical conductivity of molten iodine has in part been ascribed to the following self-ionization equilibrium:

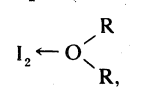
$$2I_2 \rightleftharpoons I^+ + I_3^-.$$

The alkali iodides are soluble in molten iodine and give conducting solutions typical of weak electrolytes. Alkali iodides react with compounds containing iodine with the oxidation number +1, such as iodine bromide, as in the following equation:

$$KI_3 + IBr \rightleftharpoons KBr + 2I_2.$$

In such reactions the alkali iodides may be regarded as bases.

The iodine molecule can act as a Lewis acid in that it combines with various Lewis bases. The interaction is weak, however, and few solid complex compounds have been isolated. The complexes are easily detected in solution and are referred to as charge-transfer complexes. Iodine, for example, is slightly soluble in water to give a yellowish-brown solution. Brown solutions are also formed with alcohol, ether, ketones, and other compounds acting as Lewis bases through an oxygen atom, as in the following example:



in which the R groups represent various organic groups.

Iodine gives a red solution in benzene, which is regarded as the result of a different type of charge-transfer complex. In inert solvents, such as carbon tetrachloride or carbon disulfide, violet-coloured solutions are obtained that contain uncoordinated iodine molecules. Iodine reacts also with iodide ions, because the latter can act as Lewis bases, and for this reason the solubility of iodine in water is greatly enhanced in the presence of an iodide. When cesium iodide is added, crystalline cesium triiodide may be isolated from the reddish-brown, aqueous solution. Iodine forms a blue complex with starch, and this colour test is used to detect small amounts of iodine.

The electron affinity of the iodine atom is not much different from those of the other halogen atoms. Iodine is a weaker oxidizing agent than bromine, however, because the iodide ion is a weaker Lewis base than the bromide ion and is hydrated to a smaller extent. In fact, the oxidizing properties of iodine are considerably weaker than those of bromine, chlorine, or fluorine. The following reaction—oxidation of arsenite, $(AsO_3)^{3-}$—in aqueous solution proceeds only in the presence of sodium hydrogen carbonate, which acts as a buffer:

$$(AsO_3)^{3-} + I_2 + 2OH^- \rightleftharpoons (AsO_4)^{3-} + 2I^- + H_2O.$$

In acidic solution, arsenate is reduced to arsenite, whereas, in strongly alkaline solution, iodine is unstable, and the reverse reaction occurs.

The most familiar oxidation by iodine is that of the thiosulfate ion, which is oxidized quantitatively to tetrathionate, as shown:

$$2(S_2O_3)^{2-} + I_2 \rightleftharpoons (S_4O_6)^{2-} + 2I^-.$$

This reaction is used to determine iodine volumetrically. The consumption of iodine at the end point is detected by the disappearance of the blue colour produced by iodine in the presence of a fresh starch solution.

Volumetric determination of iodine

Iodine combines directly with many elements. Silver and aluminum are easily converted into the respective iodides. White phosphorus unites readily with iodine, but no compounds of sulfur and iodine are known. The ionization potential of the iodine atom is considerably smaller than that of the lighter halogen atoms, and this is in accord with the existence of various compounds containing iodine in a positive oxidation number.

Principal compounds. As with the other halogens, iodine forms both ionic and covalent compounds in which it has the −1 oxidation state. Because of the low electronegativity of iodine as compared with those of the lighter halogens, bonding in iodides is considered to be less ionic than in other halides. Higher iodides are frequently unstable; for example, the highest iodides are the triiodide for phosphorus, the monoiodide for copper, and the triiodide for vanadium. No binary iodides are known for oxygen or sulfur. Iodides of transition metals are usually intensely coloured and less volatile than the corresponding bromides. It has been mentioned that the iodide ion is a weak Lewis base and shows a tendency to form polyiodide ions. In contrast to the fluoride ion, the iodide ion is considered a "soft" Lewis base in that it gives stable complex compounds with soft metal ions, such as palladium(II) ion, Pd^{2+}, and mercury(II) ion, Hg^{2+}. The tetraiodomercurate(II) ion, $(HgI_4)^{2-}$, is contained in a reagent used to detect small amounts of ammonia. The iodide ion can act also as a reducing agent; for example, it reduces chlorine to chloride, dichromate to chromium(III), permanganate to manganese(II), and aqueous hydrogen peroxide to water. In each case, iodine is liberated. Since iodine can be titrated with standard thiosulfate, these reactions can be used quantitatively.

Hydrogen iodide. Hydrogen iodide is obtained when iodine vapours and hydrogen are passed over a catalyst of platinum asbestos at 500° C (932° F). An alternative procedure is to allow water to react with a mixture of iodine and red phosphorus, as follows:

$$P + \tfrac{3}{2}I_2 \rightleftharpoons PI_3$$

$$PI_3 + 3H_2O \rightleftharpoons H_3PO_3 + 3HI.$$

An aqueous solution of hydrogen iodide is obtained when hydrogen sulfide is passed into a suspension of iodine in water and sulfur is filtered off:

$$H_2S + I_2 \rightleftharpoons 2HI + S.$$

Hydrogen iodide cannot be produced by the action of sulfuric acid on an iodide, because iodides are readily oxidized by sulfuric acid (see below). Hydrogen iodide is a colourless gas at room temperature and readily dissolves in water to give a strongly acidic solution. The solution, known as hydriodic acid, is one of the strongest acids in water. The salts formed from it are called iodides. Potassium iodide, a white crystalline solid melting at 686° C (1,267° F), is produced commercially to a greater extent than any other iodide. It is made by the reaction of ferrous iodide (prepared from iron and iodine) with potassium carbonate, as follows:

Hydriodic acid

$$2FeI_2 + 2K_2CO_3 + \tfrac{1}{2}O_2 \rightleftharpoons 4KI + Fe_2O_3 + 2CO_2.$$

It can also be prepared by the reaction of cuprous iodide with potassium carbonate:

$$2CuI + K_2CO_3 \rightleftharpoons 2KI + CO_2 + Cu_2O.$$

Hydrogen iodide acts also as a reducing agent; for example, it reduces sulfuric acid to a mixture of sulfur and hydrogen sulfide,

$$H_2SO_4 + 8HI \rightleftharpoons H_2S + 4I_2 + 4H_2O.$$

It also reduces arsenates to arsenites. Further examples are the reduction of dinitrogen monoxide and nitric acid:

$$N_2O + 10HI \rightleftharpoons 2NH_4I + H_2O + 4I_2$$

$$HNO_3 + 2HI \rightleftharpoons HNO_2 + I_2 + H_2O.$$

Iodides of the alkali and alkaline-earth metals are soluble in water, but iodides of silver, lead(II), mercury, and copper(I) are scarcely soluble. Mercury(II) iodide is red in colour; lead and silver iodides are yellow. In contrast to the chloride and the bromide, silver iodide is insoluble in aqueous ammonia, but all of the silver halides dissolve in the presence of thiosulfate with complex formation:

$$AgI + 2Na_2S_2O_3 \rightleftharpoons Na_3[Ag(S_2O_3)_2] + NaI.$$

Silver iodide is used in a fine crystalline form as the photosensitive constituent of photographic emulsions. Sodium thiosulfate is used to remove unreacted silver iodide. Covalent iodides, such as phosphorus(III) iodide or arsenic(III) iodide, are hydrolyzed by water with liberation of hydrogen iodide. Many organic iodides are useful in organic synthesis. Iodine is introduced into organic molecules by direct addition to double bonds or by replacement of hydrogen atoms. The latter reaction occurs less readily than with chlorine or bromine, and an organic iodide is in general more reactive than the corresponding chloride or bromide. When used as a reducing agent in organic chemistry, hydrogen iodide is more effective in the presence of phosphorus, because the liberated iodine forms the more reactive phosphorus iodide. Alkyl iodides may be used for alkylation reactions.

Oxo acids and oxides. Iodine is readily absorbed in alkaline solutions to give a hypoiodite:

$$I_2 + 2KOH \rightleftharpoons KIO + KI + H_2O.$$

The hypoiodite then undergoes hydrolysis to give hypoiodous acid:

$$KIO + H_2O \rightleftharpoons HIO + KOH.$$

The free acid is unstable and is amphoteric (acts as either an acid or a base), as shown in the following equation:

$$HIO + H_2O \rightleftharpoons (H_3O)^+ + (IO)^-$$

$$HIO + H_2O \rightleftharpoons (H_2OI)^+ + OH^-.$$

The hypoiodite ion is also unstable, because it readily disproportionates to iodate and iodide:

$$3(IO)^- \rightleftharpoons 2I^- + (IO_3)^-.$$

Iodic acid is precipitated when iodine is oxidized with concentrated nitric acid:

$$3I_2 + 10HNO_3 \rightleftharpoons 6HIO_3 + 10NO + 2H_2O.$$

It may be recrystallized from water. Because it is a strong acid with oxidizing properties, it first turns litmus red and then bleaches it. The solid acid reacts readily with certain nonmetals, such as phosphorus or sulfur, and with numerous organic compounds. The free acid is dehydrated above 110° C (230° F) to give iodine(V) oxide:

$$2HIO_6 \rightleftharpoons I_2O_5 + H_2O.$$

Iodates

The salts of iodic acid, the iodates(V), may be obtained by neutralization of the free acid or by dissolving iodine in hot alkali solutions:

$$3I_2 + 6KOH \rightleftharpoons 5KI + KIO_3 + 3H_2O.$$

This reaction is reversed in acid solution, with iodide and iodate(V) forming iodine. Iodate(V) is also produced by anodic oxidation of an iodide or by oxidizing the latter by potassium chlorate. Iodates are, in general, more stable than bromates and chlorates, and they are usually less soluble than the latter. Potassium iodate melts at 560° C (1,040° F), and by further heating it is decomposed to potassium iodide and oxygen.

When iodine is oxidized with potassium chlorate, the main product is potassium acid iodate, $KH(IO_3)_2$:

$$11KClO_3 + 6I_2 + 3H_2O \rightleftharpoons 6KH(IO_3)_2 + 3Cl_2 + 5KCl.$$

There is no known analogous compound of chlorine or bromine.

Whereas perchloric acid, $HClO_4$, contains a tetracoordinated halogen atom, orthoperiodic acid, H_5IO_6, has an iodine atom octahedrally coordinated by six oxygen atoms. It is a weak, pentabasic acid in aqueous solution.

The acid may be prepared by addition of sulfuric acid to a solution of barium periodate, the latter being prepared by heating barium iodate:

$$5Ba(IO_3)_2 \rightleftharpoons Ba_5(IO_6)_2 + 4I_2 + 9O_2$$

$$Ba_5(IO_6)_2 + 5H_2SO_4 \rightleftharpoons 5BaSO_4 + 2H_5IO_6.$$

A solution of the acid is also obtained by electrolysis of iodic acid at low temperature at a lead anode.

Periodic acid may be crystallized from aqueous solution. It is a white, deliquescent (water absorbing) solid, which is dehydrated to the composition HIO_4 by heating above 100° C (212° F) in a vacuum. Attempts to further dehydrate the material to a composition of I_2O_7 have not been successful, chiefly because oxygen is lost on further heating. Periodic acid is a stronger oxidizing agent in solution than perchloric acid, as witnessed by the fact that it oxidizes alcohols to aldehydes, ketones to carboxylic acids, and manganese(II) to permanganate. On the other hand, iodic acid is weaker in oxidizing properties than chloric acid. Most periodates are sparingly soluble in water.

Iodine oxides

Oxides with the following formulation have been prepared: iodine dioxide, I_2O_4; tetraiodine nonoxide, I_4O_9; and diiodine pentoxide, I_2O_5. The last is readily obtained by dehydration of iodic acid at 170° C:

$$2HIO_3 \rightleftharpoons I_2O_5 + H_2O.$$

The white solid is decomposed at 300° C without melting. When mixed with concentrated sulfuric acid and silica, the pentoxide is an oxidizing agent for carbon monoxide at room temperature:

$$5CO + I_2O_5 \rightleftharpoons 5CO_2 + I_2.$$

The oxide readily combines with water to give iodic acid. In spite of its name (based on a misconception), commercial I_2O_5 has almost entirely the formulation HI_3O_8. The oxide of formula I_2O_4 is prepared by treating iodic acid with concentrated sulfuric acid; this oxide has a polymeric structure composed of IO and IO_3 groups covalently bonded by oxygen bridges.

Other compounds. Because the ionization potential of iodine is lower than that of the other halogens, it shows a higher tendency to attain positive oxidation states. Iodine is found with oxidation number +1 in iodine halides, such as iodine monochloride and monobromide, as well as in hypoidous acid. A small percentage of ions in this oxidation state are believed to be present in molten iodine. The iodine cation is stabilized by coordination with strong Lewis bases, such as pyridine. Iodine gives a charge-transfer complex with pyridine, and this is partly ionized in appropriate nonaqueous solvents, as shown in the formulations below:

$$py + I_2 \rightleftharpoons py \longrightarrow I\overset{\curvearrowright}{I}$$

$$2py \cdot I_2 \rightleftharpoons (py_2I)^+ + I_3^-$$

in which the arrow indicates movement of electrons, and py stands for a pyridine molecule. The perchlorate $(py_2I)^+(ClO_4)^-$ is also known.

Oxidation of iodine with perchloric acid gives iodine(III) perchlorate $[I(ClO_4)_3 \cdot 2H_2O]$, and oxidation of iodine by nitric acid in the presence of acetic anhydride gives io-

dine(III) acetate [$I(CH_3COO)_3$]. During electrolysis of the latter in glacial acetic acid, iodine is deposited at the cathode, as would be expected for positive iodine. All these compounds are hydrolyzed by water with disproportionation of iodine(III):

$$5I(CH_3COO)_3 + 9H_2O \rightleftharpoons I_2 + 3HIO_3 + 15CH_3COOH.$$

Analysis. Free iodine is detected (1) by the violet colour of the vapour or of its solution in carbon tetrachloride or carbon disulfide or (2) by the bright-blue colour produced in the presence of fresh starch solution in water, a very sensitive test.

Detection of iodide ions

Iodide ions may be detected in water (1) by the yellow precipitate of silver iodide, insoluble in water and ammonia solution, which is produced by addition of silver nitrate in the presence of dilute nitric acid, (2) by the formation of iodine on addition of chlorine or bromine water, (3) by the formation of iodine in the presence of other oxidizing agents, such as hydrogen peroxide or potassium dichromate, or (4) by the scarlet precipitate of mercury(II) iodide formed on addition of mercury(II) chloride, as in the equation below:

$$2I^- + HgCl_2 \rightleftharpoons HgI_2 + 2Cl^-.$$

This precipitate is dissolved by excess of iodide ions because of formation of a complex ion:

$$HgI_2 + 2I^- \rightleftharpoons (HgI_4)^{2-}.$$

Iodate or periodate is reduced by sulfurous acid to iodide and may be detected as such.

For the quantitative determination of iodine, one of the following methods may be recommended: (1) gravimetrically, by precipitation as silver iodide; (2) volumetrically, by titrating iodine with a standardized solution of sodium thiosulfate (using starch as an indicator); or (3) potentiometric titration with silver nitrate, which is applicable in the presence of both chloride and bromide. The second method is applied in the determination of many oxidizing substances. Dichromate, for example, reacts with excess potassium iodide in the presence of sulfuric acid, as shown:

$$(Cr_2O_7)^{2-} + 6I^- + 14H^+ \rightleftharpoons 2Cr^{3+} + 3I_2 + 7H_2O.$$

The iodine liberated is treated with standard thiosulfate solution.

ASTATINE

Because the element astatine has no stable or long-lived isotopes, it was given its name from the Greek word *astatos*, meaning "unstable." Minute amounts of the very short-lived isotopes, astatine-215, -218, and -219, occur in nature in radioactive equilibrium with certain long-lived, naturally occurring radioelements. In the body, astatine is concentrated in the thyroid gland. A substantial portion, however, distributes throughout the body, where it acts as an internal radiation source.

Production and use. The only practical way of obtaining astatine is by synthesizing it through nuclear reactions. The first synthesis was effected in 1940 by the bombardment of bismuth with alpha particles to obtain astatine-211.

Preparation of astatine

Astatine is usually prepared according to the general equation:

$$^{209}Bi\,(\alpha, xn)^{(213-x)}At,$$

which indicates that bismuth-209 takes up one alpha particle and emits x neutrons to form an isotope of astatine, whose atomic weight depends on the number of neutrons lost. Metallic bismuth may be used as a target material. From this, astatine may readily be removed by distillation in air from a stainless-steel tube. The free element begins to distill at 271° C (520° F, the melting point of bismuth), but the operation is best carried out at 800° C (1,470° F) with subsequent redistillation. If an aqueous solution of astatine is desired, the element may be separated by washing with an appropriate aqueous solution. Alternatively, the halogen may be removed from the target by chemical methods, such as dissolving in nitric acid, the latter being removed by boiling.

Another procedure involves the use of a metallic thorium target, which—after bombardment—is dissolved in concentrated hydrochloric acid containing hydrogen fluoride and chlorine.

Analysis. With the exception of a few spectrographic and mass-spectrographic studies, all investigations of astatine chemistry have utilized tracer techniques at extreme dilution—concentrations around or below 10^{-10} molar, molarity being the number of moles (gram molecular weight) per litre of solution. At such concentration, the effects of impurities can be very serious, especially for a halogen such as astatine, which exists in several oxidation states and can form many organic compounds. Iodine has been used as a carrier in most experiments. Techniques applied include coprecipitation, solvent extraction, ion exchange, and other forms of chromatography (separation by adsorption differences), electrodeposition (deposition by an electric current), electromigration (movement in an electric field), and diffusion. A direct identification of some astatine compounds has been made by mass spectrography.

Except for nuclear properties, the only physical property of astatine to be measured directly is the spectrum of atomic astatine. Other physical properties have been predicted from theory and by extrapolation from the properties of other elements.

Chemical properties. The astatide ion, At^-, is quantitatively coprecipitated with insoluble iodides, such as silver iodide or thallium(I) iodide. The diffusion coefficient of the iodide ion is 1.42 times that of the astatide ion, which moves more slowly toward the anode than the former under given conditions. The ion is formed by reduction of the element, using, for example, zinc and acid. It is oxidized to the zero valence state by ferric ion, Fe^{3+}, iodine (I_2), and dilute nitric acid. Thus, the astatide ion is a stronger reducing agent than the iodide ion, and free iodine is a stronger oxidizing agent than astatine.

Free astatine is characterized by volatility from solution and by extractability into organic solvents. It undergoes disproportionation in alkaline media. Astatine is coprecipitated with cesium iodide and thus appears to form polyhalide anions. Astatine extracted into chloroform has been shown to coprecipitate homogeneously with iodine when a portion of the latter is crystallized. Astatine seems to be present as the iodide, which appears to be more polar (*i.e.*, showing separation of electrical charge) in character than iodine bromide.

Astatine is known to occur in positive oxidation numbers. The astatate ion, $(AtO_3)^-$, is coprecipitated with insoluble iodates, such as silver iodate ($AgIO_3$), and it is obtained by oxidation of lower oxidation states with hypochlorite, periodate, or persulfate. So far no evidence for perastatate has been found, but this may be because the ion, $(AtO_6)^{5-}$, may show little tendency to coprecipitate with potassium iodate (KIO_4).

Astatine in the +1 state is stabilized by complexation, and complexes formulated as dipyridine astatine(I) perchlorate $[At(py)_2]\,[ClO_4]$ and dipyridine astatine(I) nitrate $[At(py)_2]\,[NO_3]$ have been prepared. Compounds with the formulas $(C_6H_5)AtCl_2$, $(C_6H_5)_2AtCl$, and $(C_6H_5)AtO_2$ have also been obtained. A variety of methods may be used to synthesize astatobenzene, C_6H_5At.

Hals, Frans

One of the three or four greatest portrait painters of the 17th century, the Dutch painter Frans Hals belonged to that large group of artists who worked to order, fulfilling through their commissions a social function much as the modern photographer records contemporary life in his portraits. Hals never ventured in his art beyond the functional boundaries fixed by his clients. Yet he took far more than a mere inventory of the little world of Haarlem, its pompous notables, and its common people, of which he was the most faithful and accurate historian. In fact, with his uniquely expressive and facile style, he gave new life to the art of painting; and his sensitive observation and portrayal of the character of his subjects has rarely been excelled.

By courtesy of the Rijksmuseum, Amsterdam

"The Merry Toper," oil on canvas by Frans Hals. In the Rijksmuseum, Amsterdam. 81 cm × 66.7 cm.

Early life and works. Frans Hals left no written evidence about his life or his works, and only a brief outline of his biography is known. Though Flemish by birth, he was brought by his family to Holland at an early age. His birth date is uncertain (somewhere between 1581 and 1585), but it is definitely known that he was born in Antwerp, the son of a clothworker from Malines (Mechelen) and of a local girl. The family had at any rate settled in Haarlem by 1591 at the latest; the local townhall records give this date for the christening of Frans' younger brother Dirck, who also became a painter. Except for a brief visit to Antwerp in 1616, Hals lived all his life in Haarlem.

What he did for the first 25 or 30 years of his life is not known. The earliest indication of his activity as an artist was that, in about 1610, he joined the Guild of St. Luke of Haarlem, a body empowered to register artists as masters. Shortly afterward he married his first wife, Annetje Harmensdr. Abeel. She bore him two children before her death in 1615. Two years later, Hals married Lysbeth Reyniers, who was to survive her husband by some nine years. In all, Hals had ten children, and five of his eight sons became painters. None, however, was of note.

Formative influences

Tradition has it that Frans Hals was the pupil of Karel van Mander, a minor painter and poet who helped found a successful painting academy at Haarlem. There is no evidence either to support this claim or to refute it. From the beginning, however, Hals's work conflicted with the typical mannerisms of his presumed master. His early work is actually closer in spirit to that of Jacob Jordaens, an outstanding Baroque genre painter from Antwerp and pupil of Rubens who was younger than Hals by several years. The good humour of Hals's popular scenes recalls the joyous gatherings painted by the contemporary Dutch followers of the earthy, sensuous Italian painter Caravaggio.

Frans Hals seems, from the evidence of extant works, to have begun his career with sober portraits and with group portraits of members of the local guilds and military societies. The best of these early works—which already shows complete competence in portraiture—is a monumental painting entitled "Banquet of Officers of the Civic Guard of St. George at Haarlem," painted with a loose brushstroke technique that is unlike anything else in Dutch art of the time. It already has a sense of life and of relationship between the figures that was then unknown in this type of subject matter. By about 1620, however, Hals had begun to introduce into his paintings the jovial spirit that characterized his early works and that portrays with accuracy and enthusiasm one important aspect traditionally ascribed to Dutch character. Many of his portraits are simply pictures of merrymakers. The portrait of Hans Wurst in "The Merry Company" shows the sitter in a tall, wide-brimmed hat, wearing a necklace made of pig's feet, herrings, and eggs. The portrait of Mr. Verdonck shows the subject joyfully brandishing the jawbone of a horse. Similar in spirit are the portrait of Peeckelhaering clenching his beer mug, "The Merry Toper," and two later portraits, a picture entitled "Malle Babbe," which portrays an old madwoman laughing, with an owl perched on her shoulder, and a joyful picture in the Louvre of a laughing, carelessly dressed Gypsy girl. In Hals's group portraits, too, the spontaneous *joie de vivre* that is evident in the individual portraits is felt to a degree that revolutionizes the hitherto austere genre. One such painting is his second "Banquet of Officers of the Civic Guard of St. George at Haarlem," in which the figures take up postures normally employed for the expression of mystical religious rapture to celebrate their well-nourished contentment. In this painting, Hals displays his unmistakable genius for *mise en scène;* the dramatic effects he achieves here set him apart from most other painters. His militiamen are linked in a harmonious composition that makes the viewer aware of the cohesion of their group as a whole. Each conducts a dialogue with his neighbour, and here and there one figure is made purposely to disrupt the scheme with a gesture or a glance in the viewer's direction. Nothing is happening except a meal shared by typical members of the Dutch middle class and their conversations. Yet there is a majesty to this scene that is equal to any depiction of an incident from the life of a king. This painting also hints at the sense of mysterious spirituality, which, fostered by the artist's intimate knowledge of his subjects, came with his maturity to thread its way into his absolute realism.

Joviality of Hals's early works

By the 1620s Hals had definitively evolved a technique that was close to Impressionism in its looseness. Like the contemporary Spanish painter Diego Velázquez, he used colour to structure forms; and this use of colour is what sets the two artists apart from their contemporaries. Unique to Hals, however, is his use of quick, loose strokes of bright colour that suggest rather than enclose form and are highly expressive of movement and of the subjects' vitality. Most painters of the 17th century approached their paintings slowly, with preparatory drawings, a certain amount of underpainting, and an elaborate finish. Although there is no certain evidence of his method, Hals seems to have started directly on the canvas and painted quickly, leaving his first spontaneous expression, which is almost an oil sketch, as the finished work. Hals continued to use this technique, which gave a striking immediacy to his perceptive portrayals of character, all his life, painting with increasing freedom as he grew older.

Hals's loose painting technique

It has often been suggested that Frans Hals's life resembled the lives of the *bon-vivants* he portrayed at the beginning of his career. It is true that from 1616 he began to incur claims from creditors, and he was in financial

difficulties most of his life. He belonged, however, to the Haarlem St. George militia company and was a member of the Haarlem De Wijngaertranken (Society of rhetoricians) in 1618–19 (he was an associate of the society from 1616 to 1625); both of these facts are quite inconsistent with the romantic picture of dissipation that traditionally has been associated with the painter. Moreover, the stern preachers and theologians, the high-ranking officials, the surgeons, the admirals, the writers, and the respectable shopkeepers whose portraits Hals painted in great numbers were not likely to have posed for a dissolute high liver.

Later life and works. At any rate, the joviality began to disappear from the paintings of Hals's middle age. In the portraits painted after he reached the age of 40, the subjects seem to eye the world knowingly, with a shade of sadness in their faces. The earliest portrait that strongly shows this quality is "Man with Arms Crossed." Others follow that contain the same theme: "The Laughing Cavalier"; "Portrait of Isaac Abrahamsz. Massa"; "Pieter van den Broecke"; "Nicolaes Hasselaer"; "Willem van Heythuyzen"; and "Daniel van Aken Playing the Violin." These portraits seem to reveal a sense of foreboding; still, their mood ranges somewhere above the midpoint in the "human comedy." The period from 1630 to 1650 was Hals's most productive. He was very popular among the staid citizens of Haarlem's middle class, and during this time he painted more than 100 single portraits and six group and family portraits.

Increasing sobriety in Hals's mature works

Frans Hals lived to be very old, and it is in the paintings of his old age that his genius for portraying human character is fully revealed. The last years of his life were difficult materially, and he was harassed by discouraging family problems. Although he continued to work steadily, he received markedly fewer commissions after 1650. He had, during his long career, achieved an impressive reputation; he had been honoured by many important commissions, had become in 1644 an officer of the Guild of St. Luke, and in 1649 had painted the philosopher René Descartes. Still, although some continued to value his subtle perceptions, the public had generally begun to favour a more elegant style made popular by the English portrait painter Anthony Van Dyck. What commissions he did receive were not enough to support him, and, like his two great compatriots Rembrandt and Vermeer, he saw his possessions sold at auction for debt (1654). It was not until 1662 that his right to public assistance was recognized, and he was accorded a yearly pension by the city. In spite of this adversity, however, the portraits of Hals's last 16 years are his masterpieces. At this point, a view of the world is revealed in his painting in which the human comedy takes a tragic turn, and something breaks in the order that had kept the reasonable man and the madman separated. His portraits, no longer tempered by laughter, seem to express a realization that simply being is enough, after a certain age, for life to impress its tragic seal on everyone.

Henceforth, Hals drew gradually closer to traditional subjects and stored away his drinking glasses and his tableware. At the same time he diminished the intensity, the vividness of his themes, a greater simplicity appeared in his compositions, and he took more and more liberty with his painting. His palette lost a good deal of its lustre. But through decades of work he had evolved a remarkably broad range of blacks and whites to choose from, and these colours were sufficient for what he wanted to show.

Tragic masterpieces of Hals's old age

From 1650 on, his subjects begin almost to look awestruck, and Hals ceases to bind his compositions into powerfully articulated human masses. Instead, he strings the solitude of each figure together on a flimsy thread, with the pattern broken only here and there by some ultimate spark of vitality. The light seems to act as a nervous system in his subjects that whips their drowsy flesh back to life, and the magic of the brushwork seems to startle their faces out of a swoonlike slumber. In the two celebrated portraits of the "Governors of the Old Men's Home at Haarlem," one a group of old men and the other of old women, his men seem overcome with drunkenness and his women entranced by the obsession of death. Here he presents us with the most extraordinary reunion of senile decay ever assembled in the history of the pictorial arts; he shows us the quavering flame of dying life. It is not known whether these portraits were comprehensible to his models. Apparently, none of the regents of the home objected to the paintings hanging in their Hall of Honour. Perhaps his subjects shared the old painter's humility in the face of destiny. Thus, the harmony in the colourful blare of the early works came to be succeeded by an art that seemed to give form to elusive nervous twitches, sudden motions, and to heartbeats accelerating, only to falter and start again. All his life Frans Hals had acted as a lucid observer of Haarlem. He painted it in the loud mirth of youth, and, reflecting in the image that he made of it his own life and declining health, he remained its faithful companion until his death.

Old age fostered self-denial and a strict discipline in Hals, along with a new freedom in his painting. It most certainly was a painful time for the great painter. But the years had also sharpened his vision. There is no sign of religion in the evolution of his art; and it may be assumed that to Frans Hals, painting was a secular concern. Nevertheless, the loving compassion that permeated his art becomes, in his last years, something spiritual.

Frans Hals died on September 1, 1666, and was buried in the choir of the church of St. Bavo, in Haarlem. Like many artists whose style is unique in their own time, he left few direct followers; the closest was Adriaen Brouwer, who used Hals's techniques well to portray tavern scenes and similar subjects. Hals was for a long time regarded as a competent but limited painter whose consistent neglect of any subjects other than portraits gave him no place in the history of significant art. It was not until the 19th century that interest in his work was revived. He influenced Édouard Manet with his free style and Vincent van Gogh with his subtle range of colours. In modern times he has been appreciated for the serious and excellent realist painter that he was.

MAJOR WORKS

"Banquet of Officers of the Civic Guard of St. George at Haarlem" (1616; Frans Halsmuseum, Haarlem); "The Merry Company" (*c.* 1616–17; Metropolitan Museum of Art, New York); "Portraits of Paulus van Beresteyn and His Wife" (1620; Louvre, Paris); "Nurse and Child" (*c.* 1620; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Man with Arms Crossed" (1622; Trustees of the Chatsworth Settlement, Chatsworth, England); "The Laughing Cavalier" (1624; Wallace Collection, London); "Portrait of Jacob Pietersz. Olycan" (1625; Mauritshuis, The Hague); "Portrait of Aletta Hanemans" (1625; Mauritshuis, The Hague); "St. Matthew and the Angel" (*c.* 1625; State Museum, Odessa, U.S.S.R.); "Portrait of Isaac Abrahamsz. Massa" (1626; Art Gallery of Ontario, Toronto); "Young Man Holding a Skull" ("Hamlet"; *c.* 1626–28; Sir Richard Proby Collection, Peterborough, England); "Banquet of Officers of the Civic Guard of St. George at Haarlem" (1627; Frans Halsmuseum, Haarlem); "Verdonck" (*c.* 1627; National Gallery of Scotland, Edinburgh); "Peeckelhaering" (*c.* 1628–30; Staatliche Kunstsammlungun, Kassel, Germany); "The Merry Toper" (*c.* 1628–30; Rijksmuseum, Amsterdam); "Gypsy Girl" (*c.* 1628–30; Louvre, Paris); "Portrait of a Man" (1630; Buckingham Palace); "Malle Babbe" (*c.* 1630–33; Staatliche Museen Preussischer Kulturbesitz); "Nicolaes Hasselaer" (*c.* 1630–33); Rijksmuseum, Amsterdam); "A Burgomaster" (*c.* 1631–33; Frick Collection, New York); "Portrait of an Elderly Lady" (1633; National Gallery of Art, Washington, D.C.); "Portrait of a Man in His Thirties; Bust" (1633; National Gallery, London); "Pieter van den Broecke" (1633; Iveagh Bequest, Kenwood House, London); "Portrait of a Woman" (1635; Frick Collection, New York); "The Company of Captain Reynier Reael and Lieutenant Cornelis Michielsz. Blaeuw" or "The Meagre Company" (1637; Rijksmuseum, Amsterdam); "Willem van Heythuyzen" (*c.* 1637–39; Musée Royal des Beaux-Arts, Brussels); "The Violinist" ("Daniel van Aken Playing the Violin"; *c.* 1640; Nationalmuseum, Stockholm); "Portrait of a Young Man" (an unidentified member of the Coymans family) (*c.* 1645; National Gallery of Art, Washington, D.C.); "Portrait of Isabella Coymans, Wife of Stephanus Geraerdts" (*c.* 1650–52; private collection, Paris); "Man in a Slouch Hat" (*c.* 1660–66; Staatliche Kunstsammlungun, Kassel, Germany); "Governors of the Old Men's Home at Haarlem" (1664; Frans Halsmuseum, Haar-

lem); "Lady-governors of the Old Men's Home at Haarlem" (1664; Frans Halsmuseum, Haarlem).

Hamamelidales

Hamamelidales is an order of woody flowering plants that includes three families, 30 genera, and about 80 to 150 species. Knowledge is still very incomplete concerning several genera; thus the actual number of species remains uncertain. The families and most of the genera are isolated both morphologically (*i.e.*, with respect to structure and form) and geographically, although the order as a whole is distributed worldwide. Thirteen genera contain only one species each and five genera only two species each. The order Hamamelidales is especially interesting as a group from the standpoint of the phylogeny of flowering plants because it apparently forms a link between groups with extreme types of floral organization; viz., the primitive woody plants with large, petalled flowers (the magnolias, buttercups, saxifrages, and roses) and the catkin-flowered plants (Amentiferae), which include the beeches, birches, alders, and oaks.

General features. *Size range and diversity of structure.* All representatives of the order are woody: trees and shrubs, partly evergreen, partly deciduous; there are no herbaceous species. Most members of the order are medium-sized trees, but some are small shrubs (*e.g.*, *Hamamelis*, witch hazel; *Fothergilla*, witch alder); others are giant trees up to 60 metres (200 feet) high (*e.g.*, *Liquidambar*, sweet gum; *Altingia; Symingtonia;* and *Platanus*, plane tree).

Distribution and abundance. The actual distribution of the order is worldwide (except in Arctic regions), but most of the species and genera have very limited individual ranges of distribution and it is possible that some of them will soon become extinct. Moreover, there are only a few species that grow in large pure stands. Several species are widely represented in northern fossil deposits.

Economic importance. Some genera are attractive for their early blossoming; some are even truly winter blooming as is especially true of *Hamamelis* (witch hazel) and *Corylopsis*. Others are known by their brilliant yellow, orange, or crimson leaf coloration in the fall (*e.g.*, *Disanthus; Fothergilla*, the witch alder; *Hamamelis; Liquidambar*, the sweet gum; and *Parrotia*, ironwood) or for being impressive, large trees (*Liquidambar* and *Platanus*). All these genera are more or less hardy in temperate regions. *Rhodoleia*, which has showy, red, bird-pollinated flowers, can be cultivated only in tropical or subtropical regions. Parts of *Hamamelis* (witch hazel) plants have long been used as raw material for various purposes. The North American Indians used the fluid from boiled stems to stop bleeding and heal wounds. Today alcoholic extracts from leaves and bark are used for styptic (antibleeding) remedies, and watery extracts are used for various cosmetics and household liniments. Medicinal uses

The wood of several trees is used as construction material or for furniture (*e.g.*, *Altingia, Liquidambar, Parrotia, Symingtonia*, and *Platanus*). In other genera the twigs or bast (fibres) are used as a tough binding and plaiting material (*e.g.*, *Molinadendron* and *Parrotiopsis*).

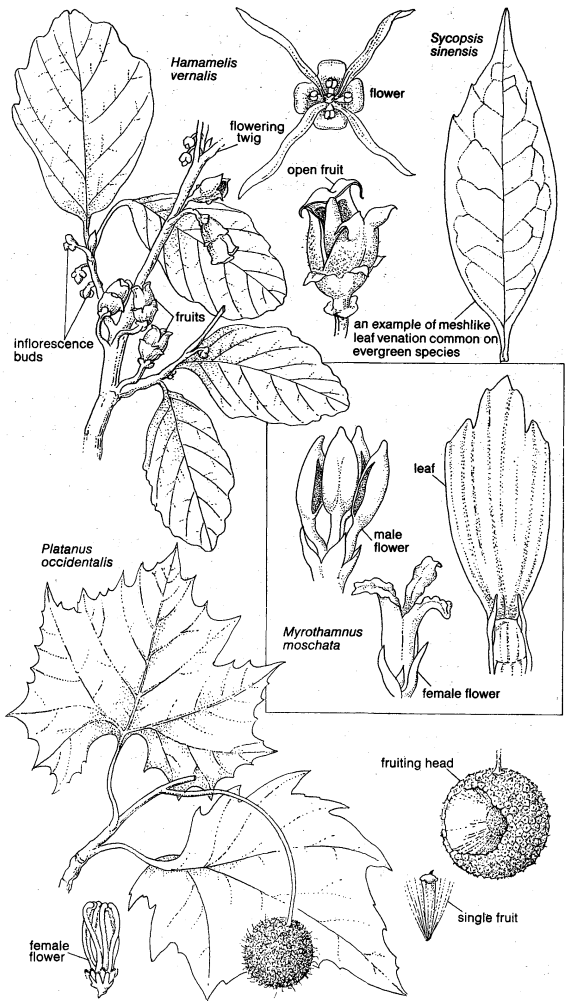
Natural history. *Life cycle.* The reproduction biology of the Hamamelidales shows some outstanding features. The range of pollination mechanisms is relatively wide. Pollination may be effected by bees or bumblebees (*e.g.*, in *Corylopsis*), by flies (in *Disanthus* and *Hamamelis*), by birds (in *Rhodoleia*), or by wind (in *Liquidambar, Parrotia, Sinowilsonia, Sycopsis*, and *Platanus*). In certain members of the family Hamamelidaceae fertilization of the ovules occurs long after pollination—*e.g.*, five to seven months in *Hamamelis virginiana*.

In the genera of Hamamelidaceae with one seed per carpel (structural unit of pistil), seed dispersal takes place by an ejecting mechanism. As the fruit opens, the bony endocarp (inner layer) bends in a characteristic manner and presses against the very hard and smooth surface of the seeds. The seeds are then forcibly discharged over distances of several metres. In contrast, the small, winged seeds of the many-seeded fruits of *Liquidambar* are distributed by wind. In *Platanus* the tufted nutlets are wind dispersed. In many species of the family Hamamelidaceae, seed germination is usually delayed because of the very hard and impervious seed coat; the seeds sometimes take one or two years to germinate.

Ecology. The family Platanaceae and a large part of the family Hamamelidaceae occur in moist woodlands, especially on stream banks, and on steep woody slopes. Other species grow best on drier rocky soils. The exact ecological range is unknown for most species. Many members of the family Hamamelidaceae grow in tropical and subtropical mountain regions, particularly in undisturbed forest areas. In general, representatives of the families Hamamelidaceae and Platanaceae are not specialized for extreme habitats, but the species of Myrothamnaceae are quite remarkable in being among the most extremely drought-resistant of all seed plants and ferns—twigs and leaves can dry out and remain in a dry condition for several years without dying. They are found in the arid regions of tropical and southern Africa and Madagascar. Adaptation to arid habitats

Form and function. *Vegetative characters.* All species of the order are woody plants. The leaves are simple and have small appendages at the base of the leaf stalks called stipules (except in *Rhodoleia*). They are usually arranged alternately along the stems. The anatomical structure of the wood is relatively uniform; the small, angular vessel elements (water-conducting cells) mostly have very oblique end plates with many crossbars, the scalariform condition.

Flower and fruit characters. The individual flowers are usually medium-sized or small, but they often form dense inflorescences (flower clusters). Several genera bear unisexual flowers, but only the family Myrothamnaceae seems to be dioecious; *i.e.*, its species bear male and female flowers on separate plants. The perianth—sepals and petals—especially the petal portion, is often reduced or absent, and the number of floral parts sometimes varies considerably within one species. The stamens (male flower structures) are usually provided with a short or long anther-connective protrusion—an appendage on the pollen sacs. The anthers open by means of valves except in the family Myrothamnaceae and in some genera of Hamamelidaceae. The female flower parts (the pistils) are composed of fused carpels (structural units of the pistil), except in the family Platanaceae, in which they are not fused, but they always show free styles, the elongate upper parts of the pistils. Each carpel usually contains a single ovule except in the family Myrothamnaceae and some Hamamelidaceae. The fruits are capsules (nutlets in Platanaceae) that split open along a ventral (inner-side) line. In the family Hamamelidaceae, other



Vegetative, floral, and fruiting structures of three families of the order Hamamelidales.

Drawing by M. Pahl based on (*M. moschata* flowers) *Beitrage zur Biologie der Pflanzen* (1966); Duncker and Humboldt, and (*P. occidentalis* flowers) G.H.M. Lawrence, *Taxonomy of Vascular Plants* (1951); The Macmillan Company

modes of opening are also common. The seeds of the families Hamamelidaceae and Platanaceae contain no starch, but protein and oil are present.

Evolution. *Fossil record.* The family Hamamelidaceae was widely distributed in the Northern Hemisphere, possibly in the Cretaceous Period (about 65,000,000 to 136,000,000 years ago); certainly in the Tertiary Period (2,500,000 to 65,000,000 years ago). In Europe the group is known at least from the Eocene Epoch (beginning about 54,000,000 years ago) until the lowest Pleistocene (about 2,500,000 years ago). *Liquidambar* is known from the Upper Cretaceous of North America. The Tertiary discoveries have been attributed with more or less certainty mainly to the genera *Corylopsis*, *Hamamelis*, *Liquidambar*, and *Parrotia*. Some other fossils have been described as separate genera; the oldest ones from the European Eocene are *Hamamelidanthium* and *Steinhauera*. The oldest remains of *Platanus* are known for America from the Upper Cretaceous; for Europe from the middle Oligocene Epoch (about 30,000,000 years ago). *Credneria*, known by leaves from the Cretaceous and long considered as ancestor of *Platanus*, has been transferred to the family Menispermaceae.

Phylogeny. The fossil record is too sparse to give sufficient information about the evolution of the group as a whole and about phylogenetic (evolutionary) relationships to other orders. Nevertheless, the characters of the living groups are interesting enough for certain phylogenetic conclusions. Floral structure, inflorescence morphology, leaf structure, wood anatomy, and chemical data show relationships to orders of the so-called "Amentiferae" (catkin bearers—catkins are elongate clusters of many small unisexual flowers), especially to the order Fagales (which includes the beech and birch families). Possible relationships are also indicated to the order Urticales (elm, mulberry and nettle families), and less probably to the orders Myricales (sweet gale family), Juglandales (walnut family), and Casuarinales, but not to the Salicales (willow order—one of the catkin-bearing plant groups). *Corylopsis* and *Sinowilsonia* (family Hamamelidaceae) are the most interesting genera with respect to the relationships shown to the catkin-bearing plant orders. *Sinowilsonia*, for example, has reduced unisexual flowers arranged in catkins. There are connections, on the other hand, to certain groups of the order Saxifragales, especially to the family Cunoniaceae. Certain superficial resemblances are also seen to the primitive woody families Cercidiphyllaceae, Eupteleaceae, Tetracentraceae, and Trochodendraceae, but they are considered to be the result of convergent evolution and not close phylogenetic affinity. Thus, the family Hamamelidaceae is most interesting in being a sort of link between two quite different main groups of flowering plants. The order Hamamelidales, therefore, represents an ancestral tropical and subtropical stock for several plant groups that have an amentiferous life form, which mainly developed in the temperate regions. Moreover, this connection lends support to the idea of a monophyletic origin (*i.e.*, one evolutionary line of descent) of the flowering plants.

Key evolutionary position

Classification. *Distinguishing taxonomic features.* Useful characters to distinguish the three families of the Hamamelidales include phyllotaxy (leaf arrangement), leaf form, hair types, structure of the inflorescences and flowers (particularly of the gynoecium—the female flower parts), and fruits.

Annotated classification.

ORDER HAMAMELIDALES

Woody plants. Leaves simple or palmately lobed, with stipules. Vessel elements in the wood narrow, with oblique end walls, perforation plates scalariform ("ladder-like") with numerous bars. Condensed inflorescences. Flowers mostly small, often unisexual, with reductions in floral structure. Calyx (sepals) lacking in few genera. Corolla (petals) often small or lacking. Wind pollination in some genera. Stamens with connective protrusion. Carpels (structural units of pistil) free or mostly fused in the region of the ovary but with free styles. Distribution centres: Middle and Eastern Asia, the Malaysian region, Central and North America, Australia, Madagascar, and tropical and southern Africa. Three families, 30 genera, and 80–150 species.

Family Hamamelidaceae (witch-hazel family)

Trees and shrubs. Leaves simple with pinnate (feather-like) or palmate (fanlike) venation or with three prominent veins or palmately lobed. Leaves either evergreen (and then with margins often smooth and lateral veins joining each other near the leaf margins) or deciduous (and then with lateral veins mostly straight and ending in marginal teeth). Stipules paired (lacking in *Rhodoleia*). Phyllotaxy (leaf arrangement) alternate, often in 2 ranks, rarely opposite. Stellate (branched in starlike pattern) hairs present in most genera (at least in the subfamily Hamamelidoideae). Inflorescences (flower clusters) mostly spicate (in spikes) or capitate; but paniculate (many-branched) in a few genera. Flowers bisexual, but partly functionally male in some genera, rarely totally unisexual; medium-sized to small, often with a hypanthium (floral cup); mostly perigynous or epigynous (*i.e.*, the ovary is half or wholly enclosed within the basal tissues of the sepals, petals, and stamens). Calyx mostly present. Petals ribbonlike in some genera, white or yellow to dark red, absent in many genera. Stamens mostly with a short or long apical protrusion. Anthers opening by 1 or 2 valves on each side or by lateral slits. Staminodia (sterile stamens) sometimes present. Carpels 2, fused at ovary level, free above, and forming 2 distinct styles. Stigma (pollen-receiving surface at tips of styles) sometimes large (in wind-pollinated genera) and warty. Ovules 1 to several per carpel, in a lateral position. Nectaries present in some genera, localized on different floral parts, depending on the genus. Calyx, corolla, and androecium (male flower parts) often present in 5s or 4s, but in some genera the number of parts is higher and variable. Fruits are capsules with leathery exocarp (outer layer) and mostly hard, bony endocarp. Seeds often black, shining, smooth, and very hard.

Distribution centres: Middle and Eastern Asia, the Malaysian region, North and Central America, Australia, tropical and southern Africa, and Madagascar. Twenty-eight genera, about 75–140 species.

Subfamily Hamamelidoideae

Usually 1 (rarely to 3) ovule per carpel.

Subfamily Disanthoideae

Six ovules per carpel, flowers hypogynous (ovary positioned above other flower parts), bisexual.

Subfamily Symingtonioideae

Six ovules per carpel, flowers epigynous, polygamous (unisexual and bisexual flowers present on the same plant).

Subfamily Rhodoleioideae

Many ovules per carpel, flowers bisexual, forming showy, red pseudanthia.

Subfamily Liquidambaroideae

Many ovules per carpel, flowers unisexual, inconspicuous.

Family Platanaceae (sycamore or plane-tree family)

Large monoecious (male and female flowers on the same plant) trees. Stem bark exfoliating. Leaves usually palmately lobed, deciduous, with one sheathlike stipule on the leaf stalk. Candelabra-shaped hairs. Vessel elements with scalariform or with simple perforations. Inflorescences unisexual, in globose head-like clusters. Flowers small, calyx minute, petallike structures occasionally present. Staminodes present in female flowers. Stamens with broad, flat connective protrusion. Anthers open by 2 valves on each side. Carpels free. Stigma with unicellular nipple-like projections. Ovules 1 per carpel. Number of floral parts varies from 2 to 9. Nectaries lacking. Flowers wind pollinated. Fruits small, tufted nutlets. Distribution: North and Central America, eastern Mediterranean region, and eastern Asia. One genus, 2 to 9 species.

Family Myrothamnaceae

Bushy dioecious shrubs, extremely drought resistant. Leaves opposite, folded, apically toothed, persistent, long living, with paired stipules. Hairs totally absent. Inflorescences spicate. Flowers unisexual. Calyx and corolla absent. Stamens 3 to 8 with apical protrusion. Anthers open by lateral slits. Carpels 3 or 4, basally fused. Styles free. Stigmas large and warty. Ovules many per carpel, with a lateral placentation. Fruits capsules. Distribution: arid zones of Madagascar, tropical and southern Africa. One genus, 2 species.

Critical appraisal. Some authorities include additional families in the order Hamamelidales, among them Tetracentraceae, Cercidiphyllaceae, Eupteleaceae, Bruniaceae, Stachyuraceae, Daphniphyllaceae, and Buxaceae. All these families, however, occupy quite isolated positions. Furthermore, some of the subfamilies of the Hamamelidaceae, as presented here, have been raised to the status of separate families by some authors. These include Disanthaceae, Rhodoleiaceae, and Altingiaceae (= Liquidambaroideae).

Hamburg

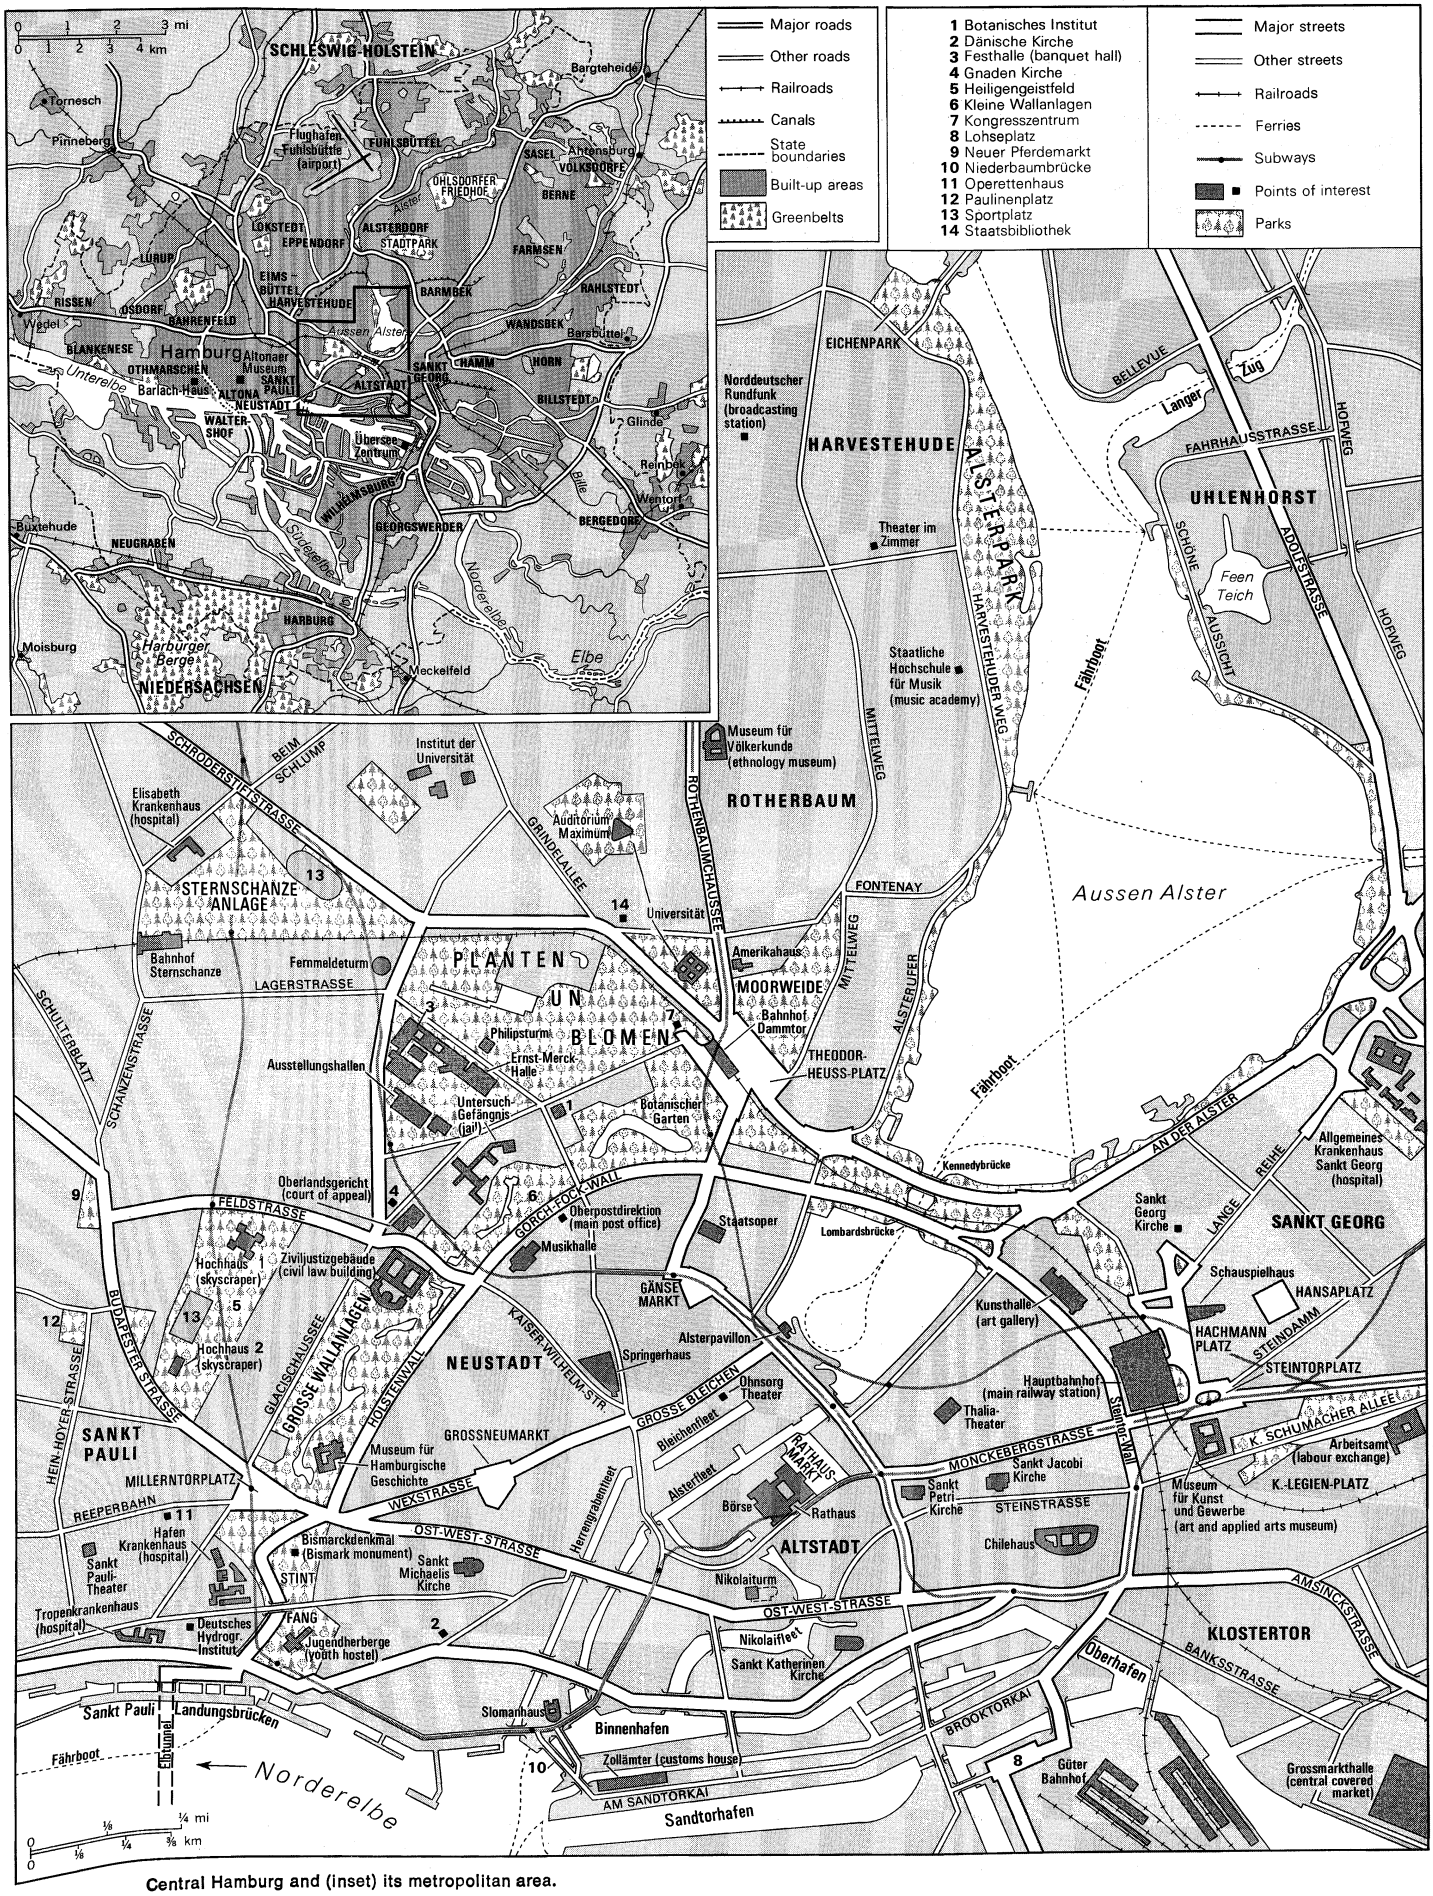
The Free and Hanseatic City (Freie und Hansestadt) of Hamburg is the second smallest of ten *Länder* ("states") of the Federal Republic of Germany, with a territory of only 291 square miles, or 753 square kilometres; but its 1,810,000 inhabitants (1971) make it the most populous municipality in West Germany. The official name, which covers both the *Land* and the actual town, reflects Hamburg's age-long tradition of particularism and self-government: Hamburg and Bremen, in fact, are the only German city-states to keep, in the 20th century, something of their medieval independence. The characteristic individuality of Hamburg has been deliberately maintained by its people so that, in many spheres of public and private life, the city's culture has not succumbed to the general trend of standardization.

Superficially, there is little in Hamburg to remind the visitor of this great city's millennial history. Only the five principal churches within the ancient city walls—dedicated to Sankt Jacobi, Sankt Petri, Sankt Katharine, Sankt Nikolai, and Sankt Michaelis—conserve traces of the past; and, even so, none of them is in its original condition. Fire has destroyed almost all the older residences and warehouses, and what was left untouched by conflagration has often been rebuilt for contemporary purposes by the citizens themselves, who are generally hard-headed businessmen for all their love of tradition. The layout of the old city centre, however, can still be detected in some of the ancient street names, and in the *Fleete* (canals such as the *Grachten* of Dutch cities), which connect the Alster River with the docks on the Elbe River. The best view of the city is to be enjoyed from the Lombardsbrücke (Lombard Bridge) across the Binnenalster (Inner Alster), whence the towers of the five churches can be seen rising high, but by the 1970s more and more glass-fronted skyscrapers were shooting up to change the horizon.

The largest port in Germany, Hamburg has prospered on trade, both inland and overseas. Merchants and shipowners, therefore, are at the top of its social scale and have set the standard of the city's life-style. With a cosmopolitan outlook, they are basically conservative and skeptical, mistrusting fashionable innovation however loudly publicized it may be. Concerned with practical realities, they are usually undogmatic and open-minded. Fairness, common sense, and understatement are among the ideas they have taken over from the English, long contact with whom has made Hamburg a remarkably Anglophile city.

History. Hamburg's history begins with the Hammaburg, a moated castle of modest size, built about AD 825 on a sandy promontory between the Alster and Elbe rivers, on the northeastern border of the Carolingian dynasty's empire. In 834, during the reign of the emperor Louis the Pious, the castle's baptistery became the seat of an archbishopric; and Archbishop Ansgar made the young city of Hamburg the base of his missions to the heathens of northern Europe. Vikings burned the city in 845, and the rebuilt Hamburg was burned down again eight times in the following 300 years. By the end of the 11th century, Hamburg's role as the spiritual metropolis of the north was fulfilled, and thenceforward commerce was to replace evangelism as the principal function of the city. Between 1120 and 1140 some trading businesses were installed there; and the foundation of Lübeck, on the Baltic, by Adolf II, count of Holstein, further promoted the economic development of Hamburg as Lübeck's port on the North Sea. In the autumn of 1188 a group of Hamburg entrepreneurs received from their feudal overlord, Adolph III of Schauenburg (Schaumburg), count of Holstein, a charter for the building of a new town, adjacent to the old one, with a harbour on the Alster River and with facilities for the use of the Elbe River as an outer roadstead; and, on May 7, 1189, the emperor Frederick I Barbarossa confirmed Count Adolph's dispositions in a charter granting special trading rights, toll exemptions, and navigation privileges to the nascent port.

The 13th century saw Hamburg growing steadily both



Central Hamburg and (inset) its metropolitan area.

Role in the Hanseatic League

in area and in economic importance thanks to the development of the Hanse (an association of merchants trading in a particular area) into a multilateral association of the north German merchant cities, the great Hanseatic League, in which Hamburg's role was second only to Lübeck's. A major entrepôt for the trade between Russia and Flanders, Hamburg proceeded to safeguard the trade routes by acquiring tracts of land along the branches of the Elbe in the immediate vicinity of the town and also on the estuary farther downstream (Ritzebüttel, nucleus of the later Cuxhaven, was acquired by Hamburg in 1393) and so came to control the use of the river and to be recognized as the protector, in the emperor's name, of navigation on its lower course. Some political complications arose with the death, in 1459, of the last Schauenburg count of Holstein, since his princely rights in Germany passed thereafter to the royal house of Denmark; but Hamburg scarcely recognized Danish suzerainty in anything but a formal and wholly ineffectual way.

Toward the end of the Middle Ages, the Hanseatic League gradually dissolved. Hamburg then went its own way and by 1550 had surpassed even Lübeck in economic importance. A stock exchange was founded in 1558 and the Bank of Hamburg in 1619; a convoy system for shipping was inaugurated in 1662, Hamburg's merchantmen being the first to be escorted on the high seas by German men-of-war; and about the same time marine insurance was first introduced into Germany. In 1678, furthermore, the first German opera house was established in Hamburg. There were two causes for this new ascendancy: firstly, the wars of religion in the Netherlands in the second half of the 16th century had prompted many Dutch merchants to emigrate to the Unterelbe (Lower Elbe) region, with the result that Hamburg was henceforth to be the focus of their already established international commerce; and, secondly, the city had been so efficiently fortified in the decade 1616–25 that it could pursue its business untroubled throughout the worst crises of the Thirty Years' War (conventionally 1618–48). By the end of the 17th century, Hamburg, with 70,000 inhabitants, was the largest city in Germany after Cologne.

The Treaty of Gottorp, concluded with the Danes on May 27, 1768, not only released Hamburg from theoretical subjection to the King of Denmark and so paved its way to being acknowledged, in 1770, as an "immediate" imperial city of Germany (that is, a city with no overlord other than the Emperor himself) but also ceded to Hamburg the islands, from Veddel to Finkenwerder, that lay between the city and the left banks of the Elbe River and that, a century later, were to be the site of new docks. Hamburg, however, was not long to enjoy its new advantage: the Napoleonic Wars overthrew the old order in Germany, and the little state was eventually annexed, in 1810, to Napoleon's French Empire.

After Napoleon's downfall (1814–15), Hamburg became a member state of the German Confederation, with the designation "Free and Hanseatic city of Hamburg" from 1819. Prosperity was quickly recovered, as Hamburg's trade was extended to newly opened territories in South and Central America, in West and East Africa, and in East Asia. Even the great fire of May 1842, which devastated one-fourth of the city centre, did not check the booming economy, and the harbour was converted into one accessible at any time, without regard to the state of the tides in the Elbe Estuary. Under the German Empire, founded in 1871, the political status of Hamburg was maintained, and development proceeded unchecked: the splendid Baroque houses of the densely populated Brook Islands were demolished in the 1880s to make room for the warehouses of the new free port; and, by the end of the 19th century, in the course of which the population grew from 130,000 to 700,000, Hamburg had expanded far beyond its previous limits, absorbing such former suburbs as Sankt Pauli and Sankt Georg and spreading its tentacles into the countryside, toward Eimsbüttel, Eppendorf, Harvestehude, and Barmbek.

Hamburg entered the 20th century determined to maintain and to strengthen its position as "Germany's gateway to the world": new docks and wharves were constructed on the left bank of the Elbe River. The outbreak of World War I in 1914 brought progress to a standstill, however. Hamburg's international trade collapsed, and its merchant fleet of 1,466 ships (3,171,246 gross registered tons) was virtually confined to port. After the war the victorious Allies demanded nearly all of Hamburg's ships by way of reparation from Germany.

The city during World Wars I and II

For many years after the war, Hamburg could undertake no further development because it had already exhausted all the potentialities of its territory. The Greater Hamburg Ordinance of January 26, 1937, changed this situation by allowing Hamburg to incorporate the neighbouring cities of Altona, Wandsbek, and Harburg, which until then had belonged to Prussia. The immediate prospect of expansion, with the development of these areas on a basis of large-scale planning, was shattered by the outbreak, in 1939, of World War II, during which repeated air raids demolished 55 percent of Hamburg's residential area and 60 percent of the harbour installations and killed 55,000 people. When the war ended in 1945, only the most strenuous efforts could supply the elementary needs for Hamburg's survival; but 25 years later reconstruction was almost complete. Two mayors gave conspicuous service to Hamburg in the postwar years: Max Brauer, in office from 1946 to 1953 and again from 1957 to 1960; and Herbert Weichmann, from 1965 to 1971.

The contemporary city. Hamburg stands at the northern extremity of the Lower Elbe Valley, which is between five and eight miles (eight and 12 kilometres) wide there. To the southeast of the old city, the Elbe divides itself into two branches, the Norderelbe and the Süderelbe; but these branches meet again opposite Altona, just west of the old city, to form the Unterelbe, which flows into the North Sea some 68 miles (110 kilometres) downstream from Hamburg. Tides on the Elbe produce an average difference of about 7.5 feet (2.3 metres) between high and low water in Hamburg's harbours. Two other rivers flow into the Elbe at Hamburg—the Alster from the north and the Bille from the east.

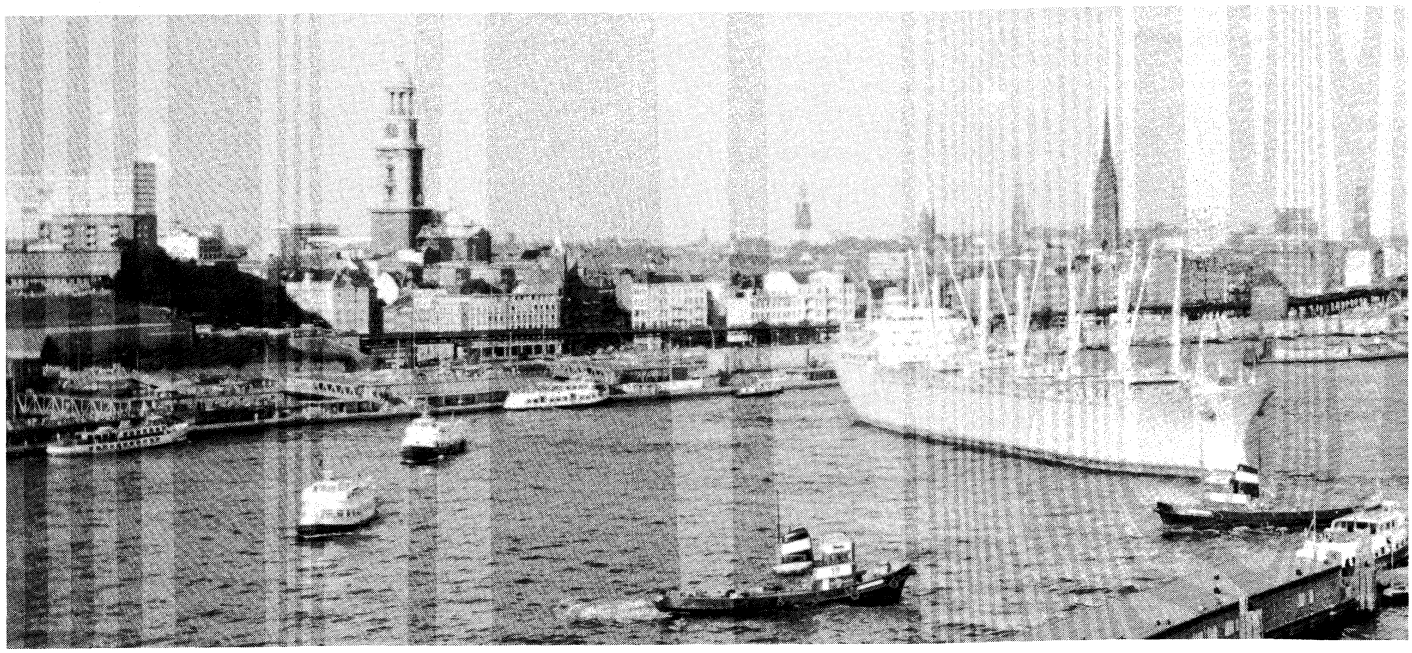
Hamburg's state territory covers 291 square miles (753 square kilometres) and is approximately 25 miles in diameter. Its border with Niedersachsen, to the south, is 49 miles long; and its border with Schleswig-Holstein, to the north, 79. Of the total area, 7.7 percent consists of running or standing water; 35 percent is agricultural land; 6.3 percent is forest; 41 percent is residential; 8.7 percent is devoted to industry; and 1.3 percent is occupied by railroads or by the airports.

Hamburg has mild winters, late springs, cool summers, high humidity, and frequent fog. The mean annual temperature is 47° F (8° C).

Population. The decline of Hamburg's population from 1,854,000 inhabitants in 1965 to 1,800,000 in 1971 led statisticians to forecast that by the mid-1980s there would be only about 1,735,000. Already by 1971 there were only 800,200 wage earners officially recorded, including 287,600 in manufacturing industry, 148,700 in commerce, and 38,600 in banking and insurance. These figures take no account of some 100,000 people employed in Hamburg but domiciled in Niedersachsen or in Schleswig-Holstein.

More than three-quarters of Hamburg's population is Protestant Christian, but there were about 140,000 Roman Catholics in 1971. Jews, of whom there had been 27,000 in 1933 (when Hitler took power), counted only 1,400 but had a new synagogue. There were two mosques for the 3,000 Muslims. Hamburg's non-German labour force amounted to 46,000 out of the 98,000 foreign residents.

Economy. There were some 2,000 Hamburg firms engaged in worldwide trade by the end of the 1960s. In 1970 they handled 32.6 percent of West Germany's total imports and 36.8 percent of her total exports. Chief among imports were vegetable oils and fats, tea, coffee, petroleum, tropical fruit, and uncured tobacco. Exports comprised machinery, electrotechnical products, processed petroleum fuel and lubricants, copper, and pharmaceutical products. Most of this foreign trade was with the



The harbour and city of Hamburg.
Hans Hartz

United States, Great Britain, The Netherlands, France, and Italy. Furthermore, Hamburg was dealing with more than 50 percent of the transit trade of West Germany as a whole. Of Hamburg's 110 credit institutions, over 40 are private banks.

Industrial importance to Germany

Having absorbed Altona, Harburg, and Wandsbek in 1937, Hamburg has become West Germany's major industrial city. All processing and manufacturing industries are represented there. Though few of the latter are in the hands of large-scale firms, Hamburg treats 80 percent of West Germany's copper supplies (the Norddeutsche Affinerie, on Veddel, is Europe's second largest copperworks), 40 percent of its vegetable oil, and 35 percent of its mineral oil, besides building 35 percent of its shipping and producing 25 percent of its cigarettes. The inauguration of a nuclear plant near Stade, in Niedersachsen, to provide power at a reasonable cost to the industries bordering the Unterelbe was obviously beneficial to Hamburg.

Government and institutions. According to the constitution of June 6, 1952, legislative authority is vested in the Bürgerschaft, or State Parliament, which comprises 120 members elected for a four-year term. The general election of March 22, 1970, returned only three political parties to this assembly: the Social Democrats, with 70 seats; the Christian Democrats, with 41; and the Free Democrats, or Liberals, with 9.

The State Parliament elects the government, the Senat, which is organized on a collegiate basis, the president, or "first mayor," (*erster Bürgermeister*) being elected by the Senat itself for one calendar year of office. The Senat as a whole represents the Free and Hanseatic City of Hamburg in its dealings with the other federal *Länder,* with the federal government, and with foreign states. Each senator is responsible for a particular department, but administrative problems of a local nature are delegated to the seven district offices and to the 15 local authorities.

The Rathaus (City Hall), where the Senat and the Bürgerschaft meet, in the centre of the city near the Binnenalster, was built late in the 19th century, in the Neo-Renaissance style.

Hamburg's coat of arms displays a three-towered castle, silver (argent), on a red (gules) field, its design being derived from the city's great seal of 1241. The state flag likewise shows a white castle on a red field. The state's anthem, "Stadt Hamburg an der Elbe Auen" ("City of Hamburg on the Shores of the Elbe"), was written by G.N. Bärmann in 1828 and set to music by Albert Methfessel.

Hamburg is second only to New York City in the international count of consulates: in 1972 there were 75 accredited foreign representatives in Hamburg.

Services. A focus of intercontinental as well as of western European and Scandinavian trade, Hamburg is the base of about 100 of Germany's 180 shipping concerns. Of its 200 miles of riverside, 40 have been built up as docks. The port dealt with 45,000,000 tons of goods in 1971, and, in an average month, 725 ships, representing 287 lines, sail from it for more than 1,000 destinations. About 19,200 oceangoing vessels docked at Hamburg in 1971, nearly 9,000 of them being liners that were calling regularly there. Hamburg's Übersee-Zentrum, with an area of 132,000 square yards (110,000 square metres), is the world's largest roofed warehouse: as many as 25,000 packages for overseas export may be handled there in a single day—sorted, stored, and finally dispatched to the appropriate vessels. There is also the Burchardkai container terminal, in the Waltershofer dock; enclosing a surface of 340,000 square metres, it is the largest accommodation of its kind in Europe. The harbour's labour force amounts to some 14,500 people, with a reputation for hard work and efficiency.

The port of Hamburg

The harbour proper has 400 miles of track linking the waterfront to the German railroad network. For motor transport, as many as 1,800 trucks enter the harbour zone in a day. To relieve the city centre of Hamburg from long-distance traffic, a 3,200-metre tunnel under the Elbe was undertaken, to be opened in 1973 as a part of the Stockholm—Lisbon highway.

The airport of Hamburg–Fuhlsbüttel, which dates from 1911, is one of the oldest in Europe. It has two runways from which even the largest jet-propelled aircraft could still take off in the early 1970s. Arrivals and departures of aircraft numbered 89,000 in 1970, with 3,130,000 passengers. As Fuhlsbüttel is reaching the limit of its capacity, another major airport is being built some 19 miles (30 kilometres) to the north of the city, between the little towns of Kaltenkirchen and Bad Bramstedt, to be one of the four German airports providing supersonic flights: it is hoped that it will be operative by the end of the 1970s.

Since World War II, Hamburg has succeeded Berlin as the chief city for much of the German press. It houses the head office of German Press Agency (DPA), which has branches in 70 foreign countries, and daily newspapers appearing in Hamburg, such as *Bild, Hamburger Abendblatt,* and *Die Welt,* have an aggregate circulation of 6,000,000. The leading weekly papers are *Bild am Sonntag, Welt am Sonntag,* and *Die Zeit.* Periodicals with an

aggregate circulation of 24,600,000, including *Stern* and *Der Spiegel*, also appear in Hamburg.

The Norddeutsche Rundfunk, Hamburg's broadcasting station, serves Niedersachsen and Schleswig-Holstein as well as its own city. Its television studios produce the daily news program of the Arbeitsgemeinschaft der Öffentlichrechtlichen Rundfunkanstalten der Bundesrepublik Deutschland (ARD, or Association of German Broadcasting Institutions).

The greatest economic centre of West Germany, Hamburg has since 1960 become the site of first-class trade fairs. The exhibition premises cover an area of 57,000 square yards on the fringe of the city. Especially worthy of mention are the German Boats Exhibition and Ship and Machine International.

Cultural life and recreation. The University of Hamburg, founded in 1919, ranks as the largest in West Germany, as its 15 departments have a total of 25,000 students. Suitably enough, in view of Hamburg's interests, the university has always given particular importance to teaching foreign languages, economics, geography, ethnology, and international law; and no less suitably, its 180 institutes and seminars include the Institute for Foreign Trade and Overseas Commerce, the German Hydrographic Institute, the Institute for Oceanography, and the Bernhard Nocht Institute for Seamen's and Tropical Diseases. Also attached to the university is the Deutsche Elektronen-Synchrotron, a research station ranking among the world's greatest particle accelerators.

Besides the university, Hamburg has a State Advanced School for Music and Interpretative Art, and a State Advanced School for the Sculptural Arts, both of which give a college-level education.

Among Hamburg's six museums, the Kunsthalle, founded in 1868 by Alfred Lichtwark, an outstanding patron of artists, is one of Europe's most remarkable galleries, in particular for its collection of 19th- and 20th-century work. The Museum für Kunst und Gewerbe (Museum of Art and Applied Arts), founded in 1877 by the jurist Justus Brinckmann, has one of the most significant collections of ancient artifacts in West Germany and especially famous examples of Japanese art and of Jugendstil (Art Nouveau). The Museum für Hamburgische Geschichte (Museum of Hamburg History), which has grown up from a collection of local antiquities started in 1839, exhibits architect's plans, artists' views, and models of the town and of the harbour, together with models illustrative of the history of navigation, in such a way as to present a most impressive conspectus of the state's past. The Museum of Ethnology and Prehistory, founded in 1878, has comprehensive collections in its own fields. The Altonaer Museum, opened in 1863, specializes in north German subjects, with special attention to Schleswig-Holstein, and houses Germany's largest collection of old ships' figureheads. The Helms-Museum, in the Harburg district, is a local museum for the part of Hamburg south of the Elbe but is soon to house all antiquities representing the prehistory and most ancient history of the whole territory. The Ernst-Barlach-Haus, in Jenisch Park, was founded in 1961–62 by another great patron of the arts, Hermann F. Reemtsma, so as to make his private collection accessible to the public. Hamburg's once famous Zoological Museum was destroyed by bombs in 1943 after a century of existence.

Music and drama in Hamburg

The Hamburg State Opera, which dates, as has been said, from 1678, won international celebrity in the 1960s and 1970s, thanks largely to its director, the Swiss composer Rolf Liebermann: its performances of classical and contemporary works bear comparison with those given by the great opera houses of Vienna, Milan, London, and New York. The Deutsche Schauspielhaus, a leading theatre, enjoyed a high reputation from 1955 to 1963, when Gustaf Gründgens directed and performed there. The Thalia-Theater, founded in 1843, with a multifaceted program that includes plenty of light entertainment, suits Hamburg's taste well enough. All these three establishments are generously subsidized by the state. There are also four other theatres, namely, the Hamburger Kammerspiele, the Theater im Zimmer, the Junge Theater, and the Altonaer Theater, which receive only meagre support from the state. Plays of a local character or in Plattdeutsch (Low German) are performed in the Ohnsorg-Theater and sometimes also in the Sankt Pauli-Theater, which dates from 1841 and is Hamburg's oldest playhouse.

The birthplace of Mendelssohn and of Brahms, Hamburg has a sustained tradition of musical activity. Three great orchestras—the Philharmonische Staatsorchester, the Symphonie-Orchester des Norddeutschen Rundfunks, and the Hamburger Symfoniker—familiarize the public with classical and contemporary compositions. There are also groups specializing in chamber music, in choral performances, and in church music; and orchestras, choirs, singers, and instrumentalists from other parts of Germany or from the outside world are also invited to Hamburg. Nearly all recitals are given in the Musikhalle, a building in the Neo-Baroque style founded in 1904–08 by the shipowner Carl Laeisz.

Sports have long been popular in Hamburg. The Hamburger Turnerschaft (1816) is Germany's most ancient athletic club. The first German rowing club, founded in Hamburg in 1836, took part in 1837 in Germany's first official rowing race—against the English Rowing Club formed by members of Hamburg's then numerous English colony. The Hamburger Rennklub, for horseracing, was founded in 1852; and the North German Derby, first run in 1869, became an annual event, as the German Derby, from 1889 onward. Hamburg's first public football matches were played in 1881–82, after disputes about the rules of the game with the local Anglo-American Football Club. Another noteworthy event is the annual German tennis championships.

BIBLIOGRAPHY. For an introduction to contemporary Hamburg, the English reader must consult guidebooks dealing with West Germany as a whole or with its northern territory specifically. The best historical presentation is still that by HEINRICH REINCKE, *Hamburg: Ein Abriss der Stadtgeschichte von den Anfängen bis zur Gegenwart* (1926), supplemented by ERICH VON LEHE, DIETRICH KAUSCHE, and HEINZ RAMM, *Heimatchronik der Freien und Hansestadt Hamburg* (1958).

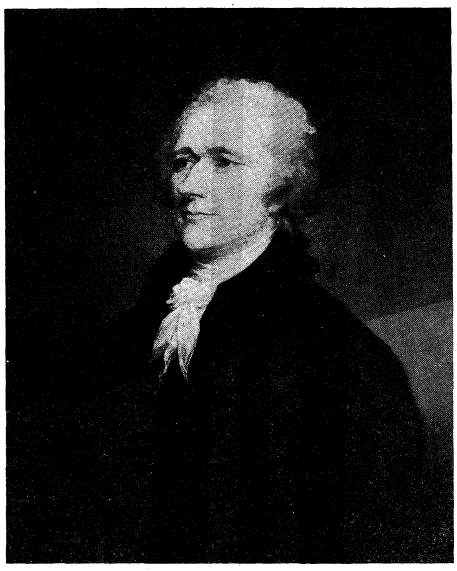
(He.Th.)

Hamilton, Alexander

Alexander Hamilton, publicist, politician, and first secretary of the treasury of the United States under George Washington, the first president, was the foremost champion of a strong central government for the newly united former colonies. As treasury secretary, he created the Bank of the United States, secured the nation's credit both at home and abroad, and established a national currency. A leader of the Federalist Party and chief author of *The Federalist Papers*, which propagated his political and financial views, his image of the United States as a prosperous industrial nation has proved singularly prescient.

Hamilton was born on the island of Nevis in the British West Indies, probably on January 11, 1755, and not in 1757 as he himself claimed. His father was James Hamilton, a drifting trader and the fourth son of Alexander Hamilton, the laird of Cambuskeith, Ayrshire, Scotland; his mother was Rachel Fawcett Lavine, the daughter of a French Huguenot physician and the wife of John Michael Lavine, a German or Danish merchant who had settled on the island of St. Croix in what were then the Danish West Indies. Rachel probably began living with James Hamilton in 1752, but Lavine did not divorce her until 1758. Although he came of good stock, Alexander Hamilton from his earliest years was sensitive to the fact that he was illegitimate. "My blood," he once said, "is as good as that of those who plume themselves upon their ancestry."

In 1765, after having brought his family to St. Croix, James Hamilton abandoned it. Destitute, Rachel set up a small shop, and at the age of 11 Alexander went to work, becoming a clerk in the countinghouse of two New York merchants who had recently established themselves at St. Croix. When Rachel died in 1768, Alexander be-



Alexander Hamilton, oil painting by John Trumbull (1756–1843). In the National Gallery of Art, Washington, D.C.

came a ward of his mother's relatives and continued to work in the countinghouse. In March 1772 young Hamilton's ability, industry, and engaging manners won him advancement from bookkeeper to manager, and several months later friends who were impressed by Hamilton's talents sent him to the North American mainland to further his education. For a year he studied at a preparatory school in Elizabethtown, New Jersey, and in the autumn of 1773 entered King's College (later Columbia) in New York. Intensely ambitious, he became a serious and successful student, but his studies were interrupted by the brewing revolt against Great Britain. Throwing himself behind the colonial cause, he publicly defended the Boston Tea Party, the name given to the destruction of several tea cargoes by the Boston colonists in defiance of the tea tax. In 1774–75, at the age of 17, he wrote three influential pamphlets, *A Full Vindication of the Measures of Congress*, *The Farmer Refuted*, and *Remarks on the Quebec Bill*. They upheld the agreements on the nonimportation, nonconsumption, and nonexportation of British products arrived at by the Continental Congress, the first federal body of the Thirteen Colonies, and attacked British policy in Quebec. Those anonymous publications, the first of which had been attributed to John Jay and John Adams, two of the ablest of American propagandists, gave the first solid evidence of Hamilton's precocity that astonished his contemporaries.

Service in Revolutionary War

In March 1776, through the influence of friends in the New York legislature, Hamilton was commissioned a captain in the provincial artillery. He organized his own company and at the Battle of Trenton, when he and his men prevented the British under Lord Cornwallis from crossing the Raritan River and attacking George Washington's main army, showed conspicuous bravery. Thereafter Hamilton's military brilliance was recognized. In February 1777 Washington invited him to become an aide-de-camp with the rank of lieutenant colonel. In his four years on Washington's staff he grew close to the general and was entrusted with his correspondence. He was sent on important military missions and, thanks to his fluent command of French, he became liaison officer between Washington and the French generals and admirals. During that time he formed some of the important friendships he was to retain for the rest of his life. He also attracted the attention of political leaders in New York. During the inactive periods of the winter campaigns he continued his studies, reading deeply in the classics and particularly in the literature of economics and public finance.

Eager to connect himself with wealth and influence, Hamilton married Elizabeth, the daughter of Gen. Philip Schuyler, the head of one of New York's most distinguished families, in December 1780. Meantime, having grown tired of the routine duties at headquarters and yearning for military glory, he pressed Washington for an active command in the field. Washington refused, and in February 1781, Hamilton impetuously seized upon a trivial quarrel to break with the General and leave his staff position. Fortunately, he had not forfeited the General's friendship, for in July Washington gave him command of a battalion. At the siege of Cornwallis' army at Yorktown in October, Hamilton gained a moment of glory in an assault on a British stronghold.

Early political activities. Meanwhile, in letters to a member of Congress and to Robert Morris, the superintendent of finance in 1780 and 1781, Hamilton had analyzed what he considered the financial and political weaknesses of the government. In November 1781, with the war virtually over, he moved to Albany where he studied law and was admitted to practice in July 1782. That same month he became receiver of continental taxes for the state of New York, a post he gave up a few months later after the New York legislature had elected him to the Continental Congress. Between July 1781 and July 1782 he wrote six essays for a newspaper, the *New York Packet*, under the pen name of "The Continentalist," in which he argued for a strong central government. In Congress from November 1782 to July 1783 he worked for the same end, being convinced that the Articles of Confederation, the nation's first constitution, were the source of the country's weakness and disunion (see UNITED STATES, HISTORY OF THE: *The Confederation and the framing of the Constitution*).

Election to the Continental Congress

In November 1783 Hamilton began to practice law in New York City. He defended unpopular Loyalists who had remained faithful to the British during the Revolution in suits brought against them under a state law of that year called the Trespass Act. Using the pseudonym "Phocion," he published two pamphlets in 1784 pleading for moderation and justice in the treatment of Loyalists and in 1786, partly as a result of his efforts, state acts disbarring Loyalist lawyers and disfranchising Loyalist voters were repealed. In that year he also won election to the lower house of the New York legislature, taking his seat in January 1787. In the meantime, the legislature had appointed him a delegate to the convention in Annapolis, Maryland, that met in September 1786 to consider the commercial plight of the Union. Hamilton suggested that the convention exceed its delegated powers and call for another meeting of representatives from all the states to discuss various problems confronting the nation. He drew up the draft of the address to the states from which emerged the Constitutional Convention that met in Philadelphia in May 1787. After persuading New York to send a delegation, Hamilton, through the influence of his father-in-law, General Schuyler, obtained a place for himself on the delegation.

Hamilton went to Philadelphia as an uncompromising nationalist who wished to replace the Articles of Confederation with a strong centralized government, but he did not take much part in the debates and his attendance was irregular. He served on two important committees, one on rules in the beginning of the convention and the other on style at the end of the convention. In one long speech on June 18 he presented his own idea of what the national government should be. His model was the England of George III. "I have no scruple in declaring . . . that the British government is the best in the world," he said, "and that I doubt much whether anything short of it will do in America." He suggested a government of three departments—legislative, executive, and judicial. The legislature would consist of an assembly or lower house elected for three years by free male citizens and a senate chosen indirectly by electors for life. The president, who also would hold office for life and was to be selected by a double set of electors, would have an absolute veto over the legislature. The central government would appoint the state governors who would have an absolute veto over state legislation. The judiciary would consist of a su-

preme court whose justices would have life tenure. Although the states were to be preserved, they would have virtually no power. The most significant feature of the plan, which was essentially monarchical, was that the national government would have unlimited sovereignty. Other than to reveal his own conservative ideas, Hamilton's plan had little impact on the convention; the delegates went ahead to frame a constitution that, while it gave strong power to a federal government, yet stood some chance of being accepted by the people. Since the other two delegates from New York, who were strong opponents of a Federalist constitution, had withdrawn from the convention, New York was not officially represented and Hamilton had no power to sign for his state. Nonetheless, even though he knew that his state wished to go no further than a revision of the Articles of Confederation, he signed the new constitution as an individual.

The Federalist

Opponents in New York quickly attacked the Constitution and Hamilton answered them in the newspapers under the signature Caesar. Since the Caesar letters did not win the influence he desired, Hamilton turned to another classical pseudonym, Publius, and to two collaborators, James Madison, the delegate from Virginia, and John Jay, the secretary of foreign affairs, to write *The Federalist*, a series of 85 essays in defense of the Constitution and republican government that appeared in the New York newspapers between October 1787 and May 1788. Hamilton wrote at least two-thirds of the essays, including some of the most important ones that interpreted the Constitution, explained the powers of the executive, the senate, and the judiciary, and expounded the theory of judicial review, the power of the Supreme Court to declare legislative acts unconstitutional and thus, void. Although written and published in haste, *The Federalist* was widely read, had a great influence on contemporaries, became one of the classics of political literature, and helped shape American political institutions. In January 1788 Hamilton was reappointed a delegate to the Continental Congress from New York. At New York's ratifying convention in Poughkeepsie, in June, where he was a delegate, he became the chief champion of the Constitution and, against strong antifederalist opposition, won approval for it.

Hamilton's financial program. President Washington launched the new federal government in April 1789 and in September appointed Hamilton the first secretary of the treasury. Congress quickly asked Hamilton to draw up a plan for the "adequate support of the public credit." This was all he needed. Envisaging himself as something of a prime minister in Washington's official family, Hamilton from this point on developed and carried out a bold and masterly program designed to build a strong union, one that would weave his political philosophy into the government. His immediate objectives were to establish the nation's credit at home and abroad and to strengthen the national government at the expense of the states. He outlined his program in four notable reports to Congress. In the first two, *Reports on the Public Credit*, which he submitted on January 14, 1790, and December 13, 1790, he urged the funding of the national debt at full value, the assumption in full by the federal government of debts incurred by the states during the Revolution, and a system of taxation to pay for the assumed debts. His motive was as much political as economic. Through payment by the central government of the states' debts he hoped to bind the men of wealth and influence, who had acquired most of the domestically held bonds, to the national government. But such powerful opposition arose to the funding and assumption scheme that Hamilton was able to push it through Congress only after he had made a bargain with Thomas Jefferson, who was then secretary of state, whereby he gained southern votes in Congress for it in exchange for his own support in locating the future national capital on the banks of the Potomac.

Hamilton's third report, the *Report on a National Bank*, which he submitted on December 14, 1790, advocated a national bank called the Bank of the United States and modelled after the Bank of England. With the bank he wished to solidify the partnership between the government and the business classes who would benefit most from it and further advance his program to strengthen the national government. After Congress passed the bank charter, Hamilton persuaded Washington to sign it into law. He advanced the argument that the Constitution was the source of implied as well as enumerated powers and that through implication the government had the right to charter a national bank as a proper means of regulating the currency. This doctrine of implied powers became the basis for interpreting and expanding the Constitution in later years. In the *Report on Manufactures*, the fourth, the longest, the most complex, and the most farsighted of his reports, submitted on December 5, 1791, he proposed to aid the growth of infant industries through various protective laws. Basic to it was his idea that the general welfare required the encouragement of manufacturers and that the federal government was obligated to direct the economy to that end. In writing his report, Hamilton had leaned heavily on *The Wealth of Nations*, written in 1776 by the Scottish political economist Adam Smith, but he revolted against Smith's laissez-faire idea that the State must keep hands off the economic processes, which meant that it could provide no bounties, tariffs, or other aid. The report had greater appeal to posterity than to Hamilton's contemporaries, for Congress did nothing with it.

Establishment of the Bank of the United States

Establishment of political parties. One of the results of the struggle over Hamilton's program and over issues of foreign policy was the emergence of national political parties. Like Washington, Hamilton had been one of the foremost among the Founding Fathers who had deplored parties, equating them with disorder and instability. He had hoped to establish a government of superior persons who would be above party. Yet he became the leader of the Federalist Party, a political organization in large part dedicated to the support of his policies. Hamilton placed himself at the head of that party because he needed organized political support and strong leadership in the executive branch to get his program through Congress. Washington usually supported Hamilton's policies and in effect became a Federalist. The political organization that challenged the Hamiltonians was the Republican Party created by James Madison, who was at this time a member of the House of Representatives, and Secretary of State Thomas Jefferson. In foreign affairs Hamilton and the Federalists favoured close ties with England, whereas Jefferson and his followers preferred to strengthen the old attachment to France. In attempting to carry out his program, Hamilton frequently interfered in Jefferson's domain of foreign affairs. Detesting the French Revolution and the equalitarian doctrines it spawned, he tried to thwart Jefferson's policies that might aid France or injure England and to induce Washington to follow his own ideas in foreign policy. Hamilton went so far as to warn British officials of Jefferson's attachment to France and to suggest that they bypass the Secretary of State and instead work through himself and the President in matters of foreign policy. This and other parts of Hamilton's program led to a feud with Jefferson from 1791 to 1793 in which the two men attempted to drive each other from the Cabinet. They even used party newspapers to attack each other and the policies each espoused, and each tried to turn Washington against the other.

Feud with Jefferson

When war broke out between France and England in February 1793, Washington asked his Cabinet's advice in formulating American policy toward the conflict. Hamilton wished to use the war as an excuse for jettisoning the French alliance of 1778 and steering the United States closer to England, whereas Jefferson insisted that the alliance was still binding. While not challenging the validity of the alliance, Washington essentially accepted Hamilton's advice and in April issued a proclamation of neutrality that Republicans said favoured England. In that month an emissary from republican France, Edmond-Charles Genet, called Citizen Genet, reached the United States. In trying to advance the cause of his own country he violated American neutrality by arming privateers in U.S. ports. Hamilton in June began a series of articles under the name "Pacificus" in defense of the

neutrality proclamation and in August another series under the title "No Jacobin" that condemned Genet's activities. He also took the lead in demanding Genet's recall, which, despite Jefferson's initial opposition, was accomplished early in 1794.

Jay treaty

At the same time, British violations of American neutrality, such as the seizure of American ships trading with the French West Indies, and other grievances led to strident popular demands for war against Britain, a clamour that Hamilton steadfastly opposed. He believed that war with England would be national suicide, for his program was anchored on trade with Britain and on the import duties that supported his funding system. To save his program, Hamilton persuaded the President to send John Jay to London to negotiate American grievances. Hamilton wrote Jay's instructions, manipulated the negotiations, and helped defend the unpopular treaty Jay brought back in 1795, notably in a series of essays he wrote for the New York newspapers beginning in July 1795 and continuing in 1796 under the signature "Camillus." As Hamilton planned it, the treaty kept the peace and saved his system.

The Republicans in Congress, meantime, had tried to destroy Hamilton. In January 1793 they had demanded a full accounting of treasury operations from the beginning until the end of 1792. Hamilton promptly offered the information. A month later William Branch Giles of Virginia introduced a number of resolutions in the House of Representatives charging Hamilton with dereliction of duty and irregularities in the management of the treasury. Hamilton's friends defended him so well that when the resolutions came to a vote, he was vindicated on every count. In 1794 his program was also challenged from another direction, by farmers in western Pennsylvania, who rose against an excise tax he had been instrumental in placing on distilled liquors, an important source of income for the frontiersmen. He had advanced the tax to raise money and to strengthen the power of the federal government at the expense of the states in an area of taxation that they had considered theirs exclusively. To Hamilton, who urged Washington to use every means to suppress the resistance, the Whiskey Rebellion presented an opportunity he had long desired, a chance for the first time to test the power of the federal government, as opposed to local defiance, by a showdown of arms. Congress authorized the president to call out the militia, and Hamilton in September took a leading part in the expedition sent to chastise the rebels, who melted away before the overwhelming federal force. Hamilton looked upon the suppression as a triumph for law and order that added immeasurably to the prestige of the federal government.

Out of the Cabinet. Lashed by criticism, tired and anxious to repair his private fortune, Hamilton left the Cabinet on January 31, 1795. He did not, however, sever his connection with the government; his influence, as an unofficial adviser, continued as strong as ever. Washington and his Cabinet consulted him on almost all matters of policy. When Washington decided to retire, he turned as usual to Hamilton, asking his opinion as to the best time to publish a farewell to the nation. With his eye on the coming presidential election, Hamilton advised withholding the announcement until a few months before the meeting of the presidential electors. Following that advice, Washington gave his *Farewell Address* to the nation in September 1796. Hamilton drafted most of the address, one of the great documents of American history, and some of his ideas were prominent in it. In the election, Federalist leaders passed over Hamilton's claims and nominated John Adams for the presidency and Thomas Pinckney for the vice presidency. Since Adams did not appear devoted to Hamiltonian principles, Hamilton tried to manipulate the electoral college so as to make Pinckney president. Adams won the election and Hamilton's intrigue succeeded only in sowing distrust within his own party. Nonetheless, Hamilton's influence in the government continued, for Adams retained Washington's Cabinet and its members consulted Hamilton on all matters of policy, gave him confidential information, and in effect urged his policies on the President.

Early in 1797 James T. Callender, a Republican hack, published a *History of the United States for the Year 1796* in which he accused Hamilton of corruption in connection with an affair Hamilton had had six years earlier with an attractive adventuress, Mrs. Maria Reynolds. Hamilton met the attack by writing a pamphlet in which he confessed the "irregular and indelicate amour" and printed the blackmailing letters that the woman's husband, a confidence man, had sent to him, but denied any corrupt dealings with him. Although Hamilton successfully defended his integrity as a public man, he subjected his private life to a bitter humiliation.

In retaliation against Jay's treaty, France meantime had broken relations with the United States. Although he stood for firmness, Hamilton agreed with the president's policy of trying to re-establish friendly relations. After the failure of a peace mission President Adams had sent to Paris in 1798, followed by the publication of certain dispatches insulting to American sovereignty, Hamilton wanted to place the country under arms immediately. He even believed that the French, who had embarked on an undeclared naval war against the United States, might attempt to invade the country. Still eager for military glory, Hamilton sought command of the new army, though Washington would be its titular head. Adams resisted Hamilton's desires, but in September 1798 Washington forced him to make Hamilton second in command of the army, the inspector general, with the rank of major general. Adams never forgave Hamilton for this humiliation. Hamilton wanted to lead his army into Spain's Louisiana and the Floridas and other points south, but never did. Through independent diplomacy, Adams kept the quarrel from spreading into a full-scale conflict and at the order of Congress disbanded the provisional army. With his dream of military glory faded, Hamilton resigned his commission in June 1800. Meantime Adams had purged his cabinet of those he regarded as "Hamilton's spies."

Attempt to command the army

In retaliation, Hamilton tried to prevent Adams' re-election to the presidency. In October 1800 he privately circulated a bitter personal attack on Adams, entitled *The Public Conduct and Character of John Adams, Esq., President of the United States.* Aaron Burr of New York, the Republican candidate for vice president and Hamilton's political enemy, obtained a copy and had it published. Hamilton was then compelled to acknowledge his authorship and to bring his quarrel with Adams into the open, a feud that revealed an irreparable schism in the Federalist Party. Thomas Jefferson and Aaron Burr won the election but because both had received the same number of electoral votes, the choice between them for president was cast into the House of Representatives. Hating Jefferson, the Federalists wanted to throw the election to Burr. Hamilton helped to persuade them to select Jefferson instead. By supporting his old Republican enemy, who won the presidency, Hamilton lost prestige within his own party and virtually ended his public career.

The Burr quarrel. Hamilton then concentrated on his law practice and his family. In 1801 he built a country house on Manhattan Island called The Grange, and helped found a Federalist newspaper, the *New York Evening Post.* Although Hamilton did not write for it under his own name, its policies reflected his ideas. Through the *Post* he hailed the purchase of Louisiana in 1803, even though New England Federalists had opposed it. Some of them talked of secession and in 1804 began to negotiate with Aaron Burr for his support. Almost all the Federalists but Hamilton favoured Burr's candidacy for the governorship of New York in that year. Hamilton urged the election of Burr's Republican opponent, who won by a close margin, but it is doubtful that Hamilton's influence decided the outcome. In any event, Hamilton and Burr had long been enemies, and Hamilton had several times thwarted Burr's ambitions. In June 1804, after the election, Burr demanded satisfaction for remarks Hamilton had allegedly made at a dinner party in April in which he said he held a "despicable opinion" of Burr. Although Hamilton held an aversion to the practice of dueling, as a man of honour he felt himself compelled to accept

Burr's challenge. If he declined, his reputation as a gentleman would be lost, as would whatever political influence he still retained. The two antagonists met early in the morning of July 11 on the heights of Weehawken in New Jersey where Hamilton's eldest son, Philip, a young man of 19, had died in a duel three years before. Burr's bullet found its mark and Hamilton fell. "This is a mortal wound, Doctor," he said and became unconscious. He died the following day. A poor man, Hamilton left his wife and seven children heavily in debt; friends, however, paid off the debts.

Death

Assessment. Hamilton was a small, slender man, about five feet seven inches tall, with a fair complexion, light hair, strong features, and deep-set eyes. He had an erect, dignified bearing, made striking by elegant clothes and fine manners. Some people found him stiff and formal, even vain and arrogant, but friends saw him as witty, warm, benevolent, and loyal. Although a fine orator, he was more persuasive as an essayist. He was both a man of action and of ideas, but all of his ideas involved action and were directed toward some specific goal in statecraft. Unlike Benjamin Franklin or Thomas Jefferson, he did not have a broad inquisitive mind nor was he speculative in his thinking in the philosophical sense of seeking intangible truths. He was ambitious, purposeful, a hard worker, and one of America's administrative geniuses. In foreign policy he was a realist, believing that self-interest should be the nation's polestar; questions of gratitude, benevolence, and moral principle, he held, were irrelevant.

Most of all, Hamilton was one of America's first great nationalists. He believed in an indivisible nation where the people would give their loyalty not to any state but to the nation. Although a conservative, he did not fear change or experimentation. The conservatism that led him to denounce democracy as hostile to liberty stemmed from his fear that democracy tended to invade the rights of property, which he held sacred. His concern for property was a means to an end. He wished to make private property sacred because upon it he planned to build a strong central government, one capable of suppressing internal disorders and assuring tranquillity. His economic, political, military, and diplomatic schemes were all directed toward making the Union strong. Hamilton's most enduring monument was the Union, for much of it rested on his ideas.

BIBLIOGRAPHY. The most satisfactory complete biography, particularly strong on Hamilton's public career, is JOHN C. MILLER, *Alexander Hamilton: Portrait in Paradox* (1959). The most scholarly, but uncompleted, study is BROADUS MITCHELL, *Alexander Hamilton*, 2 vol. (1957–62). NATHAN SCHACHNER, *Alexander Hamilton* (1946), is a short, well-balanced, and readable study; even briefer is STUART G. BROWN, *Alexander Hamilton* (1967). For Hamilton's economic and political ideas, see LOUIS M. HACKER, *Alexander Hamilton in the American Tradition* (1957); CLINTON L. ROSSITER, *Alexander Hamilton and the Constitution* (1964); and GERALD STOURZH, *Alexander Hamilton and the Idea of Republican Government* (1970). BROADUS MITCHELL, *Alexander Hamilton: The Revolutionary Years* (1970), covers the military career. Three books analyze Hamilton's influence in shaping the foundations of foreign policy: JULIAN P. BOYD, *Number 7: Alexander Hamilton's Secret Attempts to Control American Foreign Policy* (1964); HELENE J. LOOZE, *Alexander Hamilton and the British Orientation of American Foreign Policy, 1783–1803* (1969); and GILBERT L. LYCAN, *Alexander Hamilton and American Foreign Policy: A Design for Greatness* (1970). Publication of a multivolume work designed to be definitive, *The Papers of Alexander Hamilton*, ed. by H.C. SYRETT and J.E. COOKE, began in 1961. The following are biographical accounts of varying quality: DAVID G. LOTH, *Alexander Hamilton: Portrait of a Prodigy* (1939); HENRY JONES FORD, *Alexander Hamilton* (1920); ALLAN M. HAMILTON, *The Intimate Life of Alexander Hamilton* (1910); FREDERICK S. OLIVER, *Alexander Hamilton: An Essay on American Union* (1906); WILLIAM GRAHAM SUMNER, *Alexander Hamilton* (1890); HENRY CABOT LODGE, *Alexander Hamilton* (1882, many later editions); JOHN T. MORSE, JR., *The Life of Alexander Hamilton*, 2 vol. (1876); and the works of Hamilton's son, JOHN C. HAMILTON, *The Life of Alexander Hamilton*, 2 vol. (1840–41), an unfinished biography that goes only to 1787; and his valuable but uncritical *History of the Republic of the United States of America, As Traced in the Writings of Alexander Hamilton and of His Contemporaries*, 3rd ed., 7 vol. (1868).

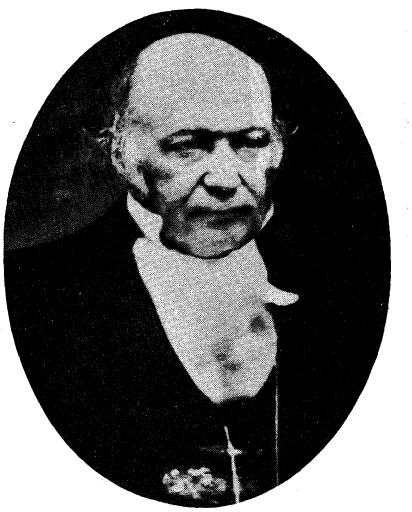
Hamilton, Sir William Rowan

William Rowan Hamilton, who excelled in modern languages and the classics, brought honour to his native Ireland with his achievements in mathematics. His unification of dynamics and optics have had a lasting influence on mathematical physics, even though the full significance of his work was not fully appreciated until after the rise of quantum mechanics. He also contributed to the development of modern algebra.



William Rowan Hamilton, 1862.
By courtesy of the Royal Irish Academy, Dublin

Early life. Hamilton was born at midnight, August 3/4, 1805, in Dublin, Ireland. Like his English contemporaries Thomas Babington Macaulay and John Stuart Mill, he showed unusual intellect as a child. Before the age of three his parents sent him to live with his father's brother, James, a learned clergyman and schoolmaster at a Church of England school at Trim, a small town near Dublin, where he remained until 1823, when he entered Trinity College, Dublin. Within a few months of his arrival at his uncle's he could read English easily and was advanced in arithmetic; at five he could translate Latin, Greek, and Hebrew and recite Homer, Milton, and Dryden. Before his 12th birthday he had compiled a grammar of Syriac, and by the age of 14 he had sufficient mastery of the Persian language to compose a welcome to the Persian ambassador on his visit to Dublin.

Hamilton became interested in mathematics after a meeting in 1820 with Zerah Colburn, an American who could calculate mentally with astonishing speed. Having read the *Eléments d'algèbre* of Alexis-Claude Clairaut and Isaac Newton's *Principia*, Hamilton had immersed himself in the five volumes of Pierre-Simon Laplace's *Traité de mécanique céleste* (1798–1827; *Celestial Mechanics*, 1966) by the time he was 16. His detection of a flaw in Laplace's reasoning brought him to the attention of John Brinkley, professor of astronomy at Trinity College. When Hamilton was 17, he sent Brinkley, then president of the Royal Irish Academy, an original memoir about geometrical optics. Brinkley, in forwarding the memoir to the Academy, is said to have remarked: "This young man, I do not say *will be*, but *is*, the first mathematician of his age."

College and early career. In 1823 Hamilton entered Trinity College, from which he obtained the highest honours in both classics and mathematics. Meanwhile, he continued his research in optics and in April 1827 submitted his "Theory of Systems of Rays" to the Academy. The paper transformed geometrical optics into a new mathematical science by establishing one uniform method for the solution of all problems in that field. Hamilton started from the principle, originated by the 17th-century

French mathematician Pierre de Fermat, that light takes the shortest possible time in going from one point to another, whether the path is straight or is bent by refraction. Hamilton's key idea was to consider the time (or a related quantity called the "action") as a function of the end points between which the light passes and to show that this quantity varied when the coordinates of the end points varied, according to a law that he called the law of varying action. He showed that the entire theory of systems of rays is reducible to the study of this characteristic function.

Rapid rise to prominence

Shortly after Hamilton submitted his paper and while still an undergraduate, Trinity College elected him to the post of Andrews Professor of Astronomy and Royal Astronomer of Ireland, to succeed Brinkley who had been made a bishop. Thus an undergraduate (not quite 22 years old) became ex officio an examiner of graduates who were candidates for the Bishop Law Prize in mathematics. The electors' object was to provide Hamilton with a research post free from heavy teaching duties. Accordingly, in October 1827 Hamilton took up residence next to Dunsink Observatory, five miles (eight kilometres) from Dublin, where he lived for the rest of his life. He proved to be an unsuccessful observer, but large audiences were attracted by the distinctly literary flavour of his lectures on astronomy. Throughout his life Hamilton was attracted to literature and considered the poet Wordsworth among his friends, although Wordsworth advised him to write mathematics rather than poetry.

Domestic life and honours. Six years after his move to Dunsink, Hamilton married Maria Bayley, daughter of a former rector in County Tipperary, who bore him two sons and a daughter. But his wife was less successful at running the household; as a result, Hamilton never had regular meals and came to rely excessively on alcohol. He would usually work all day in the dining room, and the cook would bring him a mutton chop from time to time. After his death scores of bones were found on plates sandwiched among his papers.

In 1835 Hamilton was the chief local organizer of the British Association for the Advancement of Science meeting in Dublin and at the closing dinner was knighted by the Lord Lieutenant. Two years later he became president of the Royal Irish Academy. In 1843 he was awarded a Civic List life pension of £200 a year by the British government.

During Hamilton's last illness, an attack of gout, he received with great satisfaction the news that his name had been placed at the head of the first list of Foreign Associates elected by the newly formed National Academy of the United States. He died on September 2, 1865, after months of suffering.

Life work and significance. In 1832 a supplement to Hamilton's theory of rays was published. In it he predicted that, as a result of the theory, a wholly unexpected phenomenon would be found in connection with the refraction of light in biaxial crystals, which produce interference figures consisting of two sets of concentric rings when light passes through them. It had been known for some time that certain crystals of this kind, such as topaz, give rise to two refracted rays for each incident ray. The theory of this double refraction had been worked out a few years earlier by Augustin Fresnel. Hamilton found by his general method that under certain conditions a single ray of incident light could actually produce an infinite number of refracted rays in a biaxial crystal and that they would form a cone. Hamilton's prediction of conical refraction, regarded in his lifetime as his most brilliant achievement in optics, was confirmed experimentally within two months by a colleague, Humphrey Lloyd.

Today his unification of optics and dynamics is regarded as far more important than his work on conical refraction. In 1835 his memoir, "On a General Method in Dynamics," was published. In it he applied his idea of the characteristic function to the motion of systems of bodies and expressed the equations of motion in a form that revealed the duality between the components of momentum of a dynamical system and the coordinates determining its position. Although Hamilton's canonical equations expressing this duality and his principle that reduces the whole of dynamics to a problem in the calculus of variations, have long been familiar to students of dynamics, the deep significance of the duality he discovered was not appreciated for nearly 100 years, until the rise of quantum mechanics.

"General Method in Dynamics"

Discovery of quaternions

In the same year Hamilton made his famous discovery of quaternions; these ordered sets of four ordinary numbers, satisfying special laws of equality, addition, and multiplication, are useful for studying quantities having magnitude and direction in three-dimensional space. This discovery was a landmark, since it freed algebra from the commutative postulate of multiplication—that the order or sequence of factors does not determine the result. His investigations in algebra had begun ten years before with a pioneer paper on algebraic couples of numbers in which the basic entity was not a single number but ordered pairs of numbers. Hamilton used this idea to develop a rigorous theory of complex numbers, involving the square root of -1. This paper was remarkable as a pioneer attempt to put algebra on an axiomatic basis like geometry. The geometry of complex numbers (*i.e.*, numbers of the form $a + bi$, in which i is the square root of -1) is that of the two-dimensional vectors in a plane. In attempting to develop an analogous technique for three-dimensional space, Hamilton was delayed for many years by a fundamental difficulty that could not be resolved so long as he restricted his attention to *triplets*. Suddenly, on October 16, 1843, the solution flashed into his mind as he was walking to Dublin along the Royal Canal: geometrical operations in three-dimensional space require not triplets but *quadruplets*. The reason is that, whereas the algebraic couple suffices in the plane because it is equivalent to a multiplier and an angle, in three dimensions the orientation of the plane itself is variable, and this gives rise to two more numbers. Hamilton was so excited by his discovery that as he passed Brougham Bridge he cut the fundamental formulas of quaternions on the stonework: $i^2 = j^2 = k^2 = ijk = -1$.

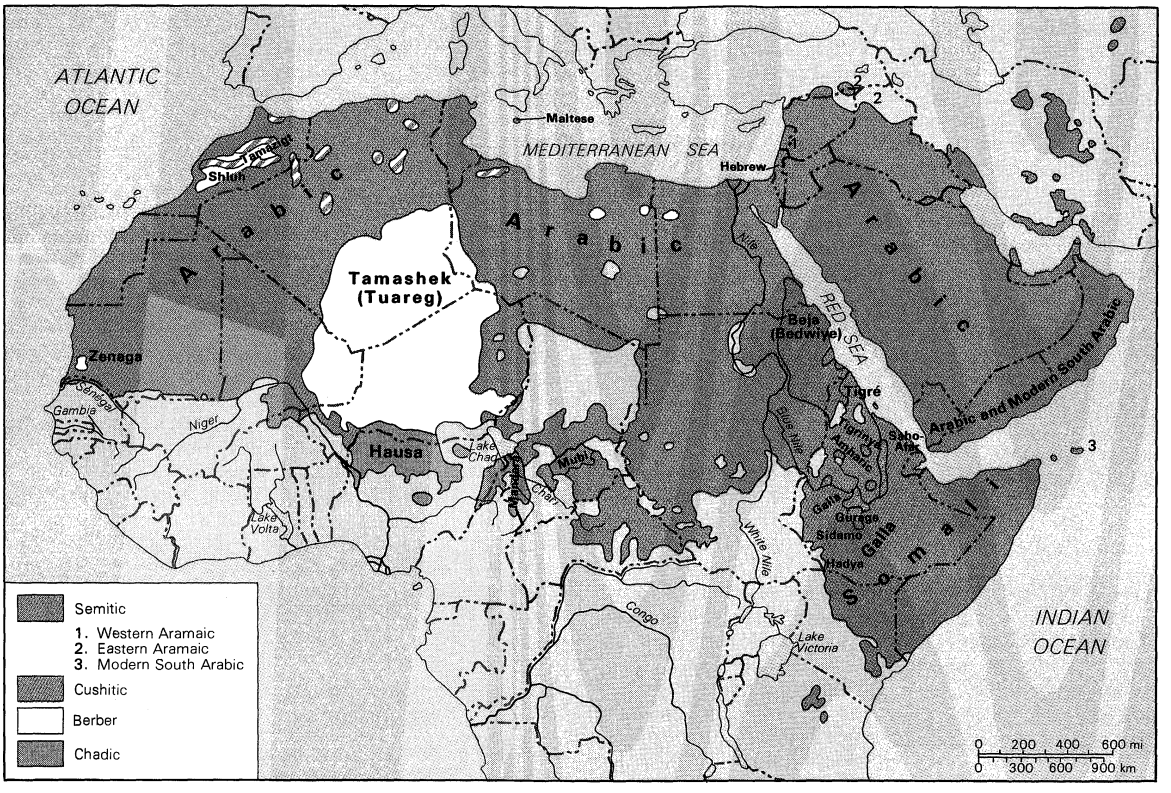
Hamilton's discovery was a break with tradition because it involved the surrender of the commutative law of multiplication—that b times a is the same as a times b. The remaining 22 years of his life were devoted to developing the algebra of quaternions and its applications. Following his death in Dublin on September 2, 1865, this work was published posthumously in 1866 as *The Elements of Quaternions*. Unfortunately, Hamilton believed that quaternions were ideally suited for the solution of problems in applied mathematics, but it was the simplified version of J. Willard Gibbs, known as vector analysis, that was eventually adopted by mathematical physicists. The value of Hamilton's discovery lay rather in pure mathematics, through its effect on the development of modern abstract algebra.

BIBLIOGRAPHY. A full-scale Victorian style biography, containing Hamilton's poems, correspondence, and miscellaneous writings is R.P. GRAVES, *Life of Sir William Rowan Hamilton*, 3 vol. (1882–89). *The Mathematical Papers of Sir William Rowan Hamilton* have been published in 3 volumes: vol. 1, *Geometrical Optics*, ed. by A.W. CONWAY and A.J. MCCONNELL (1931); vol. 2, *Dynamics*, ed. by A.W. CONWAY and J.L. SYNGE (1940); and vol. 3, *Algebra*, ed. by H. HALBERSTAM and R.E. INGRAM (1967). There are useful introductions by the editors in vol. 1 and vol. 3 and all three volumes have been beautifully produced.

(G.J.W.)

Hamito-Semitic Languages

The Hamito-Semitic languages, a family of genetically related languages, developed from a common parent language that presumably existed about the 6th–8th millennia BC and was perhaps located in the present-day Sahara. Also known as the Semito-Hamitic, Erythraean, Afro-Asiatic, and Afrasian language group, it is the main language family of northern Africa and southwestern Asia and includes such languages as Arabic, Hebrew, Amharic, and Hausa. The total number of speakers is estimated to be about 175,000,000.



Distribution of the modern Hamito-Semitic languages.

The term Hamito-Semitic, or Semito-Hamitic, was introduced by a German Egyptologist, Karl Richard Lepsius, in the 1860s. Although it has become traditional, it is an unfortunate label in suggesting that the family is divided into a group of Semitic and a group of Hamitic languages; in fact, the family has at least four other branches of the same order as the Semitic languages. The term Erythraean is inappropriate in implying that the family originated on both shores of the Red Sea, an assumption that cannot be proved; and Afro-Asiatic (proposed by a U.S. linguist, Joseph Greenberg, in 1950) may be too comprehensive insofar as it suggests that all the languages of Africa and Asia are included. Igor Diakonoff, a Soviet linguist, has suggested the term Afrasian, meaning "half African, half Asiatic," which corresponds to the area of the actual distribution of the languages of this family since at least the 5th millennium BC.

The five branches of Hamito-Semitic

The languages belonging to the Hamito-Semitic family can apparently be subdivided into branches representing dialects of the original parent language—namely, Semitic, Egyptian, Berber, Cushitic, and Chadic. Some linguists deny the genetic affinity of the Chadic languages with the other branches of Hamito-Semitic, while others (*e.g.*, Joseph Greenberg) accept it. Certain scholars have expressed doubts concerning the Hamito-Semitic character of some of the Chadic languages but not of others. Among the linguists who classify the Chadic languages as Hamito-Semitic there is some hesitation as to the degree and character of their affinity with the languages of the Cushitic branch, especially with West Cushitic. On the basis of the low percentage of vocabulary items held in common between the West Cushitic languages and the other Cushitic languages, some scholars classify West Cushitic as a separate branch of Hamito-Semitic, called Omotic. There is, however, a probability that the parent language common to Omotic and the Cushitic languages proper is not the Common Hamito-Semitic protolanguage but a later dialect (namely, Common Cushitic) and that Omotic (West Cushitic) is thus, nevertheless, a subgroup of Cushitic. Others connect Omotic with the Chadic group.

Some linguists have suggested that the Hamito-Semitic languages are related to the Indo-European languages; others have favoured the existence of a superfamily, including the Hamito-Semitic, Indo-European, Altaic, Finno-Ugric (Uralic), Kartvelian, and Dravidian languages; but most scholars regard such far-flung genetic ties as unproven and, indeed, hardly provable.

Because there has been a considerable difference of opinion as to the criteria to be applied when identifying a language as Hamito-Semitic, the basic principles of linguistic classification as applicable in this case should be stated. The only real criterion for classifying certain languages together as a family is the common origin of their most ancient vocabulary as well as of the word elements used to express grammatical relations. A common source language is revealed by a comparison of words expressing notions common to all human cultures (and therefore not as a rule likely to be borrowed from a group speaking another language) and also by a comparison of the inflectional forms (for tense, voice, case, or whatever). If, as a result of a step-by-step reconstruction of forms having existed at earlier periods, scholars arrive at an identical original phonological structure for each of the words or word elements compared in several different known languages, then such original forms can be ascribed to a common language, which, in the case of the languages here discussed, is conventionally termed Common Hamito-Semitic (or Proto-Hamito-Semitic). It also stands to reason that wherever one parent language has existed the daughter languages must to some degree reflect some of its grammatical characteristics.

Reconstruction of Common Hamito-Semitic

Despite the work of several scholars, only an approximate, provisional reconstruction of the parent language forms of Hamito-Semitic has so far been made. More has been done in comparing the language typologies.

COMMON HAMITO-SEMITIC CHARACTERISTICS

Certain typological features seem to have been common to all Hamito-Semitic languages at an early stage of their development. Among the phonological features are (1) a six-vowel system (*a, i, u, ā, ī, ū*—that is, short and long *a, i, u*), perhaps developed from an earlier two-vowel system (of **a*, and **ə* [pronounced as the *a* in "sofa"]; an asterisk before a sound or a word-form indicates that it is not attested but is reconstructed hypothetically); (2) pharyngeal fricative consonants, indicated by the symbols ʿ (voiced) and *ḥ* (voiceless) and produced in the

region of the pharynx; (3) the functioning of the glottal stop (articulated by closing the glottis, the space between the vocal cords) as a separate distinctive sound (phoneme)—this is conventionally indicated by ʾ; (4) the use of the semivowels *u̯* (*w*) and *i̯* (*y*) in the structural role of consonants; and (5) three types of consonants: voiceless, voiced, and "emphatic," the last type being phonetically realized either as voiceless consonants combined with a glottal stop, as pharyngealized voiceless or voiced consonants, or as consonants in which the air is drawn into the mouth (injective [preglottalized], or implosive), consonants in which the tongue is retracted from the usual position (velarized), or in which the tongue tip is curled upward toward the hard palate (retroflex or cerebral).

Common morphological features include (1) word bases for verbs and for nouns derived from verbs consisting of two elements that interweave with one another, a "root" consisting of consonants, and a "scheme" consisting of vowels (for examples see below); (2) a predominance of word roots consisting of three consonants over roots of two consonants; (3) a strongly developed system of infixation—*i.e.*, the insertion of elements within the root of a word to show grammatical changes and form new words with related meaning; and (4) a comparatively poorly developed system of prefixes and suffixes.

Morphological similarities among the languages

In the area of morphological typology, there are numerous similarities among the Hamito-Semitic languages, such as a system of declension of the noun and pronoun with at least three cases (nominative, genitive, accusative, with traces of a still earlier system including only the agentive [ergative], and unmarked [zero] cases, or agentive, genitive, and unmarked). There are three numbers in the noun, pronoun, and verb—singular, dual, and plural. An event considered from the point of view of the resulting state, as opposed to the point of view of the action itself, is expressed by a special predicative (zero) form of the noun that later developed into a new verbal "tense." In addition, there is a well-developed binary system of verbal aspects, indicating the mode of an action (*i.e.*, punctual contrasts with durative, or perfective [completed action] contrasts with imperfective [ongoing action]), but tenses and voices of the verb remained undeveloped until the later stages. Pronominal possession markers and object markers in the form of suffixes are another common Hamito-Semitic feature, as are the prefixing of certain actor markers to the verb and a two-gender system in the noun, pronoun, and verb, perhaps developed from a still earlier system of many genders. In syntax, the Hamito-Semitic languages show certain favoured types of attributive constructions, among other common characteristics.

The above inherited Hamito-Semitic characteristics are listed, for each linguistic level, in the approximate reverse order of their stability. Languages retaining all or most of these features can be classified as belonging to the Ancient Stage of Hamito-Semitic; those that retain no less than two-thirds of the ancient consonantal system and about one-half to two-thirds of the above-listed other features belong to the Middle Stage; those that have lost more than half of these characteristics belong to the New Stage. At the New Stage, however, there are usually enough of these features still preserved to identify the language as belonging to the Hamito-Semitic family, and most of the other features can, as a rule, be reliably reconstructed for one of the former stages of its development. Moreover, the original form of the word elements that express the typical Hamito-Semitic grammatical features is usually apparent in all languages of the family. All modern Hamito-Semitic languages except Literary Arabic and Hebrew belong to the New Stage.

The character of the relationship between the five branches of the Hamito-Semitic family—Semitic, Egyptian, Berber, Cushitic, and Chadic—can best be seen by comparing their systems of verbs and pronouns. There are several types of verbal systems in Hamito-Semitic, but all of them (with the exception of the Egyptian, which has developed in a quite different direction) can apparently be traced back to one single system. In this system the action (including intransitive action) is expressed by a verbal form proper, with a prefixed actor marker (singular: 1st person **'a-*, 2nd **ta-*, 3rd **ya-*) probably deriving from a separate personal pronoun in an oblique case; the state is expressed by a form of a noun used as a predicate, plus a personal pronoun in the direct case (this is called ṣtative). Hamito-Semitic apparently developed from a protolanguage with an ergative type of sentence construction (in which there is a special case denoting the agent of an action but no marker for the subject of a state and the direct object of an action) to a language of the nominative type (in which the subject both of an action and a state is always in the nominative case and the direct object is in the accusative case). At the same time, the predicate of state (the so-called stative) either developed into a perfective aspect (marking completion of the action of the verb) or a past tense of the verb, or it disappeared altogether. There are, however, enough traces of its existence in all branches of the family (*e.g.*, in Egyptian, in Kabyle of the Berber branch, in Sidamo of the Cushitic branch, in Mubi of the Chadic branch, and in all Semitic languages) to see that the form goes back to the parent language.

Hamito-Semitic verbal systems

As for the verbal forms that express action and have a prefixed actor marker, there is some discrepancy of opinion. Some scholars posit for the parent language only one form. It may be, however, that there were two forms for the transitive, a perfective and an imperfective type, and possibly only one form for the intransitive type.

In several languages of the New Stage, new verbal types have developed for all aspects and tenses, particularly in the languages of the Cushitic branch (the Northern, Eastern, and Central groups, in part; and the Southern and Western [Omotic] group, always), the Chadic branch (in most languages), and the Semitic branch (typically in Neo-Syriac). These verbal forms consisted originally of a noun (for the most part, derived from a verb) plus an auxiliary verb with a prefixed actor marker. Everywhere, as a rule, the perfective aspect (or the past tense) is formed from bases of the auxiliary verb with a reduced vowel scheme in the verbal base, while the imperfective aspect (or the present/future tense) is formed from bases with a full vowel scheme (*cf.* the Akkadian perfective form **yaprus* "he divided," with a reduced vowel scheme, and the imperfective form **yaparras* "he divides," with a full vowel scheme). (There are also forms based on the participle of the auxiliary verb; *e.g.*, Neo-Syriac *biktäv-övin* "I am writing" from **bi-ktābā-hāwē-ʾānā* "in-write-being-I.")

In that the Central Semitic verbal system (which has the imperfective with a reduced vowel scheme, as in Arabic, Hebrew, and Aramaic) is restricted to only two groups of languages inside only one branch of the entire family, it is improbable that it is this verbal system that is descended from the parent language.

Stem modification

A typical feature of the Hamito-Semitic verbal system is the existence of so-called stem modifications—*i.e.*, groups of systematically related verbal stems deriving from a single root, each having its own type of semantics —that variously characterizes the action or state from the point of view of its quality, quantity, frequency, causal relations, direction, and so on. In Hebrew, for example, *šāḇar* "he broke," *šibbēr* "he broke to pieces," *hišbīr* "he let (him) break out," and *nišbar* "he was broken, destroyed, stranded" all are from the root *šbr*.

The pronominal systems in the different branches of Hamito-Semitic are more or less alike. Some pronouns are virtually identical everywhere; *e.g.*, the possessive pronouns (2nd person masculine—"your": Semitic **-ka*, Egyptian *-k*, Berber *-k*, reconstructed Cushitic *-ka* or **-k^{w}a*, Chadic [Hausa] *-ka*). Suffixed pronouns expressing the object of the verb are very similar to the possessive.

Linguistic substrata

The diverging of the branches and the individual languages of the Hamito-Semitic family from the common ancestral language, although mainly explained by the internal development of the languages after loss of contact, also results to a great extent from the influence of different linguistic substrata. Thus, the ancient Hamito-Semitic language had in many cases probably spread to originally alien populations. This view is supported by

Table 1: Common Hamito-Semitic Vocabulary Items

	Semitic	Egyptian	Berber	Cushitic	Chadic
"bone"	*qōṣ* ("thorn," Hebrew)	*qs*	*i-ghəs*	**m-kkac*	**kasi* (Hausa)

the different racial types of the speakers. In some cases the substratum language (*i.e.*, that of the original population) can be identified—*e.g.*, Sumerian, Hurrian, and others for North Semitic; Nilo-Saharan and East Sudanese for Cushitic; East Sudanese and possibly some others for Chadic. The least substratum influence seems to have been experienced by the Berber branch.

SEMITIC LANGUAGES

Languages of the group. The Semitic languages can be subdivided into four groups: the Northern Peripheral, the Northern Central, the Southern Central, and the Southern Peripheral.

Northern Peripheral Semitic. The Northern Peripheral group, from the Ancient to Middle Stage, includes Akkadian with its dialects of Babylonian and Assyrian, spoken in Mesopotamia from about 3200 BC to the beginning of the Christian Era. Typical features are stative verb forms conjugated with suffixes and two verbal forms with a prefixed actor marker for the imperfective and perfective (with full and reduced vowel schemes, respectively; later a new "perfect" with an infixed *-ta-* in the stem developed). Originally there were five cases of the noun, plus an unmarked form for the nominal predicate and the noun without grammatical relations. Later three cases remained but were lost in the 1st millennium BC. Loss of the *gh*, *ḥ*, *ʿ*, and *h* sounds occurred from *c.* 2000 BC. The vowels were *a, e, i, u* (both long and short).

Northern Central Semitic. The Northern Central Semitic group includes the Canaanite, Ugaritic, and Amorite languages of the Ancient Stage, which were spoken in Palestine, Phoenicia, Syria, and Mesopotamia from the 3rd to the 2nd millennium BC. To the Middle Stage belongs Phoenician-Punic, spoken in Phoenicia, on islands of the Mediterranean, and in North Africa, from the 2nd millennium BC to the 1st millennium AD. Also to the Middle Stage belong Hebrew, Moabite, Ya'ūdī, and Old Aramaic. Hebrew, originally spoken in Palestine from the 13th century BC to the 2nd century AD, later spread all over the world as a written language. At present there are about 3,000,000 Hebrew speakers in Israel. Moabite and its kindred dialects in the Transjordan were alive in the 1st millennium BC but are now extinct. Ya'ūdī, spoken in northern Syria in the 9th century BC, is also extinct. Old Aramaic, from Syria and Mesopotamia, existed from the 14th century BC(?) through the 15th century AD. Its oldest written texts date from the 9th century BC. The dialects of Aramaic include Ancient Aramaic proper; Imperial Aramaic (the official language of Assyria and Achaemenid Persia, including also Biblical Aramaic, or Chaldean); Western Aramaic, with Palmyrenean, Nabataean, Palestinian, Galilean, and other varieties; Eastern Aramaic, including Syriac (Edessan, with subdialects), Babylonian Talmudic, and Mandaic. Most Aramaic dialects gave way to Arabic beginning with the 7th century AD. Aramaic dialects

The New Stage of Northern Central Semitic is represented by New West Aramaic, or Maʿlūla, in Syria, with a small number of speakers, and Neo-Syriac, or "Assyrian," in Iraq (al-Mawṣil), Turkey (Ṭūr-ʿAbdīn), Iran (Urmia), the Soviet Union, and the United States, with up to 1,000,000 speakers.

Typical features of the Northern Central Semitic group are the perfective aspect with suffix conjugation and the imperfective aspect with prefix conjugation and stems with a reduced vowel scheme. (An entirely new verbal system developed in Neo-Aramaic.) The group is also characterized by the article *ha-* (prefixed, in Hebrew and Punic) or *-ā* (suffixed, in Aramaic). The system of declension was lost from the Middle Stage on. In this group the number of vowel qualities increased beyond just *a, i, u*, while the number of consonants diminished considerably from the Middle Stage on. The sounds *p, t, k, b, d, g* became aspirated after vowels—*i.e.*, pronounced with an accompanying puff of breath (and are now pronounced as *f, t* or *s, kh, v, d, g* in Modern Hebrew).

Southern Central Semitic. The Southern Central group includes Classical, or Literary, Arabic belonging to the Ancient and Middle stages. Originally spoken in Arabia, Classical, or Literary, Arabic is now found from the Indian to the Atlantic Ocean and has been attested from the 5th century BC to the present time. From the New Stage come the modern Arabic dialects, some of them mutually unintelligible. They have about 100,000,000 speakers all over northern Africa, on the Arabian Peninsula, in Jordan, Palestine, Lebanon, Syria, and Iraq, and in some districts of Turkey, Iran, and the Soviet Union. Maltese, on the island of Malta, has developed into a separate language, spoken by about 300,000. A typical feature of the group is a verbal system that is very similar to that of the Northern Central group (with minor differences) but that developed tenses instead of aspects from the late Middle Stage (*e.g.*, in the Egyptian dialect, from prepositional constructions). There were three cases of the noun, but declension was lost at the late Middle and New Stage. Also characteristic of South Central Semitic are the article *al-* and a strongly developed system of internal inflection with the plural mostly of the *pluralis fractus* type ("broken plural," in which plurality is shown by means of internal vowel changes). The Proto-Semitic phonological system has been on the whole well preserved, but **š* has become *s*, **ṯh* has become *z*, and other similar changes.

Southern Peripheral Semitic. To the Southern Peripheral group of the Ancient to Middle Stage belong the South Arabic dialects, Sabaean (*cf.* Sheba), Minaean, Qatabānian, and Ḥaḍramawtian, spoken from the 1st millennium BC to the 1st millennium AD. The Middle Stage is represented by Geʿez (Geez or Gəʿəz), or Ethiopic, found in northern Ethiopia in the 1st millennium AD; and the New Stage by the South Arabic group, including Mahrī, Shaḥrī (Eḥkalī), Ḥarsūsī, and Baṭḥarī on the Arabian shore of the Indian Ocean, and Suquṭrī (possibly a dialect of Mahrī) on the island of Socotra, with the total number of speakers probably being around 50,000. Also of the New Stage is the Ethiopic group, consisting of three subgroups: North Ethiopic, Central Ethiopic, and the Gurage subgroup. North Ethiopic, nearest to Geʿez, includes Tigrinya (Tigrai) and Tigré, spoken in northern Ethiopia and Eritrea by 3,700,000 speakers. Within the Central Ethiopic group (7,800,000 speakers) are Amharic, the official language of Ethiopia, the near-extinct Argobba language, and the entirely extinct Gafat. Ethiopic group of languages

The Gurage cluster of languages is found south and east of Addis Ababa and has 550,000 speakers. In all, there are somewhat more than 12,000,000 speakers of Southern Peripheral Semitic languages.

Typical features of the group include traces of two types of verbal forms with prefixed actor marker (one type with full vowels and the other with reduced vowel schemes). In other respects the verbal system is as in South and North Central Semitic; considerable innovations, however, have developed at the New Stage, especially in the Ethiopic group (with a Cushitic substratum). Declension was lost from the Middle Stage. Phonetic development is as in Arabic, but more of the ancient consonants were lost. The Ethiopic group has lost most of the pharyngeal and laryngeal consonants.

Historical and cultural background. Glottochronological methods, which attempt to measure degrees of differences between related languages by comparing a list of basic vocabulary items, indicate that the first group to separate from the Common Semitic ancestral language was Akkadian (Northern Peripheral group, *c.* 3300 BC) and the second was the Southern Peripheral group (second half of 3rd millennium BC). The Northern Central group had contacts for a long time with the Southern Central languages, and linguistic division within the North Central group is dated at the beginning or middle of the 2nd millennium BC. The relative position of Arabic to the other Semitic languages is not quite clear, probably because of its uninterrupted contacts with Aramaic and other nomadic Semitic groups for many centuries.

The oldest of the attested Semitic languages, Akkadian, was the vehicle of a great ancient literature written in a logosyllabic cuneiform writing system of Sumerian origin. Records of other ancient Semitic languages exist in various forms. Amorite, another ancient Semitic language, is known from glosses and proper names; Ugaritic was written in a quasi-alphabetic cuneiform script unconnected with the Akkadian. The Canaanites of Phoenicia used a still undeciphered syllabic script, the Proto-Byblian, in the 2nd millennium BC, while those of Palestine and the Sinai Peninsula employed another undeciphered writing, the Sinaitic script, which may be alphabetic in nature. All the other Semites used and, for the most part, still use consonantal quasi-alphabets with no means or only imperfect means to distinguish the vowels. All such alphabets—of which the more important are the Hebrew, the Syriac, and the Arabic—are descended from the Phoenician linear quasi-alphabet of 22 signs,

*Final forms in parentheses. †Hebrew has a "ciphered" numeral system in which the letters of the alphabet have numerical value and are used as numbers. For example, numbers 11 through 19 are written with the letter *yod* (10) plus the letter for 1, 2, etc. (except 15 which is written *ṭet* [9] plus *waw* [6], and 16 which is written *ṭet* [9] plus *zayin* [7]); the 20s are combinations of *kaf* (20) plus the letter for 1, 2, etc; 500 is written *taw* (400) plus *qof* (100). ‡Functions as both a consonant and a vowel. See *ḥolam male* and *shuruq* in "vowel signs" table above. §Functions as both a consonant and a vowel. See *tzere male* and *ḥiriq male* in "vowel signs" table above. ‖In formal pronunciation, pronounced as a pharyngeal voiced fricative sound. ¶The long horizontal line represents the consonant; vowel signs are placed above, below, or to the left of it, as shown. ♀In Ashkenazi pronounced as in "ball." *Note:* In transliteration, a letter is usually doubled to indicate a strong *dagesh* (*dagesh* is indicated in Hebrew by a point in the middle of a letter). *Pattaḥ* under final *he*, *ḥet*, and *ʿayin* is pronounced before the consonant under which it is written.

first attested at Byblos and externally similar to the Proto-Byblian script. (All the European alphabets are descendants of the Phoenician, and all the Asiatic alphabets are descendants of the Aramaic variants of the Phoenician.) From a South Arabic variant of the earliest Semitic alphabet the Ethiopians developed a syllabic writing still in use for the languages of Ethiopia. Maltese uses the Latin alphabet.

Two of the later Semitic languages, Hebrew and Arabic, have been the languages of great religions, Judaism and Islām. The religious significance of Hebrew explains why the language, although already partly replaced by an Aramaic vernacular in the everyday life of Palestine in the late 1st millennium BC and early 1st millennium AD, was still preserved as a literary language by the Jews who were expelled from Palestine by the Hellenistic kings and the Romans between the 3rd century BC and the 2nd century AD. It has been revived in a modernized form as a spoken and written language in Israel. Classical Arabic has been preserved as a literary language since the Arabic conquest of North Africa and the Near and Middle East in the 7th and 8th centuries AD. The language was used for literary purposes by Muslims of different nations all through the Middle Ages and is still used as a language of the school and the administration and as the spoken language of the educated in all Arabic countries, although the vernacular New Stage Arabic idioms are to a great extent mutually unintelligible. There is a great amount of literature—scholarly, religious, scientific, and fiction—both in Hebrew and in Arabic. Of the other Semitic languages, Syriac was and is the language of certain Eastern Christian sects and was the means by which the Greek tradition was passed on to the Arabs. Another Christian sect, that of the Monophysites of Ethiopia, used Geʿez (Ethiopic) and still retains it in ecclesiastical use, but the literary and other secular remains are less important.

Linguistic characteristics. The Semitic branch of this language family is characterized by several general features.

Common Semitic sounds

Phonology. In phonology, the emphatic stop consonants *ṭ* and *q* (from **ḳ*) were retained but not **ṗ*. The affricates of the parent language (which are begun as stops and released as fricative sounds), if they ever existed, were lost or replaced by sibilant and interdental sounds (which scholars symbolize as *s*, *ṣ*, *z*; *th*, *ṯh*, *dh*); the lateral sounds and the interdentals were subsequently lost in most languages. The labialized velar sounds (except in the Ethiopic group) and all postvelar stops were lost. As for the glottal, pharyngeal, and laryngeal consonants, six of them (*g̱h*, *k̲h*, *ʿ*, *ḥ*, *ʾ*, *h*) are retained in Arabic and were retained in the other Semitic languages at the Ancient Stage. Hebrew and Aramaic retain *ʿ*, *ḥ*, *ʾ*, and *h* (but only *k̲h* and *h* in Modern Hebrew and in most New Aramaic dialects); later Ethiopic and Punic retained only *ʾ* and *h*, and Akkadian only *k̲h* and *ʾ* (but *a* became *e* in words that formerly included *g̱h*, *ʿ*, or *ḥ*). The original six-vowel system changed everywhere as early as the Middle Stage; Arabic preserved it the longest.

Word formation. Word formation is achieved by an intricate system of vowel infixation, sometimes accompanied by a few suffixes or prefixes. Each pattern of infixation ("scheme"), in combination with a consonantal root, plus the affixes, has its own peculiar type of meanings. The Arabic noun *ma-KTaB-*, for example, means "place of writing, school," and *KaTTāB-* means "writer, scribe"; *KāTiB-*, a participle, means "writer, [the one] writing"; *ya-KTuB-u*, the imperfective form, is "he writes"; *yu-KaTTiB-u*, another imperfective, is "he writes, he teaches to write"; and *KaTaBa*, the perfective, means "he wrote." (The capital letters indicate the sounds of the consonantal root.) The need to correlate these diverse patterns with the basic meaning of the root resulted in the absence of important positional changes in the Semitic consonant sounds as well as in the comparative scarcity of borrowed terms, especially of verbs. The primary nouns, those not derived from verbal forms, are not included in this system of patterns, except, by analogy, in Arabic and the other Southern languages.

Morphology. In regard to morphology, the masculine gender marker is zero (*i.e.*, it has no structural marker), but traces of a *-u* can be detected; the feminine gender marker is *-a* or *-ā* or more usually *-(a-)t-*, although *-t-* belonged originally to another series of gender markers (in which there were more than two genders). The declension of the noun and pronoun was retained in the Ancient Stage of Semitic, with nominative, genitive, accusative, dative-locative, and locative-adverbial cases. The dative-locative ending was lost in Arabic, and the locative-adverbial form appeared only in Akkadian. There are traces of an earlier suffixed definite article, *-m(a)* or *-n(a)*, retained in Arabic as the marker of the indefinite form of the noun. Later new definite articles developed.

Dual and plural forms

The dual number was expressed at the Ancient Stage but became lost in the later stages. The plural of the noun is formed in North Semitic by lengthening the singular form. This means of expressing the plural exists also in South Semitic, but here it is to a great extent replaced by the so-called *pluralis fractus* "broken plural" (*e.g.*, Arabic *kalb-* "dog," *kilāb-* "dogs").

The West Semitic languages (except, in part, for Ethiopic and the South Arabic dialects) have lost the old imperfective form with a full vowel scheme and have replaced it by the form next in frequency, namely, the subjunctive mood (ya-qtul-u) with a reduced vowel scheme. The stative verb form, still preserved in Akkadian, developed into a new perfective (Arabic *qatala* "he killed," *mariḍa* "he was ill"), leaving the form **ya-qtul*, which was originally the perfective and jussive (a form expressing a wish or command), for the jussive only.

Syntax. Typical of the Semitic languages are attributive constructions: (1) a construction in which the governing noun appears in a shortened form before the governed noun in the genitive, as well as (2) a construction in which the two nouns, each in its complete case form, are connected by a pronoun (*e.g.*, Old Akkadian *t̲hu*, Aramaic *d̲hī*).

Vocabulary. As mentioned above, the system of word formation in Semitic does not favour borrowings, especially verbal ones. There are, however, a number of nouns borrowed from Sumerian in Akkadian; from Akkadian, Iranian, and Greek in Aramaic; from Persian and Turkic in Arabic; and from the Agau and other Cushitic languages in the Semitic languages of Ethiopia.

EGYPTIAN

The Egyptian branch of the Hamito-Semitic family includes only one language (with local dialects), namely, Egyptian. It can be differentiated into several stages. The Ancient Stage, Old Egyptian, extended from before 3000 to *c.* 2200 BC; the transition from the Ancient to the Middle Stage, Middle Egyptian, lasted from *c.* 2200 to *c.* 1600 BC and, as a dead literary language, until *c.* 500 BC. The Middle Stage, Late Egyptian (also called Neo-Egyptian), is dated from *c.* 1550 to after *c.* 700 BC and the Demotic language between *c.* 700 BC and some time after AD 400. Finally, the New Stage, called Coptic, began in about the 2nd century AD and lasted at least to the 17th century and possibly, in some villages, until the 19th century. Thus, five literary dialects are differentiated. All these language periods refer to the written language, which often differed greatly from the spoken dialects. Coptic is still in ecclesiastical use (along with Arabic) among the Arabic-speaking Monophysite Christians of Egypt.

Phonology. The Egyptian hieroglyphic writing was not adapted for expressing vowels. By the Coptic period, when an alphabetic writing came into use, the Egyptian vowel system had undergone so radical a change that the original vowels can be reconstructed only very approximately. In the consonantal system the loss of the emphatics (except *p* from **ṗ* and *q* from **ḳ*) is characteristic, as are the changes of **-r* (at end of syllable) to *-ʾ*, **li-* and **lu-* to *i-*, **ki-* and **ku-* to *ṯ* (pronounced as *tch*), **gi-* and **gu-* to *d̲* (pronounced *dj*). In some cases *ṯ* and *d̲* apparently reflect the affricates of the parent language. In addition, the original lateral sounds were lost as well as the postvelar stops and labialized velars, and the system of

Characteristic Egyptian sound changes

spirants was simplified. Beginning with Middle Egyptian, *d*, *ḏ*, and *ṯ* developed gradually to *t*, and many final consonants (*e.g.*, *-t*, *-r*) were dropped.

Word formation, morphology, and syntax. Word formation in Egyptian was similar to the Semitic type, although probably less consistent. As for the inflection, there may have been only two cases of the noun in Old Egyptian. The actor case coincided with the genitive, and this may have been responsible for a drastic rearrangement of the entire verbal system. Of the original Hamito-Semitic verbal forms only the stative ("pseudo-participle") is preserved; its subject, when a pronoun, is in the ancient direct (zero) case. Verbal forms expressing action were replaced by attributive and prepositional constructions, with the person of the actor being expressed by a suffixed possessive pronoun or by a noun in the genitive. Stem modifications are less developed in Egyptian than in Semitic; a habitative form with reduplication (repetition) of the third consonant of the root exists along with the normal imperfective of the main stem. In the later periods a new complicated system of secondary verbal tenses developed. Masculine gender was marked by zero (the absence of any ending) or **-aw-*, feminine gender by *-at-*, plural masculine by **-ā-w-*, and plural feminine probably by **-ā-w-āt-*.

Typical of Egyptian syntax are a construction in which two nouns, each in its complete case form, are connected by a pronoun, called the *nota genitivi;* and a *status constructus*, in which the governing noun appears in a shortened form before the governed noun in the genitive.

Writing. The ancient Egyptian writing was a logosyllabic one, having symbols representing either complete words or syllables of words; identical signs were used for syllables with identical consonants but different vowels. According to the external form of the signs, the writing is classified as hieroglyphic when it is found on inscriptions on stone, metal, and other hard surfaces and as hieratic and later demotic when it is used for cursive writing on papyrus manuscripts. Typologically the three forms of writing are identical. Coptic was written in an alphabet based on Greek and partly on Demotic. There is a considerable literature in Egyptian and in Coptic (in the latter, mostly of a religious nature; see also HIEROGLYPHIC WRITING).

Hieroglyphic, hieratic, and demotic writing

BERBER LANGUAGES

The Berber (Berbero-Libyan) branch is represented by a multitude of New Stage Berber dialects distributed all over North Africa, from the Siwa Oasis in the Arab Republic of Egypt to Senegal (about 7,000,000 speakers). The more important dialect clusters are Tamashek (Tuareg), in the central Sahara and south of the Niger; Chaouia and Zouaouah (Kabyle), both in Algeria; Riff and Tamazigt, predominantly in Morocco; Tashelḥayt (Shleuh or Shilha), in Morocco and Mauritania; and Zenaga, in Senegal. Little is known of ancient Libyan, also called Numidian. It is attested by inscriptions found in Tunisia, Algeria, and elsewhere, dating from the times of the Roman Empire and written in a native consonantal quasi-alphabetic script still surviving in a modified form among the Tuaregs of Sahara. Whether the extinct language of the Guanches in the Canary Islands and of the Iberians of Spain belonged to the Berber branch or even to Hamito-Semitic is doubtful.

Phonology. In the phonologies of these languages the vowels **a*, **i*, **u* were lost or reduced to *ə*, and **ā*, **ī*, **ū* became *a*, *i*, *u*; **w* and **y* may appear both as consonants and as vowels, and the emphatics are represented by *ḍ*, *gh* (but in reduplication *ṭṭ*, *qq*), and *ẓ*. The system of spirants has been simplified but retains *š* (*sh*) and *ž* (*zh*) sounds. Interdentals, laterals, and affricates were lost.

Word formation and morphology. Except in the verb, there are only traces of the internal inflection type of word formation characteristic of the Semitic branch. Among grammatical features, a former article no longer retaining its determinative function (masculine **hā-*, plural *hī*, feminine **tā-*, plural **tī-*) is prefixed under certain conditions to the noun, displacing the prefixed markers of gender, *w-* and *t-*. These latter gender markers are at present used in a form of the noun as an attribute or as a subject of a verb when following the predicate in the sentence. The plural of the noun is masculine *-ən* and *-an* and feminine *-in*. A *pluralis fractus* "broken plural" has also developed (mostly an infixation of *-a-*). The perfective of the main verbal stem also has a habitative form (reduplication of the second consonant of the root, or prefixation of *-tt-* to the word base). Tamashek has several verbal tenses.

There is little or no intelligibility between the dialects, except for historically neighbouring ones. A great number of Arabic borrowings are evident in most dialects; there are also a number of borrowings from Punic, Latin, and from the languages south of Sahara.

CUSHITIC LANGUAGES

The Cushitic branch goes back to a reconstructed Common Cushitic parent language; this, according to the Soviet scholar A.B. Dolgopolsky, was the dialect of Common Hamito-Semitic that best preserved the original phonological system. Whether or not West Cushitic (Omotic) is a descendant of Common Cushitic is not clear. The Cushitic languages are all from the New Stage and have more than 13,000,000 speakers.

Languages of the group. The Cushitic languages, including the West Cushitic group, can be subdivided into five groups. The Northern group is represented by Beja, or Bedawiye, spoken mainly in The Sudan close to the Red Sea and also in Eritrea; it has about 30,000 speakers. Typical linguistic features include the scanty representation of affricates, velars changing partly to ', and postvelar consonants changing to *h*. Two or, in some cases, three verbal forms with prefixed actor markers exist ("strong conjugation"), but many verbs are conjugated by suffixes (developed from an auxiliary verb with prefix conjugation). There are stem modifications similar to those of Berber in the strong conjugation, formed by suffixes in the other verbs (this is also typical of the other Cushitic languages). In addition, declension of the noun, with traceable relics of the ancient type similar to the Semitic, also can be seen.

The five Cushitic language groups

The Eastern group has several subgroups. The highland languages, spoken east of Addis Ababa, include Hadya (100,000 speakers), Kambata (300,000 speakers), Sidamo (850,000 speakers), Darasa (250,000 speakers), Burji, and some related languages. The total number of speakers of this subgroup is more than 2,000,000. The other subgroups include Saho-Afar in Eritrea, northeast Ethiopia, and the Territory of Afars and Issas, with 500,000 or more speakers; the Somali subgroup, with Somali, Bayso, Rendile, and other languages in Somalia, eastern Ethiopia, and eastern Kenya, having a total of about 3,000,000 speakers; the Galla subgroup, comprising Oromo (Galla, with several dialects) in western, central, and southern Ethiopia and northern and eastern Kenya; the subgroup of Arbore, Dathanaic (Geleba), and other languages, together having more than 7,000,000 speakers; Konso, Gidole, and related dialects, with about 70,000 speakers in western Ethiopia; Warazi (Warize) and related languages also in western Ethiopia, with about 50,000 speakers; and Mogogodo of northern Kenya. Typical features of the group are the presence of emphatic affricate sounds and the change of postvelar sounds to ' and *h;* in some languages the older **l* sound is represented as *j* or *r*, and **r* as *r*, *d*, or *n*. The number of verbs of the "strong conjugation" is very small in some languages and nonexistent in others. In addition, there are grammatical genders differing from the ancient type.

The Central, or Agau, group includes languages or dialects dispersed over Ethiopia. They include Bilin, Khamta, Awngi, and Kemant (Qimant), among others, and are spoken by about 100,000 people. The Quara dialect, spoken formerly by the Falashas, an Ethiopian Jewish ethnic group, is now extinct. Although the vocabulary of all Agau dialects is very similar, there is little mutual intelligibility as a result of the dissimilarity in the phonetic reflexes of the Proto-Cushitic sounds and the strong influence of Ethiopic and Amharic.

The Southern group, located in Tanzania, south of the

Equator, includes Iraqw and its related dialects, Asa, Ngomwia, and others. Characteristic of the group is the loss, for the most part, of emphatic consonants. The laterals, however, are partly preserved, as are the pharyngeal ʿ and a few of the affricates. Both *l and *r are reflected as l- and -r-. In spite of numerous innovations as a result of substratum influence, there are many similarities with Eastern Cushitic in grammar.

The Omotic languages

The Western group, also called the Omotic branch by some scholars, encompasses Ometo, a dialect cluster including the Walamo language, with about 1,000,000 speakers; Janjero (Yamma), Bworo (Shinasha, Gonga), Anfillo (Southern Mao), Benesho-She (Gimira), Ari-Banna, and others, all of which are languages with small numbers of speakers, perhaps about 100,000 in all; and Kafa (Kaficho)-Mocha, with 170,000 speakers. All of these languages are spoken along the western border of Ethiopia and in northern Kenya. Typical features include the change of *s to š, the preservation of most affricates, but the loss of laterals and of all postvelar, pharyngeal, and laryngeal fricatives. The sonants *l, *r, and *n are usually represented alike as n- and -r-. Some languages have tones that serve to differentiate word meaning. Also characteristic are drastic innovations in the pronoun and the verb. Traces of the genders are usually represented as masculine -ō (from *-aw) and feminine -ā and -ē (perhaps from *at).

There have been some attempts to create a written language for Oromo and especially for Somali on the basis of Ethiopic, Latin, or Arabic writing. An original Somali writing system was invented in the beginning of the 20th century, but at present Somali is written in the Arabic alphabet.

Linguistic characteristics. *Phonology.* All the Hamito-Semitic groups of consonants were preserved in Common Cushitic, and separate reflexes of each group can be traced in the different Cushitic languages. Because of an imperfect development of the system of word formation by vowel infixation, however, the stability of the consonantal root was not as necessary for correlation of forms as in Semitic. The reflexes of the sounds of the protolanguage in the individual Cushitic languages therefore depend to a great extent on positional circumstances; thus, a Proto-Cushitic *c, pronounced as *ts*, may have developed into a *d-* in an initial position and an *-s-* in an intervocalic or final position, and so forth. Emphatics are mostly preserved (ḍ, ç or ç, ḳ, etc.); *p is distinguished from *p by different reflexes (Omotic partly retains *p*). Affricates (and also *d*, š, *s*, etc.) represent what in Semitic are interdental consonants.

Morphology. Verbal conjugation by means of prefixed actor markers is preserved only in a part of the verbs or else in traces; in most of the verbs it is replaced by a new system of conjugation (originally a combination of verbal noun plus prefix conjugation of an auxiliary verb). Two genders (masculine *-w, feminine *-t) and traces of noun declension can be observed; partial and sometimes complete reduplication of stems is used as a means of expressing the plural, along with the means known from the other branches. The pronominal system (except in Omotic) is very close to that of Semitic. In vocabulary, there are many borrowings from Ethiopic, Amharic, Arabic, and Nilo-Saharan.

CHADIC LANGUAGES

Hausa

Languages of the group. Of the Chadic (Chado-Hamitic) branch the most important language by far is Hausa. Its approximately 25,000,000 speakers live in northern Nigeria, in the Republic of the Niger, in the northern part of Ghana, in Cameroon, and in parts of Togo, Dahomey, the Chad Republic, and the Central African Republic. Hausa is also spoken as a second language by many speakers of other African languages. All the other languages of the Chadic branch are spoken by smaller ethnic groups; for example, the Bura, with about 685,000 people; the Mandara, with about 382,000; the Angas, with about 280,000; the Bolewa and Karekare, numbering about 220,000; and the Kanakuru, with about 150,000. In regard to the classification of the Chadic languages, some units are at times classified as languages but should preferably be treated as dialects, and vice versa, and the information on many languages (dialects?) is very scanty. Thus, all attempts at classification must be regarded as provisional only. The more important of the approximately 150 "languages" follow.

1. Western group: Hausa, Gwandara, Ngizim, Bedde (Bade), and related languages; Warjawa, Afawa (Pa'a), and related languages; Gezawa, Seiyawa, Barawa of the Dass region; Bolewa, Karekare, Kanakuru, and related languages; Angas, Sura, Ankwe, Gerka, and related languages; Maha (?).
2. Ron group: Fyer, Bokkos, Daffo-Butura, Sha, and Kulere.
3. Kotoko group: Logone, Buduma, Afade, Gulfei, and related languages and dialects.
4. Musgu (Musgum).
5. Masa group: Masa (Banana), Bana, Kulung; Mussoi (?); Marba (?); and Dari (?).
6. Eastern group: Somrai and related languages; Gaberi and related languages and dialects; Sokoro and related languages; Modgel; Tuburi (Kera); Mubi; Dangla-Jegu, Jonkor, and related languages.

The affiliation of the following languages and dialects to the Hamito-Semitic family has been questioned by some scholars:

7. Tera, Jera; Hona, Ga'anda, and related languages; Bata, Gundu, and related languages; Margi, Bura, Chibak, and related languages; Higi (Hiji) and related languages; Laamang (Hidkala); Mandara (Wandala), Glavda, Yawotatakha, Sukur, and related languages.
8. Daba, Hina, Gauar, Musgoi (?); Matakam, Mofu, Gisiga, and related languages.
9. Gidder.

The total number of speakers of Chadic languages is probably about 30,000,000.

It is probable that the linguistic area of the Chadic branch formerly extended farther to the east, thus contacting the Omotic (Western Cushitic) group.

No Chadic language except Hausa has been reduced to writing; for Hausa, Arabic writing began to be used in the 16th century, and now a modification of the Latin alphabet is used.

Linguistic characteristics. In relation to the original phonological system of Proto-Hamito-Semitic, there are many missing sounds in the individual Chadic systems, but a comparison of the different Chadic groups shows that all the distinctive sounds of the parent language are represented in one way or another. Typical of all Chadic languages are tones serving to differentiate meaning in otherwise identical words.

The verb is for the most part a combination of an auxiliary verb (prefix conjugation) followed by a verbal noun (the reverse order is typical for Cushitic); the nominal part often has a vowel suffix pointing out certain qualities of the verb (transitiveness, intransitiveness, and so on). Verbal stem modifications exist, being expressed by such devices as reduplication and suffixes, but in most languages they are not strongly developed. Most of the languages have more or less clearly expressed genders but no declension. Plural is shown as in Cushitic and Berber. Chadic languages have innovations in the pronominal system. In vocabulary there are borrowings from English, Arabic (especially in Hausa), Fulani, and East Sudanic.

BIBLIOGRAPHY

General works: There is still no general survey of the field (including bibliography) to replace I.M. DIAKONOFF, *Semito-hamitskie iazyki* (1965; Eng. trans., *Semito-Hamitic Languages*, 1965), although the developments in the field after 1965 have been considerable (see the *Colloquium on Hamito-Semitic Comparative Linguistics, London, March 1970*). Among other general surveys are G.R. CASTELLINO, *The Akkadian Personal Pronouns and Verbal System in the Light of Semitic and Hamitic* (1962), and T.W. THACKER, *The Relationship of the Semitic and Egyptian Verbal Systems* (1954).

The theoretical problems of the Hamito-Semitic family have, until recently, been studied mostly on the basis of the Semitic branch alone. Especially important in this respect are I.J. GELB, *Sequential Reconstruction of Proto-Akkadian* (1969); JERZY KURYLOWICZ, *L'Apophonie en sémitique* (1961); FRI-

THIOF RUNDGREN, *Intensiv und Aspektkorrelation* (1959). Perhaps the most crucial problem of the Proto-Hamito-Semitic linguistic typology is the reconstruction of the verbal system, for which, besides the above-mentioned works, see also MARCEL COHEN, *Le Système verbal sémitique et l'expression du temps* (1924); O. ROESSLER, "Akkadisches und libysches Verbum," *Orientalia*, vol. 20 (1951): A. KLINGENHEBEN, "Die Präfix- und die Suffixkonjugation des Hamitosemitischen," *Mitteilungen des Instituts für Orientforschung*, vol. 2 (1957), and the critical, although certainly not final review of some later ideas in PELIO FRONZAROLI, "Ricostruzione interna del verbo semitico in alcuni studi recenti," *Accademia Toscana "La Colombaria,"* pp. 71–85 (1972). Another theoretical problem is broached in I.M. DIAKONOFF, "Problems of Root Structure in Proto-Semitic," *Archiv Orientální*, 38:453–480 (1970). The best general review of the Semitic branch of Hamito-Semitic is GOTTHELF BERGSTRAESSER, *Einführung in die semitischen Sprachen* (1928, reprinted 1963). See also GEORGIO LEVI DELLA VIDA (ed.), *Semitic Linguistics: Present and Future* (1961); SABATINO MOSCATI, *An Introduction to the Comparative Grammar of the Semitic Languages* (1964); I.M. DIAKONOFF, *Jazyki drevnej Perednej Azii* (1967), on languages of the Ancient Near East, including Semitic and a general survey of Common Hamito-Semitic. Recent developments are evaluated in *Current Trends in Linguistics*, vol. 6: *Linguistics in South West Asia and North Africa*, with a comprehensive bibliography.

For the individual Semitic languages and the other branches of Hamito-Semitic, the following works may be consulted:

Akkadian: WOLFRAM VON SODEN, *Grundriss der akkadischen Grammatik*, 2nd ed. (1969), and *Akkadisches Handwörterbuch* (1959–); ERICA REINER, *A Linguistic Analysis of Akkadian* (1966); *The Assyrian Dictionary*, published by the Oriental Institute, the University of Chicago (1956–).

Northern Central Semitic: C.H. GORDON, *Ugaritic Textbook*, 2nd ed. (1965); JOSEPH AISTLEITNER, *Wörterbuch der ugaritischen Sprache* (1963); I.J. GELB, "La lingua degli Amoriti," *Rendiconti d. Accademia Nazionale dei Lincei*, 13:143–164 (1958); GIOVANNI GARBINI, *Il Semitico di Nord-Ovest* (1960); Z.S. HARRIS, *Development of the Canaanite Dialects* (1939); JOHANNES FRIEDRICH, *Phönizisch-punische Grammatik* (1951); GEORG BEER and RUDOLF MEYER, *Hebräische Grammatik*, 2 vol. (1952–55); WILHELM GESENIUS and GOTTHELF BERGSTRAESSER, *Hebräische Grammatik*, 29th ed., 2 vol. (1918–29); HANS BAUER and PONTUS LEANDER, *Historische Grammatik der Hebräischen Sprache des Alten Testamentes* (1922); H.B. ROSEN, *A Textbook of Israeli Hebrew*, 2nd ed. (1966); LUDWIG KOEHLER and WALTER BAUMGARTNER, *Lexicon in Veteris Testamenti Libros* (1958); E. Cushitic: M.L. BENDER, "The Languages of Ethiopia: A New Lexicostatistic Classification and Some Problems of Diffusion," *Anthropological Linguistics*, vol. 13 (1971); on the individual branches and languages of Cushitic, see C.R. BELL, *The Somali Language* (1953), a manual of the Isāq dialect; M.M. MORENO, *Il somalo della Somalia* (1955), devoted to the Benadir, Darod, and Digil dialects; ENRICO CERULLI, *Studi etiopici*, 4 vol. (1936–51), contains grammars and vocabularies of Sidamo, Janjero, some Ometo dialects, and Kafa (Kaficho). For a good survey of the individual branches and languages of Cushitic, see F.R. Palmer, "Cushitic," in *Current Trends in Linguistics*, vol. 6, pp. 571–585.

Chadic: On the general problems of the Chadic branch see PAUL NEWMAN and ROXANA MA, "Comparative Chadic: Phonology and Lexicon," *Journal of African Languages*, vol. 5 (1966); D. WESTERMANN and M. BRYAN, "Languages of West Africa," *Handbook of African Languages*, vol. 2 (1952); JOSEPH H. GREENBERG, "Studies in African Linguistic Classification, IV, Hamito-Semitic," *SWest. J. Anthrop.*, vol. 6 (1950). Among the studies of individual Chadic languages those devoted to Hausa are the most numerous of all; the following may be especially useful: C.T. HODGE and IBRAHIM UMARU, *Hausa: Basic Course* (1963); CHARLES H. KRAFT, *A Study of Hausa Syntax*, 3 vol. (1963); R.C. ABRAHAM, *The Language of the Hausa People* (1959). Among the grammatical studies of the other Chadic languages are HERRMANN JUNGRAITHMAYR, *Die Ron-Sprachen* (1970); CARL HOFFMAN, *A Grammar of the Margi Language* (1963); and H.D. FOULKES, *Angass Manual* (1915). Of the many vocabularies of Hausa the most important is G.P.A. BARGERY (comp.), *A Hausa-English Dictionary and English-Hausa Vocabulary* (1934).

(I.M.D.)

Hammurabi

Hammurabi (more correctly Hammurapi) was the sixth ruler of the 1st dynasty of Babylon, which was—as were most other royal houses in Mesopotamia at this time—of nomadic stock. The dynasty belonged to the Amnanum, an Amorite tribe. Hammurabi ruled Babylon from 1792 to 1750 BC, carrying on with the attempts of his predecessors to gain control of the vital waters of the Euphrates River. In so doing he unified Mesopotamia and elevated its northern region to a position of prime historical importance. He was a just ruler who promulgated a famous set of laws for his people. His laws, however, have less historical significance than was once thought.

Like all the kings of his dynasty except his father and grandfather, Hammurabi bore an Amorite name. Only scanty information exists about his immediate family: his father, Sin-muballit; his sister, Iltani; and his firstborn son and successor, Samsuiluna, are known by name.

Early reign

When Hammurabi succeeded Sin-muballit in 1792 BC he was still young, but as was customary in Mesopotamian royal courts of the time he had probably already been entrusted with some official duties in the administration of the realm. In that same year Rim-Sin of Larsa, who ruled over the entire south of Babylonia, conquered Isin, which served as a buffer between Babylon and Larsa. Rim-Sin later became Hammurabi's chief rival.

The reconstruction of Hammurabi's rule is based mainly on his date formulas (years were named for a significant act the king had performed in the previous year or at the beginning of the year thus named). These show him engaged in the traditional activities of an ancient Mesopotamian king: building and restoring temples, city walls, and public buildings, digging canals, dedicating cult objects to the deities in the cities and towns of his realm,

Hammurabi, limestone relief. In the British Museum.

and fighting wars. His official inscriptions commemorating his building activities corroborate this but add no significant historical information.

The size, location, and military strength of the realm left to Hammurabi made it one of the major powers in Babylonia. That Hammurabi was not strong enough to change the balance of power by his own will is well expressed in a diplomatic report: "There is no king who is powerful for himself: with Hammurabi, 'the man of Babylon,' go ten or 15 kings, so with Rim-Sin, 'the man of Larsa'; with Ibalpiel, 'the man of Eshnunna,' . . . go 20 kings."

Hammurabi inherited one major direction for his political activity: to succeed in controlling the Euphrates waters—important in an area that depended exclusively on irrigation agriculture. Such a policy naturally led to conflicts with the kingdom of Larsa, situated in a disadvantageous downstream position. This policy, begun by Hammurabi's great-grandfather but most forcefully and partially successfully pursued by his father, Hammurabi himself took up in 1787 BC, near the beginning of his reign, when he conquered the cities Uruk (Erech) and Isin, held by Rim-Sin, and clashed again with Rim-Sin the year after. But according to Hammurabi's date formulas and contemporary diplomatic correspondence, these operations led no further because Hammurabi shifted the direction of his military operations in 1784 toward the northwest and the east. For almost 20 years thereafter no significant warlike activity is reported. These years were characterized by changing coalitions among the main kingdoms—Mari, Ashur, Eshnunna, Babylon, and Larsa. Hammurabi used this time of uneasy stalemate to fortify several cities on his northern borders (1776–1768 BC).

Warfare against rivals

The last 14 years of Hammurabi's reign were overshadowed by continuous warfare. In 1764 Hammurabi dealt with a coalition of Ashur, Eshnunna, and Elam—the main powers east of the Tigris—whose position threatened to block his access to the metal-producing areas of Iran. It can be assumed, however, that Hammurabi took the initiative in moving against Rim-Sin of Larsa in 1763 BC. Few particulars are reported about this latter war, but it seems that Hammurabi successfully employed a stratagem that apparently had been used before by Sin-muballit against Rim-Sin: damming up the water of a main watercourse and then either releasing it suddenly to create a devastating flood or simply withholding it—the main resource of life—from the enemy's people (that Hammurabi used this device to bring about Rim-Sin's defeat can be assumed from the fact that in 1760 he rebuilt a canal—the western branch of the Euphrates—to facilitate the resettlement of the uprooted population that lived along its course before this war). The final siege of Larsa, Rim-Sin's last stronghold, lasted for several months. It was the last step to Hammurabi's victory.

In 1762 BC Hammurabi again engaged in hostilities with the eastern powers. It is unknown whether this was a protective move on his part or a reaction on theirs to the change in the balance of power. The motives that led Hammurabi in 1761 BC against his longtime ally, Zimrilim, king of Mari, 250 miles upstream from Babylon on the Euphrates remain enigmatic. Two explanations are likely: either it was again a fight over water rights or an attempt by Hammurabi to gain control over Mari's excellent location at the crossroads of the ancient Near East's overland trade.

Two years later Hammurabi had to direct his armies eastward for a third time (1757–1755 BC). The final destruction of Eshnunna during this campaign—again achieved by damming up the waters—most likely proved to be a pyrrhic victory because it removed a buffer zone between Babylonia proper and the peoples of the east (among them probably the Kassites, who were to take over in Babylonia 160 years hence). During his last two years, Hammurabi thus had to concentrate on the construction of defense fortifications. By this time he was a sick man; and he died in 1750 BC, with the burden of government already being carried by his son, Samsuiluna.

Significance of Hammurabi's reign

Changes affecting nearly all spheres of life took place during Hammurabi's reign. They were aimed at the consolidation of conditions resulting from the transformation of a small city-state into a large territorial state. His letters show that he personally engaged in the details of implementing these changes and in the daily routine of the administration of his realm. This personal style is characteristic for Hammurabi and also for other contemporary rulers. Hammurabi's laws—not a law code in the modern sense—must also be considered as an expression of his concern to be a just ruler—an ideal pursued by Mesopotamian kings at all times.

That Hammurabi failed to set up an effective bureaucratic system may be attributed to his personal style in the governance of his realm and the fact that he was fully engaged in wars during the last part of his reign. The lack of effective administration might have been one reason for the fast deterioration after his death of what he had achieved in military terms.

When Hammurabi conquered southern Babylonia he did not follow the century-old tradition of having himself deified during his lifetime. There is reason to believe that this was his personal decision, probably based on a different view of the nature of kingship, setting a precedent for the concept of kingship until Hellenistic times.

Hammurabi's eminence in Mesopotamian history has long been exaggerated. It was first based on the discovery of his laws but subsequent discoveries of older, though less voluminous collections of laws have led to a less enthusiastic view. Moreover, the frequently noted resemblance between Hammurabi's laws and the Mosaic laws is now seen in terms of common heritage rather than as proof for direct dependency.

Hammurabi is also credited with bringing Mesopotamia again under a single rule. Although there existed certain trends toward such unification—particularly expressed in the themes depicted on contemporary seals and in the apodoses of omens evoking a past, when such kings as Sargon of Akkad and Shulgi ruled Mesopotamia from the Persian Gulf to the Mediterranean Sea—it is doubtful that unification was the only motive for Hammurabi's conquests. The lasting achievement of Hammurabi's rule was that the theatre of Mesopotamian history, which had been in the south from the beginning of the 3rd millennium BC, was shifted to the north, where it remained for more than 1,000 years.

Handball and Fives

Handball and fives are similar games played in walled courts or against a single wall, with a small rubber ball that is struck with hand or fist against the wall. The object is to cause the ball to rebound with variations of power or speed and at such an angle that the opposition cannot return it.

HANDBALL

There are three versions of handball: four-wall, three-wall, and one-wall. Each may be played by two (singles) or four (doubles). (There is an unofficial three-player practice game called "cut-throat" handball.) Although handball fundamentals can be explained and learned quickly, developing the skill, strategy, and stamina required to play well presents a continuing challenge.

Background. One of the oldest games played with a ball, handball has been traced back to the *thermae*, or baths, of Rome. Played later as a bare-handed game called *pelota* in Spain and France, it was the forerunner of modern jai alai (*pelota vasca* or *pelota basque*), a three-wall game in which players hurl, catch, and return a small, hard ball using a wicker scoop strapped to one arm. Handball was adapted in the British Isles during the 16th century and called fives.

Irish origins

The immediate forerunner of the modern game was developed in Ireland, where handball was played about 1,000 years ago. In the 1850s, Irish town and county championships were regularly played, using a hard leather-covered ball on courts that were about 80 feet (24 metres) long and 40 feet (12 metres) wide. Irish emigrants took the game to the United States in the 1880s, and Phil Casey built the first U.S. walled court in Brooklyn in 1886. Kicking was permitted, and some players developed unusual skill in returning low balls with their feet.

The first international match was played in 1887 between the Irish champion, John Lawlor, and the U.S. champion, Casey. Begun in Ireland on August 4, the match ended on Casey's U.S. court on November 29. Casey won, 11 games to six, and then retained his title against all challengers until his retirement in 1900.

During the 1890s play began with a soft ball—usually a tennis ball with the outer covering removed. This ball was used in smaller four-wall courts in the New York City area. Then young players began using this larger ball outdoors against the solid wall of a building. The use of the soft ball spread to other cities, mostly for four-wall play. Dissatisfaction with the large, slow ball led to development of a smaller gas-filled ball that proved to be more acceptable to players and stimulated new interest in the game.

The four-wall soft-ball game was taken up avidly in such midwestern U.S. cities as Detroit, Cleveland, Milwaukee, and Chicago. When the Milwaukee fire department converted from horse-drawn to motorized equipment, its stables were converted into handball courts. The sport helped keep fire fighters fit, and a number of the firemen developed into ranking competitive players.

The one-wall game

At about the same time, the game underwent changes and courts were reduced in size. A one-wall game was developed in New York about 1913 and played on the beaches against bathhouses and bulkheads, with the hard sand forming the floor of the court. Within a few years, the one-wall game was played by both men and women throughout the eastern United States. It was taken indoors by YMCA's and clubs and, where space in large cities was at a premium, was even installed on roofs. As a forerunner of the three-wall game some one-wall courts were equipped on each side of the front wall with a hinged triangular "wing," which swung out and locked into position on the forward portion of the two side lines, forming a partial three-wall court and making difficult shots into the front corner possible.

Irish handball. The Irish game of handball was originally played on a hard clay floor, with one wall of stone at the front of the court, against which the ball was struck. The ball, the four-wall court, and the system of scoring were developed during the 18th century, when the game was a popular pastime in many parts of Ireland. The Irish ball has a cork or wood centre covered by woolen thread and thin pieces of cork or rubber. The outer cover is of thin sheepskin. This ball is called an alley cracker or hard ball. Some tournaments or championships are played with a soft, rubber ball, but the Irish ball is the recognized championship medium. The standard ball is 1⅞ inches (4.7 centimetres) in diameter and weighs 1½ to 1¾ ounces (43–50 grams).

Rules have changed little since the 1880s, when the first Irish championships were played. For many years challenge and championship games for stakes as high as £1,000 were not uncommon. Then the Gaelic Athletic Association took over supervision of the game, betting was abolished in 1924, and Irish handball became an amateur game. Regular county, provincial, and all-Ireland championships were established. There are many courts throughout Ireland and at most schools and colleges, although a soft, rubber ball is now generally used in schools.

Organized competition. National handball championships in the United States have been conducted by the Amateur Athletic Union (AAU), since 1919; the Young Men's Christian Association (YMCA), since 1925; the National Jewish Welfare Board (JWB); and the United States Handball Association (USHA). Collegiate tournaments sponsored by the USHA and junior tournaments involving younger players contribute to the increasing number of handball participants.

During a consultation held in Chicago in 1959 that involved representatives from the AAU, JWB, USHA, and YMCA, an agreement was reached recommending one set of uniform playing rules to be used by all four groups. Three years later it was decided to conduct an All-American Handball Championship on a quadrennial basis, during each Olympic year. Sponsored by three of the four national organizations the first such event was conducted successfully in St. Louis in the spring of 1964. Unfortunately, no subsequent similar events were conducted.

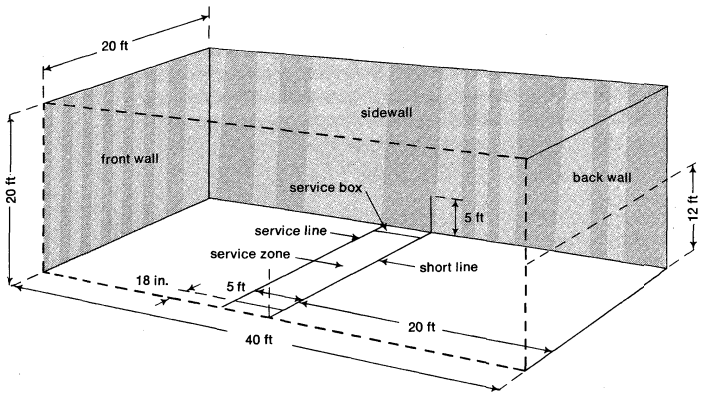
Handball is now also played in Canada and Ireland and to some extent in Mexico, Argentina, Australia, New Zealand, and France. International competition has been stimulated in recent years through invitational events conducted by Canada and the United States. One, announced as a world championship, held during the 1964 New York World's Fair, brought together players from Ireland, Mexico, Australia, Canada, and the United States. The U.S. team won both the singles and doubles events over Canadian players. Another international event held in the fall of 1967, in Toronto, involved players from Ireland, Australia, Canada, and the United States. A third international event planned by Ireland for 1970 was postponed because "standard" courts could not be provided and some top players were not able to participate.

International status

The desire for international recognition of handball continues to build. Efforts have been made to standardize playing facilities, equipment, and rules, and to bring about a recognized international organization to plan and govern handball competition. A proposal was made to have handball included as a demonstration sport during the 1976 Olympic Games.

The court. Standard four-wall courts are 40 feet (12 metres) long, 20 feet wide, and 20 feet high, with a back wall 12 feet high. A short line, parallel to the front wall, divides the court in half; the service line is parallel to and five feet in front of the short line. Between these two lines on each side of the court is a service box, formed by a line parallel to and 18 inches (46 centimetres) from each sidewall. The serving zone is the space between the outer edges of the short and service lines. A vertical line marked on each sidewall, five feet behind the short line, indicates the front edge of the back court receiving zone.

In one-wall handball the wall (front) is 20 feet wide and 16 feet high, with a playing zone 34 feet long (the back edge is the long line) by 20 feet wide. The sidelines extend three feet farther from the wall than the long line. The



Four-wall court according to handball unified playing rules.

short line runs parallel to and 16 feet from the wall. Service markers (lines) six inches long, parallel to and midway between the long and short lines, extend inward from the sidelines. The imaginary joining of these markers forms the service line. The service area, 20 feet by nine feet, includes the short lines, service lines, and sidelines. The 20 feet by 18 feet receiving zone behind the short line includes the long and sidelines. One-wall courts are popular because they permit more spectators to watch games and are less expensive to build.

Three-wall courts also permit more spectators to view matches but are less common and are not standardized. They may have a front and two sidewalls, the back being open, or a front wall, back wall, and one sidewall as in a jai alai court. Court dimensions and markings are similar to four-wall courts, with a back court (long) boundary line or a sideline added for the jai alai type court.

Development of courts with one or more glass walls allowed more spectators to watch four-wall matches and enjoy skillful play off the back wall.

Principles of play. The ball is made of black rubber; it is 1⅞ inches in diameter and 2.3 ounces in weight. Only one hand may be used in striking the ball; no other part of the body may be used. When attempting to return the ball, the player cannot strike it more than once. Gloves made of soft material or leather must be worn to prevent moisture from affecting the ball.

Serving the ball

To start the game a server stands anywhere within the serving zone, drops the ball to the floor, and strikes it on the first bounce with one hand, causing it to hit the front wall on the fly. In the four-wall game, the rebounding ball must land on the floor back of the short line, either before or after striking one of the sidewalls. If it does not cross this line, it is a short ball, which is a fault. Two successive faults retire the side. In the one-wall game, if the ball lands beyond the long line, it is a long ball, also a fault; if it goes outside the sidelines, it is a handout—that is, the side (hand) serving loses service but the score remains the same. A fault is called if, while serving, the server steps beyond the serving zone or leaves the zone before the rebound passes the short line. In four-wall doubles, the server's partner must remain within the service box until the rebound passes the short line; in one-wall doubles, he must be outside the sidelines straddling the service line. Breaches of these regulations are faults. If a server's partner enters the playing zone before the served ball passes him, it is a fault.

The return

The receiving side may return the serve (rebound) either on the volley (fly) or on the first bounce; the return may hit the sidewalls and must hit the front wall. In four-wall handball the receiver or receivers must be at least five feet back of the short line until the server strikes the ball; in the one-wall game the receiver must remain back of the service line until the rebound passes the short line. The rally continues, sides alternating in hitting the ball until one side misses. If a receiver misses, the server scores a point; if the serving side misses, the receiving side wins only the right to serve. The server continues to serve as long as he scores. Game is 21 points.

In doubles, one player on the starting side serves. If he faults twice, service passes to the other team. Thereafter, both players on each team must serve before the serve goes to the opposition.

Players cannot block each other from playing the ball. If they do, or if the ball hits an opponent before hitting the front wall, the ball is dead and must be served again.

Three-wall regulations are the same as those for four-wall, except that a ball in play striking outside the long line (a long ball) is a point if struck last by the receiver or handout if struck last by the server.

Any shot beyond an opponent's reach is called a placement. The most effective placement is a kill, in which the ball rebounds at a height so low that it is impossible to return it. An ace is a legal serve that eludes the receiver. The greater variety of angle shots—for example, sidewall to front wall, ceiling to front, side to back—makes the four-wall game the most demanding form of handball. All versions require good physical condition, speed, control, and stamina, and many athletes play handball to condition themselves for other sports.

Strokes

The three strokes used in handball are the underhand, the basic service stroke; the overhand for high bounding balls or fly balls; and the sidearm, the best stroke for the kill shot. It is important to move into position in the court to be ready to make the return stroke. A player who can strike the ball with either hand can save energy and be a double threat to his opponent. (H.T.F.)

FIVES

The predominantly British games of fives had their origin in the casual play of boys hitting a ball against any convenient wall. They differ from handball games insofar as they are played with a small, hard, composition ball (leather-covered until recently) and because in their present sophisticated form they are a product of the British public schools, as reformed in the 19th century for the sons of the aristocracy and the well-to-do. The word fives derives from the same source as "a bunch of fives" meaning the closed fist or the five fingers held together.

Eton fives. The Eton fives court is a remarkably close copy of the court used by generations of Eton College boys on the steps of the school chapel. It is enclosed on three sides and open at the back. A shallow step divides the court into an upper and lower part. On the left-hand sidewall, by the step, there is a small buttress, known as the "pepper-box." With the step it makes a small, square cavity on the lower floor, called the "Dead Man's Hole." The upper court has an angled ledge, the lower part of which (four feet six inches from the ground) runs across the front wall and is called the "line." There is a vertical line marked on the front wall, three feet eight inches from the right-hand sidewall, that has to do with returning service. There is a second and straight ledge below the top ledge in the upper court, which is an additional hazard but has no further significance.

The game is played between four players, two on each side, who wear leather gloves to protect their hands. There is no recognized singles game. When the game starts, the server alone stands in the upper court. To begin the game he throws the ball so that it hits the front wall above the line, then the right-hand side wall, and falls to the lower court.

The "first cut"

The opponent who returns the service is said to make the "first cut," and he need not do so until he gets a service to his liking. Serving is only a method of putting the ball in play. The ball must be hit with a single blow of the hand or wrist and must not touch any other part of the striker's person.

After the first cut the ball is played alternately by a player of each side, providing the ball is played not later than after the first bound on the floor and is returned above the line, the rally continues.

A game is won by the side that first obtains 12 points. When the server's side wins a rally, a point is won; if the server's side loses a rally, the server's partner serves and no point is scored; if the server's side loses another rally, the service changes to the opponents. A point can only be

won if the winners of the rally are the serving side. A match is usually the best of five games.

Governed by the Eton Fives Association, the main competitions are for an amateur championship and a Public Schools competition.

For the uninitiated spectator the game is bewildering. The ball rebounds in many unexpected ways off the hazards, and the players seem often to be in each other's way. It involves mental as well as physical exercise, there being a variety of ways to outwit an opponent.

Rugby fives. The Rugby fives court has four plain composition walls and a hard composition floor. The front wall, which is 15 feet high, has a board running across it, the top being two feet six inches from the floor. The height of the sidewalls is 15 feet for the first 12 feet from the front wall, thence sloping down to six feet, the height of the back wall. Courts are enclosed, the spectators at the back wall. All courts built since 1930 have been of standard dimensions, but older courts are still in existence.

The game is played like Eton fives, except that the player who makes the first return is called the server. He can either throw the ball up for himself, and usually does, or he can require his opponent, called the receiver, to do so. The ball must be hit only with the hand or forearm. The receiver is "up," and only a side that is "up" can score points. Matches are usually the best of three games, the first team or player to get 15 points winning the game. Club and school games are won on total points. Both singles and doubles are played.

Competition, regulated by the Rugby Fives Association, includes several regional championships, a universities championship, amateur singles and doubles championships, and schools championships.

The emphasis in Rugby fives is physical. The games can be exhausting because of the speed of the ball, the low board, and the use made of the back wall. It is the most popular of the three games.

Winchester fives. Winchester fives is a game confined to a few schools, there being no association or championships and few courts. The court is similar to the Rugby one, but a change of direction of the left-hand wall makes the court slightly narrower at the back than at the front. This changes the positioning of players and Rugby fives players are at a disadvantage. Despite these differences, Winchester players have little difficulty in adapting to the Rugby game, and several schools that play the Winchester game are affiliated with the Rugby Fives Association. Handel, George Frideric

One of the greatest composers of the late Baroque era, George Frideric Handel, German by birth and an Englishman by adoption, mastered the techniques of German, French, and Italian musical styles and adapted them to a new environment to create works of such power that he became a familiar institution in Britain and a key figure in the national tradition of Germany. Ultimately his work became an essential factor in the popularization of European music throughout the world.

By courtesy of the National Portrait Gallery, London

Handel, oil painting after Thomas Hudson, 1756. In the National Portrait Gallery, London.

Handel was born in the city of Halle-an-der-Saale in Saxony on February 23, 1685. His father, Georg Händel (the usual German form of the name), was a successful surgeon; his mother was the daughter of a Lutheran clergyman.

Education in Halle. Handel showed a marked gift for music. Since at that time music was eagerly cultivated in all sections of German society and was considered a useful social accomplishment, his talent was encouraged by his family. A romantic legend stating that Handel's father disliked music is without foundation; actually, he was a friend of several well-known musicians. Handel had the opportunity to hear excellent church and civic music in Halle; also at nearby Weissenfels, where his father was court surgeon to the duke of Saxe-Weissenfels, he was brought into contact with the music played at court. He became a pupil in Halle of the composer F.W. Zachow, organist of the Liebfrauenkirche and director of the town choir, and from him he learned the principles of keyboard performance and of composition; others instructed him in oboe and violin. Oboe sonatas composed by him at that time still survive. In 1696 he was taken to Berlin, where his talents were noticed by the elector Frederick III (later King Frederick I of Prussia) and the electress Sophia Charlotte.

Musical training

His father died when Handel was 11, but his general education had been provided for, and on February 10, 1702, he enrolled as a law student at Halle University. Directed by forward-looking professors, this institution rapidly became a strong influence in the liberal, humanitarian, scientific movement of the 18th century known as the *Aufklärung* (Enlightenment). The stimulating character of this intellectual community played a notable role in Handel's later development.

Between 1700 and 1702 Barthold Heinrich Brockes, who was to become an important figure in the literary and musical life of Hamburg, was a student at Halle, where Handel probably attended concerts organized by him. Later in life Handel set Brockes' poems, as well as a Passion text of his, to music. The composer Georg Philipp Telemann passed through Halle on his way to

Leipzig in 1701, and he and Handel became close friends.

In order to enlarge his musical experience and to guarantee some part of his living expenses, Handel became organist of the Reformed (Calvinist) Cathedral in Halle when he entered the university. The appointment was for one year, and at the end of that time he decided to go north to Hamburg, where greater opportunities awaited him.

Young composer in Hamburg and Italy. In Hamburg, Handel made friends with Johann Mattheson, musician and man of letters, who became secretary to the British resident there. Before settling down in Hamburg, however, Handel travelled with Mattheson to Lübeck in August 1703 to inquire about the chances for either to succeed the famous Lübeck organist Dietrich Buxtehude. Unsuccessful in their attempts, the two young men returned to Hamburg where Handel joined the violin section of the opera orchestra. He also undertook to instruct the children of the British resident in music.

Encouraged by the director of the Hamburg opera, Handel took over some of the duties of harpsichordist, and at the beginning of 1705 he presided over the premiere of his first opera, *Almira*. This was sufficiently successful for him to be invited to contribute further works to the repertoire. The music for these works—*Nero* (1705) and *Florindo* and *Daphne* (1706)—is, however, lost.

First opera

At this time Italy was considered to be the musical centre of Europe, and ambitious musicians who could raise the necessary money went there to study. Handel, who had already made the acquaintance of several eminent Italians, was unusual in that not only did he manage to support himself for three years in Italy but was able to leave that country richer both in funds and reputation. His "grand tour" was a great success, indicating command both of musical expression and social graces. He resided for periods of varying length in Florence, Rome, Naples, and Venice. In Florence, he met the composer Alessandro Scarlatti, and it was in this city, in 1707, that his first Italian opera, *Rodrigo*, was written. The production of *Rodrigo* resulted in enthusiastic acclaim for Handel from the principal patrons of art in Rome. Handel moved to Rome, where, responsive to environment, stimulated by the competition afforded by the presence of such masters as the violin composer and player Arcangelo Corelli, and eager to realize his ambitions, he composed prolifically. His works included many Italian solo cantatas (vocal compositions) and duets, the extended cantata *Il trionfo del tempo e del disinganno* (1708), Latin church music, and the oratorio *La Resurrezione*.

From Rome, threatened by hostilities during the War of the Spanish Succession, Handel moved on to Naples. Here he composed the serenata—a dramatic cantata—*Aci, Galatea e Polifemo* in June 1708, an interesting set of French songs, a *Cantata Spagnuola* (*No se enmenderá jamás*) that apparently stemmed from a flirtation with a "Donna Laura" from Spain or Portugal, and began to compose the opera *Agrippina*. The librettist was Cardinal Vincenzo Grimani, the Venetian viceroy of Naples. *Agrippina*, first performed in Venice on December 26, 1709, enjoyed sensational success, the performance being frequently interrupted by cries of "Viva il caro Sassone!" ("Long live our beloved Saxon!").

Before his arrival in Italy Handel enjoyed a national reputation; his mastery of the Italian opera style made him an international figure. Through his friend Agostino Steffani—a papal ambassador at large and, until lately, musical director in Hanover—he met Prince Ernest Augustus of Hanover, who offered him Steffani's place at court. Handel accepted and remained director of music at Hanover officially until 1716, but mostly he held the post *in absentia*. He arrived in Hanover at the beginning of 1710 and left in the autumn for London. Since the aged electress Sophia of Hanover was heir-presumptive to the English throne, a special relationship already existed between the two countries, so that Handel's departure for England did not seriously imperil his position.

Musical director at Hanover court

Successful career in England. Early in 1711 his sparkling opera *Rinaldo* was performed in London and aroused the normally phlegmatic English to such enthusiasm that Handel sensed the possibility of continuing popularity and prosperity. A year later, with electoral permission for a limited stay, he was back in London for the production of *Il pastor fido* and *Teseo*. In 1713 he won his way into royal favour by his *Ode for the Queen's Birthday* and the *Utrecht Te Deum and Jubilate* in celebration of the Peace of Utrecht that ended the War of the Spanish Succession, and he was granted an annual allowance of £200 by Queen Anne.

Recognized and respected as man and musician by prominent members of both the English aristocracy and the intelligentsia, Handel was in no hurry to return to Hanover. Since, on the death of the Queen in 1714, the elector George Louis—whose mother Sophia had died in the previous June—became King George I of England, Handel had no need to do so. On October 26 the King and his family heard music by Handel in the Chapel Royal, one fact (among others) that destroys the legend that the King was annoyed by Handel's lengthy absences from Hanover and became reconciled to him only in 1717 by his *Water Music*. By that time Handel had again visited Hanover in the retinue of the king-elector. While in Germany he also went to Hamburg, where *Rinaldo* had been performed in 1715 and where his setting of Brockes' Passion (*c.* 1716) was sung several times from 1717 on; to Dresden, where he spent three months and engaged some singers for the London opera season; to Halle to see his family; and to Ansbach, once the home of his friend Caroline, princess of Wales, where he persuaded a local tradesman and old acquaintance, Johann Christoph Schmidt (who in England changed his name to John Christopher Smith), to become his secretary. Two years later Handel was again in Germany, primarily to gather singers for the Royal Academy of Music, newly established for the purpose of producing operas, but also to see his family and friends again. A German cantata attributed to Handel, dated 1719, may belong to this visit; in any case it serves as a reminder that despite increasing commitment to English affairs Handel still felt himself to be German.

In 1718 Handel became director of music to the Duke of Chandos, whose palace at Cannons lay a little north of London. There Handel composed 12 *Chandos Anthems*, a setting of the poet John Gay's *Acis and Galatea* (a different work from *Aci, Galatea, e Polifemo*), and *Haman and Mordecai*. This last—the text by several hands (probably including Alexander Pope, the English satirical poet) and after the French playwright Jean Racine's *Esther*—was to be the effective starting point for English oratorio—a large musical composition for solo voices, chorus, and orchestra, without acting or scenery, usually dramatizing a story from the Bible.

Secure in his profession Handel now bought the house in Brook Street, which was to be his home for the rest of his life. In 1726 he became a British subject, which enabled him to be appointed a composer of the Chapel Royal. In this capacity he wrote much music, including the *Coronation Anthems for George II* in 1727, and the *Funeral Anthem for Queen Caroline* ten years later.

British citizenship

From 1720 until 1728 the operas at the King's Theatre were staged by the Royal Academy of Music, and Handel, as a director of the academy, was responsible for composing the music of most of them. Although the songs from them were very popular, the operas themselves enjoyed varying degrees of success. From 1728, after the sensation caused by the satirical *Beggar's Opera*, the future of opera—which meant opera in the Italian style—appeared increasingly uncertain. Handel, however, was loath to relinquish interest in what he took to be not only the highest form of composition but also the most lucrative. In 1729 he once more visited Europe in search of singers, and in order to visit his mother whom, now in failing health, he was not to see again. During this visit, in June, Johann Sebastian Bach, sending his son Wilhelm Friedemann as emissary, attempted to meet a master whom he admired and from whose works he had made copies. Handel and Bach, however, were never able to meet.

In spite of the vagaries of some of his Italian star singers and the uncertainties of public taste, Handel went on composing operas until 1741, by which time he had written about 40 such works. Opera went into decline in London for a variety of reasons, one of them being the impatience of the English with a form of entertainment in an unintelligible language sung by artists of whose morals they disapproved, and as it did oratorio became increasingly popular. Oratorio, comparable in structure to opera, was already firmly established in southern Europe. Its adoption by the English was more or less fortuitous. It was primarily due to revivals in 1732 of *Acis and Galatea* and *Haman and Mordecai* (renamed *Esther*), but also to a general love of choral music, to the importunities of those who wished Handel to use English lyrics, to the interest of the royal family, and to the moral value set on it by the middle class. General approval was generated by the use of biblical words and by the fact that Handel's music afforded a combination of pleasure and piety. Handel, however, did not apply the form exclusively to biblical subjects, although these preponderated. He and his collaborators chose excellent plots and with the extra dimension allowed by considerable chorus participation he made it a fine medium for dramatic expression.

Growth of oratorio in England

As musical director, impresario, composer, virtuoso performer on harpsichord and organ, and fashionable teacher, Handel expended his energy recklessly and in 1737, having suffered what appears to have been a mild stroke, was very ill. After recuperating at Aix-la-Chapelle, he was saddened by the death of the Queen. The sombre anthem, incorporating a German chorale melody, composed for her funeral was publicly performed on December 17 and privately for the royal family in the Chapel Royal a week later. Soon Handel was as active as ever. He produced one of his most charming and humourful operas, *Serse*, published the Opus 4 organ concerti, composed *Saul* and *Israel in Egypt* as well as shorter works, and helped establish the Fund for the Support of Decayed Musicians (now the Royal Society of Musicians). In May 1738, the general public was able for the first time to see the statue of Handel by the French sculptor Louis-François Roubillac, erected in the composer's honour in Vauxhall Gardens where his music was frequently sung and played.

The extent to which Handel had steered away from Italian opera is indicated by his use of classical English texts in 1739 and 1740. These were the English poet John Dryden's "Ode for St. Cecilia's Day" and John Milton's "L'Allegro" and "Il Penseroso." In 1740 Handel published the concerti grossi of Opus 6 and a second set of organ concerti. But during that year, in response to the decline of opera, Handel may seriously have considered a change of course but appears to have been discouraged. In September a Hamburg newspaper reported that Handel had lately played the organ in the Dutch town of Haarlem and that he was en route to Berlin. If this account was accurate it would indicate the possibility of overtures having been made to him by Frederick the Great of Prussia, who was then reorganizing his own musical establishment. Whatever the veracity of these reports, Handel returned to England where he held a "farewell concert" on April 8, 1741.

At this juncture an invitation from the duke of Devonshire, the lord lieutenant of Ireland, to furnish a work for Dublin charities pulled Handel out of his state of dejection. Characteristically, he now moved to the opposite extreme and worked so intensively that his promised oratorio, *Messiah*, was written in its first form between August 22 and September 14. A month later its scarcely less inspired successor *Samson* was also ready for the copyists. In November, accompanied by some of his performers, Handel travelled to Dublin by way of Chester, where, with the aid of the cathedral musicians, he tried out *Messiah* in private. On December 23 he began a series of subscription concerts in Dublin and on April 13, 1742, *Messiah* was given its first performance. It created a deep impression and was repeated on June 3. Handel remained in Ireland through the summer, during which time he rearranged the suite of pieces comprised in *Forest Music.*

Messiah

The works of the next three years included the oratorios *Joseph and his Brethren* (first performed in 1744) and *Belshazzar* (1745), the secular oratorios *Semele* (1743) and *Hercules* (1745), and the *Dettingen Te Deum* (1743) celebrating the English victory over the French at the Battle of Dettingen during the War of the Austrian Succession. In 1745, however, there was further concern about Handel's health, and a contemporary wrote that he appeared "dejected, wan, and dark [as he sat by] not playing the harpsichord" at a performance of *Alexander's Feast.* Yet the decade that followed *Messiah* was one of great significance in Handel's career. During this time he made oratorio and large-scale choral works the most popular musical form in England, a fact of some social importance. In the mid-1740s many voices were being raised against "permissiveness," and the feeling that the great oratorios were some sort of bulwark against moral laxity grew stronger. This feeling of righteousness grew when, after 1749, *Messiah* became especially associated with the Foundling Hospital. A general benefactor of the hospital, and a governor since 1750, Handel superintended *Messiah* performances in its Chapel until 1754. In his testament Handel gave a score and a set of the parts of *Messiah* to the institution.

Handel's last years. Handel's sense of charity and his general concern for other people raised him to a high place in the affections of the British. His music was even then recognized as a reflection of the national personality, and his capacity for realizing the common mood was nowhere better shown than in the *Music for the Royal Fireworks* with which he symbolized the end of the Silesian Wars, a part of the War of the Austrian Succession, in 1749. Twelve thousand people are said to have attended a rehearsal of this music in Vauxhall Gardens.

Music for the Royal Fireworks

In the summer of 1750 Handel, having visited Germany for the last time, was seriously injured in a coach accident in Holland. Recovered from the mishap, he returned home to compose *Jephtha*, the last of his oratorios. While working on this—as he noted on the manuscript on February 13, 1751—his eyes began to trouble him, and he underwent eye surgery. Although he never became completely blind, there is no doubt that he was gravely handicapped in his work in his final years.

Jephtha was performed at Covent Garden Theatre (where the oratorios were usually performed), London, on February 26, 1752. From then on the Lenten oratorio seasons were eagerly anticipated. Handel attended the performances, and he sometimes played concerti on the organ. He had indeed become an institution to the English people. His friendships, however, extended far beyond his own profession and England's borders.

Assisted by his friend and secretary John Christopher Smith, Handel kept his interests in musical activities alive until the end, and on March 30, 1759, he was present at the Foundling Hospital *Messiah* performance. He was not well enough to attend a second performance a week later. On April 14 he died, and on April 20 he was buried in Poets' Corner in Westminster Abbey in the presence of a congregation of 3,000 people who had come to mourn the passing not only of a great composer but of one held in universal esteem as a man.

Death

By naturalization Handel was British, and he thoroughly and happily adapted himself to the English way of life and was deeply involved—not least through his many benefactions—in public affairs. He was a keen student of English literature and set the language to music with understanding of its structure and inner significance. He never married but was a lifelong friend of Mrs. Mary Delany, who first made his acquaintance as a small girl in 1710. Handel, however, never forgot that by birth he was German. As a boy he had often walked along the leafy road from Halle to his grandfather's parish. In his testament he recalled those days in generous bequests to his relatives in Germany. Although from time to time he suffered financial embarrassment (but never bankruptcy), he possessed a keen business sense and through prudent investment accumulated a considerable fortune.

Growth of Handel's reputation after his death. Handel, accorded the status of a classic in England during his

own lifetime, is unique among musicians in never having suffered diminution of reputation either as man or artist. As a young man he was aware of, and to some extent supplied, the demands of aristocratic patronage. In England, however, by adapting himself to a different climate of opinion and taste he came to serve and indeed to express the needs of a wider public. More than anyone else he democratized music, and in this respect his popular oratorios, his songs, and his best loved instrumental works have a significance transcending their purely musical importance. Handel's music became an indispensable part of England's national culture. In 1784 the first of many Handel Commemorations took place in Westminster Abbey and exerted a profound influence on the already existing cult of Handel. Amateur singers all over Britain were stimulated by the 1784 Commemoration to the extent that musical festivals, largely based on the oratorios, were held in countless urban and even rural centres. Some instrumentalists who had played in the first Commemoration emigrated to the United States and, together with organists who had preceded them, implanted an interest in Handel, which led to the foundation of the Handel and Haydn Society of Boston in 1815.

In Germany, meanwhile, interest in Handel was growing apace. In September 1771, the English conductor and composer Michael Arne directed *Alexander's Feast* in Hamburg as well as the first performance of *Messiah* in Germany in April 1772. These ventures in Hamburg, the city where Handel's music had been most cultivated in Germany, led to performances of the choral works under Carl Philipp Emanuel Bach—the first, and most important, of *Messiah*, taking place in December 1775. Through performances of his works and the critical attention paid to Handel, he became re-established in Germany as a national composer.

In the present century, the fact that Handel wrote much more music than had become generally familiar, together with a further secularization of values, has led to re-examination of works other than the oratorios. The production of his opera *Rodelinda* in Göttingen in 1920 had important consequences, leading to productions of the operas elsewhere and to the establishment of an annual Handel Festival in Göttingen. Since World War II, efforts to secure proper recognition for Handel in Halle, the city of his birth (where interest in Handel had remained sporadic), led to the formation of a new Händel-Gesellschaft (Society). The headquarters of this society is in the house in which Handel was born, now maintained as a museum and a centre for lectures and recitals. Halle has also promoted (since 1952) an annual festival of Handel's work, which has proved notable especially for the production of the operas. The most important undertaking of the Händel-Gesellschaft, however, is the inception of a new complete edition of his music. Under the supervision of an editorial board representing scholars from various countries, a number of volumes have already appeared. The vast bulk of Handel's autographs, which passed to the English Royal House and was in 1957 presented by Queen Elizabeth II to the nation, are kept together in the British Museum.

MAJOR WORKS

Theatre music

OPERAS: About 40, including *Almira* (1705), *Agrippina* (1709), *Rinaldo* (1711), *Radamisto* (1720), *Ottone* (1723), *Giulio Cesare* (1724), *Tamerlano* (1724), *Rodelinda* (1725), *Scipione* (1726), *Admeto* (1727), *Partenope* (1730), *Sosarme* (1732), *Orlando* (1733), *Ariodante* (1735), *Alcina* (1735), *Serse* (1738), *Deidamia* (1741).

Choral and other vocal works

ORATORIOS AND MAJOR SECULAR WORKS: About 20, including *Acis and Galatea* (*c.* 1720), *Esther* (1732), *Alexander's Feast* (1736), *Saul* (1739), *Israel in Egypt* (1739), *L'allegro, il penseroso ed il moderato* (1740), *Messiah* (1742), *Samson* (1743), *Semele* (1744), *Hercules* (1745), *Belshazzar* (1745), *Judas Maccabaeus* (1747), *Susanna* (1749), *Solomon* (1749), *Theodora* (1750), *Jephtha* (1752).

CHURCH WORKS: *Dixit Dominus* (1707), *Utrecht Te Deum and Jubilate* (1713), *Brockes' Passion* (*c.* 1716); 11 *Chandos Anthems* (*c.* 1717–20); four *Coronation Anthems for George II* (1727); various anthems and hymns.

OTHER VOCAL MUSIC: 22 Italian duets; 72 Italian cantatas; *Nine German Songs;* English songs; *French Cantatas* and various other cantatas.

Instrumental music

CONCERTOS: *Six Concerti Grossi* (known as *The Oboe Concertos*), op. 3; *Twelve Grand Concertos*, op. 6; 21 organ concertos; concertos for various instruments.

MISCELLANEOUS ORCHESTRAL WORKS: *Water Music* (1717); *Fireworks Music* (1749); various overtures.

CHAMBER MUSIC: *Six Sonatas for Two Oboes and Continuo* (*c.* 1696); *Six Sonatas for Two Violins, Oboes or German Flutes and Continuo*, op. 2 (*c.* 1731); *Seven Sonatas or Trios for Two Violins or German Flutes*, op. 5 (*c.* 1739); various solos, sonatas, and trios.

HARPSICHORD MUSIC: *Suites de pièces* (*c.* 1720); *Suites de pièces* (*c.* 1733); 12 fugues; *Fantasia in C Major* (*c.* 1732); various sonatas, suites, and short pieces. The so-called *Harmonious Blacksmith* variations are in No. 5 of the first set of *Suites de pièces.* The *Chaconne and Variations* is No. 9 of the second set.

BIBLIOGRAPHY. O.E. DEUTSCH, *Handel: A Documentary Biography* (1955), the life and career of Handel exposed through contemporary documents; P.M. YOUNG, *Handel*, rev. ed. (1965), a comprehensive, popular study, and *A History of British Music* (1967), includes a description of Handel in relation to British music as a whole and a discussion of the importance of the Handelian tradition; G.E.H. ABRAHAM (ed.), *Handel: A Symposium* (1954), a detailed examination of the works by various specialists, prefaced by a short study of Handel's personality; P.H. LANG, *George Frederic Handel* (1966), a monumental study.

(P.M.Y.)

Hand Tools

Hand tools, within the original meaning of the term, are manual instruments, traditionally, operated by the muscular energy of the user. The present array of hand tools have as common ancestors the sharpened stones that were the keys to early mankind's survival and rise. Rudely fractured stones, first found and later "made" by hunters who needed a general-purpose tool, were a "knife" of sorts that could also be used to hack, to pound, and to grub. In the course of a vast interval of time, a variety of single-purpose tools came into being. With the twin inventions of agriculture and animal domestication, roughly 10,000 years ago, the many demands of a settled way of life led to a higher degree of tool specialization; the identities of the ax, adz, chisel, and saw were clearly established over 4,000 years ago.

Hand tools may conveniently be categorized as those used by craftsmen in the performance of a manual operation, such as chopping, chiselling, sawing, filing, or forging, that directly shapes a piece of material into a desired form. (The development of agricultural implements is detailed in AGRICULTURE, HISTORY OF.) The common denominator of these tools is removal of material from a workpiece, usually by some form of cutting. The presence of a cutting edge is therefore characteristic of most tools, and the principal concern of toolmakers has been the pursuit and creation of improved cutting edges. Tool effectiveness was enhanced enormously by hafting—*i.e.*, the fitting of a handle to a piece of sharp stone otherwise held in the hand. An invention of almost unparalleled consequences, hafting endowed the tool with better control, more energy, or both.

The common denominator of most hand tools

After a cutting tool has functioned, other implements—*e.g.*, the carpenter's hammer for nailing—may be necessary for the completion of a task. Complementary tools, often needed as auxiliaries, include such things as tongs or a vise for holding. The advanced craftsman also needs layout instruments that outline the desired shape or establish final orientation by measuring or marking: the rule, divider, square, and others. Today, power tools perform many of the old manual operations; these too are hand tools in the modern sense.

The tools of different crafts may often be similar to each other, though proportioned to the size of the task: the heavy chisel and stout mallet of the stonemason and the dentist's delicate chisel and tiny mallet are analogous. Refinement of a tool and adaptation to a particular job are dependent upon available materials and the acquisi-

tion of experience. Special-purpose tools developed as needs for them appeared and the toolmaker's ingenuity met the challenge with new designs and the exploitation of new materials.

The date of the earliest tools is incredibly remote. Tools found in northern Kenya in 1969 have been given an age of about 2,600,000 years, and their state of development suggests that even older tools may remain to be discovered.

The history of tools is easily divided into two parts. The first phase of the story spans over 2,000,000 years, a period that saw the genesis of a few basic tools in the Stone Ages and their slow evolution to modern form in the early centuries of the Age of Metals, as first copper, then bronze, and lastly iron came under man's control as tool materials. Because it was so plentiful, iron was the ultimate metal to supplant stone and other materials. The stage was set, perhaps 4,000 years ago, for the forms of the basic tools to be defined; the ax, chisel, file, and saw of today are only the latest versions of ancient forebears.

The second part of a tool's history lies within the span of approximately the last 2,000 years and includes improvements in detail and innovations that extended the range of the tool. A number of the principal tools of this short period are treated separately, with occasional references to earlier times for the sake of clarity and completeness.

This article is divided into the following sections:

I. Early history of hand tools

GEOLOGICAL AND ARCHAEOLOGICAL ASPECTS

The oldest known tools date from 2,600,000 years ago; geologically, this is close to the end of the Pliocene Epoch, which had extended over 4,500,000 years and was the last of five epochs constituting the Tertiary Period (the 65,000,000 years of which had seen the rise of mammals). The Pliocene was succeeded by the Pleistocene Epoch that began about 2,500,000 years ago and was terminated only recently, perhaps 10,000 years ago, with the recession of the last glaciers, when it was supplanted by the geologists' Holocene (Recent) Epoch. Pleistocene and Stone Age are in rough correspondence, for, until the first use of metal, about 5,000 years ago, stone was the principal material of tools and implements.

At first, man was a casual tool user, using a convenient stick or stone to achieve a purpose and discarding it. But man may have shared this characteristic with some other animals, and part of his differentiation from them may have begun with the deliberate making of tools to a plan and for a purpose. A cutting instrument was most essential, for, of all carnivorous animals, man is the only one not equipped with tearing claws or canine teeth long enough to pierce and rend skin: man needs a sharp tool to get through the skin to the meat. Naturally fractured pieces of stone with a sharp edge that could cut after a fashion were the first tools; they were followed by intentionally chipped stones. Archaeologically, it is the finding of primitive cutting tools intentionally made that is taken to indicate and confirm man's early presence at a site. Once understood, fire helped shape wooden implements before adequate stone tools were available for the purpose. Fire is also the basis of metallurgy. When in historic time the powers of water and wind were applied to the daily tasks of grinding grain and raising water, the way to industrialization was opened.

The idea of relating the history of man to the material from which he made his tools dates from 1836, when Christian Jürgensen Thomsen, a Danish museum director, was faced with the task of exhibiting an undocumented collection of clearly ancient tools and implements. Thomsen used three categories of materials, stone, bronze, and iron, to represent what he felt had been the ordered succession of man's technological development. The idea has since been formalized in the designation of a Stone Age, Bronze Age, and Iron Age.

Thomsen and the three-age system

The three-age system does not apply to the Americas, many Pacific Islands, or Australia, in which places no Bronze Age existed before the natives were introduced to the Iron Age or rather the products of it by European explorers. The Stone Age is still quite real in some remote regions of Australia and South America and existed in the New World at the time of Columbus' first visit. Despite these qualifications, the Stone–Bronze–Iron sequence is of value as a concept in the early history of tools.

Nor does the three-age system imply equal length for the periods; the Stone Age was of vast duration, having occupied practically all of the Pleistocene Epoch. Copper and bronze came on the scene over 5,000 years ago; iron followed in the next millennium or so and as an age includes the present.

The apparently abrupt transition from stone to bronze tends to mask the critical discovery of native metals and their utilitarian use and fails to indicate the significant discoveries of melting and casting. From bronze one can infer the really crucial discovery of smelting, the process by which most of the common metals can be recovered from their ores. Smelted copper necessarily preceded bronze; bronze is a mixture of copper and tin, the first alloy. Iron came later when technique, experience, and equipment were able to provide higher temperatures and cope with problems involved with its use.

STONE AS A TOOL MATERIAL

The Stone Age subdivides into two contrasting periods, the Old Stone Age, a long era of stagnation, and the New Stone Age, a brief period of swift progress.

During the Paleolithic Period, or Old Stone Age, flashes of keen empirical perception, few and far between, set standards for hundreds of millennia. The Paleolithic that endured until about 10,000 years ago was characterized by tools of chipped stone, cutting tools with rough and pock-marked surfaces and generally serrated cutting edges. The later Paleolithic was also an era of wood, horn (antler), and bone. These three materials, all softer than stone but nevertheless intractable, could not be worked successfully without the aid of a harder stone tool such as a serrated, or sawlike, blade and the graver, or burin, a small scraper with either pointed or narrow, chisel-like end. Bone was a particularly useful material, for its toughness made feasible barbed fishhooks, eyed needles, and small leatherworking awls.

The term Neolithic Period, or New Stone Age, defines the second period, at the beginning of which ground and usually polished stone tools, notably axes, came into widespread use after the adoption of a new technique of stoneworking. The beginning of the Neolithic, the retreat of the last glaciers, and the invention of food crops, involving agriculture and animal domestication, were more or less contemporary events. The period terminated with the discovery of metals, which showed the way to superior tools.

The revolutionary art that created the definitive ground and polished tool of Neolithic man was essentially a finishing operation that slicked a chipped tool by rubbing it on or with an abrasive stone to remove the scars of the chipping process that had produced the tool in the

rough. Not only was the edge keener than ever before but the smooth sides of the edge promoted deeper penetration and, hence, greater effectiveness, with the added advantage of easier tool extraction from a deep and wedging cut.

Stones for tool-making

As a tool material, the term stone covers a wide variety of rocks, ranging from the dense and grainless flint and obsidian to coarse-grained granite and quartzite. Each kind of stone has certain unique properties that are further influenced by heat or cold, wet or dry. Stone of any kind is difficult to manipulate, as is readily discovered by knocking two stones together with the intention of producing no more than a sharp but jagged crest. Some archaeologists have studied stoneworking techniques and become adept at producing good imitations of artifacts; further insight has been gained by observing the methods of modern stoneworking peoples in Africa and Australia. It has been noted, for example, that the Australian Aborigines reject as unsuitable a great many of the flints they have worked on, sometimes in the ratio of 300 rejects to one accepted tool. This high discard rate may help explain the thousands upon thousands of stone artifacts that have been found.

Flint, homogeneous and isotropic (equal properties in all directions), is the stone of first choice for toolmaking. Reasonably well distributed over much of the world, it is an impure quartz or silica, usually opaque and commonly of gray or smoky-brown colour. It is harder than most steels, having no cleavage planes, but instead the conchoidal, or shell-like, fracture of a brittle material that leaves a sharp edge when small or large flakes are detached from a piece (glass, which may be considered an artificial quartz, also exhibits the conchoidal fracture). Obsidian, a volcanic glass and also a silicate, but of rather limited distribution, is usually black or at least very dark and, because of its conchoidal fracture, was used like flint. Most edged stone tools, however, are of flint. Flint was once an object of trade, and flint mines were in Neolithic time what iron mines were at a later age.

Three principal types of tools appeared in the long Paleolithic Period with substantial variations occurring within each type. The types are distinguished principally by workmanship but vary also in size and appearance and are known as core, flake, and blade tools. The core tools are the largest; the earliest and most primitive were made by working on a fist-sized piece of stone (core) with a similar stone (hammerstone) and knocking off several large flakes on one side to produce a jagged but sharp crest. This was a general-purpose implement for the roughest work such as hacking, pounding, or cutting. The angle of the cutting edge was rather large because of the sphericity of the stone. With time, thinner, sharper, and more versatile core tools were developed.

Although large flakes with sharp edges of small angle were a by-product of core-tool manufacture and well suited for slitting and scraping, they were not flake tools in the proper sense. True flake tools derived from an advanced technique practiced more than 2,000,000 years later that sought the flake and discarded the core from which it had been detached; flake tools were made deliberately to serve a certain function and were not the casual spin-off of another operation. Finally, there were the blade tools, longish slivers of stone with keen unserrated edges, directly useful as knives or as stock from which other pieces might be skillfully broken to serve numerous purposes. While flake and blade tools were developing, core tools were refined by overall chipping to create thinner and more efficient forms.

Archaeologists have noted three different techniques for working stone to successive stages of refinement in the Paleolithic. The first and always basic method employed the hammerstone to fashion either a large and rude core tool such as the chopper, whose form persisted for perhaps 2,000,000 years or for roughing out (blocking in) large tool blanks that would be brought to final form by removing small flakes. The hammerstone technique produced short and deep flake scars. A variation employed the anvil stone, a large stationary stone against which the workpiece was swung to batter off some large flakes.

Soft-hammer technique

The second method was the soft-hammer, or baton, technique, based upon a discovery of perhaps 500,000 years ago that hard stone (flint in particular) could be chipped by striking it with a softer material. The baton was a light "hammer," an almost foot-long piece of bone, antler, or, even, wood, whose gentler blows detached only quite small flakes that left smooth, shallow scars. Such small flakes, when removed from the large scars left by the hammerstone, reduced the coarse and jagged edge to many small serrations, giving a straighter and more uniform cutting edge whose angle was also more acute than formerly and, hence, sharper.

Pressure flaking was the third technique. In this, a short, pointed instrument of bone, antler, or wood was used to pry (not strike) off tiny flakes to leave the smallest scars. As the least violent and most advanced of the methods of working stone, it gave the craftsman the ultimate in control for the removal of materials in the shaping of his implement.

To judge from the few remaining hand-tool making societies, it is likely that every early man was adept at making new tools quickly and easily and on the spot, as fast as the old ones were blunted or broken. The earliest, simple tools, made by taking a stone of size convenient to the hand and giving it a sharp crest by a few well-placed blows, were evidently discarded after use, for their widespread dispersal suggests that they were made at the place of use and abandoned after serving their purpose. Tens of thousands of prehistoric stone tools survive, compared with only very few bits and pieces of the skeletal remains of the makers. Stone of course is imperishable whereas bone is not, and one individual might have made several hundred tools.

The possibilities in the design of stone tools are limited by the inflexibility and brittleness of the material. The design effort was constrained to the sizing of the tool to the intended task and the development of sharper, longer, and more usefully shaped cutting edges that always required backing to support them. In use, bending and twisting of long knifelike tools had to be avoided lest the action destroy them; this would also have been true of chisels and gouges. Similarly, even the much later heavier tools, such as ax and adz, required care in use.

The effectiveness of stone tools has been demonstrated from time to time by both archaeologists and modern workmen unaccustomed to such tools. An experienced operator using a stone knife can skin a small animal about as quickly and deftly as he could using steel. When the stone tool is subjected to substantial forces, however, the worker must use caution, intelligence, and control. Care is required to avoid twisting or prying with a stone blade (knife or ax); if thin it may snap or, if thick, collect local nicks.

Quality of Stone Age tools

Ancient objects such as stone implements should not be judged by contemporary standards. The use of such adjectives as clumsy, crude, inefficient, and other depreciations is inappropriate. Given Stone Age materials and tools and within the framework of experience then possible, modern man can probably do no better than his forebears; indeed, his product might be worse because of his impatience and frustrations with the unfamiliar tools and the lack of a holding fixture. An ancient artifact and its workmanship are a problem solution, and it may be assumed that the implement was the best possible for the time and circumstances and may even represent an unprecedented achievement.

PALEOLITHIC TOOLS

Early tools are classified by their industry, or type of workmanship. Such tool traditions are identified by a name derived from the site at which the type first drew archaeological attention. For example, the primitive chopping tools that persisted for nearly 2,000,000 years, first identified in Olduvai Gorge, east of Lake Victoria, Tanzania, constitute the so-called Oldowan industry regardless of the part of the world in which implements of similar workmanship happen to be found.

The sequence of traditions shows growth and development; it does not imply abrupt transitions at certain times nor the disappearance of an old industry with the advent of another. A new technique simply meant that something better or different could be accomplished, from the refinement of the cutting edge or the upgrading of old tool forms to the manufacture of a completely new tool. Innovation sometimes was possible only by drawing upon previously unworkable materials.

It becomes apparent from an overview of the products of the successive toolmaking industries that much effort went into cutting edges in the longitudinal direction of the pieces of flint: knifelike instruments predominate and, thus, define the nature of the fundamental need, namely, that of a cutting tool, one that can slit and sever.

With the passage of time and the acquisition of skills, the average size of the tool decreased; there was more cutting edge per pound of material, an important factor when flint had to be imported to a region. This trend was reversed in the Neolithic Period when the heavy woodsman's ax and adz became essential elements to forest clearance for agriculture and timber utilization in settlements, for the world was in transition from an economy based on gathering and hunting food to a way of life founded on food raising.

Archaeologists have named the early tools by guessing at their presumed use, often in the light of other known facts about the culture in which the tradition appeared. As the tools move closer to the present and specialized forms are seen in the creation of a wider variety of products, the descriptive name is on firmer ground. A name, however, can designate only a principal or design use. Even a modern screwdriver is typically used for many tasks other than driving screws.

Eoliths. The first act of the man–tool drama is hazy. There are what have been called eoliths, "tools from the dawn of the Stone Age." Such stones with sharp fractures, found in great quantities in the layers of the geological epochs before the Pleistocene, were once assumed to be tokens of man's presence in the preceding Pliocene and even prior Miocene. These rocks, fractured by glacier pressure or wave action or temperature change, are no longer taken as indices of man, although primitive man undoubtedly used them as ready-made objects before he started deliberately to fracture similar rock in the late Pliocene. There are detail criteria by which human-flaked and nature-flaked stones can be distinguished almost unerringly. Human origin is also evidenced by association with detached flakes and the stones that served as hammers.

The oldest known tool

The tools found in 1969 at the Koobi Fora site, near Lake Rudolph in northern Kenya, consisted of five choppers, a number of flakes, and a couple of battered stones. The tools lay on the surface; three feet below them were found flakes in tuff datable to about 2,600,000 years ago. The oldest previously known tools had been from Olduvai Gorge, Tanzania. These Oldowan tools, as well as the jaw and teeth of a man who may have been the toolmaker, were found in the 1950s fortuitously lying under volcanic rock (tuff) having a potassium–argon date of about 1,800,000 years, a lower Pleistocene age.

All these tools are of a single type, a general-purpose implement that during the next 2,000,000 years hardly changed in form. It is variously known as pebble tool, pebble chopper, chopping tool, or simply as chopper (see Figure 1A). Waterworn and hence rounded, up to about the size of a fist, the pebble, preferably flattish rather than spherical, was given a few violent but skillfully applied blows by a hammerstone or pounder. Several large flakes or chips were knocked off the tool stone to create on it a sharp and roughly serrated crest or ridge, yielding an implement that was edged at one end and could be gripped at the opposite end. Rudimentary yet versatile, the chopper could be used to hack, mash, cut, grub roots, scrape, and break bones for their marrow.

Although the large, sharp-edged flakes struck from the pebble were themselves useful for light cutting and scraping, it was not until perhaps 40,000 years ago that there was a development of flake-tool industries in which preshaped flakes were purposefully detached from a core that was then discarded. But the Oldowan chopper together with the struck-off flakes—the earliest primitive, generalized tools—between them solved the problems of how to get through the skin of a slain animal, dismember it, and divide the meat.

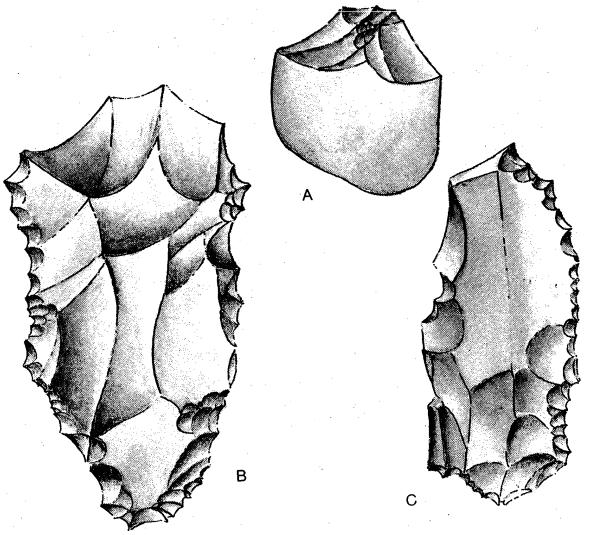

Figure 1: *Paleolithic tools.*
(A) Oldowan chopper, the oldest manufactured tool.
(B) Acheulean hand ax or fist hatchet, a superior chopper.
(C) Scraper, a flake tool.

The Acheulean and Mousterian industries. As the Pleistocene moved along, man slowly developed the primitive chopper into a better instrument. About half a million years ago a superior implement finally appeared after nearly 2,000,000 years of effort. The industry or style is known as the Acheulean, and the typical implement was the hand ax (sometimes called fist hatchet) of flint in the Western part of the world (Figure 1B). Over the ages the plump chopper and its bluntly angled crest had been streamlined by starting with a longer piece of stone and flaking the entire surface to produce an almond-shaped (amygdaloid) implement eight to ten inches (20 to 25 centimetres) long. This stone, much thinner than the chopper, was also sharper and more effective because the cutting edges were formed from the intersection of two curved and flaked surfaces (bifacial working).

The Acheulean hand ax

This Acheulean hand ax was the product of evolution; certain of the intermediate stages, clearly leading to the typical and standardized form, have been identified as Chellean and Abbevillean. Despite the term ax, the tool was not hafted but was simply held in the hand. One end was tapered, the other rounded. The tapered end might be rather pointed or have a small straight edge. The tool was sharp for most of its periphery and seems to have been primarily a hunter's knife but probably very useful, too, for other purposes such as chopping, scraping, grubbing, and even piercing. Sharp, thin and symmetrical, light and elegant, it was quite different from the heavy chopper with its rather blunt edge.

Another biface, the Acheulean cleaver, assumed prominence about 250,000 years later. A variant of the hand ax, it had a wide cutting edge across the end instead of a point, better suited than the hand ax for either hunting purposes or hacking wood.

Although the hand ax is the first and principal index of the Acheulean, the industry had a broader scope, dealing also heavily in smaller flake tools suited to lighter tasks. Of particular importance was the discovery of soft-hammer flaking, a technique described previously.

The Neanderthal tool kit

Neanderthal man, an excellent hunter and toolmaker, appeared on the scene about 110,000 years ago just ahead of the last glaciation, well within the Acheulean. His tool kit was impressive for the wide variety of hand axes, borers, knives, and choppers that it contained. The

kit was novel for the scrapers and the heavily serrated blades having a sawlike appearance, implements that were essential to the working of wood, bone, and horn into tools and weapons. The Neanderthalers regularly used fire, and it is presumed that they could make it, although the direct evidence is missing. Fire was useful in tool manufacture, for charring the end of a stick not only helps shape the point by making it easier to scrape but also hardens it, as for a spear point. This fire hardening was probably the first man-made modification of a natural property. Thoroughly wet wood, bent to shape and brought to dryness over the heat of a fire, retains its bent form, a most useful property.

Flake tools. Another distinct phase of toolmaking is the Mousterian–Levalloisian, sometimes assigned to the upper part of the Acheulean, or it may be said to overlap. This phase is marked by the major innovation called the prepared-core technique, a flake-tool industry. In this, a core was craftily trimmed in such a manner that a skillfully applied last blow would detach a large, preshaped flake directly usable as an implement; the core was discarded. Such a flake tool has one flat surface and is known as a unifacial tool because a single bevel forms the working edge. There are two principal kinds of flakes, the points and scrapers. The former are roughly triangular with two trimmed or sharp edges meeting in a point, the base or butt of the triangle being thick and blunt. The side scrapers have a sharp edge in the long direction of the flake with an opposite, thicker butt section (Figure 1C). The scraper could function as a knife, although it is speculated that it was used for working wood and skins, a supposition leading to the idea that skins were being used for clothing.

Late Paleolithic toolmaking. Phase four of Paleolithic toolmaking was introduced perhaps 40,000 years ago by Aurignacian culture, pregnant forerunner of the last and most brilliant achievements of the Old Stone Age. Extraordinary inventiveness is characteristic of this Aurignacian tradition and its several short-term successors. They can be lumped into a unit of development over the next 25,000 years.

Fully modern man—whose first representative is the Cro-Magnon—emerged within this period, perhaps 35,000 years ago, during a time of action, of development and elaboration of stone technology, which, by providing a variety of specialized tools, mostly of the flake and blade types, would at last bring materials other than stone into extensive use. It was also a time of great plains in northern and eastern Europe that carried such a heavy reindeer population, in addition to wild horses and mammoths, that it has been called the Reindeer Age. This meant a hunting economy providing food and great quantities of bone, horn, skin, sinews, and, while the mammoth lasted, ivory; with it grew new technologies exploiting the unique properties of materials hitherto unworkable because of their hardness. This technological diversification was possible only by reason of stone tools and new techniques, specialization and complexity fitting them to the fresh tasks. The most significant tool was the burin, or graver, a stout, narrow-bladed flint able to cut (scrape is more like it) narrow grooves in bone; two parallel grooves, for example, would allow a sliver of bone to be detached as stock for a needle, pin, awl, or other small object. Larger pieces of bone were worked into hooks with one or more barbs or points. Sections of antler were carved into splitting wedges to work out long pieces of bone to form the dartlike projectiles of the spear-thrower. Sandstone polishers were added to the tool kit to sharpen and shape tips and needles and other articles.

The stone burin

A spectacular item that developed by the end of the Paleolithic was the spear-thrower, the first projectile weapon. This was a hand-held stick, of wood or antler, notched at one end. Functioning as an extension of the arm, it added considerable kinetic energy to a short spear or javelin tipped with flint or bone; the toolmaking hunter no longer had to creep close to his game but could attack from a distance. The tipped projectile represented still another innovation, for it was the first hafted implement, the first evidence of fitting of a "handle" to a tool point, which heightened the utility of both small and large cutting edges.

Hafting, or the fitting of a handle to a cutting edge, was a momentous and far-reaching invention of about 35,000 years ago. By hindsight an obvious idea, it was, nevertheless, over 2,000,000 years in the making. Hafting was a critical step toward the creation of new tools and improved models of the old. A hafted tool is also called a composite or compound tool, for it consists of two or more pieces connected to form a single implement. In its simplest form, the haft may be no more than a grass or leaf bundle whose limited function is to protect the hand when a fractured stone is used as a knife. At the other extreme, where the higher function of making the previously impossible a practicality is realized, there is woodchopping: a man using a hand-held axhead can cut only small trees, whereas with a hafted ax he can fell a tree of almost any size. Mechanically, a handle, whatever its form, is a force-transmitting intermediary between the source of the force and the toolhead. The handle, viewed as an extension of the arms, provides an increased radius of swing. This moves the toolhead faster to give it more kinetic energy for a harder and more telling blow than the arms alone can provide.

The prepared-core technique that provided preshaped flakes was refined and extended to provide preshaped blades, long and slender pieces of flint of trapezoidal cross section, each corner having a straight cutting edge without the serrations of a chipped tool. This is known as the blade-tool industry, a final complement to the core- and flake-tool technologies. Such blades made thin and splendid knives of great variety; many of these knives were backed; that is to say, the back of the blade was blunted for safer handling. Thin blades were further reduced to smaller pieces, often having a geometric form such as triangular, square, or trapezoidal, called microliths. These small bits of sharp flint were cemented (using resin) into a groove in a piece of wood to form a tool with a cutting edge longer than it was feasible to produce in a single piece of brittle flint: a spear with a long cutting edge or the farmer's sickle of later date.

The second major mechanical invention of the Upper Paleolithic was the bow, a device even more effective than the spear-thrower for increasing the distance between the hunter and the hunted. It is difficult to date precisely, for the only conclusive evidence is found in cave paintings. Mere finds of stone points without bows prove nothing because such tips were used on the projectiles of spear-throwers. The earliest representations of the bow come from North Africa, 30,000–15,000 BC. Once the bow had been devised, it spread with astonishing rapidity, its effectiveness making it the weapon *par excellence*. When a bow is pulled, it stores the gradually expended energy of the archer's muscles; this energy is suddenly released to give the projectile a "muzzle velocity" far higher than that possible from a spear-thrower and of superior accuracy. It was a principal weapon through the 15th-century AD and was ousted then only by gunpowder.

The first bows

NEOLITHIC TOOLS

The Neolithic Period, or New Stone Age, the age of the ground tool, is defined by the advent, around 7000 BC, of ground and polished celts (ax and adz heads) as well as similarly treated chisels and gouges, often made of such stones as jadeite, diorite, or schist, all tougher than flint. A ground tool is one that was chipped to rough shape in the old manner and then rubbed on or with a coarse abrasive stone to remove the chip scars either from the entire surface or around the working edge (see Figure 2A). Polishing was a last step, a final grind with fine abrasive. That such a tool is pleasing to the eye is incidental; the real worth of the smoothing lies in the even cutting edge, superior strength, and better handling of the tool. The new ax would sink deeper for a given blow while delivering a clean and broad cut; its smooth bit, more shock resistant than the former flaked edge, had less tendency to wedge in a cut.

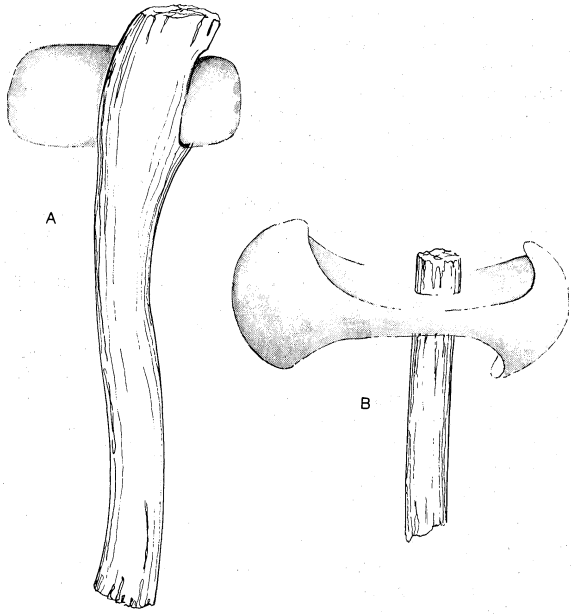

Figure 2: *Neolithic tools.*
(A) Stone ax, a ground tool, made by chipping to rough shape, then rubbing to give a nonserrated edge. (B) Stone ax made by pecking, a technique involving light, rapid blows followed by grinding.

Although the polished stone tool is the index to the Neolithic Period, it may be noted that the ice sheets were receding and climatic conditions were assisting the conversion of hunter into herdsman. The new, relatively sedentary life spawned further inventions, such as pottery. From a tool standpoint, the potters' kiln and art were necessary steps to the metals, for a modification of the kiln probably provided the high temperatures and equipment needed for metalworking, first for melting native metals and later for the ultimate smelting process that gave rise to a wealth of metals, several of which proved superior tool materials.

The polished Neolithic ax, a heavy implement, was in sharp contrast to the delicate small-stone work of the last stages of the Paleolithic and was, as has been noted earlier, a reversal of the traditions the products of which had yielded ever more lineal feet of cutting edge per pound of stone. The ax and its companion adz met the needs of forest-land clearance as agriculture developed. An efficient tree-cutting tool was indispensable for the slash-and-burn agriculture then devised and practiced the world over for millenia. Trees were either cut down or killed by ringing with an ax; the debris was burned over, with the ashes conferring a slight enrichment of the stump-filled field. The earth was next scarified with sticks or stone-headed hoes resembling the adz to prepare it for the seeding among the stumps. Without manuring or other treatment, the land was exhausted after a few years, necessitating a repetition of the clearing process elsewhere. The consequence was a shifting settlement pattern, with a good ax needed not only for felling the trees but also for working the timber for settlement purposes.

The ax in land clearance

Wood began its broad role in the life of man with the ground and polished tools of the Neolithic. Home and fire, furniture and utensils, cradle and coffin were products of the ax, adz, and chisel that could fashion wood intricately and with precision. This kit of tools turned wood into an almost universal building material, for a whole host of new things was now possible, as dugout canoes of oak, paddles, framing for hide-covered boats, sledges, skis, wooden platters, ladles, and other household gear. Mortise and tenon joints were invented for the structural framing of substantial habitations. Some of the gabled houses were up to 100 feet long and 20 wide and are believed to have served as both granaries and living quarters for perhaps 20 people comprising several families.

In a revealing experiment, 4,000-year-old polished stone axes, furnished by the Danish National Museum and carrying the sharpness left after their last use 4,000 years ago, were fitted with ash handles modelled after that of a Neolithic hafted ax preserved in a bog, giving the ax an overall length of nearly 25 inches (a modern steel felling ax has a 36-inch handle). When these were used in a Danish forest, it was soon found that the violent action of the modern technique of swinging a steel ax and putting shoulder and weight behind the blade to give long and powerful blows was disastrous, either ruining the edge or breaking the blade. Proper handling meant short, quick strokes that chipped at the tree, the body action being constrained to mainly elbow and wrist motion. After getting into form, the men found it possible to fell oak trees of more than one-foot diameter in half an hour or a two-foot-diameter pine in less than 20 minutes. Six hundred square yards (one-eighth acre) of silver-birch forest were cleared by three men in four hours. One axhead cut down more than 100 trees on its original (old) sharpening. It was concluded that Neolithic men and their ground flint axes had no great difficulties in making large clearings in the forest for the purposes of cultivation. It may be remarked that it was less trouble to clear the forest than to break the ages-old and tough sod of the plains.

The Neolithic farmer of northern Europe and his program of deforestation for agriculture were completely dependent upon polished axes, creating a heavy demand for good stone that depleted local sources. The response to this was flint mining in well-endowed locations in England, Belgium, Holland, France, Denmark, Sweden, Poland, Portugal, Sicily, and Egypt. Actually, it was often more than just mining; it would be proper to speak of ax factories, for the flints were shaped to rough form by chipping at the pithead and then traded, grinding and polishing being done by the ultimate consumer.

Flint mining

An idea of the magnitude of such a mining enterprise is offered by the well-explored workings known as Grimes Graves about 80 miles northeast of London. The site covers about 34 acres and includes both opencast workings and 40-feet-deep shafts with radiating galleries that exploited the flint deposit laid down as a floor under chalk beds. Excavation was probably by wooden shovel (product of polished ax and chisel) or possibly the shoulder blade of oxen. It is estimated that perhaps 50,000 picks made of red-deer antler were used during the 600-year-long activity begun about 2300 BC.

A last innovation of the Neolithic was the augmentation of the two older techniques of working stone, chipping (or flaking) and grinding, by a third way, the pecking, or crumbling, method (Figure 2B). In this procedure, a point of the stone being worked is bruised by a hard hammerstone, the struck points crumbling to powder under relatively light but rapidly delivered blows. This technique allowed the manufacture of tools from numerous varieties of appropriate but nonflaking stone and the production of hollow ware, such as querns for grinding grain, mortars, and bowls. It could also be applied to flakable stone, and such a stone, after having been roughed out by flaking, was pecked to level the ridges between flake scars before grinding and polishing.

Stone tools maintained themselves during the Metals Age, yielding only slowly to the new material, which was expensive and the product of specialists' skills. The copper and bronze tools and weapons for hunting, warfare, husbandry, and domestic use that constitute impressive displays in museums were rare luxuries. Even the much more abundant iron that overtook and replaced copper and bronze articles was only sparingly available for many centuries.

EARLY METALS AND SMELTING

The discovery that certain heavy "stones" did not respond to hammerblows by flaking or fracturing but were instead soft and remained intact as their shapes changed marked the end of the almost infinitely long Stone Age. Of the pure, or native, metals, gold and silver seem to have attracted attention at an early date, but both were too soft for tools. The first metals of value for toolmak-

ing were natural copper and meteoric iron. As tough and potentially versatile, if scarce, materials, they were suited for new purposes, as well as many of the old. They also introduced a new problem, corrosion.

Metalworking. Copper occurs in the native state in many parts of the world, sometimes in nuggets or lumps of convenient size. It is malleable; that is, it can be shaped by hammering while cold. This also hardens it by giving it a closer texture and allows it to carry a sharp edge, the hammered edge being capable of further improvement on an abrasive stone. After a certain amount of hammering (cold-working), copper becomes brittle, a condition that can be removed as often as necessary by heating the material and plunging it into cold water (quenching): the whole softening operation is known an annealing. Repeated annealings are necessary if much hammering is required for shaping. Nuggets were hammered into sheets, divided into strips and then pieces to be worked into arrowheads, knives, awls, choppers, and the like. Copper was also shaped by beating pieces of the soft metal into appropriately shaped stone cavities (molds).

Naturally pure, or virgin, iron (as differentiated from iron ore) is so rare as to be of no significance in the history of toolmaking, despite one spectacular occurrence in Greenland, where metallic iron and basalt happen to lie over coal beds; it is thought that the underlying iron ore, while erupting through the coal, was reduced to iron. Eskimos have long used this exceptional source of iron for knife and small-implement manufacture.

Use of meteoric iron

Meteoric iron, widely distributed but not in heavy deposits, was a highly prized material more difficult to fabricate than the softer copper. Its celestial origin was recognized by the ancients, for the Egyptians called it black copper from heaven, and the Sumerians denoted it by two characters representing heaven and fire.

This meteoric iron was beaten into tools in much the same way as copper, although it could not be forced into a mold in the manner of the softer metal. Like copper, iron hardens under the hammer and will then take a superior edge. Iron can be annealed, but the process is quite different from that of copper because, with iron, slow cooling from a high temperature is necessary. Meteoric iron is practically carbonless and, hence, cannot be hardened in the manner of steel; a high nickel content of about 8 percent makes it relatively corrosion resistant.

Much rarer than copper, meteoric iron was often used for jewelry, attested to by burial finds of necklaces of iron and gold beads, iron rings along with gold rings, and ornaments in sheet form. Small meteorites were the most convenient sources, but larger bodies were hacked at with copper and stone tools to yield tool-size pieces for knives, spear points, arrowpoints, axheads, and other implements.

Casting. A great step forward was made with the discovery that gold, silver, and copper could be melted and cast with many advantages. In casting, a liquid metal is poured into a cavity or a mold to give it the shape of the mold on congealing; casting shapes the metal to essentially final form once a proper cavity has been prepared. Some touch-up work may be needed; for an edged copper tool, such as an ax or knife, hammering the cutting side gives a keen edge.

Casting meant that the size of the tool was no longer dependent on the size of a chunk of available copper. Old tools could be added to a melt instead of being thrown out. This reuse of old metal accounts in part for the scarcity of virgin-copper implements.

To make viable procedures of melting and casting required a round of innovations, all minor but vital to success.

Pottery making, already well established, provided the knowledge of heat-based processes. Clay vessels are essential to working with fluid metal, for, in all but the most primitive operations, it is necessary to convey the melt from furnace to mold. Aside from providing crucibles, pottery making taught restructuring the fire with a deep bed of prepared charcoal to provide a heat superior to that of a simple campfire. Tongs of some sort had to be devised to carry the hot crucible; it is surmised that green branches were bent around the pot and replaced as needed.

Molds

As for the molds themselves, a number of forms were developed. The most primitive was simply an impression of a stone tool in clay or sand to give a cavity of the desired form. A more durable mold resulted when the cavity was worked into stone. Cavities of uniform depth allowed flat but profiled pieces to be cast. For example, some ax-blade castings were roughly T-shaped, the arms of the T being afterward bent around to clasp a handle of some sort, with the bottom of the T becoming the cutting edge. A one-piece mold, prepared for a dagger, could have a groove for most of the length of the cavity to provide a stiffening rib on one side. With experience, closed but longitudinally split and, hence, two-piece molds were devised, each side now having a groove down the middle to furnish a strengthening rib on both sides of the blade. Split molds for copper left much to be desired because pure copper is a poor metal for casting. It contracts a good deal on cooling and has a tendency to absorb gases and thereby become porous, blistered, and weak. Also, molten copper exposed to atmospheric oxygen contains embrittling cuprous oxide.

Smelting. Perhaps 1,000 years after man learned about melting virgin copper, he found that still another stone, a brittle one directly useless for tools, would produce liquid copper if sufficiently heated while in contact with charcoal. This step was epoch-making; it was the discovery of smelting, or the separation of a metal from a chemical compound called ore. Smelting (as differentiated from melting) was the first metallurgical operation and is still the principal method of gaining metals from their ores. Copper was the first tool metal to be won in this fashion; it was another 1,000 years before iron could be reduced from its ores.

It has been hypothesized that metallic copper and iron were discovered from the accidental reduction of their ores to metal in a campfire or other large blaze. An ordinary open wood fire has a maximum temperature of about 600° C (1,100° F), enough to produce a red heat in metals, but the necessary temperature for producing copper from an ore such as malachite is 700° to 800° C (1,300° to 1,500° F) under a proper combination of circumstances. With a big fire in a good wind and with pieces of copper ore in direct contact with much charcoal, small copper beads may be sweated out to be recovered when the ashes are cold; even if primitive man had recognized the beads as copper, he would not have had a useful amount of metal. It is more likely that copper ore was inadvertently placed in the reducing atmosphere of an overheated pottery kiln and that the strange and malleable residue was recognized as being similar to the very utilitarian copper.

As mined, raw ore is a mechanical mixture of ore proper (heavy) and earthy matter, or gangue (light); the two may be largely separated by crushing the raw ore and washing away the lighter gangue. The ore proper is a chemical compound of oxides, sulfides, carbonates, hydrates, silicates, and such impurities as arsenic and other elements in small amounts. Smelting frees the metal from the various combinations with which it is bound into the compound form. A preparatory step is to heat the washed ore (roasting or dressing) not only to dry it but also to burn off sulfides and organic matter. Early practice involved heating the ore in intimate contact with charcoal to provide the essential reducing atmosphere, producing a metallic sponge made up of metal and slag.

Some of the earliest copper smelting was terminated at the spongy stage. For chemical as well as practical reasons the iron of tools, wrought iron, continued to be worked out of the spongy mass until the Middle Ages. With copper smelting, the metallic sponge was soon allowed to remain in the furnace and subjected to draft-induced high temperature. The metal became liquid and seeped down to the hearth, as did the slag, which, being lighter than the metal, floated over it, permitting recovery of the copper.

At some time during the copper period, a new kind of "copper" happened to be made by smelting together two

separate ores, one bearing copper, the other tin. The resulting metal was recognized as being far more useful than copper alone, and the short period of copper tools came to an end. The new metal, a copper–tin alloy of mostly copper, was bronze. It was produced in the fluid state at a temperature less than that needed for copper, could be formed economically by casting, and could be hammer hardened more than copper. The tin noticeably increased the liquidity of the melt, checked the absorption of oxygen and other gases, and suppressed the formation of cuprous oxide, all features that facilitated the casting operation. A two-piece, or split, mold, impracticable for copper, works very well with bronze. Furthermore, bronze expands just a bit before solidifying and thus picks up the detail of a mold before it contracts in cooling.

Dawn of the Bronze Age

The earliest bronzes were of uneven composition. Later, the tin content was under good control, 10 percent was a common amount, with a little less for hammered goods, a little more for ornamental castings. The edges of hammered bronze tools of this composition are more than twice as hard as those obtained from copper.

The Bronze Age of tools and implements began about 3000 BC. In the course of 1,000 years the much more abundant iron supplanted bronze for tools, but bronze continued to be used in the arts.

All the early metals were expensive commodities in antiquity and were monopolized by kings, priests, and officials. Most metal was diverted to weapons manufacture for professional soldiers. Industrial use was severely limited. The metal chisel was used on the stone for buildings of state or fashioning furniture for the wealthy; the common man living in a mud or reed hut had no reason to own such a tool.

Generally speaking, molds were of baked clay, although soft stone was sometimes carved; metal molds are known from about 1000 BC. Sectional molds of three and four pieces, permitting more complex castings, are known from about 2600 BC. The earliest metal tools and implements were simply copies of existing stone models. It was only slowly that the plasticity of the new medium and especially the possibilities inherent to casting were appreciated. The stone dagger, for example, was necessarily short because of its extreme brittleness. With copper and then bronze, it became longer and was adapted to slashing as well as stabbing. Casting allowed forms impossible of execution in flaked stone, such as deeply concave surfaces. Holes could be cast in, rather than worked out of, the solid.

Sometimes the process was reversed. There were, for example, pottery imitations of bronze vessels for the poorer classes, with such necessary adjustments as a heavier lip for the pottery jug. The lines of bronze daggers have been noted in stone daggers of a later date, despite the difficulty of imitating a metal object in stone. Bronze axheads were copied in stone, even to the shaft hole, difficult to produce and impractical for a stone tool; it is possible that some of the stone replicas of bronze daggers and axes were for ceremonial rather than utilitarian purposes.

Pottery imitations of bronze

Malleable metal has several advantages over a brittle material, such as stone or bone or antler, the first of which is that it can be severely deformed without breaking and, if badly bent, can probably be returned to service after straightening. It is shock resistant and chipproof, welcome qualities for ax, adz, and chisel, and the edges can be kept keen by hammering or abrasion; sharpness is, however, inferior to that of good stone. In particular, metal allows the fashioning of many small items, articles of a size awkward to make of bone or horn, such as pins, fishhooks, and awls. Copper pins were stronger, tidier, and more attractive than the fish bones and thorns they replaced for securing clothing; even in the 3rd century BC there were shapes resembling the modern safety pin. Tweezers were invented, but whether for depilatory or surgical purpose is unknown; there are artifacts presumed to be scalpels. Plates, nails, and rivets also came early.

The most common tools were awls and pointed instruments suitable only for wood and leather. Woodworking was facilitated by the invention of the toothed copper saw, made of smelted metal and cast to shape. Edged tools—ax, adz, and chisel—at first similar to stone models—asserted themselves and, although not nearly as sharp as the tools they replaced, had the advantage of toughness and could be easily resharpened. In particular, the chisel made it possible to use cut stone for construction purposes, principally in temples and monuments. Abrasive sand under metal "saw blades" allowed stone to be cut neatly, just as the sand under tubes (made from rolled-up strips) that were turned provided a boring device for larger holes.

IRON AND STEEL TOOLS

Iron technology was derived from the known art of reducing copper and bronze. The principal requirement was a furnace capable of maintaining a reducing atmosphere—*i.e.*, one in which high temperature could be maintained from a good draft of air. The furnace had to be of sufficient height to allow the iron to drop from the smelting zone, forming a slaggy lump usually called a bloom.

After aluminum, iron is the most abundant metal, constituting about 5 percent of the earth's crust. Copper is in short supply, having a presence of, but 0.01 percent, iron is thus 500 times more plentiful. Iron ore suitable for simple smelting was widely distributed in the form of surface deposits that could be scraped up without elaborate mining procedures.

The limitations imposed by the dearth of metals in the Bronze Age were now lifted; new tools and implements became possible, and their numbers could increase until even the poorer classes would have access to metal tools. The iron of antiquity was wrought iron, a malleable and weldable material. Brittle cast iron, versatile and widely used in modern industry, was unknown to the ancients, which is just as well, for it would have been of no value for their edged tools and implements. Tools require toughness—shock or impact resistance—an inherent property of wrought iron that is subject to enhancement by forging. The earliest history of smelted iron is obscure, with the first scanty evidence of man-made iron dating from about 2500 BC in the Near East. A thousand years later, the abundance of ores had brought the displacement of copper and bronze by iron in the Hittite Empire.

During most of its history, iron was not recovered in a molten state but reduced to a spongy aggregate of iron and slag formed at a temperature well below the melting point of pure iron (1,535° C, or 2,795° F). This plastic metallic sponge was consolidated by hammering to squeeze out slag and weld the iron particles into a compact and ductile mass; thus it was called wrought iron, essentially pure iron with remnants of unexpelled slag coating the iron particles. Wrought iron contains so little carbon that it does not harden usefully when cooled rapidly (quenched). When iron containing 0.4 to 1.25 percent carbon is heated to 950° C, or 1,740° F, and then plunged into water or oil, it is hardened.

By about 1200 BC, when iron had become important in the Near East, man had learned how to create a steel surface, or case, on wrought iron, a case that could be hardened by heating and quenching. This case had been produced by the prolonged heating of wrought iron packed in a deep bed of glowing charcoal; the principle is that the surface of red-hot but carbonless iron readily absorbs up to 1 percent carbon from the carbon monoxide generated in the enveloping charcoal fire.

Iron importance in Near East

But iron did not offer up its virtues without a price, since all of the casting experience gathered from working with smelted copper and bronze was of no moment with a metal whose shape could only be changed by hammering. Moreover, the malleability of iron is less than that of copper for the same temperatures, which means that the smith has to work harder to promote a desired change in form. Stone hammers gave way to hafted bronze hammers, iron itself coming into use later. The first anvils—for copper and bronze—were convenient flat stones, to be

followed by increasingly larger cast-bronze models that in turn were superseded by rudimentary forms of the modern type, several pieces of iron being welded together. The earliest iron artifacts were of ruder appearance than the bronze articles that came before them.

A most valuable property of wrought iron is the ease with which two or more pieces may be united by hammering while the metal is at a high heat; iron has a high plasticity throughout a considerable temperature range below the welding, or white, heat. Even at the production stage, small pieces of spongy iron were united into larger blooms. Hammer-welding, however natural it was to ironworking, had been practiced before by goldsmiths and, in spite of the difficulties due to gassing, was even used for joining copper to make, for example, tape by welding together strips cut from plate. Welding became an essential production procedure. When iron tools had reached the end of a useful life, they could be used as bases for a new round of tools by welding the scrap into a blank and starting over, a process akin to the melting of copper and bronze scrap to cast new tools.

Iron led only slowly to generally superior tools and weapons, the gradual process being dependent upon the evolution of new techniques suited to fuller exploitation of its properties, the most singular being weldability. Like most new materials, iron had to overcome traditional usage and inertia and again, like most new materials, was not superior to the old in all points but only in some, involving a degree of compromise between its attractive and its less desirable qualities.

Iron compared to bronze

Iron ordinarily has twice the flexibility of bronze and is very much tougher, for a bar of iron can be bent back upon itself without fracturing, whereas a bronze bar (as a sword blade) breaks after only a light bend (bronze blades repaired by casting new metals into the factured sections are known). Bronze, in other words, is brittle when compared to iron, although copper is not. As the tin content of bronze rises, ductility is lost with the increasing hardness; with even 5 percent tin most of the malleability is missing from cold bronze, the ductility becoming practically nil at 20 percent tin content. The cutting edge of a hammered bronze tool is superior to that of its similarly treated iron counterpart, and is corrosion resistant.

In the Early Iron Age, when the metal was still in scarce supply, local armament makers were the chief consumers of the new metal. Agricultural tools, always subject to hard usage, entered the picture next, under the demands for adequate tools for forest clearance and subsequent cultivation. Axes, picks, and hoes were needed. Iron was smelted in the Near East before 2500 BC, but the Iron Age proper was 1,000 or more years in maturing. The long delay was due to several factors—tradition has already been mentioned, but there was the necessity for a strong air blast, and the time-consuming hammer forming as opposed to the easy process of casting. The fully developed Iron Age came with the discovery of hardening by carburization (addition of carbon) and heat-treating, which led to superior edge tools of great toughness.

II. Later development of hand tools

From the evolution of tools over more than 2,000,000 years with principal materials successively stone, bronze and iron, a number of particular tools emerged. Taken together, these specialized tools form an inverted pyramid resting upon the first general-purpose tool, the almost formless chopper. With the discovery of metals and the support of numerous inventions allowing their exploitation, first approximations to the modern forms of the basic tools of the craftsman established themselves, with the main thrust of further development directed at improving the cutting edges. Before speaking of specific tools, some generalities are necessary to provide an appreciation of the problems they were designed to solve.

A design is a concept that is only incompletely realized in physical form by reasons of necessary compromises imposed by the materials of the workpiece and tool, by the motion the workman can give the tool, and by the forces that can be applied. It is here that hafting, or the fitting of a handle to a cutting edge, provides the opportunity for the differentiation of tools and their wide variety of forms.

The need for specialized tools

The earliest tools were multipurpose in the same sense that an ordinary pocketknife is. Specialized tools were latecomers. A multipurpose tool, whereas able to do a number of things, does none of them as well as a tool designed or proportioned for one job and one material; compromise in function means compromise in product. The way in which a tool is hafted provides the primary distinction between knife, ax, saw, and plane. An application or craft is best served by a further specialization or form within a category: the knives of the butcher, woodcarver, and barber reflect their particular tasks. When confronted with the unusual, a skilled mechanic rises to the occasion with a special tool to cope with the situation. In the early 19th century, for example, a joiner had dozens of planes in his kit to deal with the many moldings, rabbets, and jointings he had to produce before the day of machine-made stock and mill-planed lumber.

PERCUSSIVE TOOLS

In looking at the tool spectrum, it will be seen that several involve a violent propulsion to deliver a telling blow. These have been named percussive tools; their principal representatives are the ax and hammer, one an edged tool and the other not. Under these two names are found an immense number of variations of which only a very few can be touched upon. The percussive group may also be called dynamic by reason of their swift motion and the large, short-term forces they develop. This means that mass and velocity and, hence, kinetic energy and momentum are factors related to the force generated or transmitted. Weight distribution between head and handle and mechanical properties of the head (suitability for cutting edge, lack of elasticity) must also be recognized in the design of a percussive tool. Obviously, these various influences were not formally considered during the ages-long trial-and-error evolution of a now successful tool, but their recognition now will aid in identifying the several evolutionary stages.

Percussive tools generally have handles that allow them to be swung; that is, they are endowed with kinetic energy by reason of their rapid motion. The attainable energy of a blow depends upon a number of factors, including the weight of the toolhead, the angle through which it is swung while gaining speed, the radius of the swing (handle length plus part or all of the arm length), and the muscle behind it all. There is a permissible energy level for a given task and tool, set by either the nature of the task or the material of the tool. Thus, a blacksmith flattening a one-inch iron bar wants a heavy, fairly long-handled hammer, whereas a light and short-handled hammer, used with wrist action, is appropriate to forging a small, soft-gold wire. A hafted flint ax is an effective tool, but may be destroyed if swung too hard or if twisted while in the cut. Bronze and steel axes can and do use longer handles than the stone ax and, being of tougher material, will not break under usage that would fracture a stone head.

The physics of percussive tools takes into consideration the centre of gravity and what is technically called the centre of percussion—*i.e.*, a unique point associated with a rotation, in this case the arc through which the tool is swung before delivering its blow and coming to rest. The tool's centre of gravity is readily found because it is the balance point, or location along the handle at which the tool can be picked up loosely and still remain in the horizontal position. The centre of percussion is the ideal point at which striking should occur on the toolhead to minimize the sting of the handle in the operator's hand as well as deal the maximum blow; this point will be outboard of the centre of gravity and should be as close to the centre of the head as possible. This last condition is best met with a light handle and heavy toolhead, placing the centre of gravity close to the head and the centre of percussion in an optimum location in the cutting edge. The centre of percussion is readily defined for a mechanical system in which there is a fixed pivot about which rotation

Centre of percussion

takes place; with the human body, where wrist, elbow, and shoulder joints can contribute rotations to the swing of the tool, the centre of percussion can be discussed only in principle—its location cannot be defined precisely.

It is apparent that the sheer weight of the head is of paramount importance in promoting the proper balance, or hang, to the tool. On this basis alone, the shift from stone axheads to metal was a step in the proper direction because metal heads of the same size as those of stone are about three times as heavy. With the heavier head, the centre of gravity of the hafted tool is further out, closer to the head, and the centre of percussion is more likely to be properly located in the head.

With the mallet and chisel, still other interrelations are involved. When working stone, a brittle material that responds to the sharp tool point by breaking out in small chips, the sculptor strikes many light blows to remove material. In consequence, mallets have short handles, and the amplitude of swing is small, allowing a succession of rapid blows without undue operator fatigue. To provide energy and momentum, the mallet head is heavy. Being of wood, it does not rebound in the manner of a metal head but stays on the chisel that transmits the blow to the cutting edge that focusses it into a small area of stone to be spalled off. The net effect of the proper combination of all elements, the properties of wood, chisel, and stone, the weight of the head (perhaps even heightened by reason of a lead-filled cavity), and short handle, is to waste the least energy. The wooden head is of course expendable, particularly if of one-piece clublike construction, for it becomes badly battered from contact with the metal chisel. A more refined mallet consists of separate head and handle, the head having a working face of end-grain wood.

Working metal with a chisel—the process is called chipping and was the only way of removing metal before the development of machine tools—requires that heavy blows be struck to enable the chisel to dig into the metal and lift out a chip. A steel hammer with a hardened face is used, and in this operation it is the soft end of the chisel that is battered and needs periodic dressing.

Hammers and hammer-like tools. "Hammer" is used here in a generic sense to cover the wide variety of striking tools distinguished by other names, as pounder, beetle, mallet, maul, pestle, sledge, and others, as well as the common hammer. The best known of the tools that go by the name hammer is the carpenter's claw type, but there are many others, such as rivetting, boilermaker's, bricklayer's, blacksmith's, machinist's ball- and cross-peen, stone or spalling, prospecting, and tack hammers. Each has a particular reason for its form. Such specialization was evident under the Romans, and a craftsman of the Middle Ages writes (AD 1100) of hammers having "large, medium and small" weight, with further variations of "long and slender" being coupled with a variety of faces.

Since a pounder or hammerstone was the first tool to be used, it may also have been the first to be fitted with a handle to increase the blow. Although some craftsmen of the soft metals still favoured the hand-held stone, presumably for its better "feel," hafting was an enormous technological advance. Yet it created a problem of major proportions that still persists: that the connection between handle and head must carry shock loads of high intensity, a situation even more complicated with the ax than the hammer because the ax may be subjected to twisting on becoming wedged in a cut. The most satisfactory solution for metal heads is the shaft hole in the toolhead; it is a poor solution for a stone tool because of the weakening effect, although it was tried, especially in stone imitations of bronze axheads.

The hafting problem in percussive tools

In hammer hafting, it is possible to distinguish between the long handles that allow tools to be swung to give them speed, and those simpler handles by which a tool such as a pavement tamper may simply be picked up so that it can be dropped. A long handle, even if not needed for dynamic effect (light blows), makes the tool easier to control and generally reduces operator fatigue.

The oldest form of hafted hammer, probably the miner's maul of Neolithic date, had a conical or ovoid stone head with a circumferential groove on a diameter at midheight; many such rilled stones have been found in flint, copper, and salt mines and elsewhere, though very few handles have survived. Such a stone could be bound to a short section of sapling with a branch (handle) coming off at an angle, twisted fibres or sinew serving as the ties (Figure 3A). With such a side-mounted head it is most likely that the handle's principal function was to lift the head that it might do its work by simply dropping, the binding-fastening being too weak to carry much extra shock produced by swinging the tool. Better shock resistance could come with bending a long flexible branch around the groove in the stone, secured with lashings (Figure 3B).

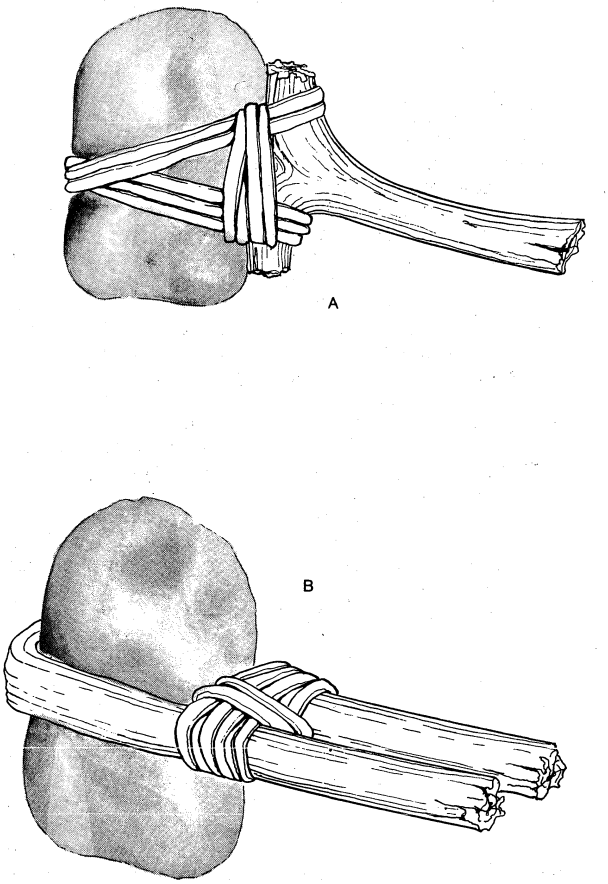

Figure 3: *Hafted hammers.*
(A) Hammer of rilled stone bound onto a knee-shaft handle, a device that was most satisfactory when merely lifted and dropped onto work. (B) Hammer bound into a bent branch; used when the work required a heavier swing.

Hammers and pounders of material other than stone were widely used; essentially clublike, they may be called self-handled. Clubs of hardwood might have one end thinned for grasping, or a mallet-like tool could be made from a short section of log with a projecting branch serving as handle. Similar mallets were made by piercing a short piece of wood and fitting a handle; this also gave an end-grain strike, more durable than a simple club. Antlers modified by trimming off tines are known from the Paleolithic Period. Such "soft" hammers were used for striking chisels of stone to prevent the destruction of the more valuable tool. Such tools, especially the wooden mallet, were used on metal chisels as well, particularly by stonecutters, because a very heavy blow on a light tool does not necessarily remove more stone than a moderate blow. There is a good deal of evidence that bone, antler, and flint wedges were used to split wood; here the use of a soft hammer would have been imperative.

The hammer as it is best known today—*i.e.*, as a tool for nailing, rivetting, and smithing—originated in the Metal Age with the inventions of nails, rivets, and jew-

elry. For beating lumps of metal into strips and sheet, heavy and compact hammers with flat faces were needed. These, in lighter form, were suited to rivetting and driving nails and wooden pegs.

In the beginning, hafting followed the stone-tool tradition. The first step away from lashing came with casting a socket opposite the head into which the short end of an L-shaped wooden handle was fitted and further supported by lashings. Such a tool was necessarily light. Ultimately the idea of piercing the head with a shaft hole (acceptable in metal where it had not been for stone) for a handle occurred to the Europeans in the Iron Age. This was several hundred years after it had become common practice among the bronzeworkers of the Near East. The shaft hole, whereas posing fastening problems that still exist, allowed heavy hammers—mauls and sledges—to be made for smithing iron.

Shaft holes for handles

The familiar claw hammer that can pull bent nails is known from Roman times in a rather well-proportioned form, for the expensive handmade nails of square or rectangular cross section did not drive easily and needed to be set into a hole prepared with an awl.

Aside from the claw hammer, other special forms of the peen—the end opposite the flat face—were developed. Hemispherical, round-edged, and wedgelike shapes helped the metalworker stretch and bend metal or the mason to chip or break stone or bricks. An especially important hammer was the filemaker's, equipped with two chisel-like heads used to score flat pieces of iron (file blanks) that were subsequently hardened by heating and quenching.

Ax and adz. The ax and adz are similar enough to be considered together. This is especially true of ancient tools that were small and ineffective because of either brittle stone or unsatisfactory hafting. The generic difference between the tools lies in the relation of the cutting edge to the handle. In the ax, the cutting edge and handle are parallel, whereas in the adz they stand at right angles. The ax and some adzes chop diagonally across the grain of the wood, but the developed adz with long handle cuts with the grain; the nature of the chips is quite different. The ax is for felling or cutting through, whereas the adz is for smoothing and levelling, although some forms were developed to scoop out gutters or dig out logs to make canoes. The great problem of both tools is satisfactory hafting; the shock impact between toolhead and handle threatens any type of connection, however ingenious.

The celt, a smooth chisel-shaped toolhead that formed either ax or adz, dates from the inventions of agriculture and animal domestication. By 6000 BC north European man was also tending toward an agricultural life; for him forest clearance was a necessity and possible only with the ground and polished ax that has been made the principal index of the Neolithic Period. The earliest true axheads, made of fine-grained rock with ground edges, are of Swedish provenance and date from about 6000 BC. Even earlier, self-handled axes, made of reindeer antler, were used. The brow tine, an antler branch running nearly at right angles to the main stem (beam), was sharpened, giving a small ax, with a haft of about eight inches (Figure 4A). By sharpening the tine the other way, a tiny adz was created. Some of these small bone implements have survived as the Lyngby tools, from a Danish site of perhaps 8000 BC.

A subsequent design socketed a stone blade in a short length of antler that was perforated for a handle (Figure 4B). This Maglemosian style, from a Danish site of about 6000 BC, was a popular model for several thousand years despite its narrow cutting edge and length of about 20 inches (50 centimetres). For comparison, it may be noted that a modern camping ax is about 12 inches (30 centimetres) long, that axes for ordinary home use are 28 inches (70 centimetres) overall, and that the professional's tool has a length of 36 inches.

The desire for a better feel or a longer cutting edge or perhaps the shortage of antlers led to a great variety of haftings. A common arrangement involved fastening heavy celts to knee-shaft handles, made from branched tree sections, by lashings. To permit the use of larger

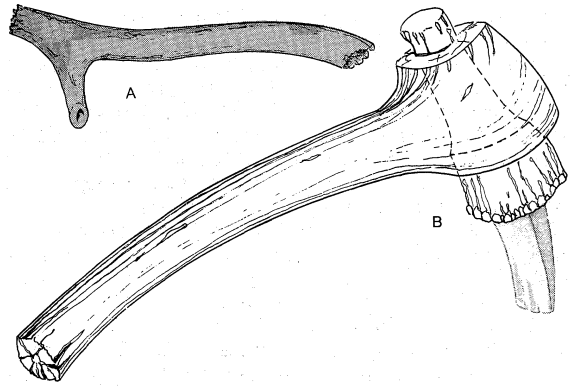

Figure 4: *Ax and adz.*

(B) Stone adz head with a socket of antler inserted in a wooden haft.

celts, the stone was sometimes fitted into a wooden handle, but this at once created the danger of failure of the handle due to the weakening hole. Heavy, clublike handles with ample strength at the hole gave the tool an unfavourable balance.

Surviving examples of celts of soft stone are believed to have been restricted to nonwoodworking axes, such as for killing game or perhaps for certain ritual purposes. Hard-stone axes with shaft holes, often obvious imitations of bronze axes, are associated with the Bronze Age. They are among the supreme examples of stoneworking and are products of the pecking technique. From their very delicacy it may be inferred that these axes were not for the working of wood.

Parallel to the development of the ax ran that of the adz. It was often shorter handled than the ax and, because of this, was essentially a chipping tool rather than the shaving tool it became when the handle was lengthened.

The first adzes

An Egyptian relief of about 2500 BC, the pyramid-building era, shows a metal ax (copper or bronze) of curious shape, almost semicircular, lashed to a wooden handle along its diameter. The same picture shows a knee-shaft adz whose metal blade makes an angle of about 30° with the handle. If the number of pictures and artifacts of the adz is meaningful, the adz was more widely used than the ax. Generally speaking, the adz has a short handle, with angles of the order of 60° between blade and handle. Although the Egyptians became skilled metalworkers, this was not reflected in their tools, the designs of which hardly changed over 2,000 years.

On the other hand, bronze axes and adzes from Mesopotamia of even the period 2700 BC are shaft-hole types, the hole for the handle being formed in the mold. Aside from eliminating the nuisance of lashing the blades, these castings meant a heavier head than the thin-bladed Egyptian models, with better dynamic characteristics.

In the Crete of 2000 BC shaft-hole axes and adzes were also being cast, with a distinctly new tool being added to the kit. The double-bit (two-bladed), shaft-hole ax, classically associated with the Minoans, was first known about 2500 BC as a votive ax, a piece of tomb furniture made of riveted bronze plates.

The emblematic double-bit ax became a working tool on being cast in bronze with a shaft hole about 2000 BC. Double-bit adzes are also known from this time, as are ax–adz combinations. Succeeding civilizations, the Mycenean, Greek, and Roman, carried these designs forward. According to Homer, Ulysses used a double-bit ax, a type that disappeared with bronze. Illustrations or artifacts from the Middle Ages reveal only iron single-bit types, in a bewildering variety of profiles. By mid-19th century the double-bit was again in use, principally as a lumberman's ax in the United States, where it was called a back wounder by the awkward. Canada and Australia know this type, too, and it is still marketed.

The ax of Ulysses

In western Europe the advent of metal was about 500 years later than in the Middle East. In making the transi-

tion from stone to metal, the European continued the tradition of knee-shaft handle, but not in the Egyptian manner unless a flat blade (celt) had been cast. Another and more popular line of castings was given a wide slot by either forging or casting into which a cleft knee-shaft was fitted and lashed. This was the palstave. To minimize splitting of the shaft a stop was later cast in at the bottom of the slot. Subsequently, one or two eyes, or loops, were furnished in the casting to allow firmer lashing.

The socketed head, perhaps carried over from spearhead technology, was an improvement because the knee-shaft stub sat in a socket with greater security, although still requiring lashing. Like its predecessors, this tool was small, almost toylike; the cutting edges of the order of 1½ inches and short handles suggest a one-hand operation. Adzes were similarly proportioned, as were hammers.

The Bronze Age smiths of Europe were slow in inventing the shaft hole that those of the Middle East had developed in an earlier millennium. The knee-shaft tradition with socketed head entered even the Iron Age in which, at long last, the shaft-hole tools appear in Europe. To forge a socket is a difficult enough operation with even modern equipment. A shaft hole, however, is fairly simple to make by folding a rectangular plate around an iron bar, creating a roughly V-shaped forging that needs some further work to become a shaft-hole tool with cutting edge parallel to the eye, the weld being at the lower part of the eye. Such shaft-hole tools appeared in northern Europe well after the Iron Age was under way, perhaps after 500 BC. By this time, expensive bronze had been supplanted by plentiful iron for tool use.

The bronze tools had been relatively delicate in design; their iron successors soon gained size and developed in character and effectiveness to display specialized forms. Of these, two are especially important. First, there was the felling ax of the woodcutter, the blade bevelled on both sides for symmetry and often fitted with a flat end suited to driving splitting wedges. There were numerous variations within this form as it evolved toward the modern conformation, a tool distinguished by its fine balance.

The iron ax had little advantage over its bronze forerunners until smiths discovered carburization and could produce a temperable steel along the cutting edge. This must have occurred early, for repeated heating of the edge region in forging would draw at least small quantities of carbon from the charcoal of the fire. A number of Roman axes subjected to analysis have been found to contain steel.

Steeling the axhead

Steeling, or the welding of strips of steel to the iron head, was invented in the Middle Ages. The head had been rough forged by bending a properly shaped piece of flat iron stock around an iron handle pattern to form the eye. Steeling could take one of two forms. In the first, a strip of steel was inserted between the overlapping ends and the whole welded into a unit (inserted steeling). For the second, the overlapping ends were welded together and drawn to a V-shape over which a V-shaped piece of steel was then welded (overcoat, or overlaid, steeling). Inserted steeling was regarded as superior because it furnished about three times as much steel to resist loss of metal in repeated grinding and sharpening. The manufacture of steeled, or two-piece, axes ceased in the early 20th century, the heads then being made of a single piece of high-carbon steel whose properly tempered edge is backed by a tough body.

To convert felled timber to squared timber, special tools were required. As the log lay on the ground or on low blocking, vertical sides were developed by the broadax, or side ax. Somewhat shorter handled than the felling ax, it had a flat face, the single bevel being on the opposite or right side; it sliced diagonally downward as the carpenter moved backward along the log. The head is rather heavy, about twice that of a felling ax, for, whereas it is a two-handled tool, the broadax is never swung in the manner of a felling ax but raised to waist height and allowed to fall with minimum added pressure. The handle was bent, or offset to the right, to give finger clearance when hewing to the line on a debarked log. Deep vertical cuts had been made to this line with a felling ax—"scoring to the line"—after which the broadax split off the wood between score marks while hewing to the line. Hewn timber found in old buildings often carries the faint marks of the scoring.

If the timber was to be presented to view it was smoothed by the adz that removed the last of the score marks to leave a kind of ripple finish. For this purpose a long-handled adz was used, the radius of its gentle swing originating in the carpenter's shoulder. The blade was bevelled on the inside and removed material in the same sense as does a plane.

The adz was once an indispensable tool of general utility, for, in addition to surfacing, it was particularly useful for trueing and otherwise levelling framework such as posts, beams, and rafters, in setting up the frames of wooden ships and in dressing their planking. For special purposes the blade was round instead of flat, allowing the adz to cut hollows such as gutters. Dugout canoes, log coffins, and stock watering troughs, all cut from a single log, were products of the adz. Short-handled adzes, reminiscent of the ancient patterns, were used by coopers and makers of wooden bowls.

CUTTING, DRILLING, AND ABRADING TOOLS

Knife. The same jagged crest on the Paleolithic chopper that developed into the ax, in another direction developed into another broad tool category, the knife, a combination of a uniquely shaped sharp blade and a handle that optimizes the position of the cutting edge. The motion of a knife is in the direction of its edge for slicing action, in contrast to the blades of ax, adz, chisel, or plane.

The jagged edge of the chopper could slit, sever, and cut after a fashion; these operations became more effective as the bifacial-flaking technique developed to produce the Acheulean hand ax, the blade of which, whereas still short, had many small serrations instead of only a few because of the advance in flaking control. A continuous edge was achieved with the blade technique that separated slivers of stone carrying a long edge.

The knife handle

The first hafting may have taken the form of a protective pad of leaves or grass. Next, pieces of flint were set into grooves of wooden handles by cementing with resin or bitumen to leave sharp cutting edges exposed. The handle at the end of a blade had to wait until the Metals Age, which produced a longer and tougher blade that could be set into a handle, or riveted to a handgrip. Some knives, as surgical types and razors, were cast with a handle (self-handled). Copper, bronze, and iron blades were hammered to produce a locally hard edge.

Aside from the knife's utilitarian use in the field, kitchen, and workshop, variations giving it the status of a weapon appeared in the form of daggers and short and long swords. The stabbing dagger probably had its conceptual origin in the Neolithic, although an effectively thin and adequately strong blade had to wait for the Iron Age.

As various individual crafts emerged, an impressive number of convenient but single-purpose knives were fashioned to suit particular tasks, such as those of the goldbeater, the farrier, and the shoemaker, not to mention those adapted for agricultural purposes. The first illustration showing a knifesmith forging blades comes from the early 15th century.

Hunting knives, equally useful as fighting knives, developed an overall style, proportion, and balance that changed little over the centuries after the introduction of iron. The first folding knife is a Roman model of the 1st century AD. Beginning in the late Middle Ages many improvements in detail were introduced. These included fancy handles and springs and locks for the blade. Folding knives were made in many configurations from large to small, and some have come to carry scissors, bottle openers, files, and other accessories.

Drilling and boring tools. The terminology related to making holes with revolving tools is confused. A hole may be drilled or bored; there is a tool called a drill but none known as a borer; and awls, gimlets, and augers also produce holes. An awl is the simplest hole maker,

for, as a pointed instrument such as a needle, it simply pushes material to one side without removing it, whereas drills, gimlets, and augers have cutting edges that detach material to leave a hole. A drilled hole is ordinarily small and usually in metal; a bored hole large and in wood or, if in metal, is usually done by enlarging a small hole. Drilling usually requires high speed and low torque (turning force), little material being removed during each revolution of the tool. Low speed but high torque are characteristic of boring because the boring tool is of larger radius than a drill.

The Upper Paleolithic furnishes the first perforated objects of shell, ivory, antler, bone, and tooth, although softer, perishable materials, such as leather and wood, were undoubtedly provided with holes by the use of bone or antler splinters. How holes were made in harder materials is subject to speculation; it has been suggested that flint blades were trimmed to sharp points by bilateral flaking and that these points were turned by hand, a very slow process. Another scheme, evident in later time, may be ancient; it involves the use of an abrasive sand under the end of a stick that is twirled back and forth between the palms. At some unknown time, more efficient rotation was provided by wrapping a thong around the stick or shaft and pulling on the ends of the thong; this gave rotation first in one direction and then in another. Such an arrangement, the strap, or thong, drill, could be applied to drilling either with abrasive or with a tool point hafted to the end of the stick. The upper end of the shaft required a pad or socket (drill pad) in which it could rotate freely.

Invention of the bow

After the invention of the bow, sometime in the Upper Paleolithic, the ends of the thong were fastened to a bow or a slack bowstring was wrapped around the shaft to create the bow drill. This simple and effective drill was widely distributed. Because of its simplicity, it maintained itself in Europe in small shops down to the present century and is still in use in parts of the world.

Abrasive drilling in stone was well suited to the high-speed bow drill. For larger holes the amount of material that had to be reduced to powder led to the idea of using a tube, as of rolled copper strip, instead of a solid cylinder. This is the core drill, for, with abrasive trapped between rotating tube and stone, a ring is ground out, containing a core that can be removed.

A new and more complicated tool, the pump drill, was developed in Roman times. A crosspiece that could slide up and down the spindle was attached by cords that wound and unwound about it. Thus, a downward push on the crosspiece imparted a rotation to the spindle. A flywheel on the spindle kept the motion going, so that the cords rewound in reverse to raise the crosspiece as the drill slowed, and the next push down brought the spindle into rotation in the opposite direction. Whether such a drill cut while turning in either direction depended upon the cutting edge. If the edge had a double bevel, it cut in both directions.

The earliest (perhaps Bronze Age) drill points were rather casual, of more or less pointed form with sharp edges that ultimately developed into conscious arrow shapes with two distinct cutting edges. This shape was quite effective, especially when made of iron or steel, and remained popular until the end of the 19th century, when factory-made, spiral-fluted drills became available at reasonable cost to displace the blacksmith-made articles.

The basic auger originated in the Iron Age; a tool for enlarging existing holes, it had a crossbar so that it might be turned with two hands. It resembled a half pipe and was sharpened in several ways, as on the inside of the semicircular end, along the length, or both. The end might be forged into a spoon shape and the edges sharpened so that cutting might take place at the bottom of the hole in addition to the sides. To clear the hole of parings it was necessary to pull the auger and turn the workpiece over. Augers with spiral or helical stems that bring the shavings or chips to the surface are an invention of the Middle Ages, though one example is known from Roman Britain.

The so-called breast auger is a short version in which the operator could apply pressure by leaning on a drill pad or socket in which the upper end of the auger could swivel freely.

The brace and breast swivel

The familiar and common brace, a crank with a breast swivel at one end and a drill point at the other, is first seen in a painting of about 1425 that shows Joseph at his bench. This brace, as well as later but still early examples, is shown fitted with a bit of small diameter. It has been suggested that the function of the new tool was to make the small, or pilot, holes for the larger auger bit. This is a reasonable assumption, for the crank, fashioned from a wide board, had insufficient strength because of the cross grain to drive a large bit (see Figure 5A). This

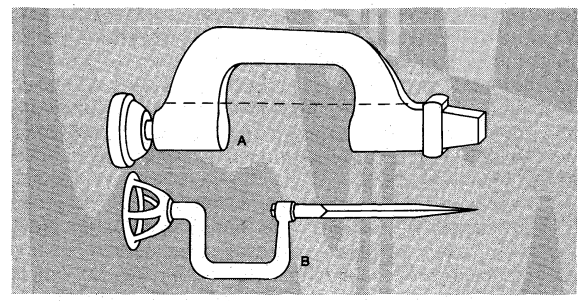

Figure 5: *Braces.*
(A) Early one-piece wooden brace showing weak sections (dotted lines). (B) All-metal blacksmith's "wimble" of late 17th century; the metal crank was not generally applied to the woodworker's brace until two centuries later.

weakness was later counteracted by reinforcing the two weak sections with metal plates, a practice continued until about 1900 despite the commercial introduction of iron sweeps (cranks) about 1860 (Figure 5B). With this, holes up to one inch in diameter can be bored with the one-handed operation; larger holes still require the two-handed augers. An iron sweep is noted in a German manuscript of 1505, and an English book of 1683 has a metal brace as part of a blacksmith's kit.

The early wooden braces were equipped with a large socket into which bits with appropriate shanks could be fitted to give interchangeability. When the sweep came to be made of iron, the bits were given square shanks that fitted into simple split chucks (holders) secured with a thumbscrew, and it was not long before the screwed shell chuck and ratchet appeared to set the standard for the modern tool. By 1900 the swivel was turning on ball bearings instead of a leather washer, and the metal parts were nickel-plated.

The bow and pump drills, suitable only to small work, required two hands, one to steady the tool, the other to operate it. One-hand drills began to appear about 1825. Their essential elements are a steeply pitched screw and a nut that mates with it; when the latter is pushed down, the screw and attached bit turn. Many variations of the principle were offered before the modern push drill assumed its present, convenient form. It is still suitable for only light work in wood.

Both the bow and pump drills remained the metalworker's prime tool for small holes until the beginning of the 19th century, when the first geared hand drill was invented (1805). Like every other tool, it underwent many improvements before acquiring its present rugged simplicity. Its great advantage lies in its unidirectional motion and the gearing that rotates the drill faster than the rate at which the crank is turned. The one-directional motion allowed better drills to be designed, and, with their greater efficiency in chip production, it was not long (1822) before drills with spiral flutes were proposed. Again there was a manufacturing problem—the flutes had to be hand filed—that was not solved until the 1860s and the invention of a milling machine for making the now universal twist drills.

Augers were used for boring both across the grain of wood and along the grain. The latter operation produced wooden pipes and pump casings or wheel hubs; special bits of many forms were designed for these purposes.

The modern auger

The common use of the auger or bit was in the cross-grain direction to make holes for wooden pins (treenails, or trunnels) or bolts for connections. The modern auger bit has a screw ahead of the cutting edges to pull the auger into the work. This screw provides an automatic feed and relieves the workman of the necessity of pushing the tool. The idea appeared in the mid-16th century but was long in being generally applied, for the screw had to be hand filed, a disadvantage not overcome until the advent of screw-making machinery in the mid-19th century.

Saw. The chipped flint knife with its irregular edge, as differentiated from a straight-edged blade tool, has been called a saw because of the serrations' superficial resemblance to sawteeth. A little reflection will show that the tool was not a saw in the proper sense at all, for though it could sever wood fibers and gash bone or horn, it could not possibly remove small pieces of material in the manner of a saw. Furthermore, the necessarily broad V-shaped profile of this flint "saw" severely limited its penetration into the workpiece; an encircling groove on a branch or a notch on something flat defined the nature of the cut.

The real saw, a blade with teeth, one of the first great innovations of the Metals Age, was a completely new tool, able to cut through wood instead of merely gashing the surface. It developed with smelted copper from which a blade could be cast. Many of the early copper saws have the general appearance of large meat-carving knives, even to bone or wooden handles riveted to a tang at one end. Egyptian illustrations from about 1500 BC onward show the saw being used to rip boards, the timber being lashed to a vertical post set into the ground. The teeth were raked to cut on the pull stroke, for the hooks of the teeth point toward the handle.

The use of relatively narrow, thin, and not quite flat blades, made of a metal having a tendency to buckle and with poorly shaped teeth with high friction, required that the cutting take place on the pull stroke. In this stroke the sawyer could exert the most force without peril of buckling the saw. Furthermore, a pull saw could be thinner than a push saw under the circumstances, making for less waste of material.

The familiar modern handsaw, with a thin but wide steel blade, cuts on the push stroke, which permits downhand sawing on wood laid across the knee or on a stool, the sawing pressure helping to hold the wood still. With this sawing on the push stroke, operator control is superior, and, because the line being sawn to is not obscured by the fuzz of undetached wood fibers or sawdust, greater accuracy in following the line is possible. Some tree-pruning saws have teeth raked to cut on the pull stroke to urge the branch toward the operator instead of away from him. Blades that are thin and narrow, as in the coping saw (fretsaw or scroll saw), are pulled through the work by the frame holding the blade. The thin hacksaw blade is pulled by the frame the operator pushes. Electric reciprocating and sabre saws, the narrow blades of which are supported at only one end, pull the blade when cutting to prevent buckling. The carpenter's pull saw for wood was for a long period forgotten by the Western world but kept alive in China and Japan, where some craftsmen still favour it. The craftsman sits on the floor and uses his feet to restrain the wood. The pull saw is also used in some parts of Albania and Greece.

Although there is no positive evidence of either the method or the saw, the Egyptians were able to saw hard stone with copper and bronze implements. The blade, probably toothless, rode on an abrasive material such as moistened quartz sand. The 7½-foot (two-metre) granite coffer still in the Great Pyramid carries saw marks.

During the Bronze Age, the use of saws for woodworking was greatly extended, and the modern form approached. There are some saws with narrow blades looking very much like hacksaw blades, even to the holes at either end. It is supposed that they might have been held in a frame or pinned into a springy bow of wood, either arrangement keeping the narrow blade taut and furnishing a handle as well.

Iron saws, looking much like those of copper or bronze, are known from the middle of the 7th century BC. A major contribution to saw design was noted in the 1st century AD by Pliny the Elder, whose works are one of the major, though often fanciful sources, on the technology of the ancients. Pliny observed that setting the teeth—that is, bending alternate teeth to one side or the other, creating a kerf, or saw slot wider than the thickness of the blade—helps discharge the sawdust. He seems to have missed the more practical point that the saw also runs with less friction in the now wider slot. The Romans, always ingenious mechanics, added numerous improvements to both simply handled saws and frame saws but did not make push saws despite the advantage of the kerf that made the saw easier to work and less liable to buckle. Roman saw sets and files have been found in substantial numbers. The small handsaws were sometimes backed with a stiffening rib, to prevent the buckling of thin blades; today's backsaw still carries the rib. Frame saws, in which a narrow blade is held in tension by a wooden frame (see Figure 6), were exploited in many sizes, from the small carpenter's saw to two-man crosscut saw and ripsaws for making boards.

Roman improvements in saws

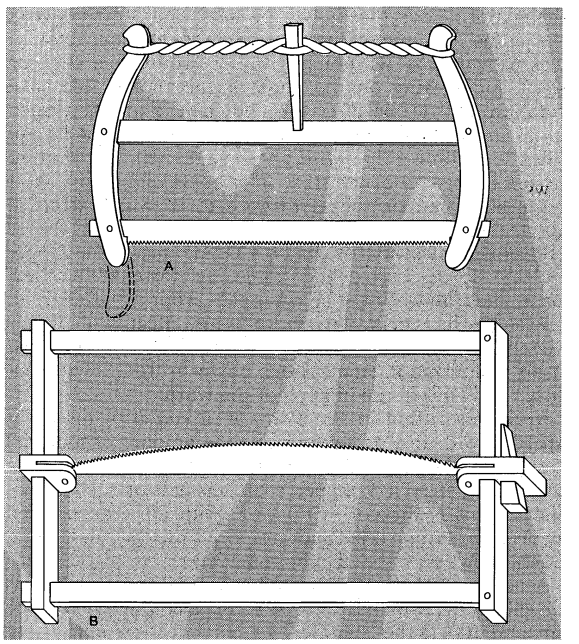

Figure 6: Framed saws in which a thin blade is put under tension (A) by a cord and twisting stick and (B) by a wedge.

The time and provenance of the push saw are uncertain, although it appears that it may be dated from the end of Roman times, well before the Middle Ages. Nevertheless, after the decline of the Roman Empire in the West, the use of the saw seems to have declined as well. The ax again became the principal tool on the return to the more primitive state of technology. Saw artifacts are very few in number, and even the Bayeux tapestry of about 1100 shows no saw in the fairly detailed panels dealing with the construction of William the Conqueror's invasion fleet: only ax, adz, hammer, and breast auger are among the woodworking tools. It may be remarked that pioneers have always found the ax a universal tool, able to take care of the fundamental needs and, whereas wasteful of material, rugged and easily cared for.

With the Middle Ages came the search for a nonclogging tooth for use when crosscutting green and wet wood. The saws themselves were long, with handles at both ends, so that two men might each pull, alternate teeth being raked in opposite directions. To provide space for the cuttings, M-shaped teeth with gaps (gullets) between them were developed; this tooth conformation, first noted in the mid-15th century, is still modern practice in crosscut saws for coarse work and heavy timber.

Perhaps even more important than crosscutting was the need to rip a log lengthwise to produce boards. Saws for

this purpose were generally called pit saws, for they were operated in the vertical plane by two men, one of whom, the pitman, stood sometimes in a pit below the timber, or under a trestle supporting the timber being sawn. His mate stood on the timber above, pulling the saw up; the pitman and gravity did the work of cutting on the downstroke for which the teeth were raked. A pit saw might be just a long blade with two handles, giving the so-called whipsaw, but more often it was constructed as a frame saw, which used less steel and put the blade under tension.

A new invention, a result of progress in spring-driven clocks, came in the mid-16th century. It was the fretsaw, in which a U-shaped metal frame stretched a narrow blade made from a clock spring, the best and most uniform steel available, for it was not forged but rolled in small, hand-powered mills. These very thin (for the time) blades with their fine teeth were well suited to cutting veneer stock from decorative wood for furniture of all kinds.

Water-powered rolling mill products

By the middle of the 17th century, larger, waterpowered rolling mills in England and some parts of the Continent were able to furnish broad strips of steel from which wide saws could be fashioned in many varieties. In particular, the awkward framed pit saw was largely replaced by a long, two-handled blade of adequate stiffness. Smaller general-purpose saws, especially in England, developed from the rolling-mill stock into the broad-blade saws of today. The modern broad-blade handsaw is taper ground, that is, the blade is not of uniform thickness, but is several thousandths of an inch thinner at the back than at the toothed edge. This makes for no-bind cutting, and such saws require little set for fast and easy cutting. The Continental craftsman, however, is fond of the frame saw for even his benchwork; the only purchased part is the blade itself, the worker often making his own wooden frame, which is tightened by twisting a cord with a short stick.

File. The file's many tiny chisel-like teeth all point in the direction in which it must be pushed in order to be effective. Because little material is removed with each stroke, the tool is well suited to smoothing a rough workpiece or altering its shape in substantial detail. The file was unknown in early antiquity, during which smoothing was done with abrasive stone or powder or with sharkskin, the granular surface of which approximates sandpaper or abrasive cloth. In Greek, an older form of the word file is also the name of a fish having a strong skin that is used for the finishing of wood or marble.

Files of copper are unknown, but bronze, the inherently hard derivative of copper, was shaped into flat files in Egypt about 1500 BC. A combined round and flat file of bronze is known from Europe by 400 BC. The file became popular in the Iron Age, a number of specimens surviving from Roman times. The longest is flat, about 15 inches (38 centimetres) long including the handle, leaving about eight inches (20 centimetres) of working length one inch (2.5 centimetres) wide. A number of shorter files of about four-inch (ten-centimetre) working length are particularly interesting because of the notch they carry near the handle. This notch, together with their V-shaped cross section (called knife-shaped today) indicates that these files were intended for dressing sawteeth, the notch enabling the workman to set the teeth—*i.e.*, bend successive teeth to alternate sides to gain a free-running saw. These files had straight-across and coarse toothing, but the advantages of obliquely cut teeth and of the double-cut (intersecting) teeth were appreciated early.

A treatise of 1100 AD mentions files of square, round, triangular, and other shapes. At this time files were made of carburized steel that could be hardened after completion of the cutting, which was done with either a sharp, chisel-like hammer or chisel and hammer. An illustrated manuscript of 1405 shows a file of polygonal section that is copied by a succession of later authors; the screeching of the filing operation is commented upon, too, with the curious suggestion that files be made hollow and filled with lead to eliminate the noise. A writer on things mechanical in 1578 asserted that the only way in which threads could be cut in screws was with the file.

Even earlier Leonardo da Vinci had sketched a file-making machine to do a better job than the freehand technique could produce. The first file-making machine, however, has a date of 1750, and it was a century later before machine-cut files replaced those cut by hand. Power-driven, hand-cut rotary files are still used on dense metals because the hand-formed and discontinuous teeth dissipate the heat better.

The ordinary file, in terms of its material and cut, is for use on cast iron and soft steel. Other materials—various nonferrous alloys, stainless steels, plastics—are better accommodated with files of special composition and tooth formation (cut). A wide selection is manufactured.

Rasps, or, more correctly, rasp-cut files, have a series of individual teeth produced by a sharp, narrow, punchlike chisel. The very rough cut is suited to soft substances, such as wood, hoofs, leather, aluminum, and lead, for fast removal of material.

Chisel. It may be speculated that the remote origin of the chisel lay with the stone hand ax, the almond-shaped tool that was sharp at one end. Chisel-shaped flints, long and of rectangular cross section, appear about 8000 BC. The somewhat later Neolithic time brought a more workmanlike version that was finished by grinding. With care, flint and, especially, obsidian chisels can be used on soft stone, as intricate sculptures in pre-Columbian South and Central America testify. Gouges—*i.e.*, chisels with concave instead of flat sections, able to scoop hollows or form holes with curved instead of flat walls—are also known from this period. Chisels and gouges of very hard stone were used to rough out both the exteriors and interiors of bowls of softer stone such as alabaster, gypsum, soapstone, and volcanic rock, with final finish by abrasion and polishing.

The advent of smelted copper meant that a tough and readily sharpened material could replace the brittle stone. Cutting edges were hardened by hammering. The earliest copper chisels were long in the manner of their flint forebears. Such so-called solid chisels of copper (and later of bronze) were used for working not only wood but soft rock as well, as many magnificent Egyptian monuments of limestone and sandstone testify.

Copper chisels

With bronze, a better casting metal than copper, and with the experience of making molds, it was possible to economize on metal by hafting a short chisel to a wooden handle, which was also less injurious to the mallet. The round handle was either impaled on a tang with a cast-on stop (tanged) or set into a socket (socketed); both forms of hafting presage modern forms. The Egyptians used the chisel and clublike mallet with great skill and imagination to make joints in the construction of small drawers, panelled boxes, furniture, caskets, and chests.

The use of iron meant that tools had to be forged; no longer were the flowing lines and easily made cavities of casting available to the toolmaker. In consequence, early iron chisels are rude and solid. Tanged chisels were made with less trouble than socketed chisels, for which the socket had to be bent from a T-shaped forging. Hardenable steel edges were developed at first accidentally and then deliberately by giving the iron repeated contact with carbon from the charcoal of the forge fire.

Chisels and gouges came to be made in great variety in later centuries as generally increasing wealth brought a demand for more decoration and luxury in both churchly and secular fittings and furniture. The rough and heavy tools of the carpenter were refined to more delicate models suited to the woodcarvers, to the joiners who did wall panelling and made stairs, doors, and windows, and the cabinetmakers. In the 18th century a woodcarver's kit might contain upward of 70 chisels and gouges. Some special-purpose chisels of cabinetmaker, coachmaker and patternmaker had quite long handles and were never used with a mallet but worked from the shoulder.

Plane. The plane is a cleverly hafted cutting edge the function of which is to skin or shave the surface of the wood (see Figure 7). Its purpose is to finish and true

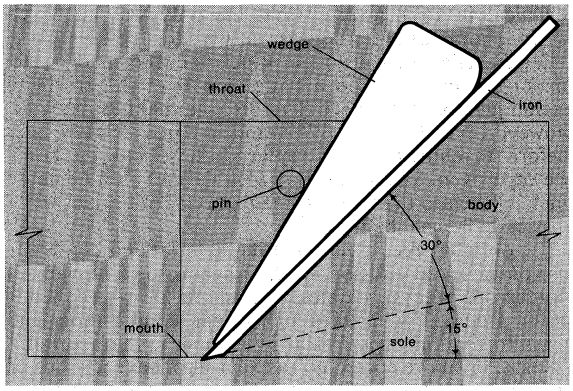

Figure 7: *Essential features of a plane.*
The body is pierced by a wide throat with a narrow slit (mouth) on the bottom, or sole. In this case, the iron (blade) is held in place by a wedge and pin, an arrangement common from Roman times to the 16th century. The cutting edge makes a 15° angle with the horizontal.

a surface by removing the marks of a previous tool (adz, ax, or saw), leaving the surface smooth, flat, and straight. Two tools, the plane and its kin the spokeshave, are unique, since both depend upon a constant depth of cut that is given by the slight projection of the blade beyond the sole, or base. The plane is a luxury item associated with the good life; while convenient to have, it is not an imperative tool such as the ax, adz, chisel, saw, and even drill.

The plane is an anomaly, for which no line of descent has yet been identified. Pliny the Elder ascribes the invention of the plane to Daedalus, the mythical Greek representative of all handiwork.

Origins of the plane

It has been suggested that the Paleolithic unifacial (flat) scraper is the remote ancestor of the plane. It is true that localized planing of a very poor sort, as in removing high spots, can be done with such a scraper, but the difference in design and action between the scraper and plane is too great to permit invoking the scraper as forerunner of the plane. The adz seems a more likely progenitor. Early adzes were bevelled (sloped) on the outside, although later on, with better hafting and longer handles, the bevel was moved to the inside. The blade and handle of an outside-bevelled adz could be used in a plane-like fashion to lift a shaving; the tool would chatter badly and cut discontinuously but might lead to the provision of a sole from which only a small portion of the blade projected and which would provide support. The control of the blade projection, or depth of cut (or thickness of shaving), is critical to the concept of the plane and is met with in only one other tool, the spokeshave.

The earliest illustrations of wood finishing, the surfacing of pieces of furniture, are Egyptian and show the surfaces being scrubbed with flat objects taken to be abrasive stone or blocks riding on abrasive sand.

Presumably the surfaces had been dressed by an adz, but now the marks of this tool needed to be erased. Stone scrapers are not in evidence, and, although the adz is shown, it is being used as an adz, not as an improvisation of a plane.

The Romans are the first definitely known users of the plane, the earliest examples coming from Pompeii. In a manner of speaking, these planes are full-blown, without a prehistory, without even vague antecedents. The modern plane differs in details, but not in principle nor in general appearance.

These Pompeii planes are of comfortable size, being about eight inches (20 centimetres) long and 2¼ inches (57 millimetres) wide. The blade was relatively narrow, about 1½ inches against the modern width of two inches (five centimetres). The sole was made of one-quarter-inch-thick iron bent to form a shallow box that was filled with a wooden core, cut away at the back to form a handgrip, while the mouth was cut in about one-third of the way from the front. The blade, or plane iron, was held in position by a wooden wedge tapped under an iron bar across the mouth. Frontier posts in Great Britain and Germany have yielded nearly a dozen Roman planes, ranging in length from 13 to 17 inches (33 to 43 centimetres). Three constructions are represented: iron sole plus wooden core, all wood, and wood reinforced with iron plates at the sides of the mouth.

Planes may be divided into two main categories, the first, the common bench plane, with straight-across iron and flat sole for working flat surfaces such as panelling, and the second, all others, in a wide variety defined by the profile of the iron and sole. If the iron has a concavity, a projection or molding will remain; if the iron has a projection, a groove will be dug. Generally speaking, planes with profiled irons and correspondingly fluted soles are molding planes, with each molding identified by its own name. Some of the Roman planes show irons for cutting rectangular grooves.

After the decline of the Roman Empire, the plane almost disappeared from view, although there is mention about AD 1100, of iron strips being planed to create a good, lighttight match when laid together. Practically no planes and only a very few other tools have survived from the period AD 800–1600. Secondary sources, such as illuminated manuscripts, legal documents, carvings, and stained-glass windows do provide some information, but details are obscure either because of the coarseness of the medium or the fact that the artist did not understand the fine points of the craft he was representing.

Categories of planes

By the late 17th century the plane was again firmly established, with the distinction between bench planes and the myriad molding planes being quite clear. Bench planes might be called the common planes; they were used for surfacing panels, or for creating straight edges on boards so that two or more might be made up into a wide panel. Boards were sawed or split (riven) from the log and were, in consequence, quite rough. The first planing operation was done with the roughing, or fore, plane of medium length, possibly 16–18 inches (41–46 centimetres). This fore plane had a slightly convex iron that removed the saw and adz marks but left hollows. The fore plane was followed by planes with straight irons that levelled the hollows. If the workpiece was long, a long-bodied, or trying, or jointing plane of, say, 30-inch (75-centimetre) length was necessary to remove large curves in the wood. Short planes—a common length was of the order of nine inches (23 centimetres)—were called smoothing planes for the final finish they gave.

Planes with straight irons and flat soles could be made by the craftsman himself without undue expenditure of time. There was, however, a change in taste and fashion in the 17th century, wood carving giving way to decorative features such as moldings and beadings; also the generally lighter furniture and a demand for wooden window sash for larger panes of glass called for molding and grooves. The proliferation of plane types established plane making as an industry.

The indispensable common plane with the straight iron was improved in a number of details to ease the working and increase the accuracy of the tool. When speaking of Roman planes, it was noted that the wedge holding the iron was jammed against a cross bar through the mouth of the plane. This feature, awkward because it impaired the free escape of the shaving, was eliminated in the 16th century by seating the wedge in tapered grooves let into the sides of the mouth. An early attempt to dispense with the wedge altogether by securing the iron with a thumbscrew remains an isolated case. In England and America wooden planes were gradually displaced by cast-iron bodies with wooden handles as advanced metallurgy and machine tools allowed good castings to be machined accurately on a mass-production basis. Metal predominated by the mid-19th century, but this was also the beginning of the decline of the molding planes, for machinery was now making millwork, tongue-and-groove flooring, door and window moldings, picture rails, baseboards, sash stuff, stair work, blinds, and much more.

The top iron, an English innovation

A capital improvement was the invention of the top iron, apparently an English innovation toward the end of the 18th century. This top iron, or chip breaker,

is like an inverted plane iron placed over the cutting iron; it limits the thickness of the shaving and helps it to curl out of the mouth. Now called the double iron, it is a feature of all but the smallest of modern planes.

The 19th century saw much effort, again in England and America, aimed at eliminating the wedge and the need for hammer adjustment of the iron. Various methods for easy and accurate setting of the iron, as well as its quick removal for sharpening, culminated in the screw and lever adjustments of the iron and the cam-actuated cap. This final evolution was completed about 1890, and changes since that time have been trivial. Despite their advantages, continental Europe has not been partial to iron-bodied planes with screw and lever adjustments, such tools commanding a much higher price than the still common wooden plane with wedge and hammer adjustment.

The spokeshave, which may be likened to a short-bodied plane with a handle on either side allowing the tool to be pulled toward the operator, has left little in the way of a record. The term has been known some 400 years, but the earliest example seems to be only half as old. Both the English word and the German *Speichenhobel* suggest that the tool was originally a wheelwright's specialization that became generalized for use on convex surfaces. As with the plane, the cutting blade (iron) projects only slightly from the short sole to regulate the depth of cut.

The drawknife is a handled blade that is pulled toward the operator. It may be considered as a rather questionable relative of the plane, for it lifts shavings in a similar manner, without, however, having the positive thickness control of the plane. In the modern form, the tangs at the ends of the knife are bent at right angles in the plane of the blade, and, while operating in much the manner of a spokeshave, it is a roughing tool for quick removal of stock. Skill is required in its use, for the blade tends either to follow the grain or to skip over it, the depth of cut being regulated by the tilt of the blade, until the wood grain asserts itself. The drawknife appears to be an older tool than the spokeshave and has undergone a change since the Viking time from which it is first known. Under the Viking craftsmen the handles were bent at right angles to the plane of the blade, and the tool seems to have been used for smoothing axed or adzed timber, in medieval Scandinavia, Russia, and elsewhere.

TOOL AUXILIARIES

Workbench and vise. Workbench and vise form an organic unit, for the vise, a fixture, is either part of the carpenter's bench or is attached to the machinist's bench; in consequence, the stories of bench and vise merge, as do those of the benchwork of the woodworkers and metalworkers.

Neither bench nor mechanical fixture provides an advantage when chipping or flaking stone. On the contrary, complete freedom in the positioning of workpiece and hammer is essential in such stoneworking to give the most advantageous apposition of stone and hammer, for many relatively small yet discretely placed and directed blows are the crux of fashioning stone tools. When large and unidirectional forces need to be applied, as in woodworking and many phases of metalworking or even in the manipulation of bone and horn, the advantage of a bench or a fixed rest of some sort becomes apparent.

Wood assumed its important role in structures and furniture and fittings with the polished stone tools (ax and chisel) of the Neolithic Period and was skillfully exploited for finer work under copper and bronze tools. Most of the furniture of ancient time no longer exists because of fire or rot. There is, however, a good deal of visual evidence, provided largely by sculptures, representations on vases, mosaics, and wall frescoes, that shows all manner of furniture: thrones, stools, benches, footstools, couches, cupboards, tables, chests, beds. Oddly enough, a stout table or workbench is missing from the renderings of busy Egyptian shops. The workpieces are on the floor with the craftsman kneeling or bending over his work or sitting on a low stool, even in those scenes in which tables are being finished. It is not known how the joinery, including the mortise-and-tenon joints and other niceties, was carried out; perhaps the craftsman used his feet to position the work on the floor while using chisel and mallet, a practice still known in some areas. Notably, a sloping board supported by a prop, probably a tanner's beam, is depicted in a leatherworker's shop. Timber being ripped is shown lashed to a vertical post; perhaps this may be viewed as a primitive vise. Little is known of Egyptian use of the copper pull saw for crosscutting in the absence of pictures, but, if the tool was used, the workman probably sat on the floor, bracing his feet against the timber that the saw was urging toward him.

Evidences of ancient furniture

Evidence in Europe for even Neolithic time suggests that the woodworker made use of the table, the distinction between a table and a workbench perhaps depending upon the kind of litter on the top or the decorative quality of the feet. Such a table bench was of the simplest form, a short length of heavy board split from a trunk and supported on four legs made of saplings set into bored holes.

This style of bench becomes quite evident in Roman times, often being only a length of half log with four legs somewhat splayed for greater stability. It is with the Romans that a stout bench became a necessity, since they were the first users of the plane, and truing a surface without a bench on which to lay and secure the wood is nearly impossible.

Two methods, still in use, were devised for holding the workpiece. The simplest procedure was to use wooden pegs set into holes in the bench top; the other was to use what are variously known as bench stops, holdfasts, or dogs, the stem of such more or less T-shaped iron fittings also being set into holes, one end of the horizontal part of the T being sharp to engage the wood.

Other arrangements came into use, as trestles for supporting wood to be sawed with the improved saws or specialized benches—horses—on which the leatherworker or coppersmith sat while facing a raised section arranged for his particular job. The small workpiece was often held by means of a strap that was made taut by a foot in the loop that formed the free end. Such horses proliferated from medieval times onward as new specialties developed; modified versions often serve today as cocktail tables.

The anvil and horn

A frequent accessory of the metalworker's bench was the anvil, still informally present on many machinist's vises in the form of a rudimentary anvil and horn suited to light work. Aside from making castings, metalworking was largely concerned with forging. The earliest anvils were convenient flat stones, usable for only the simplest kind of flat work. With increasing skill, anvils with the characteristic overhang, or horn, were first cast in bronze and, later, welded from short lengths of iron. Bench anvils were necessarily small, since large free-standing specimens of the smith had to await the cast iron that made larger masses of metal conveniently available.

Pictorial records are scant until the 15th century, when it becomes evident that the medieval carpenter's bench was still very much like the Roman, with pegs serving as end fixtures. The metalworker, especially the man using the by now indispensable file to shape and clean small forgings and castings (harness gear, buckles, and so on), used a simple rest, essentially a notch cut into the top of a post driven into the ground in front of his bench, to support his workpiece.

Within a century, according to the pictorial record, the metalworkers' rest disappears, being replaced by a screw vise, at first quite small. This vise was like a hinge, one leaf or jaw being fastened to the bench, with the other pulled up to clamp the workpiece by tightening the nut on a bolt passing through the "hinge" at midheight. The square nut was on the far side of this vise and tightened by means of a box wrench. Even clamp-on vises—the portable kind that can be applied to a handy plank or tabletop or bench top—are known from 1570.

It was, of course, slow and awkward to close the vise by running up the tightening nut with a wrench, and,

by the end of the 16th century, the inversion had taken place—the screw was now turned, from the front, by means of the T-handle that is part of every modern vise. The vise now had a form that would remain an integral element of every smithy as long as the trade lasted (see Figure 8).

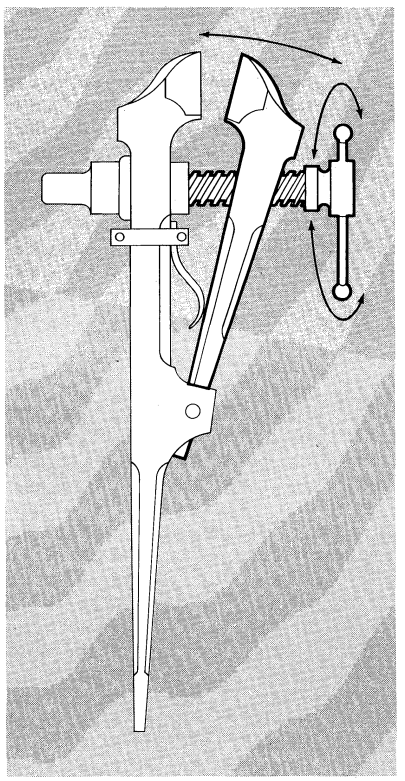

Figure 8: Blacksmith's vise, with long spike-like foot for extra support.

The modern machinist's vise has jaws that run parallel, and the vise as a whole may be turned about a vertical axis (swivel-base vise). Both of these features came before the end of the 18th century.

To return to the carpenter's bench, it remained in the 15th century equipped only with pegs to restrain the wood being planed, the older (by well over 1,000 years) Roman iron dogs, or holdfasts, not having been re-invented. Real fixturing of the workpieces is possible only with a screw arrangement of some sort, and, while all the necessary elements were described as early as 1505, nothing came of this, the approach to bench vises and indeed the use of the screw, well-known to the woodworker, taking long to mature.

Two kinds of vises are necessary to the woodworker. One is to hold (clamp) the board so that its long edges may be trued and planed; custom places this vise at the left front of the bench, a location convenient for the right-handed workman. The second vise is at the right end on the side; its moving jaw has a bench stop, and long pieces of wood to be surfaced are caught between this adjustable stop and a fixed stop in the bench top at an appropriate place. Both types of vise had been developed and even made part of the same bench by the early 19th century.

Tongs, pincers, and pliers. Tongs, pincers, tweezers, and pliers have in common the task of holding or gripping something for ease in handling. Usually, but not always, the arrangement is such that the gripping force is larger than the operator-applied force.

Handling hot coals

After man came to use fire he acquired a new problem, that of handling hot coals. Two sticks probably first served as uncertain holders. An Egyptian wall painting of about 1450 BC shows a crucible that is supported between two bow-shaped metal bars, bronze having replaced wooden sticks for this purpose about 3000 BC. The same painting shows a craftsman with a blowpipe in his mouth holding a small object over a fire with a tweezer-like instrument about eight to ten inches (20 to 25 centimetres) long. It was at about this time that bronze loops that were able to cope with large and heavy crucibles made their appearance.

Spring-back, or tweezer-like, tongs were the model used by the early ironsmith. The change to the mechanically more effective hinged tongs was slow, and it was not until 500 BC that they became common enough to give the blacksmith's kit, as shown on the vases from the classical age of Greece, a quite modern look. Pivoted tongs, with short jaws but long handle, have quite a mechanical advantage, a pair of 20-inch (50-centimetre) tongs being able to exert a gripping force of say 300 pounds (135 kilograms) for a 40-pound (18-kilogram) squeeze from the smith's hand. Such tongs had one handle slightly shorter than the other so that an oval ring could be slipped over the two to help secure the grip. This old feature of locking the tongs onto the workpiece is in common use today.

Tongs both large and small, the latter often called pliers or forceps, proliferated into many uses. A significant variation in which the jaws were sharpened were the cutters known from Roman remains, as well as the pincers that were useful for pulling bent nails because of the leverage they were capable of exerting. Although they were originally a carpenter's tool, pincers were a principal tool of the farrier, since the old nails had to be pulled from horses' hoofs before new shoes could be fitted and nailed on.

SCREW-BASED TOOLS

Invention of the screw. Before speaking of either wrench or screwdriver one must glance at the screw, the reason for both tools. Archimedes in the 3rd century BC is credited with the invention of the screw. But Archimedes' screw was not the ordinary fastener now known so well in its many varieties but had two other forms. One was a kind of water pump, still used today for large-volume, low-lift applications, seen in its essentials in the inclined screw conveyor of industry. The second was the "endless screw," actually the worm of a worm and gear set, one of the ancients' five devices for the raising of heavy weights. With the state of the mechanic arts as it was then, this concept of the screw, really a motion-transforming device, was more hypothetical than practical.

By the 1st century BC, heavy wooden screws were elements of presses for making wine and olive oil and pressing cloth. The character of the screw had been given a new dimension, for these screws were used to exert pressure; their modern counterparts are called power screws. Such press screws were turned by means of hand-spikes thrust into radial holes in the cylindrical end. The principal problem, making the nut with its internal thread, would defer the use of small threaded fasteners in metal construction, where either nuts or threaded holes are needed. The external thread was readily if tediously made by filing.

Problem of the nut

Metal screws and nuts appear in the 15th century, the square or hexagonal head or nut being turned with an appropriate box wrench; a T-handled socket wrench is also known from the 16th century. Some screws to be seen in 16th-century armour have slots (nicks) in which a screwdriver may have been used, although this tool is not shown. Deep notches on the circumferences of the heads of other armour screws suggest that some kind of pronged device was used to turn them. A drawing of a machine—again, 16th century—shows slotted, round-headed screws but, of course, no tool to turn them is depicted. These metal screws would be called machine, or machinery, screws since they are of metal and mate with threaded holes. It is worthy of mention that few screw-and-nut-fastened clocks are in evidence earlier than the 17th century, parts until that time being secured by little wedges driven into holes.

The wood screw differs from the machine screw in that the wood into which it is turned is deformed into a

nut. It must, however, be started in a hole made by awl or drill. Aside from a few and sometimes doubtful artifacts from Roman times, the wood screw does not appear until the mid-16th century, and then it appears in a mining treatise. Here a screw tapered to a point and, carrying a slotted head, looking very familiar except for its left-handed thread, is described so casually as to suggest that it was a common article. It is remarked that the screw is superior to the nail, which is also shown being driven by a claw hammer. There is no mention of a screwdriver.

Screwdrivers and wrenches. The simple screwdriver is preceded, at least in illustration, by a flat-bladed bit for the carpenter's brace (1744). The handled screwdriver begins to be shown on the woodworker's bench after 1800 and appears in inventories of tool kits from that date. Screwdrivers did not become common tools until automatic screw machines, about 1850, began the mass production of tapered, gimlet-pointed wood screws. In its early form, the screwdriver was made from flat stock, with sometimes scalloped edges that contributed nothing to function. Being flat, the blade was easy to haft but weak when improperly used for prying. This and the easy availability of round-wire stock led to the present form, round and flattened only at the end.

Origin of the screwdriver

Early box and socket wrenches (see Figure 9) fit only

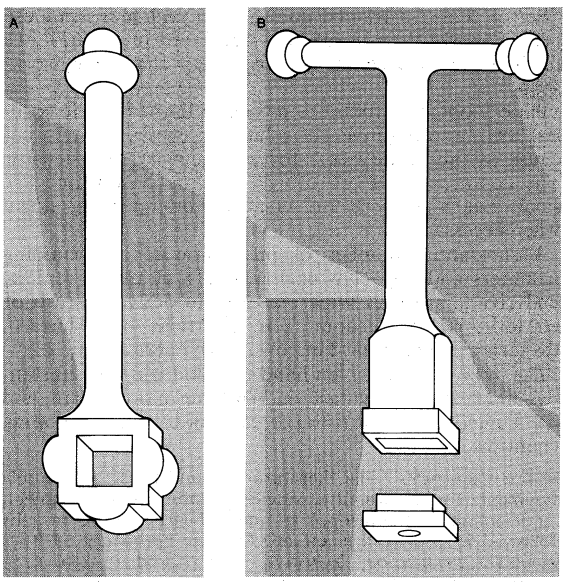

Figure 9: (A) Box and (B) socket wrenches; 16th century.

a particular nut or screw with flats on the head. The open-end wrench may have rectangular slots on one or both ends. In their earliest forms such wrenches, with either straight, angled, or S-shaped handles, were of wrought iron, cast iron entering the picture around 1800. Modern wrenches are drop forgings and come in many formats.

The very real limitations of fixed-opening wrenches were challenged in the early 19th century by sliding-jaw types able to accommodate to a range of flats. In these, the end of an L-shaped handle provided the fixed jaw, a parallel jaw being arranged to slide along the handle to engage the flats. With the first models of the 1830s, the sliding jaw was fixed in position by a wedge that was hammer tapped into place. By 1835 patents for screw wrenches began to proliferate: the sliding jaw was positioned and held by means of a screw whose axis was parallel to the handle. The most familiar example is the monkey wrench, whose name first appeared about 1858. A convenient variation is found in the thin and angled crescent wrench, a fairly recent innovation.

Although not a carpenter's tool, a serrated-jaw variation of the monkey wrench, with the additional feature of a pivotable movable jaw and called a pipe wrench by the plumber, is of interest since it can engage rounds, such as rod and pipe.

MEASURING AND DEFINING TOOLS

Plumb line, level, and square. A plumb line is a light line with a weight (plumb bob) at one end which, when suspended from the other, defines a vertical. "Plumb" comes from the Latin *plumbum*, or "lead," a material that replaced stone as the weight for the bob or plummet. Modern plumb bobs are often nickel-plated cones whose hollow interiors are filled with mercury, the greater weight allowing such bobs to come to rest more quickly in a breeze or draft.

While an end-weighted string defines a vertical, its direct use for plumbing walls (making them vertical) is awkward. The Egyptians devised a tool like a letter E, a plumb line being suspended from the upper outboard part of the E. With the E placed against a wall, the wall was vertical when the string just touched the lower outboard part of the E. The middle bar of the E can be dispensed with. Oddly, this useful tool was apparently forgotten for many centuries, reappearing only in modern times.

The tool for checking the horizontal direction is a level. The Egyptians used an A-frame, suspending a plumb line from the vertex of the A. The feet of the A were set on the surface to be checked, and, if the plumb line bisected the crossbar of the A, the surface was horizontal.

The A-frame level came to Europe and survived until the middle of the 19th century. Sometimes a variation is shown in which the frame is an inverted T with a plumb line suspended from the top of the vertical stem; the horizontal part was laid against the surface to be checked, and, if the line bisected the part, the latter was horizontal.

The hose level

Because the surface of a body of water is horizontal, a trough or channel filled with water can serve as reference for a limited number of situations. The hose level is described in 1629. In this, a length of hose is fitted with a glass tube at each end and water added until it rises in both the vertically held tubes, the free surfaces of the water in each tube coming to the same level. This excellent idea was impractical as long as only leather hose was available. Vulcanized rubber hose (after 1831) allowed the idea to be again put forward (1849). With this instrument, levels can be established under awkward circumstances, since the hose can be carried through holes in the wall, around partitions, and so on.

The spirit, or bubble, level, a sealed glass tube containing alcohol and an air bubble stems from 1661. It was first used on telescopes and later on surveying instruments and did not become a carpenter's tool until the factory-made article of the mid-19th century. Tubes with carefully made interior curvature date from 1812. The circular level, in which a bubble floats under a circular glass to indicate level in all directions, was invented in 1777. It lacks the sensitivity of the conventional level.

The square appears in the ancient Egyptian world as two perpendicular legs of wood braced with a diagonal member. In the following centuries many variations were designed for specific purposes, as, for example, a square with shoulders that allow it to also cast a mitre (45 degrees). Iron was rarely used before 1800. Factory-made metal squares appear around 1835. The adjustable, or bevel, square for angles other than 90 degrees may be noted for the 17th century. In the earliest, the thin blade moved stiffly, being rivetted into a slot in the thick blade. Later models, as from the 19th century, are equipped with a thumbscrew to fix the thin blade with respect to the thicker.

Compass, divider, and caliper. Compass, divider, and caliper are often given plural forms, frequently as "a pair of." Basically, all three instruments have two legs pivoted to each other at the top and are concerned with small-distance measurement or transfer. The compass and divider have straight legs, the caliper curved.

The terms compass and divider are often interchanged, for each instrument can be used to draw circles or mark out divisions (divide a given distance) or simply mark out a distance. Technically, a compass as drafting instru-

ment has one pen or pencil point, the other being sharp and set into the centre of the circle to be described; a divider has two sharp points, one for the centre, the other for scribing or marking. Caliper is a corruption of "calibre," the diameter of a hole (as in a firearm) or of a cylindrical or spherical body. Inward-curved legs mark the outside caliper for measuring the diameters of solids of revolution, as lathe-turned objects; legs with their tips bent outwards are inside calipers for dealing with bores.

Dividers and calipers were known to both the Greeks and Romans, though the caliper was uncommon. A divider with circular sector (or wing) connecting the two legs was sketched in 1245; its modern counterpart is the wing divider with thumbscrew clamp and screw for fine adjustment. The caliper is mentioned in the Middle Ages, a time when the divider was the principal tool of the architect for the full-scale layouts of stonework, as in the construction of a cathedral. Such dividers were large, often half as tall as a man. The divider underwent refinement to become a drafting instrument for Albrecht Dürer and Leonardo da Vinci; da Vinci suggested improvements such as the knuckle-joint hinge for increased rigidity and proportional dividers that were adjustable (Roman proportional dividers with fixed pivot gave only one ratio). Da Vinci's notes also show the beam compass with screw adjustment for large radii, as well as a compass with interchangeable points, one leg having a clamp for different drawing media, as graphite or chalk.

Proportional dividers

Chalk line. To "snap a line" is a technique familiar to ancient Egypt and to modern building construction. The principle is that a taut, chalk-covered line or cord stretched between two points on a surface will deposit a trace of chalk when the line is plucked and released (twanged) to snap onto the surface. About the only change in 5,000 years is that the Egyptians used wet red or yellow ochre, while the modern craftsman follows the usage of Greek masons who employed white and red chalks in addition to wet ochre.

Rules. The unit of linear measure in the ancient world, the cubit, derived its name from association with elbow and forearm as the length from elbow to the extremity of the middle finger. This gave an order of magnitude but hardly a standard, and, in fact, the length of the cubit varied widely in different times and places.

To speak of but one of many, the royal Egyptian cubit had a length of 20.64 inches (52.4 centimetres). It was divided into seven palms (measured across the fingers, not knuckles) making a palm very nearly three inches. Each palm corresponded to four digits of about three-quarters of an inch. Thus, 1 cubit = 7 palms = 28 digits. On occasion, digits were subdivided into tenths, fourteenths or sixteenths.

The common rule of the Egyptian masons and carpenters was of wood, with narrow cross section and one bevelled edge, the two left-hand palms carrying the smaller divisions of digits. Stone rods of late Egyptian date are known, with digits divided into 16ths. It is supposed that these were ceremonial rods or perhaps master gauges for calibration and comparison; their brittleness would make them unsuitable for the rough handling of mason's tools.

The Romans introduced folding rules of bronze in 12- and six-inch (30- and 15-centimetre) sizes. It is suspected that these were probably "pocket" instruments for officials, since their high cost would argue against their use by ordinary craftsmen, who probably used plain strip rules.

There is only the scantiest evidence for the Middle Ages and Renaissance in the way of graduated rules, plain straightedges being prominent. Paintings and sculptures show rather odd and uncertain markings. By 1683 an English writer speaks of foot rules having ⅛-inch subdivisions. The folding rule, but this time of wood, reappears at the end of the 17th century.

Because measurement was long characterized by great national and even regional differences, with every large city in Europe and most towns having a different but locally standard "foot," rules with four different graduations, one on each face, were made. When the metric system came in at the end of the 18th century, special rules were created to bridge the transition.

Craftsmen made rules to suit their own convenience, choosing a hard and well-seasoned wood for the purpose. The folding foot rule with brass tips and hinges may be dated about 1813. Mass production of two-foot rules with three joints and brass tips seem to have started around 1840.

Power tools. Power tool is the popular name for what is technically a power-driven hand tool or, sometimes, portable power tool, to distinguish it from the stationary power tool such as the drill press.

While power tools are generally driven by electricity, the category also includes small pneumatic tools driven by compressed air, such as air impact wrenches and hammers. Gasoline-engine-driven tools (chain saws, gas-powered drills) are not included.

The two most popular power tools

The most popular power tools are the electric drill and the electric circular saw. The drill rotates a tool bit, but the circular saw has no manual prototype. Jigsaws, sabre, and reciprocating saws have familiar blades and so do electric screwdrivers, but many of the power tools are recent creations built around the ubiquitous electric motor. Among the new tools are polishers, several kinds of sanders (circular, belt, oscillating, and reciprocating), shears, and nibblers.

Power tools, in limited commercial and industrial use before World War II, are now produced in the millions in the developed countries, largely for the home workshop.

Battery-operated tools are presently limited to the cordless drill, an attractive but relatively expensive item because of the battery cost for sufficient current density. The common tools operating from the power line use small but high-speed universal motors, gearing down when necessary.

A substantial number of pneumatic tools, including hammers and impact wrenches, drills, chippers, scalers, and riveters are in wide use. An attractive feature of air tools is the freedom from electrical-shock hazard, the largest single hazard in power-tool operation.

The total power-driven-hand-tool industry is substantial and rising, particularly in West Germany, Japan, and the United States, with large exports to the developing countries.

BIBLIOGRAPHY. The literature on hand tools is generally fragmented and without a single comprehensive treatment. Archaeology and anthropology and the earliest tools may be followed in: CHESTER S. CHARD, *Man in Prehistory* (1969); ROBERT J. BRAIDWOOD, *Prehistoric Men*, 7th ed. (1968); KENNETH P. OAKLEY, *Man the Tool-Maker*, 3rd ed. rev. (1966); and F. CLARK HOWELL, *Early Man* (1965). Specific treatments are given in FRANCOIS BORDES, *Typologie du Paléolithique ancien et moyen* (1961; Eng. trans., *The Old Stone Age*, 1968); and JACQUES BORDAZ, *Tools of the Old and New Stone Age* (1970). The rise of metal tools is found in LESLIE AITCHISON, *A History of Metals*, 2 vol. (1960); and THOMAS A. RICKARD, *Man and Metals*, 2 vol. (1932). From Roman times onward, WILLIAM L. GOODMAN, *The History of Woodworking Tools* (1964), is definitive and comes to the present; but HENRY C. MERCER, *Ancient Carpenters' Tools*, 3rd ed.(1960), should not be missed; and PETER C. WELSH, *Woodworking Tools, 1600–1900* (1966), and FRANK H. WILDUNG, *Woodworking Tools at Shelburne Museum* (1957), include a wealth of illustrations. CHARLES SINGER *et al.* (eds.), *A History of Technology*, 5 vol. (1954–58); and MAURICE DAUMAS (ed.), *Histoire générale des techniques*, 3 vol. (1962–68; Eng. trans., *A History of Technology and Invention*, 2 vol., 1969–70), give wide but unconnected treatments. Illustrated by original drawings, ERIC SLOANE, *A Museum of Early American Tools* (1964); and EDWIN TUNIS, *Colonial Craftsmen and the Beginnings of American Industry* (1965), are highly informative of their period since techniques and products are shown in addition to tools. Articles relevant to this topic may also be found in serial publications such as *Beiträge zur Geschichte der Technik und Industrie*, now simply *Technikgeschichte* (quarterly); the *Transactions of the Newcomen Society* (annual); and *Technology and Culture* (quarterly). The *EAIA* (Early American Industries Association) *Chronicle* frequently contains articles on the history of hand tools.

(R.S.H.)

Han-fei-tzu

Han-fei-tzu (in Pin-yin romanization Han-fei-zu), ancient Chinese philosopher, is considered the greatest of the Legalist thinkers. He brought this school of thought, which contributed to the emergence of China's autocratic government, to the height of its development. The book that goes by his name comprises a synthesis of legal theories up to his time.

Life

Little is known of Han-fei's life. Member of the ruling family of Han, one of the weaker Warring States that were in conflict during the 5th–3rd centuries BC, he studied under the Confucian philosopher Hsün-tzu but deserted him to follow another school of thought more germane to the conditions accompanying the collapse of the feudal system in his time. Finding that his advice to the ruler of his native state went unheeded, he put his ideas into writing. A speech defect is also reputed to have induced his recourse to writing. King Cheng of Ch'in, a western state (who became the First Emperor of the Ch'in dynasty in 221 BC), read and admired some of his essays. When in 234 BC Cheng launched an attack on Han, the ruler of Han dispatched Han-fei to negotiate with Ch'in. Cheng was delighted to receive him and probably planned to offer him a high government post. Li Ssu, the chief minister and a former schoolmate of Han-fei's, presumably afraid that he might gain the King's favour by virtue of superior erudition, had him imprisoned on a charge of duplicity. Complying with Li Ssu's order to commit suicide, he drank the poison Li Ssu sent him and thus ended his life (233 BC).

To Han-fei it was axiomatic that political institutions must change with changing historical circumstances. It is folly, he said, to cling to outmoded ways of the past, as the Confucians did. It was also axiomatic that political institutions must be adapted to the prevailing pattern of human behaviour, which is determined not by moral sentiments but by economic conditions. In a year of famine people do not feed their own kin, while in a year of plenty they feast casual visitors—not because they are alternately heartless and generous but "because of the difference in the amount of food to be had." In ancient times, when goods were abundant, men made light of them, but increased population pressure on resources brought economic scarcity; consequently, "men of today quarrel and snatch." The ruler, therefore, should not try to make men good but only to restrain them from doing evil. Nor should he try "to win the hearts of the people" because, selfish as men are, they do not know their own true interests. The people's mind is as undependable as an infant's.

Royal authority: the notions of *shih* and *shu*

According to the Confucians, as virtue confers on a king the right to rule, misrule voids that right. Han-fei thought differently. Whatever the ruler's moral qualities and however he rules, possession of authority (*shih*) carries the inalienable right to exact obedience. "Subject serving ruler, son serving father, and wife serving husband" together constitute "an immutable principle of the world." Even if a lord of men is unworthy, no subject would dare to infringe his prerogative. Moreover, political duty takes precedence over other duties. A soldier, it was said, ran from battle because he thought that, if he was killed, he could no longer serve his father. Han-fei commented: "A filial son to his father can be a traitorous subject to his ruler."

Authority should be wielded not whimsically but through laws (*fa*) that the ruler promulgates and that all must obey. "The intelligent ruler makes the law select men and makes no arbitrary appointment himself; he makes the law measure merits and makes no arbitrary judgment himself." He can abrogate a law, but, so long as he allows it to stand, he should observe it.

To insure an effective bureaucracy and to protect his authority from encroachment or usurpation, the ruler must make use of *shu* ("administrative techniques" or "statecraft"). Rulers of the Warring States found it advantageous to employ men skilled in government, diplomacy, and war. But how to separate solid talent from idle chatter became a serious problem. *Shu* was Han-fei's answer to the problem. After assigning posts according to individual capacities, the ruler should demand satisfactory performance of the responsibilities devolving on their posts and punish anyone who is derelict of duty or oversteps his power. The ruler may authorize an official to carry out a proposal he has submitted. He should punish him not only when the results fall short of the stated goal but also when they exceed it.

Shu is also Han-fei's answer to the problem of usurpation, through which more than one ruler had lost his throne. The interest of the ruler and ruled are incompatible: "Superior and inferior wage one hundred battles a day." Therefore, it behooves the ruler to trust no one; to be suspicious of sycophants; to permit no one to gain undue power or influence; and, above all, to use wile to unearth plots against the throne.

Theories of military power and economic strength

With supreme authority secure and good order prevailing, the ruler proceeds to aggrandize his realm by means of military power. Might is the decisive factor in interstate relations. Military power is inseparable from economic strength. Farming being the only productive occupation, all other callings, especially that of the scholar, should be discouraged. Giving relief to the destitute is both unwise and unfair. To collect taxes from the rich in order to help the poor "is robbing the diligent and frugal and indulging the extravagant and lazy."

BIBLIOGRAPHY. Han-fei-tzu's writings, presumably compiled after his death, are entitled the *Han Fei Tzu*, comprising 55 sections of varying lengths. W.K. LIAO (trans.), *The Complete Works of Han Fei Tzu*, 2 vol. (1939–59), is the only complete English translation; BURTON WATSON (trans.), *Han Fei Tzu: Basic Writings* (1964), translates 12 of the more important sections.

Studies of Han-fei-tzu and his school of thought include: H.G. CREEL, "The Totalitarianism of the Legalists," in *Chinese Thought from Confucius to Mao Tsê-tung* (1953), a perceptive account of legalism; FUNG YU-LAN, "Han Fei Tzŭ and the Other Legalists," in *A History of Chinese Philosophy*, 2nd ed., vol. 1 (Eng. trans. 1952); "Han Fei Tzu and the Legalist School," in *A Short History of Chinese Philosophy* (1948); LIANG CH'I CHAO, "The Legalist School," in *History of Chinese Political Thought During the Early Tsin Period* (1930, reprinted 1968); LIN MOU-SHENG, "The Realistic School: Han-tzu," in *Men and Ideas: An Informal History of Chinese Political Thought* (1942), a convenient summary of leading ideas; ARTHUR WALEY, "The Realists," in *Three Ways of Thought in Ancient China* (1939); and JOHN C.H. WU, "Chinese Legal Philosophy: A Brief Historical Survey," *Chinese Culture*, 1:7–48 (1958).

(K.-c.H.)

Hannibal

One of the greatest military leaders of antiquity, Hannibal commanded, almost single-handedly, the Carthaginian forces against Rome in the Second Punic War. Hannibal was born in late 247 BC, the son of the great Carthaginian general Hamilcar Barca. According to Polybius and Livy, the main Latin sources for his life, he was taken to Spain by his father and at an early age was made to swear eternal hostility to Rome. From the death of his father in 229/228 until his own death in 183/182, Hannibal's life was one of constant struggle against the Roman republic.

Early career

His earliest commands were given to him in the Carthaginian province of Spain by Hasdrubal, son-in-law and successor of Hamilcar; and, although nothing is known of the details of his earliest campaigns, it is clear that he emerged as a successful officer, for, on the assassination of Hasdrubal in 221 BC, the army proclaimed him, at the age of 26, its commander in chief, and the Carthaginian government quickly ratified his field appointment.

Hannibal immediately turned himself to the consolidation of the Punic hold on Spain. He married a Spanish princess, Imilce, then began to conquer various Spanish tribes. He fought against the Olcades and captured their capital, Althaea; quelled the Vaccaei in the northwest; and in 221, making the seaport Cartagena his base, won a resounding victory over the Carpetani in the region of the Tagus River.

In the spring of 219 BC Hannibal made an attack on Saguntum, an independent Iberian city south of the Ebro

River. In the treaty between Rome and Carthage subsequent to the First Punic War (264–241), the Ebro had been set as the northern limit of Carthaginian influence in the Iberian Peninsula. Saguntum was indeed south of the Ebro, but the Romans had "friendship" (though perhaps not an actual treaty) with the city and regarded the Carthaginian attack on it as an act of war. The siege of Saguntum was a protracted one (eight months), and in it Hannibal was severely wounded. The Romans, who had sent envoys to Carthage in protest (though they did not send an army to help Saguntum), after its fall demanded the surrender of Hannibal, though under what terms it is difficult to see since Carthage had not violated the letter of the treaty. Thus began the Second Punic War, declared by Rome and conducted, on the Carthaginian side, almost entirely by Hannibal.

The march into Gaul. Hannibal spent the winter of 219–218 BC at Cartagena (Carthago Nova, the capital of Carthaginian Spain) in active preparations for carrying the war into Italy. Leaving his brother Hasdrubal in command of a considerable army for the defense of Spain and North Africa, he crossed the Ebro in April or May of 218 and marched into the Pyrenees (the Romans, shortly before they heard of this, decided on war). There his army—which consisted, according to Polybius, of 90,000 infantry, 12,000 cavalry (Polybius' figures are probably exaggerated; a total force of about 40,000 is more likely) and a number of elephants—met with stiff resistance from the Pyrenean tribes. This and the desertion of some of his Spanish troops greatly diminished his numbers, but he was able to reach the Rhône River with but little resistance from the tribes of southern Gaul.

Elusion of Scipio

Meanwhile, the Roman general Publius Cornelius Scipio transported his army, which had been detained in north Italy by a rebellion, by sea to Massilia (Marseille). As Scipio moved northward along the right bank of the Rhône, he learned that Hannibal had already crossed the river and was marching northward on the left bank. Now realizing that Hannibal probably planned to cross the Alps, Scipio returned to northern Italy to await his descent.

A great deal of controversy has surrounded the details of Hannibal's movements after the crossing of the Rhône. Polybius states that it was crossed while the river was still in one stream at a distance of four days' march from the sea. Fourques, opposite Arles, is thought by some calculations to be a likely place, but others indicate a crossing north of the confluence of the Isère and the Rhône. Hannibal used coracles and boats locally commandeered; for the elephants he made jetties out into the river and floated the elephants from these on earth-covered rafts. Horses were embarked on large boats or made to swim. During this operation hostile Gauls appeared on the opposite bank, and Hannibal dispatched a force under Hanno to cross farther upstream and attack the Gauls in the rear.

After this successful operation and after receiving a deputation of friendly Gallic leaders headed by those of the north Italian Boii, whose superior knowledge of the Alpine passes must have been of the greatest value to Hannibal's plans, the Carthaginians crossed the Durance River (or more probably an ancient branch of it that flowed into the Rhône near Avignon) and passed into an area that both Polybius and Livy call "the island." This area, the identification of which is the key to Hannibal's subsequent movements on land, was, according to Polybius, a fertile, densely populated triangle bounded on one side by hills, on the second by the Rhône, and on the third by a river that is probably either the Aygues or the Isère. Here on the "island" a civil war was being fought between two brothers (of what tribe it is not clear). Brancus, the elder of these, in return for Hannibal's help, provided new equipment for the Carthaginian army, which, after marching about 750 miles in four months from Cartagena, was in sore need of new supplies.

The Alpine crossing. Hannibal's army approached the Alps either by the Col de Grimone or the Col de Cabre, then through the basin of the Durance, or else by the Genèvre or Mont Cenis passes into the upper Po Valley, descending into the territory of the hostile Taurini. Hannibal's first action, therefore, was to storm their chief town, the modern Turin.

Hazards of the crossing

A number of details have been preserved about this great feat of military enterprise. In the initial days of the Alpine crossing, the danger came from the Allobroges, who attacked the rear of Hannibal's column. (Along the middle stages of the route, other Celtic groups attacked the baggage animals and rolled heavy stones down from the heights on the enfilade below, thus causing both men and animals to panic and lose their footings on the precipitous paths. Hannibal took countermeasures, but these involved him in heavy losses in men.) He was able on the third day to capture a Gallic town and to provide the army from its stores with rations for two or three days. Harassed by the daytime attentions of the Gauls from the heights and mistrusting the loyalty of his Gallic guides, Hannibal on the seventh day bivouacked on a large bare rock to cover the passage by night of his horses and pack animals in the gorge below. It was already October, and snow was falling on the summit of the pass, making the descent even more treacherous. Upon the hardened ice of the previous year's fall, the soldiers and animals alike slid and foundered in the fresh snow. On the 12th day a landslide blocked the narrow track, and the army was held up for one day while it was cleared. Finally on the 15th day, after a journey of five months from Cartagena, with 20,000 infantry, 6,000 cavalry, and only a few of the original 38 elephants intact, Hannibal descended into Italy, having surmounted the difficulties of climate and terrain, the guerrilla tactics of inaccessible tribes, and the major difficulty of commanding a body of men diverse in race and language under conditions to which they were ill fitted.

The war in Italy. Hannibal's forces were now totally inadequate to match against the proconsular army of Scipio, who had rushed to the Po River to protect the recently founded Roman colonies of Placentia (mod. Piacenzia) and Cremona. The first action between the two armies took place on the plains west of the Ticino River under conditions that turned the battle favourably for Hannibal's Numidian cavalry. Scipio was severely wounded, and the Romans withdrew to Placentia. After a number of manoeuvres that failed to lead to a second engagement, the combined armies of Sempronius Longus and Scipio met Hannibal on the left bank of the Trebia River south of Placentia and were soundly defeated (December 218 BC). This victory brought both Gauls and Ligurians to Hannibal's side, and his army was considerably augmented by Celtic recruits. After a severe winter (in which he contracted an eye infection), he was able to advance in the spring of 217 BC as far as the Arno River. Although two Roman armies were now in the field against him, he was able to outmanoeuvre that of Gaius Flaminius at Arretium and reached Faesulae (modern Fiesole) and Perugia. By design, this move forced Flaminius' army into open combat, and, as it passed between the northern shore of Lake Trasimene and the opposite hills, Hannibal's troops from their prepared positions all but annihilated it, killing thousands and driving others to drown in the lake. Reinforcements of about 4,000 cavalry under Gaius Centenius were intercepted before they arrived on the battlefield and were also destroyed.

Battle at Lake Trasimene

This was one of the greatest defeats suffered by Rome, but the Carthaginian troops were too worn to clinch their victories and march on Rome. Hannibal, furthermore, nurtured the vain hope that the Italian allies of Rome, whose attachments he always underestimated, would defect and cause civil war.

The summer of 217 was spent resting at Picenum, but toward the autumn and during the winter he ravaged Apulia and Campania; during this time the delaying tactics of the army under Quintus Fabius Maximus Cunctator prevented anything but skirmishes between the two armies. Suddenly in early summer of 216 Hannibal moved southward and seized the large army supply depot at Cannae on the Aufidus River. There early in August

Battle of Cannae

the Battle of Cannae (mod. Monte di Canne) was fought. While the Gauls and Iberian infantry of Hannibal's centre line yielded (without breaking) before the drive of the numerically superior Roman infantry, the Libyan infantry and cavalry of Hannibal's flanks stood fast, overlapped the Roman line, and in a rear encircling movement turned to pursue the victorious legionaries in the rear.

This third of Hannibal's great land victories in Italy brought the desired effect: many regions began to defect from the Italic confederacy. But, even with this victory behind him, Hannibal did not march on Rome but spent the winter of 216–215 in Capua. Gradually the Carthaginian fighting strength weakened. The strategy suggested by Fabius was put into operation: to defend the cities loyal to Rome; to try to recover, where opportunity offered, those cities that had fallen to Hannibal; never to enter battle when the enemy offered it but rather to keep the Carthaginians alert in every theatre of war. Thus Hannibal, unable because of inferior numbers to spread his forces to match the Romans and unable to employ this concentrated strength in a decisive battle, passed from the offensive to a cautious and not always successful defensive in Italy, inadequately supported by the home government at Carthage and, because of the Roman command of the sea, forced to obtain local provisions for protracted and ineffectual operations.

Between 215 and 213 Hannibal, except for the capture of Tarentum (modern Taranto), gained only minor victories; neither Philip V of Macedonia nor the Syracusans in Sicily (who had alike risen against Roman domination on the inspiration of the Carthaginian victories) were able to render direct aid. Reinforcements from Carthage were few. In 213 Casilinum and Arpi (captured by Hannibal in winter 216–215) were recovered by the Romans, and in 211 Hannibal was obliged to march to relieve the Roman siege of Capua. Despite Hannibal's countermeasure of a quick march to within three miles of the strongly fortified walls of Rome, Capua fell. In the same year (211), in Sicily, Syracuse fell, and by 209 Tarentum, in south Italy, had also been recaptured by the Romans.

The wars in Spain and Africa. Meanwhile, after years of indecisive warfare in Spain, the Roman successes there dealt severe blows to Carthaginian power in the peninsula. In 208 Hasdrubal, detaching a force from the main Carthaginian army, crossed the Alps (probably by his brother's route) to go to Hannibal's aid. Hasdrubal's army was defeated, however, at Metaurus in north Italy (207) before the Carthaginian armies could effect a junction. His last hope of making a recovery in central Italy thus dashed, Hannibal concentrated his forces in Bruttium, where with the help of his remaining allies he was able to resist Roman pressure for four more years.

Scipio, however, fresh from his victories in Spain, with the reluctant permission of the Senate, struck at North Africa, breaking Carthage's principal ally, the Massaesylian Numidians, and endangering Carthage. In order to go to the help of his country, Hannibal abandoned Italy in 203. Although a preliminary armistice had already been declared and the Carthaginian armies had accepted Scipio's severe terms (winter 204–203), Hannibal concentrated the remnants of the Carthaginian forces at Hadrumetum (modern Sousse, Tunisia). Almost at the very moment when the ambassadors were returning from Rome with the preliminary peace proposals, the Carthaginians violated the armistice.

Abandonment of Italy

The details of the campaigns that followed differed greatly. Both Hannibal and Scipio, in order to link up with their respective Numidian allies, moved up the Bagradas River to the region of Zama Regia. The actual site of the battle varies among sources. Hannibal was now deficient in cavalry; the mercenary troops of his front line and the African infantry of his second line together were routed, and Scipio, seeing that Hannibal's third line, the veteran soldiers, was still intact, reformed his front and brought up the Numidian cavalry of Masinissa, his Numidian ally, in the Carthaginian rear. Hannibal lost 20,000 men in defeat, but he himself escaped Masinissa's pursuit.

Exile and death. The treaty between Rome and Carthage that was concluded a year after the Battle of Zama frustrated the entire object of Hannibal's life, but his hopes of taking arms once more against Rome lived on. Although accused of having misconducted the war, he was made a suffete (a civil magistrate) in addition to retaining his military command, and in this office he was able to overthrow the power of the oligarchic governing faction at Carthage and bring about certain administrative and constitutional changes. He thus became unpopular with a certain faction of the Carthaginian nobility, and according to Livy he was denounced to the Romans as inciting Antiochus III of Syria to take up arms against the Romans. Before the arrival of the Roman envoy at Carthage, Hannibal fled for refuge to the court of Antiochus at Ephesus (195), where he was welcome at first, since Antiochus was preparing war with Rome. Soon, however, the presence of Hannibal and the sound advice he gave concerning the conduct of the war became a source of embarrassment, and he was sent to raise and command a fleet for Antiochus in the Phoenician cities. Inexperienced as he was in naval matters, he was defeated by the Roman fleet off Side, in Pamphylia. Antiochus was defeated on land at Magnesia in 190, and one of the terms demanded of him by the Romans was that Hannibal should be surrendered. Again accounts of Hannibal's subsequent actions vary; either he fled via Crete to the court of King Prusias of Bithynia, or he joined the rebel forces in Armenia. Eventually he took refuge with Prusias, who at this time was engaged in warfare with Rome's ally, King Eumenes II of Pergamum. He served Prusias in this war, and, in one of the victories he gained over Eumenes at sea, it is said that he threw cauldrons of snakes into the enemy vessels.

Flight from Carthage

Finally the Romans, by what means it is unknown, put themselves in a position to demand the surrender of Hannibal. Unable this time to escape arrest, Hannibal poisoned himself in the Bithynian village of Libyssa. The year is uncertain but was probably 183 BC, when Hannibal was 64 years old.

Death by poison

Hannibal as a general. In the conduct of the war with Rome, the project of the Alpine crossing probably originated with Hamilcar Barca. Strategically it was entirely successful and came to the Romans "as a thunderbolt," in the words of Florus. In men, however, it cost Hannibal dearly, between 5,000 and 10,000. Although it is said that he later regretted it, his action in not marching on Rome after Cannae is understandable. The city was strongly walled and supplied by sea and river; Hannibal had no siege craft. Hannibal hoped by a series of lightning victories to detach Rome's allies from the Italic confederacy. This was his greatest mistake: he had little realization of the strength of the ties of the confederates to Rome. Perhaps his greatest weakness, however, was at sea. He had no supporting navy and appeared indifferent to that Roman naval supremacy that was able in the first place to cut off reinforcements and in the second to bring about unimpeded the invasion of Africa. Although his tactics in the field, as attested even by Scipio, were brilliant, and he himself by his personal appearances and quick marches up and down Italy dazzled the Romans and complicated their strategy, he was at a decided disadvantage as regards reinforcements and provisions. Neither Philip V of Macedonia, with whom he made a treaty, nor the Syracusans were of material help. The winter of 216–215 spent idly at Capua and the refusal of the Romans thereafter to allow Hannibal to play the war as an army game provided the turning points in his success. Much that weighed against him was circumstantial and beyond his control; for all that went amiss in the conduct and policy of the war he cannot be entirely blamed; in tactics in the field he retained the mastery.

Personality. It is not to be expected that his Roman biographers would treat him impartially, but Polybius and Dio Cassius give the least biassed accounts. In spite of the charges of Hannibal's cruelty put forth by the Roman authors, he did enter into agreement with Fabius for the return of prisoners and treated with respect the

bodies of Tiberius Sempronius Gracchus (consul 215) and Lucius Aemilius Paulus (216), the fallen enemy generals. Of avarice, the other charge commonly laid against him, no direct evidence is found other than the practices necessary for a general to finance a war: indeed, he spared Fabius' farm. Much that was said against him (*e.g.*, cannibalism by Polybius) might be ascribed to individual activities of his generals, but even this is uncertain. His physical bravery is well attested, and his temperance and continence were praised. His power of leadership is implied in the lack of rioting and disharmony in that mixed body of men he commanded for so long, while the care he took for his elephants and horses as well as his men gives proof of a humane disposition. His treachery, that *punica fides* that the Romans detested, could from another point of view pass for resourcefulness in war and boldness in strategem, and, in assessing Roman judgments of him, the wide gulf between Roman and Carthaginian moral standards must be borne in mind. Of his wit and subtlety of speech many anecdotes remain. He spoke Greek and Latin fluently, but more personal information is absent from his biographies. He is shown in the only surviving portraits, the silver coins of Cartagena struck in 221, the year of his election as general, with a youthful, beardless, and pleasant face.

BIBLIOGRAPHY. Pronounced attitudes toward Hannibal have been taken largely by the German historians, varying from THEODOR MOMMSEN'S lack of enthusiasm in *Römische Geschichte*, vol. 1 (1854; Eng. trans., *History of Rome*, vol. 1, book 3, 1911), to the warmth of J. KROMAYER in *Roms Kampf um die Weltherrschaft* (1912); and G. EGELHAAFS, *Hannibal, ein Charakterbild* (1922). EDUARD MEYER, *Untersuchungen zur Geschichte des zweiten punischen Kriegs* (1924), stressed his charismatic leadership, whereas E. PAIS, *Storia di Roma durante le guerre puniche* (1927), argued his mercenary motives on behalf of Carthaginian trade. A convenient general account of his tactics in Spain and Italy and the opposition by Fabius Cunctator and Scipio Africanus is in H.H. SCULLARD, *A History of the Roman World from 753 to 146 B.C.* (1935; paperback, 1969); and in B.H. WARMINGTON, *Carthage*, rev. ed., ch. 8–9 (1969), where there is also valuable discussion of Hannibal's relations with the government of Carthage. A penetrating study of Hannibal's personal history together with a treatment of his political aims in Italy (largely on the basis of the terms of his treaty with Philip V) and his relations with the democratic element at Carthage has been made by E. GROAG, *Hannibal als Politiker* (1929). Classical sources were unsure of Hannibal's route to Italy. F. WALBANK, *A Historical Commentary on Polybius*, vol. 1 (1957), summarizes both the textual and topographical criticism. The two fullest English reconstructions of the Alpine crossing are C. TORR, *Hannibal Crosses the Alps* (1924), good on literary sources and a landmark in the debate; and G. DE BEER, *Alps and Elephants* (1955), a lively and practical approach not only to topography but also to the problems of elephant transport; but it is not entirely in agreement with sources on crossing the Rhône near Arles. The author tabulates all opinions on the Alpine route. G. DE BEER, *Hannibal* (1969), collects for the general reader photographs of topography together with cultural background material on Rome and Carthage in Hannibal's time. For the Barcid coinage of Cartagena, see H.H. SCULLARD, "Hannibal's Elephants," *Numismatic Chronicle*, 8:158–168 (1948); also W. GOWERS and H.H. SCULLARD, "Hannibal's Elephants Again," *ibid.*, vol. 10 (1950); and E.S.G. ROBINSON, "Punic Coins of Spain and Their Bearing on the Roman Republican Series," in R.A.G. CARSON and C.H.V. SUTHERLAND (eds.). *Essays in Roman Coinage Presented to Harold Mattingly* (1956).

(W.Cu.)

Hanoi

The capital of the Democratic Republic of Vietnam (see VIETNAM, NORTH), Hanoi is a deceptive city. Superficially, it retains even now the atmosphere and appearance of a sleepy, provincial French colonial capital, with wide tree-lined boulevards, the villas of former colonial administrators, and bicycles that move slowly and silently along the streets. But its quietude belies the dynamism that had characterized the transformation of the city's colonial economy to that of a socialist economy after the establishment of the country's independence in 1954. The name Hanoi, of comparatively recent origin, was given to the original city in 1831 by the French, who named it after Hanoi Province which surrounded the city. "Hanoi" is derived from the Chinese for "inside the river"; *i.e.*, the land lying within a loop of a river. The city stands on the right bank of the Red River; the city proper has a population of roughly 700,000 people, while greater Hanoi has an estimated population of about 1,000,000.

History. Hanoi has been an important location throughout much of Vietnamese history. During the second period of Chinese domination (AD 43–540), the Chinese established their capital near the site of present-day Hanoi. In 541 Li Bi, a local aristocrat, successfully defeated the Chinese and established the short-lived kingdom of Van Xuan with its capital at Long Bien (Hanoi). The Chinese regained authority in 547 and the site of the capital was shifted several times. It was not until 1010 that a Vietnamese emperor, Ly Thai To, moved the capital back to Thang Long (Hanoi city). Despite attacks by the Mongols in the 13th century and Chinese incursions in the 15th, Hanoi remained the main capital of the various Vietnamese governments until the 17th century, when it was replaced by Hue as the principal capital. European travellers to the city in the late 17th and early 18th centuries recorded that it was an important city with a walled citadel and with streets of artisans and merchants outside the citadel walls.

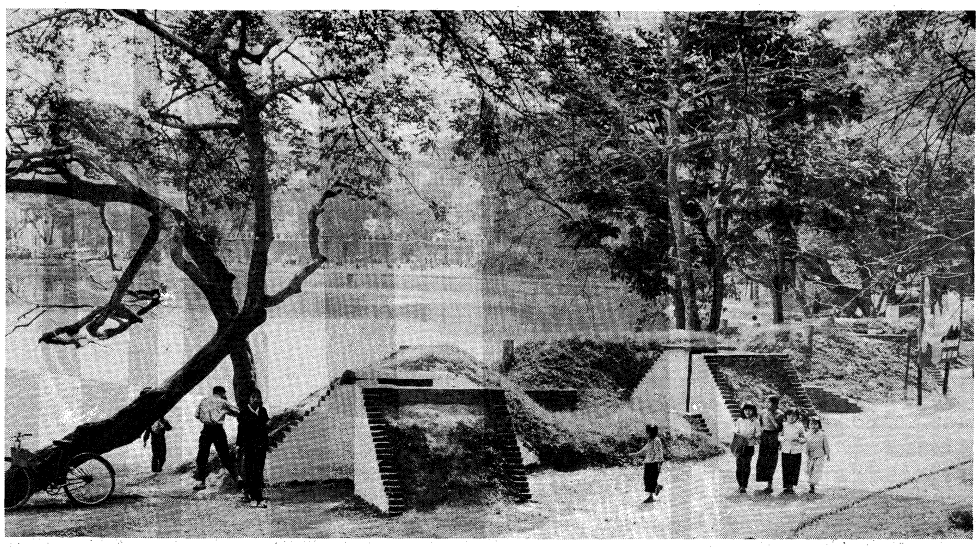
The French first occupied Hanoi in 1873; after a series of treaties with the Indochinese kingdom of Annam and with China, official French control began in 1883. The central government of French Indochina was finally organized in Hanoi in 1897. By 1902 Hanoi was considered to be the capital of French Indochina. The reason for Hanoi's emergence as the capital may be attributed to the greater importance which the French attached to Tonkin Province than to other provinces in Indochina; this was due to Tonkin's mineral resources and to French attempts to increase their influence in South China. In 1905 the population of Hanoi was recorded as 110,000—a figure which included about 103,000 Annamites, 2,000 Chinese, and 2,500 French. By 1936 the population had increased to 149,000, and the city had increased considerably in areal extent. To the city's administrative and commercial roles there was added an increasing transport function with the completion of the Hanoi–Saigon railway in 1936.

The capital of French Indochina

Hanoi remained the capital of the Indochinese territories during the Japanese occupation and the period of French–Japanese collaboration, which lasted from 1940 to 1945. In August 1945 the Indochinese Communist Party (the present Vietnam Worker's Party) seized power from the Japanese and launched a general insurrection. On September 2, 1945, the Democratic Republic of Vietnam was born when its president, Ho Chi Minh, read a declaration of independence in Hanoi's Ba Dinh Square. The French reasserted their control, however, and in 1949 Hue became capital of the short-lived State of Vietnam under a French-supported emperor, Bao Dai. Finally, on May 7, 1954, the French were defeated at Dien Bien Phu, and shortly thereafter Hanoi once again became the capital of the Democratic Republic of Vietnam.

The bombing by the U.S., which took place between 1965 and 1968 and again in 1972, caused some physical damage to Hanoi. The massive air raids of December 1972 were particularly destructive. During 1966 and 1967 one-man concrete bomb shelters were built at six-foot intervals along almost every street in the more populated areas.

The contemporary city. Hanoi is situated on the deltaic arm of the Red River, 75 miles (121 kilometres) upstream from the river's mouth. Much of the city is situated in the floodplain of the river, at an average elevation of 52 feet (16 metres) above sea level. Embankments, which are often as high as 45 to 50 feet (14 to 15 metres), protect the city from the floods that occur each summer. The city is bounded in the north by the Ho Tay (western) Lake; by a branch of the Red River, Song Hong, in the east; and by the Nhue River in the west; to the south the city merges into areas of agricultural land. A 1958 map of Hanoi, published by the North Vietnamese government, indicates that the city boundaries at that



Lake of the Returned Sword and park area in Hanoi.
Sovfoto

time encompassed most of the built-up areas, but by the early 1960s the boundaries of the city had expanded to include peripheral areas. Hanoi is linked with the left-bank suburb of Gia Lam, where railway-repair factories and the airport are located.

Climate. The city experiences a tropical monsoon climate (*i.e.*, a climate loosely characterized by seasonal rain-bearing winds). The coolest month is January, when the mean temperature is 63° F (17° C); the warmest is June, with a mean monthly temperature of 74° F (24° C). Hanoi experiences an average rainfall of some 70 inches (178 centimetres) a year; the rainy season falls between the months of May and September, and the driest months are from November to March. This dry period is often associated with a high degree of cloudiness, particularly in the months of February and March.

The city plan. The French left a mark on the physical appearance of Hanoi that 16 years of independence and war have not radically changed. With its tree-lined streets and many squares, parts of Hanoi resemble many French cities. The French were responsible for dividing the city into three main parts, or *quartiers*. The administrative quarter, located in the northern part of the city, stands on the site of the former Vietnamese citadel in the French period and contains most of the administrative buildings as well as the military barracks. Today it is still the main area for government buildings, focussing on historic Ba Dinh Square and the Ba Dinh Conference Hall; it is here that the main political functions are held. Extending southeastward along the arteries of broad streets are many of the major institutions, such as the university, the museum, the law courts, and the theatres. While some of the functions of these buildings have changed, the major educational and social institutions of the city are still located here. This was also the major residential zone of the French colonialists, who lived in stucco masonry villas. Since 1954 these villas have been taken over by the Vietnamese; they are often occupied by more than one family due to a shortage of housing.

To the north of this area lies the second quarter—a densely populated tenement zone in which the Vietnamese and Chinese were formerly the principal residents. A district of narrow, winding streets, it reflects the character of the city in its pre-industrial days.

The third quarter of the city grew up after 1928, south of the zone of French residential settlement. Vietnamese occupied this area almost exclusively, often living in housing resembling rural dwellings. Population densities in this quarter were lower than in the densely populated tenement zone to the north.

Since independence, housing for workers consisting of two- and three-story apartment houses have been built in some of the suburbs in areas such as Gia Lam; there has, however, been little transformation of the physical appearance of the city since the French colonial era, apart from the renaming of streets.

Transportation. Hanoi is an important communications centre. It has a railroad link with Haiphong, the major port (badly damaged by air raids), some 55 miles away. Railway lines also run northwest from Hanoi to Yünnanfu (K'unming, China), northeast via Lang Son to Nan-ning in the Chinese province of Kwangsi, and south to the demarcation line established in 1954 between North and South Vietnam. A road network radiates from Hanoi throughout the republic. Hanoi is served by an airport located at Gia Lam, which is linked to Hanoi by the Doumer Road and the one-mile-long rail bridge, which was completed in 1902. Internally, Hanoi has a system of streetcars, although most transportation is by foot and bicycle. The amount of car and truck traffic was reduced substantially between 1965 and 1972 during the bombing periods but is now increasing.

Road and rail networks

Demography. Reliable estimates of the population of Hanoi are difficult to obtain because it is often unclear whether these population statistics refer to the built-up area of Hanoi, the municipal area only, or to adjacent fringe areas as well. Most population figures suggest that the population of Hanoi city grew rapidly after independence, reaching 415,000 in 1960. This increased to approximately 600,000 by 1965, making Hanoi a crowded city with a density of 15,000 people per square kilometre (39,000 per square mile) in at least one area. The period of bombing, however, led to a considerable decrease in the city's population. From 1965 onward the compulsory evacuation of children and older people that took place may well have reduced the population by as much as one-third. Estimates of the city's population made in 1970, however, suggest that many people have now returned to the city and that the population, as mentioned, is now approximately 700,000.

Virtually the entire population is of Vietnamese origin, although there is a small Chinese community of largely Cantonese and Fukien origin.

Economic life. Since 1954 Hanoi has been transformed from a primarily commercial city into an important industrial centre. In 1954, when the French left, there were 12 large-scale manufacturing factories; by 1964, however, Hanoi had 88 industrial enterprises, about 750 cooperatives of artisans, and more than 1,000 handicraft cooperative cells employing over 88,000 workers. The larger factories were manufacturing such products as machine tools, electric generators and motors, plywood, textiles, chemicals, and matches. Despite relocation of industry, which took place as a result of the bombing, Hanoi is still estimated to contain one-third of North Vietnam's industry.

Industries

Commerce and retailing were considerably affected by U.S. bombing. Many shops were boarded up, and the state-run department stores were open for only two hours a day. The central market was vacated, and much of the selling had to be carried out from street markets. After the peace of 1973 the commerce of the city was reported to have returned to normal; many theatres reopened and outdoor recreation resumed.

Political and governmental institutions. Administratively, Hanoi is classified as a special municipality under direct central government control. As the capital of the Democratic Republic, it is the site of the central administrative offices of the republic.

Public utilities. The water supply of Hanoi is derived from deep wells. The system includes five treatment plants and a number of elevated storage tanks. Piped water is available in the built-up sections of the city and in the major city institutions and hospitals. Some areas of the city have a piped sewerage system, but there is also a collection system in operation. Electric power is provided by plants located in Hanoi.

Education. Hanoi contains several of the major educational institutions of the Democratic Republic. The University of Hanoi with 11 faculties was reported to have 20,000 students in 1963. The Hanoi Polytechnic College, financed in part by the Soviet Union, opened in 1956. There is a well-established system of primary and secondary schools.

Health. There are several large hospitals as well as the Medical and Pharmacological School of the University of Hanoi and an Institute of Traditional Medicine. The standard of medical treatment is generally high.

Cultural and recreational life. Hanoi is liberally provided with cultural and recreational amenities. There are over 34 libraries in the city; the National Library with over 800,000 books is the largest. There are three major museums: the Revolutionary Museum, the Historical Museum, and the Army Museum. In addition, there are many historical monuments, including the One Pillar Pagoda and the Tranvo Pagoda, both of which date from the 11th century. Popular leisure activities include visiting the numerous parks and gardens, the cinemas, and the theatres.

BIBLIOGRAPHY. There are no easily accessible book-length studies of Hanoi. The most comprehensive treatment of Hanoi in the period before Independence may be found in GEORGES AZAMBRE, "Hanoi: notes de géographie urbaine," *Bulletin de la Société des Études Indochinoises*, 30:355–365 (1955), which includes two maps of Hanoi in 1873 and 1954. Brief descriptions may also be found in PIERRE GOUROU, *L'Asie* (1953); CHARLES ROBEQUAIN, *L'Évolution économique de l'Indochine francaise* (1939; Eng. trans., *The Economic Development of French Indo-China*, 1944); and J. SION, "Asie des Moussons," *Géographie Universalle*, vol. 9 (1929). Information for the period since Independence is much more difficult to obtain, and usually takes the form of scattered references in more general texts. BERNARD B. FALL, *The Two Viet-Nams*, 2nd rev. ed. (1967); and P.J. HONEY (ed.), *North Vietnam Today* (1962), have some information on general features of Hanoi. LE-CHAU, *Le Viet Nam Socialiste: une économie de transition* (1966); and VO NHAN TRI, *Croissance économique de la République démocratique du Viet Nam (1945–1965)* (1967), have considerable information on economic developments in the city. HARVEY H. SMITH *et al.*, *Area Handbook for North Viet Nam* (1967), has useful information on public amenities and changes in the population of the city. More recent descriptions of the city may be found in journalists' reports occurring in periodicals such as *Le Monde diplomatique* (monthly); and *Far Eastern Economic Review* (weekly); and in information from official North Vietnamese sources.

Han Wu Ti

During his long reign, the self-willed and energetic Han emperor Wu Ti (in Pin-yin romanization, Han Wu Di) used and abused Imperial power in an unprecedented manner, raising to new heights the authority of the throne and extending Chinese influence abroad.

Han Wu Ti, named at birth Liu Ch'e, was born in 156 BC, probably the 11th son of Emperor Ching Ti, the fifth ruler of the Han dynasty. Not being the oldest son, he would normally not have ascended the throne, but relatives of the Emperor secured his designation as heir apparent at age seven. From his relatives and his teachers, the future Emperor absorbed influences from two basically antagonistic schools: the Taoists, inclined to the Legalist philosophy favouring an autocratic ruler guided by the rules of expediency, and the Confucianists, who sought through rituals and other means to check the growing power of the Han monarchs.

Emperor Wu Ti began his reign in 140 BC. During its early part he was under the moderating influence of relatives and court officials; however, by the late 130s he had decided that the essentially defensive foreign policy of his predecessors was not going to solve his foreign problems. In 133 he launched attacks on the nomadic Hsiung-nu, who constituted China's principal threat on the northern frontier, and thereafter he committed his realm to the expansion of the empire. By 101 his troops, spurred by an Emperor heedless of their hardships and intolerant of defeat, had extended Chinese control in all directions. South China and northern and central Vietnam were incorporated into the empire. North and central Korea, which had slipped from Chinese control in 128 BC, were reconquered and again administered by Imperial governors. Imperial troops were also sent across the Gobi desert in unsuccessful attempts to eliminate the Hsiung-nu threat. Han armies were farthest from home when they marched west to Fergana. The first expedition, in 104 BC, was a failure, but the Emperor refused to accept defeat. His intransigence stemmed from pride and his desire for horses. The horses Wu Ti wanted from Fergana were not principally intended for his war machine (although the Han armies suffered a chronic shortage of horses); rather, they were "blood sweating" horses (infected by a parasite causing skin hemorrhages), which for the Emperor had a mystical significance in that possession of them was considered a mark of Heaven's grace. The second expedition returned in 101 BC with some of the famous horses and the head of the ruler of Fergana; furthermore, the small states between China and Fergana had been humbled. Wu Ti had brought to submission all but the most distant parts of the world known to the Chinese.

Military campaigns

His wars and other undertakings exhausted the state's reserves and forced him to look for other sources of income. New taxes were decreed, and state monopolies on salt, iron, and wine were instituted. Yet by the latter part of his reign, his regime was in financial difficulties and confronted by popular unrest. The Emperor's economic controls were paralleled by his rigid control of the state apparatus. He created institutions for close supervision of the bureaucracy and drew into his personal service men who were outside the normal bureaucratic ranks and who made the bureaucracy more responsive to his will. He usually selected men whose behaviour was much like his own: harsh, demanding, and merciless.

Domestic policies

In spite of his aggressive policies, Emperor Wu Ti is also known for making Confucianism the state orthodoxy. Although he was unimpressed with the image of the ideal Confucian ruler as a benevolent father figure, he nevertheless appreciated the literary grace of the Confucianists and particularly the Confucian emphasis on ritual, which complemented his religious interests.

Most of the rituals performed by Emperor Wu Ti had a dual function; although of dynastic political and religious significance, they frequently manifested his ceaseless search for immortality. He rewarded richly men whom he believed could introduce him to immortals who would reveal their secrets to him. He sent men in search of the islands of the immortals and constructed elaborate palaces and towers designed to attract the spirits to him. At great expense he had conquered much of the world, and he invested heavily in the ardent hope that he would not have to leave it.

The last four years of Emperor Wu Ti's life were a time of retreat and regret. His empire could no longer afford an aggressive foreign policy, and he was forced to begin a period of retrenchment. The deeply suspicious Emperor suffered intense personal loss when, in 91 BC, his

Last years

heir apparent was falsely accused by an Imperial confidant of practicing witchcraft against the Emperor. In desperation, the son led an uprising in which thousands of people were killed and in which the heir committed suicide. Shortly before Emperor Wu Ti's death, he designated an eight-year-old son as heir apparent; then, anticipating his death, he had the youth's mother accused of a crime and imprisoned. Reportedly she "died of grief," but Emperor Wu Ti condoned her death, and perhaps caused it, to avoid having the young emperor dominated by relatives as he himself had been. He died on March 29, 87 BC.

Emperor Wu Ti is best remembered for his military conquests; hence, his posthumous title Wu, meaning "martial." His administrative reforms left an enduring mark on the Chinese state, and his exclusive recognition of Confucianism had a permanent effect on subsequent East Asian history.

BIBLIOGRAPHY. There is no Western language study devoted exclusively to the life of Emperor Wu or his reign. For a brief survey of his reign, see EDOUARD CHAVANNES (trans.), *Les Mémoires historiques de Se-ma Ts'ien*, vol. 1 (1895). The "Annals" of his reign have been technically translated with interpretive remarks by HOMER H. DUBS (Pan Ku's *History of the Former Han Dynasty*, vol. 2, 1944). The foreign policies of the Han rulers are surveyed in YING-SHIH YU, *Trade and Expansion in Han China: A Study in the Structure of Sino-Barbarian Relations* (1967). On Emperor Wu's economic policies, see NANCY LEE SWANN (Pan Ku, *Food and Money in Ancient China*, 1950), which is largely a highly technical translation.

Harbin

Harbin (Ha-erh-pin; Ha-er-bin in Pin-yin romanization), a city in Northeast China, is located on the right bank of the Sungari River about 325 miles (520 kilometres) north-northeast of Mukden (Shen-yang), capital of the Chinese province (*sheng*) of Liaoning. Harbin has been the capital of Heilungkiang Province (Hei-lung-chiang *sheng*), the northernmost province of China, since 1954 and is the second largest city in the Northeast, historic homeland of the Manchus. It has a population of about 2,000,000.

History. The city owes its origin to the construction of the Chinese Eastern Railway by the Russians at the end of the 19th and beginning of the 20th century. Before 1896 it was a minor fishing village and market town. Thereafter it became the construction centre for the railway, which by 1904 linked the Trans-Siberian Railroad from a point east of Lake Baikal in Siberia with the Russian port of Vladivostok on the Sea of Japan, and saved some 600 miles in the journey from Moscow over the route that ran entirely through Russian territory. Another railroad was built southward from Harbin to connect it with the Russian-developed city of Port Arthur (Lü-shun) on the Liaotung Peninsula in southern Manchuria. The early city was largely Russian built and in the early 1970s still retained many features of a pre-Revolutionary Russian city. Harbin was a base for Russian military operations in Manchuria during the Russo-Japanese War (1904–05). At the end of that war Harbin for a time came under joint Chinese–Japanese administration. After the Russian Revolution of 1917, it became a haven for refugees from Russia and for a time was the largest Russian city outside the Soviet Union.

Importance as a railroad centre

During the period of the Japanese-dominated state of Manchukuo, Harbin was known as Pinkiang and was the capital of the province of the same name. Soviet troops occupied the city in 1945, and a year later Chinese Communist forces took it over and from it directed their conquest of Manchuria.

In 1911 Harbin had a population of about 40,500; by 1931 it had some 332,000 people; by 1940, 662,000; in 1953, some 1,160,000; and in 1970 was estimated to have nearly 2,000,000. The number of Russians remaining in Harbin is believed to be very small.

The contemporary city. The climate of Harbin is similar to that of Winnipeg, Canada. The January mean temperature is −2° F (−19° C), and that for July is 72° F (22° C). Precipitation is about 21 inches (530 millimetres) annually, but most of it falls in summer, although winter snow is common.

Orthodox church in the Russian section of Harbin.
Emil Schulthess—Black Star

From the first, Harbin acted as the regional capital of the then sparsely settled lowlands of the northern Manchurian (Northeast) Plain. By the early 1970s it was a major railway centre for five railway lines as well as a major port on the Sungari River, which is open to river navigation for six months during the summer season. Before 1917, when the Amur River was regarded as an international waterway, vessels from the Amur, into which the Sungari flows, reached as far as Harbin during the summer months; Harbin then functioned as an international port. A number of major roads also converge on the city.

Long a centre for food-processing industries, and also possessing power plants, railway shops, and boat-building facilities, the city since 1949 has become the chief industrial base of Northeast China. It is a major flour-milling centre. In addition to soybean-processing plants, sugar refineries (for sugar beets), leather works, soap factories, and tobacco factories, the city also has become a major machine-tool producer and the locus of such varied production as that of ball bearings, electric motors, boilers, wire and cable, film projectors, tractors, cement, electric power turbines and generators, plastics, and synthetic as well as traditional fibre products. Since 1966 the city has also been the major outfitting centre for the Ta-ch'ing oil fields, located about 80 miles west-northwest of it.

The city is supplied with electricity from both an older Japanese-built thermal plant and at least one new ther-

mal plant, with combined capacities of about 250,000 kilowatts. In addition, power comes via a 220-kilovolt line from a Japanese-built hydro installation at Feng-man on the Sungari River, 15 miles upstream from Kirin, in Kirin Province.

The surrounding agricultural region is extremely productive despite a short growing season. Spring wheat and soybeans are the principal crops, although sugar beets, flax, sunflowers, corn, and kaoliang (a grain sorghum) also are important. Since the region is a surplus producer, Harbin acts as a major shipping centre for agricultural and forest products which are being sent to the rest of China. A major airfield is located on the southern outskirts of the city.

The city hugs the right (south) bank of the Sungari, but winter port facilities are also located on the left (north) bank near the great railway bridge across the river. New urban development also has been taking place on the left bank. Like most foreign-developed cities in China, Harbin consists of a number of quarters. These include the port and industrial district on the right bank; the adjacent Tao-li commercial district (known in Russian as the Pristan district); Fu-chia-t'ien, the old Chinese residential quarter, an area of shops and wholesale and retailing activities; Man-chou-t'un (Man-chia-k'ou), a Japanese-built residential area; and the relatively newer areas of Harbin away from the river, which include the railway station and city administrative offices and which developed primarily after World War I. These areas have been expanding very rapidly since 1949 as the total population of the city has grown. Large blocks of flats appear to have been constructed in recent years on the outskirts of these areas. In the city's layout, a rectangular grid pattern generally prevails.

The city's districts

The site of the city is generally level to undulating, except near the river itself, where low bluffs lead down to the flood plain in places. Sandy strips of bank have been used as bathing beaches during the summer months. During the winter, skating and sledding on the river ice are popular sports. Bus services connect the various parts of the city, but automobiles and trucks are comparatively scarce; many work animals, including occasional Bactrian camels, may be seen, especially on the outskirts of the city. Theatres, libraries, hospitals, and schools are well distributed. Although the city continues to have a Russian air, many of the Russian-built or Russian-influenced buildings are being replaced with contemporary ferroconcrete structures.

Since large areas of underdeveloped land still exist in the northern region of the Northeast, and since considerable immigration to the region is expected from the rest of northern China, the growth of Harbin may be expected to continue at an accelerating rate for some time to come. (N.S.G.)

Harbours and Sea Works

The construction of harbours and sea works offers some of the most unusual problems and challenges in civil engineering. The continuous and immediate presence of the sea, nature's most restless, temperamental, and most powerful element, provides the engineer with an adversary certain to discover any weakness or fault in the structure built to resist it.

MARITIME ENGINEERING: METHODS, OBJECTIVES, AND ANCIENT WORKS

Objectives of maritime engineering. The principal objectives of such works fall broadly into two classifications: transportation, and reclamation and conservancy. Under the first fall works directed at providing facilities for the safe and economical transfer of cargo and passengers between land vehicles and ships; fishing ports for the landing and distribution of the harvest of the sea; harbours of refuge for ships and small craft; and marinas for the mooring or laying up of small private craft. Under the heading of reclamation and conservancy come works directed to the protection of the land area from encroachment by the sea, to the recovery and conversion to land use of areas occupied by the sea, and to the maintenance of river estuaries as efficient means for the discharge of inland runoff. In many places, without continuous attention to such maintenance, the coincidence of high tides with heavy rainfall would lead to frequent disastrous flooding of inhabited areas.

The civil-engineering techniques used for either of these objectives are broadly similar, and indeed the realization of both objectives at the same time will frequently be a feature of the same project. An operation of maintaining a river estuary at a depth sufficient for navigation, for example, may at the same time greatly improve its capacity for the drainage of upland floodwaters.

Figure 1: Tidal model of the Humber estuary in England.

Hydraulic models. The planning of maritime civil-engineering works, whether for transportation, reclamation, or conservancy, has been facilitated by the development of the technique of model studies. Once regarded as scientific toys, such studies are now considered an essential preliminary step to any large-scale redevelopment of a port or coastal area and are useful even for minor modifications or additions.

Scale models of the area, harbour, or estuary are made, so that water can be caused to flow in such a way as to reproduce the various tidal and other streams in the same direction and with equivalent velocities to those occurring on the site. A variety of devices, usually electronically controlled, has been developed to produce both wave and tidal effects.

The value of these experiments derives from the reduction in the time scale, which has been found to correspond to the reduction in the dimensional scales of the model. Thus, the large model of the Clyde Estuary of Scotland works on a tidal cycle of about 14 minutes or about 50 times the actual frequency. The effect of three years of tides following any modification of the profile of the harbour can thus be studied on the model in a matter of three weeks, and any tendency to otherwise unanticipated scour (clearing by powerful current) or siltation can probably be detected. The relative values of alternative positions of breakwaters in affording shelter can be similarly studied, using the wave-generating devices available; and the development of secondary, or reflected, waves with undesirable disturbances within the sheltered area may be anticipated and, if possible, forestalled.

Predicting long-range tide effects

Natural and artificial harbours. In certain favoured points on the world's coastlines, nature has provided harbours waiting only to be used, such as New York Bay, which the explorer Giovanni da Verrazano described as "a very agreeable location" for sheltering a ship. Such inlets, bays, and estuaries may require improvement by dredging and of course must be supplied with port structures, but basically they remain as nature made them,

and their existence accounts for many of the world's great cities. Because such natural harbours are not always at hand where port facilities are needed, engineers must create artificial harbours. The basic structure involved in the creation of an artificial harbour is a breakwater, sometimes called a jetty, or mole, the function of which is to provide calm water inshore. Locations for artificial harbours are of course chosen with an eye to the existing potential of the coast; an indentation, however slight, is favoured. Yet it has often been found justifiable on economic or strategic grounds to construct a complete harbour on a relatively unsheltered coastline by enclosing an area with breakwaters built from the shore, with openings of minimum width for entry and exit of ships.

Classical harbour works. Improvements to natural harbours and construction of artificial harbours were undertaken in very ancient times. There is no conclusive evidence for the date or locality of the first artificial harbour construction, but it is known that the Phoenecians built harbours at Sidon and Tyre in the 13th century BC.

The engineers of those days either knew or thought little about conservancy even as applied to the ports they constructed. Evidence is to be seen in the once thriving ports around the shores of the Mediterranean that now are not merely silent ruins but seem so far from even sight of the sea that it is difficult to imagine the presence of seagoing ships at the wharves, the alignment of which can occasionally be traced in the fertile alluvial land now occupying the site. Ephesus, Priene, and Miletus, on the Aegean shores of Asia Minor, are examples of this type of harbour disappearance, the destructive agent in each of these cases being the picturesque River Meander (now the Menderes), the efforts of which toward the creation of new land from the sea are readily perceivable from high ground adjacent to the river mouth. The formation of further bars can be seen to be preceding and, as there is, at the moment, no port in the vicinity whose livelihood can be threatened, it is interesting to speculate how far out to sea this process will ultimately continue in the course of the next Millennium or so.

Disappearance of ancient harbours

At Side, facing the island of Cyprus, the remains of an ancient breakwater, built to protect the anchorage, can still be seen, but the area enclosed between it and the advancing shoreline is now not a stone's throw wide. In this case, not only the river in the vicinity but littoral drift, a current that tends to parallel the coast, that produces and maintains extensive beaches to the east and the west, must be held partly responsible for the scale of siltation.

Of many of the ancient port structures no physical trace remains, but knowledge of the fact that they existed and even a measure of technical description has come down through the written word. With these descriptions and the monuments that still remain, some picture may be formed of the work undertaken by the maritime civil engineers of ancient times.

Given the frailty of the craft for which they were providing, shelter from the weather was the prime consideration; and much effort was devoted to the construction of breakwaters, moles, and similar enclosing structures. Cheap labour was abundant and the principal material used was natural stone. Surviving structures built in this way are likely to give an appearance of indestructibility, which occasionally attracts favourable comparison with the lighter, more rapidly depreciating modern structures. It is not, however, necessary to credit the engineers of antiquity with a conscious intention to build forever. Given the materials they had to use and the purposes they were implementing, they could do little else; moreover, because there was no rapid pace of advance in the development of ships or land transport, they were undisturbed by the shadow of obsolescence. In the 20th century, far from wanting to build forever, the port engineer has to be careful to avoid saddling posterity with structures that may long outlast their usefulness and turn into liabilities. The modern balance between excessive durability and dangerous frailty is one that the ancients never had to strike.

The durability of ancient sea works

Aided by the characteristics of the material they employed, the ancients constructed maritime works on a scale that is certainly remarkable to this day, which they emphasized by the addition of embellishment, such as statues and triumphal arches.

Interesting technical practices included the use by the Romans of the semicircular arch in constructing moles or breakwaters, an arrangement that allowed a measure of ingress and egress by the sea to produce a beneficial scouring action in the harbour. The Romans underpinned their structures with timber piling and frequently resorted to the construction of cofferdams (watertight enclosures) that they could de-water by the employment of Archimedean screws and waterwheels. This practice enabled them to carry out much of their foundation work in the dry; and the use of their famous hydraulic cement, pozzolana, gave their structures a durability far exceeding that afforded by the lime cement available to their predecessors.

Among the more interesting harbours of the ancient world are Alexandria, which had on the island of Pharos the first lighthouse in the world; Piraeus, the port of Athens; Ostia, the port of Rome; Syracuse; Carthage, destroyed and rebuilt by the Romans; Rhodes; and Tyre and Sidon, ports of the earliest important navigators, the Phoenicians.

BREAKWATERS

Because the function of breakwaters is to absorb or throw back as completely as possible the energy content of the maximum sea waves assailing the coast, they must be structures of considerable substance. The skill of the designer of a breakwater lies in achieving the minimum initial capital cost without incurring excessive future commitments for maintenance. Some degree of maintenance is of course unavoidable.

Breakwater design. A common breakwater design is based on an inner mound of small rocks or rubble, to provide the basic stability, with an outer covering of larger boulders, or armouring, to protect it from removal by the sea. The design of this outer armouring has fostered considerable ingenuity. The larger the blocks, the less likely they are to be disturbed, but the greater the cost of placing them in position and of restoring them after displacement by sea action. Probably the least satisfactory type of armour block, frequently used because of its relative ease of construction, is the simple concrete cubic, or rectangular, block. Even the densest concrete seldom weighs more than 60 percent of its weight in air when fully immersed in seawater; consequently, such blocks may have to be as much as 30 tons (27,000 kilograms) in weight to resist excessive movement.

Boulders of suitably dense natural rock are generally much more satisfactory and, in a project completed in the United Kingdom in the 1960s, it was found by experiment, and subsequently confirmed in experience, that armouring of this type could be composed of blocks of as little as six to eight tons (5,400 to 7,300 kilograms) to resist the action of waves up to 18 feet (five metres) in height. The same experiments showed that to afford the same protection in the same circumstances, concrete blocks of 22 tons (20,000 kilograms) would have been necessary.

In such cases, an intermediate layer of smaller blocks or boulders is inserted between the armouring and the inner core to prevent the finer material in the core from being dragged out by sea action between the interstices of the armour—a process that leads to ultimate settlement and possible breaching by overtopping of the breakwater.

The increasing cost and frequent unavailability within economic distance of suitable natural rock has provoked considerable thought to the design of concrete armour units that can, by reason of their shape, overcome the disadvantages of the simple cubic, or rectangular, block. One of the most successful has been the tetrapod, a four-legged design, each leg projecting from the centre at an angle of 109½° from each of the other three. Legs are bulbous, or pear-shaped, with the slightly larger diameters at the outer end. These units have the property, when

Tetrapods

placed, of knitting into each other in such a way that the removal of a single unit without the displacement of several others is almost impossible, while the interstices between them act as an absorbent of wave energy. Weights substantially less than those needed for cubic blocks are adequate in the case of tetrapods in similar storm conditions. The tetrapods can be mass-produced adjacent to the site through the employment of re-usable steel forms.

It is usual to construct some form of roadway along the crest of a breakwater, even when this is not required for any other dockside purposes, to facilitate inspection and access for labour, materials, and equipment for damage repairs.

Solid breakwaters. In certain circumstances, particularly in parts of the world where clear water facilitates operations by divers, vertical breakwaters of solid concrete or masonry construction are sometimes employed. Some preparation of the seabed by the depositing and levelling of a rubble mound to receive the structure is necessary, but it is usual to keep the crest of such a mound sufficiently below the surface of the water to ensure its not becoming exposed to destructive action by breaking waves. Repulsion of the waves by vertical reflection rather than their absorption is the philosophy of protection in all such cases, but it is not possible to state categorically which arrangement produces the most economic structure.

This type of breakwater can be conveniently constructed through the use of prefabricated concrete caissons, built on shore and floated out, sunk into position on the prepared bed and filled either with concrete or, less frequently, simple rubble or rock filling. A historical example of this arrangement was the Mulberry Harbour, built by the Allies and floated into position for the invasion of Normandy in 1944. No previous preparation of the seabed was possible, and only partial filling of the caissons had been carried out when the progress of the war rendered further operations unnecessary. Nevertheless, the fact that several of the caissons remained in position basically undamaged for nearly a decade after the invasion on this notoriously stormy coast demonstrated the possibilities of the method.

Floating breakwaters. Because of the large quantities of material required and the consequent high cost of breakwaters of normal construction, the possibility of floating breakwaters has received considerable study. The lee of calm water to be found behind a large ship at anchor in the open sea illustrates the principle. The difficulty is that to resist being torn away in extremes of weather, the moorings for a floating breakwater must be very massive. They are therefore difficult to install and subject to such constant chafing and movement as to require substantial maintenance. Another problem arises, especially in areas of large tidal range. The unavoidable, indeed, essential, slack in the moorings may allow the breakwater to ride large waves, so that they pass underneath it carrying a considerable proportion of their energy into the area to be sheltered.

Despite the difficulties, floating breakwaters still held out promise in the early 1970s with such projected ones based on the concept of causing the waves to expend their energy at the line of defense by breaking on a large, floating horizontal platform.

Pneumatic breakwaters. Finally, the pneumatic, or diffusion, breakwater has been widely discussed. Experiment and limited experience have shown that a curtain of air bubbles blown up from the seabed through a row of perforated nozzles acts as a barrier to the movement of waves over the surface. The mechanics of the arrangement appear to be that the rising bubbles generate streams flowing on the surface, outward in both directions, and the flow meeting the oncoming waves can be made sufficient to hold them up. There is reason to believe that jets of water would be almost as effective as air. Although the volume of air or water necessary completely to restrain the waves generated in severe weather over a wide front would require installation of a plant of uneconomical size, the device can be useful for the temporary protection of a short length of shore to allow the execution of specific works. The air or water pipes can be laid on the seabed at the perimeter of the area to be protected and fed from a mobile plant on shore, and the whole body of equipment can be removed after the operations have been completed.

DOCKS AND QUAYS

Because the principal operation to which harbour works are dedicated is transfer of goods from one transportation form to another (*e.g.*, from ships to trucks), it follows that docks, wharves, and quays are the most important assets of a port.

Facilities required in a dock

Ships must lie afloat, in complete shelter, within reach of mechanical devices for discharging their cargoes. Although in emergencies ships have been beached for unloading purposes, modern vessels, particularly the larger ones, can rarely afford contact with the seabed without risking serious structural strain. The implications of cargo handling, as far as civil-engineering works are concerned, do not differ much whether the loading and discharge are effected by shore-based cranes or by the ship's own equipment. In either case, large areas of firm, dry land immediately alongside the ship are required; the engineer must find a way to support this land, plus any superimposed loading it may be required to carry, immediately adjacent to water deep enough to float the largest ship.

The capital cost of such works probably increases roughly in proportion to the cube of the deepest draft of ship capable of being accommodated; thus the economic challenge posed by the increase in the size of modern ships is considerable. The advent of containerization—the packaging of small units of cargo into a single larger one—has not fundamentally altered this problem except perhaps in time to reduce the number of separate individual berths required and to increase greatly the area of land associated with each berth. A figure of 20 acres (eight hectares) per berth is freely mentioned as a reasonable requirement. The problem of land support at the waterline remains the same.

Gravity walls. The solution initially favoured, and, indeed, predominant for many years, was that of the simple gravity retaining wall, capable of holding land and water apart, so to speak, through a combination of its own mass with the passive resistance of the ground forming the seabed immediately in front of it. Both to ensure adequate support without detrimental settlement of the wall, to insure its lateral stability, and to prevent problems of scour, it is necessary to carry the foundations of the wall below the seabed level, in some cases a considerable distance below. In earlier constructions, the only guide to this depth, in the planning stage, was previous knowledge of the ground and the acumen of the engineer in recognizing the characteristics of the ground when he saw it. Many projects were carried out in open excavation, using temporary cofferdams to keep out the sea. In particularly unfavourable or unstable soils, accidents caused by collapse of the excavation were not unknown.

In modern practice, no such project is initiated without exhaustive exploration of the soil conditions by means of borings and laboratory tests on the samples. Continuous monitoring of the soil conditions during construction is also considered essential. Even so, accidents caused by soil instability still occasionally occur.

Materials for gravity walls

The material composing the walls is today almost universally concrete, plain or reinforced, according to the requirements of the design. This material has entirely superseded the heavy ashlar (natural rock) masonry at one time used for such construction, when the techniques for the large-scale production of concrete were not so well developed as they are today.

In some circumstances, particularly those in which the water is reasonably clear or the design and soil conditions do not require very deep excavation into the seabed, the construction of quay walls is adopted by means of large blocks, sometimes of stone but generally of concrete, placed underwater by divers. The economics of this method of construction are influenced by the high cost

of skilled divers and by the cumbersome nature of diving equipment. The development of lightweight, self-contained equipment, which leaves the diver considerably more mobile, may relieve this problem.

Concrete monoliths. The risks and difficulties attendant on the construction of gravity walls have, in suitable conditions, been avoided through the use of concrete monoliths sunk to the required foundation depth, either from the existing ground surface or, where the natural surface slopes, from fill added and dredged from the front of the quay wall on completion. This technique amounts to the construction above the ground of quite large sections of the intended wall, usually about 50 feet (15 metres) square in plan, which are then caused to sink by the removal, through vertical shafts, of the underlying soil. Another lift of wall is then constructed on top of the section that has sunk, more soil is removed, and the process is repeated until the bottom has reached a foundation level appropriate to the required stability. Considerable skill is sometimes necessary in the sinking process to keep the monoliths (usually provided with a tapered-steel cutting edge to the lowest lift) sinking uniformly and not listing, an eventuality that can occur if any part of the periphery encounters material particularly difficult to penetrate. Differential loading of the high side and special measures to undercut the material composing the obstruction may be necessary.

The shafts through which the excavated material is removed are generally flooded throughout the operation simply from the intrusion of the groundwater; if necessary, this water can be expelled by the use of compressed air. The excavation of difficult material in detail and in the dry can then be undertaken. It is an operation of some delicacy because the flotation effect of the compressed air adds a further element of instability to the monolith, and a blow (sudden leakage of air) under the cutting edge may result in flooding of the working chamber. When the bottom edge of the monolith has reached the designed level, the excavation shafts are sealed by concrete plugs. The shafts themselves can then be filled, either with concrete or with dry filling to give the final wall the required mass for stability.

Success in this form of construction cannot be guaranteed. In the case of the Western Docks at Southampton, Hampshire, constructed between World War I and World War II, it was found impossible except at inordinate cost to get the monoliths to sink through the opposing strata to the depth required for stability as a retaining wall. It was therefore necessary to reduce the thrust involved in this function by cutting the retained material back to a natural slope and spanning the gap between the back of the monoliths and the top of this slope by means of a reinforced concrete relieving platform, supported along its other edge on reinforced concrete piles. This arrangement has served well enough as far as the quay wall itself is concerned, but the maintenance of the natural slope, stone-pitched as a protection against erosion, has been a continuing liability. In addition, the presence behind the quay of the relieving platform constitutes a formidable obstacle to further construction work; *e.g.*, warehouses or multistory transit sheds.

The problem of Southampton quay

Concrete caisson walls. In situations in which the depth from ground level to the final dredged bottom is not excessive and the material available for retention as reclamation is of good self-supporting qualities, quay walls can be constructed of precast concrete caissons floated into position and sunk onto a prepared bed in the same manner as that described for breakwaters. Care is taken to design caissons able to withstand the thrust of the retained material, which is carefully selected for the areas immediately behind the quay wall. The conditions suitable for this form of construction are generally typical of the Mediterranean, where the slightness of the tidal variation keeps the depth required to a minimum. An outstanding example of this kind of construction is the extension to the area of the Principality of Monaco, which is being increased by as much as 22 percent by reclamation retained by this technique. Similarly constructed installations for transportation and ship-repair purposes exist elsewhere in the Mediterranean, in parts of which the earthquake factor is an additional influence on the retaining-wall design.

In all cases of dock-wall construction by concrete monolith or caisson, it is the basic structure of the wall that is provided by these means; the final superstructure, above highest tide level, will depend for its detail on the requirements for dockside services, crane tracks, and other elements.

The piled jetty. The high cost, difficulties, and possible dangers of providing dock and quay walls of the kind just described have always encouraged a search for alternative solutions that would eliminate the need for operations on or below the seabed. Of these, the earliest and most obvious is the piled jetty—its piles can be driven from floating craft and the deck and superstructure added thereto, working wholly above water. In regions in which there is a large tidal range, it may sometimes be both advantageous and necessary to take the opportunity of extremely low tides to make attachments to the piles for bracing and stiffening purposes. With a reasonable programming of the work, this operation can usually be done without particular difficulty, assuming that the seabed is of a composition reasonably amenable to penetration by piles to a sufficient depth to secure the lateral stability of the structure. A hard rock is not suitable, although some of the more friable rocks can be pierced by steel piles.

Piles may be of timber, reinforced concrete, or steel. Timber is a popular choice if there is a large natural supply. Lateral stiffness and stability can be achieved by using a sufficiently close spacing of the piles in both directions and adequate rigid bracing between the tops, timber being a material readily amenable to the workmanship required. Its chief drawback is lack of durability, particularly in the area between wind and water, although a timber jetty with reasonable maintenance can often outlast normal operational obsolescence. There are examples of construction in which the piles are connected together by casting around the heads a reinforced concrete slab, its soffit (underside) just below lowest water level. By this means, the timber is kept continually submerged, a condition under which its durability is prolonged. On the other hand, in tropical or semitropical waters or waters accidentally kept warm by industrial effluents, the use of timber may be inhibited by the presence of marine borers. Timber jetties have a considerable advantage in the comparative ease with which repairs to accident damage or deterioration can be effected.

Timber piles

Reinforced concrete piled piers and jetties, soundly constructed, exhibit great durability. Attachment to the piles for bracing and similar purposes tends, however, to be more complicated than in the case of timber. This is a disadvantage that applies also to subsequent maintenance and repairs.

Sheet-piled quay. An extension of the piled jetty concept is a quay design based on steel sheetpiling, the design becoming increasingly popular with improvements in the detail and manufacture of the material. Steel sheetpiling consists in essence of a series of rolled trough sections with interlocking grooves, or guides, known as clutches, along each edge of the section. Each pile is engaged, clutch to clutch, with a pile previously driven and then driven itself as nearly as possible to the same depth. In this way a continuous, impervious membrane is inserted into the ground. In most designs the convexity of the trough sections is arranged to face alternately to one side and the other of the line along which the membrane is driven, so that a structure of considerable lateral stiffness is built up. At the same time, a measure of flexibility in the clutches allows some angular deviation so that a membrane curved in overall plan is obtainable, a feature of considerable convenience in developing the layout of a series of wharves or quays.

The development of steel sheetpiling over the years has largely been characterized by the increasing weight and stiffness of the sections becoming available from the rolling mills. In one design, the clutch is a separate unit from the main structural element, generally of broad-flanged

or universal beam section. In this case, the clutch unit appears in a profile of two grooves, or channels, back to back, each capable of embracing the flanges of adjacent beams, which are thus locked together in a continuous sheet, or membrane, of considerable strength. Each universal section is entered, when pitched for driving, into the clutch on the previously driven section and usually carries the clutch for the next section with it. In another design, made economically possible by the advances in the technique of automatic continuous welding, rolled universal beam sections are welded by one flange into the troughs, or pans, of conventional sheet piles, the composite construction producing a unit of unique strength and stiffness.

The development of steel sheetpiling has kept ahead of the development of hammers capable of driving it, probably because the stiffer the section is, the greater the length of pile that can be incorporated in a design. The combination of heavier section and greater length demands a greater proportion of the energy delivered by the hammer being unproductively absorbed in the temporary elastic compression of the pile, leaving less energy to drive the pile further into the ground. Simply increasing the amount of energy delivered, by using a heavier hammer or a higher drop, does not necessarily provide the solution; it may only result in damage to the head of the pile without achieving greater penetration. This difficulty has been in part overcome by the use of high-strength steel piles. Nevertheless, it is not unknown for a pile to appear to be going down with little or no head damage when it is, in fact, sustaining extensive damage below seabed level that gravely compromises its efficiency as a retaining quay wall. This situation, usually the buckling of a pile, can occur particularly where the material of the seabed contains boulders or similar obstacles to penetration.

The problem has obvious major implications for the construction of quay walls and has provoked much debate among engineers. The skill of the quay designer and the advice of the soil mechanics specialist both contribute to the satisfactory reconciliation of the various conflicting factors outlined in order to achieve the most effective and economical solution.

Protecting the quay

In the normal design of sheet-piled quay or wharf wall, the sheetpiling itself forms the quay face, although it is generally found advisable to protect the piles from the impact of ships berthing by timber fenders. Vertical timbers at intervals are generally used. Horizontal walings (wooden ridges) between these timbers can also be employed, but they have a disadvantage, particularly at small wharves and with ships having their own protective belting: on a rising tide the beltings become entangled with the walings, occasioning damage or even minor disaster.

The upper part of the sheetpiling, being laterally unsupported on the sea side, is generally anchored back to resist the thrust of the retained soil. This resistance is commonly effected by using tie rods secured to anchors buried in the retained soil itself to a depth that, for reasons of overall stability, is beyond the natural slope line of the soil. As often as not, these anchors are themselves composed of lengths of sheetpiling driven, if possible, below the retained soil into the strata beneath. The mild, or alloy, steel tie rods, coated and wrapped against corrosion, can be carried through the exposed sheetpiling of the quay wall with large retaining nuts on the outside or can be secured to welded attachments at the back of the piling. The latter practice is the more commonly favoured arrangement, largely on account of its more finished appearance. The sheet-piled quay just described is completed by casting a reinforced concrete cope beam to cover as well as contain the exposed heads of the sheetpiling.

The advantage of this type of quay wall is that the space behind the wall is not occupied, as in the case of the suspended-pile supported deck, by a monolithic, fully structural element, the arrangements of which can only be disturbed for subsequent modification of the services layout at some cost and usually by a potentially complicated design operation. As in the case of a gravity wall, the space can be filled with suitable material that can subsequently be treated, to all intents and purposes, as natural ground in which service ducts can be buried if required. This arrangement is often an advantage in the case of freshwater mains for fire fighting or watering ships because they can thus be protected from frost. Alternatively, it is possible to place concrete-lined service and cable trenches in this material, sometimes conveniently by the use of precast sections, because the ground loads imposed are seldom sufficient to give rise to serious settlement problems.

Structural reinforcement. Identifiable structural loading, arising, for example, from crane tracks, can be supported on reinforced concrete beams on piles driven through the filling to the strata beneath. Dockside railways, a decreasing requirement because of the transfer of much shore-to-ship delivery to road vehicles, need not necessarily have piled support because the loading from these can be spread to remain within the bearing capacity of the filling. Some settlement is bound to take place, and the need for compensating by packing up and relevelling of the track has the incidental disadvantage of breaking up the surfacing of the quay, which is almost always provided to facilitate quayside access by road vehicles.

Sheet-pile quay walls are readily applicable to sites at which only relatively shallow or medium-depth water alongside is needed. As the required depth increases, a sheet-pile section of sufficient strength and stiffness to hold the retained material without further assistance becomes impractical from the point of view of handling and driving. A solution increasingly favoured is the so-called Dutch quay. In this design, after the line of sheetpiling, using one of the heavier and stiffer sections, has been driven, the ground behind is excavated for a distance back determined by the natural slope of the material to be used as filling and taken down as far as possible to lowest water level. At this level, a reinforced concrete relieving platform is constructed up against the sheetpiling but with independent vertical support from bearing piles driven through the bottom of the excavation to an appropriate depth. Piles for crane tracks are driven at the same time as these; that is, before the construction of the relieving platform.

The Dutch quay

Filling material is returned above the relieving platform, and although the latter now prevents further pile driving in the area, the probability of this being required is remote, whereas the retained load against the sheetpiling is much reduced. The advantages of having filled material behind the sheetpiling for installing services remain. In addition, the relieving platform affords the sheetpiling considerable help in resisting horizontal blows from the impact of berthing ships, and to increase this resistance, some of the piles supporting the platform are often driven toward the quay face. Reinforced concrete counterforts between the platform and the sheeting can be an additional help.

Durability. A question mark that hung over the use of steel sheetpiling in salt water in its early years concerned its durability in potentially hostile conditions. Experience of the rate of corrosion, particularly at the waterline or within the tidal range, varied from one locality to another according to the state of the water and the effect of such factors as the degree of salinity and the presence of industrial effluents. Precoating of the pile with a protective film such as tar or a bituminous paint is only of transient value, requiring regular renewal, and is effective only down to lowest water level.

The inclusion in the composition of the sheet-pile steel of a very small percentage of copper was tried as a means of increasing its durability, but the effectiveness is doubtful.

Cathodic protection

The confirmation of the electrochemical basis of much of the corrosion affecting steel sheetpiling led to the development of cathodic protection, a process that has wide application in many other fields, especially shipbuilding. Electrolytic corrosion arises from the passage through the piling of electric currents, causing the pile, or part of it, to become the anode, or positive pole, in what amounts

to a galvanic cell, or battery. In such a cell, metal is normally removed from the anode and may reappear on the cathode, or negative pole, which remains unaffected. These currents in sheetpiling may arise from stray leakages from adjacent electrical installations or be generated within the pile itself by differences in the electrolytic conditions at differing levels on the pile.

Cathodic protection is a means whereby cathodic polarity is imposed upon the whole pile, and its operation as an anode (with consequent deterioration) is prevented. This can be done either by the supply from a suitable source—*e.g.*, a battery—of an electric current that will overcome and reverse the direction of that naturally generated or by connecting the piling at intervals to sacrificial anodes of an element—generally aluminum or magnesium—the atomic relationship of which to the steel in the piling is such as to generate such a current without external assistance. These anodes are buried in the surrounding ground and care must be taken to ensure full electrolytic continuity between them and the piling to complete the circuit. It is sometimes necessary, in order to ensure electrical continuity in the piling itself between the anode connections, to weld adjacent piles together after driving.

By whatever means cathodic protection is applied, a small liability for operational maintenance arises, either for the continuous supply of the imposed current or the periodic renewal of the sacrificial anodes. The considerably increased durability of the structure usually justifies this.

Enclosed docks. Whenever possible, commercial quays are built open to the tide range to provide maximum freedom for shipping. There are, however, some parts of the world in which the range between low water and high water is so great that the resulting variations in the level of the ship's decks and hatches impose unacceptable disabilities on the handling of cargo. In such circumstances the quay walls, the net clear height of which, disregarding depth of foundations, must span the distance from the lowest seabed level acceptable for navigation at low tide to an adequate freeboard for the coping of the quay wall above the level of the highest high tide, may become of such dimensions as to be uneconomic. This condition is equally applicable in cases in which only the berths themselves are made to be usable no matter what the stage of the tide.

Locks

The problem can be met by constructing the quays as enclosed docks in which the water level is kept constant and access to the tidal areas is by means of a lock or locks. An obvious condition for the success of such an arrangement is that the strata of the bed under the enclosed dock area be sufficiently impervious to preclude any significant loss of water through the bottom during low-tide conditions. In this way the tidal range, as a limit on the height of the quay walls, can be eliminated.

Apart from the fact that they have gates at each end, the structure of maritime navigation locks and the problems involved in their design are very similar to those of dry docks. Although, in normal usage, a lock is never completely dry, it is essential that it should be designed to be capable of withstanding the stresses imposed by this condition, so that it may be possible to de-water the lock completely for inspection and maintenance.

It is common practice to design enclosed docks so that the normal water level maintained is not below the highest likely high tide because the invasion of an enclosed dock by a high tide significantly above the normal water level can be disastrous.

Although enclosed docks are frequently of such an area that they can supply the lockage water lost when a ship passes through the lock without any drop in level that cannot be made up on the next high tide, it is normal to provide a measure of impounding capacity in the form of pumps for lifting additional water from outside into the dock. Such a provision is essential for situations in which it is required to keep the enclosed dock water level above the highest tide.

It has sometimes been possible to accommodate ships of larger draft than originally planned for in large, but relatively old, enclosed docks. This is done by installing impounding pumps for topping up the water level to give an increased depth.

Enclosed docks generally suffer the operational disadvantage of restricted times of entry and exit because they are subject to a fairly rigid tidal schedule. First of all, the lower the tide level outside, the greater the amount of water lost in the locking operation; and, second, it is seldom economically feasible to maintain full navigation depths at all states of the tide in the approach channel to the lock entrance. This situation is particularly the case in which enclosed docks are sited adjacent to and operating from a tidal river estuary. The tidal lock at Dunkirk, France, opening to allow the passage of the night channel ferry, which runs on a timetable, is an example of a tidal lock operated whatever the state of the tide.

If possible, the access locks are usually duplicated, lest an accident involving the gates or the structure of the lock put the whole dock area out of action. Stability calculations of the quay walls within an enclosed dock are important; in older installations such calculations may have been based on the continuing presence of water at the designed normal level, and in the event of a serious failure at the lock—resulting in a considerable drop in the water level—the stability of the quay walls could come into question.

ROLL-ON, ROLL-OFF FACILITIES

An enormous increase in the use of the roll-on, roll-off technique of loading and unloading developed in the late 1960s. The principle of embarking whole vehicles under their own power was not new. The report of Hannibal ferrying his elephants over the Rhône in the 3rd century BC might be regarded as the earliest example from which the vast amphibious operations of the invasion of Normandy in 1944 were descended. Since the 1960s, however, the spectacular increase in the use of road transport for heavy freight and the increase in handling charges at ports for the loading and discharge of cargo by conventional means have combined to provide the impetus for the rapid commercial development of the roll-on, roll-off technique. In addition, the tendency to assemble machinery at its place of manufacture in larger and larger units has encouraged the development of special transport vehicles, and the economies of moving load and vehicle together from origin to destination are valuable.

Berthing and access problems

The principal problem for the port engineer is the provision of the special berthing for the ferry vessels and the means of access for the vehicles from the shore to the ship's decks. Rail-car ferries, involving somewhat similar problems, have been known for some time, but because of the severer limits on gradients for such vehicles there has been a tendency to limit the operation of these services to terminals at places where the tidal range is inconsiderable. For the Dover–Dunkirk ferry, opened shortly before World War II, a special enclosed dock was constructed at Dover in which the water level could be kept constant for loading and unloading, while at Dunkirk the entire dock system is totally enclosed, accessible through sea locks.

Many of the new roll-on, roll-off terminals for road services are, by contrast, in tidal water; and where the tide range is of considerable extent, access bridges of considerable length are often needed to keep the change of gradient between low and high tide within acceptable limits. The change in the ship's trim between conditions of light loading and full loading creates yet another problem.

Disadvantages of pontoons

At first sight, the solution might appear to be to support the outer end of the link span on a float, or pontoon, so that it would automatically follow the rise and fall of the tide. Several disadvantages of structural detail arise, however, and the system is vulnerable to damage caused by the movement of the pontoon under adverse weather conditions. A means of adjustment in the height between the span and the supporting pontoon to accommodate changes in ship's trim is still required; and, therefore, the overall economies of a pontoon are less than might at first be imagined.

It is, thus, almost universal practice to support the outer end of the link span from an overhead structure, either through conventional wire-rope hoisting gear or by means of hydraulic rams. The level of the end of the span can thus be continually adjusted, either automatically or by manual control, to match changes in the level of the ship's deck, whether caused by the tide, by the trim of the ship, or by differences in deck levels between one ship and another. Maximum flexibility of access has become increasingly important with the appearance, on some services, of ships with two independent car decks, both of which must be equally accessible to the link span. This situation has sometimes been achieved by the use of two-decker link spans, which has the effect of keeping the length and, unless the span is intended to carry loads on both decks simultaneously, the weight of the span to a minimum.

The sudden proliferation of roll-on, roll-off services simultaneously has led to the rather unfortunate development: a number of the terminals have tended to be tailor-made to suit particular ships and to be unable to accept different ships without, in some cases, quite major structural alteration. This feature clearly reduces the otherwise great flexibility of this technique, and an International Commission to examine the question was appointed in 1970 by the Permanent International Association of Navigation Congresses.

Maximum advantage of roll-on, roll-off is gained in relatively short sea passages. On longer voyages, the idle-road vehicles make the economies questionable. This problem can be overcome to some extent by embarking only semitrailers and leaving the tractive units ashore; the practice has no effect on the terminal details.

BULK TERMINALS

The enormous increase in the marine transit of materials in bulk, with petroleum leading the way, has given rise to the development of special terminals for the loading and discharge of such materials. The principal factor influencing the design of these installations is the still-increasing size of the ships. A single example of the effect of this change on design limits will be sufficient. The "Queen" liners, long the world's largest ships, in conditions of maximum load never drew more than 42 feet (13 metres) of water. Supertankers, on the other hand, when fully loaded, draw up to 72 feet (22 metres). If these ships required berthing structures of the type provided for conventional cargo and passenger liners and if the formula relating the capital costs of such structures to the deepest draft were applied, the cost of building an appropriate berth for such a tanker would reach a figure over six times that of the "Queen Mary's" old berth. Fortunately, the high mobility of the cargo renders such drastic and expensive measures unnecessary. Heavy capacity access for individual shore-based vehicles to carry away the cargo is not required, nor does the provision of services for the relatively small crews who man these great ships present any problem. The berthing positions can therefore be sited well out from the shore in deep water, and the structure itself can be limited to that required to provide a small island with mooring devices.

Unloading oil from tankers

In the case of oil terminals, the link to shore can be a relatively light pier or jetty structure carrying the pipelines through which the cargo is pumped ashore, with a roadway for access by no more than average-sized road vehicles, which will probably be in small numbers or even only one at a time (see Figure 2). As the ship herself carries the pumping machinery for delivering the cargo ashore, heavy mechanical gear for cargo handling is not required.

In the case of bulk carriers bringing more solid commodities, such as iron ore, the problem is more complicated. Hoisting grabs for lifting the ore out of the holds are necessary, even though transit between ship and shore can still be effected by continuous conveyors, corresponding to pipelines. Heavier foundation work is probably necessary at the berthing point to carry this machinery, and, for this reason, ore terminals have not, up to now, sought sites as far out in deep water as the oil terminals. It seems unlikely that the size of ore carriers will reach anything like the dimensions already attained by supertankers.

The employment of piled structures to meet these requirements is almost universal, and a variety of techniques has been evolved for handling and sinking into the seabed the long heavy piles required. At the sites likely to be chosen, penetration by piles may not be easy, particularly in places where most of the reasonably accessible deepwater sites tend to be located on the rockier shores.

One problem that arises is that of shelter in adverse weather conditions. While the ships themselves are reasonably robust, the relatively fragile berthing structures might break up, setting the ship loose, possibly without power immediately available, threatening disaster. As the cost of building breakwaters to protect sites in the depth of water required is likely to be prohibitive, the search has been for natural shelter. In the British Isles, the sheltered creeks of the western shores, such as Milford Haven, Pembrokeshire, have become valuable. Milford Haven had known little shipping other than fishing fleets since the early 19th century, but in the early 1970s boasted four bulk oil terminals. Two supply refineries were built on the spot; the third pumps to a refinery 60 miles (100 kilometres) away.

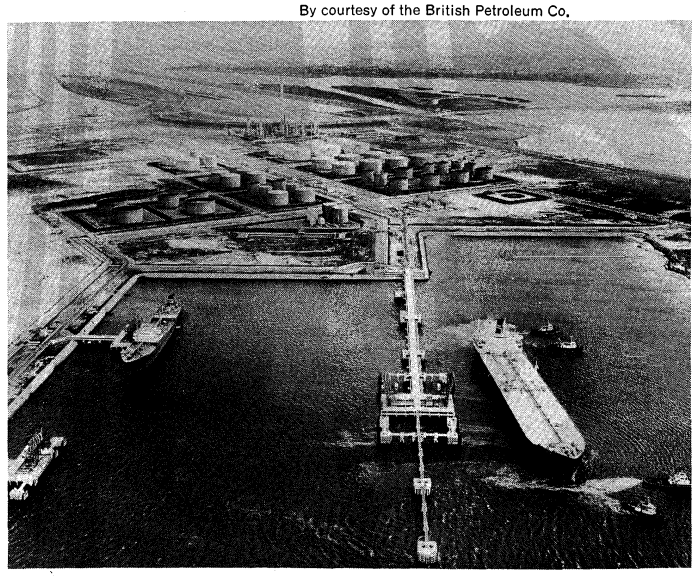

Figure 2: The oil jetty at Rotterdam, The Netherlands.

Another aspect of the terminals is the need for protection against the effects of unavoidable collision impacts. A slight impact from a vessel of these dimensions, by reason of the large kinetic energy of such a mass, can cause considerable damage to the light berthing structure. Much ingenuity and theoretical analysis have gone into devising fendering systems that will absorb this energy. Some use the displacement against gravity of large masses of material disposed pendulumwise in the berthing structure as the energy absorbent; others use the distortion by direct compression, shear, or torsion of heavy rubber shapes or sections; still others rely on the displacement of metal pistons against hydraulic or pneumatic pressure. The common feature of all the devices is that at least part of the energy absorbed is not dissipated but is used immediately to return the ship to its correct berthing position. This feature is not exhibited by the older forms of fenders, which relied on the compression and, in extreme cases, on the ultimate destruction of coiled rope or timber to absorb the impact. A major question still is the exact ship velocity to be allowed for, the determination of which is primarily an exercise in probability, balancing the economics of designing to a specified velocity against the cost of repairs after impacts at greater velocities. The key factor is the frequency of such impacts, which can only be determined by experi-

ence. In the early 1970s the development of suitable observing and recording equipment was under way.

DRY DOCKS

The largest single-purpose structure to be built by the maritime civil engineer is not directly connected with loading, unloading, or berthing but is indispensable to prolonging the life of ships. This is the dry dock, which permits giving necessary maintenance to the underwater parts of ships. The problem of dry-docking is aggravated by the tendency of ships to grow in size by increases in beam (width) and draft (depth below waterline) rather than in length, a process that rapidly renders many of the world's largest dry docks useless for servicing an increasing proportion of the traffic.

Danger of obsolescence

A classic example is the King George V Drydock at Southampton. Opened in 1933, it was 1,200 feet (370 metres) long and 135 feet (41 metres) wide and was capable of accommodating the largest vessels afloat, namely, the two Cunard liners "Queen Mary" and "Queen Elizabeth," each over 80,000 tons (73,000,000 kilograms) deadweight. The later supertankers have deadweight tonnages of 135,000 tons (122,000,000 kilograms) and more, within a length of about 1,150 feet (350 metres) but with a beam of about 175 feet (50 metres), which precludes them from entering the King George V dock. The lengthening of a dry dock would be a comparatively simple and economical operation; widening, on the other hand, involves at least the complete demolition of one sidewall and its rebuilding to give the increased clear width to the other wall, assuming space can be made available. Increasing the depth would mean a new dock altogether, but because tankers generally dry-dock in the unloaded condition in which their draft can be considerably less than that of a conventional ship, this problem has not so far been a practical one.

Structural requirements. Moreover, in a great many cases, the maximum state of stress in a dry dock occurs not when it is carrying the weight of the ship (always considerably less than the weight of the water occupying the dock when flooded) but when it is completely empty and subject to the pressures generated by water in the surrounding ground, particularly under the floor, the support of which may lie at a considerable depth below the level of the adjacent water table. To ensure against any tendency to lift under this pressure, the floor must either have sufficient weight in itself (one foot, or 300 millimetres, depth of concrete will resist a little less than 2½ feet, or 750 millimetres, head [depth] of water) or be designed as a structural element capable of transmitting this pressure laterally to the walls of the dry dock, which can then be designed to contribute the additional extra weight required. Obviously an operation involving both the complete rebuilding of one wall of a dry dock and the strengthening of the floor to cover an increase in its span as an inverted arch or beam is almost tantamount to the construction of a complete new dock.

This problem received somewhat tardy recognition, so that although several large new dry docks were built around the world in the 1960s, only a minority were capable of allowing the entry of tankers of more than 200,000 tons (180,000,000 kilograms), a considerable number of which were expected to be in commission by the middle of the 1970s.

Design. The design of a dry dock probably depends more on the ground conditions than any other engineering structure, with the possible exception of large dams. Mention has been made of the need in many cases to resist upward pressures under the floor. Apart from the simple solution of using the weight of the dock structure itself for this purpose, which is not economical, such devices have been tried as "pegging" the floor to the underlying strata by means of piles or pre-stressed anchors, or extending the floor slab itself beyond the sidewalls and so gaining assistance from the weight of the material filling behind the walls, which are designed to act as retaining walls to this filling. Venting of the floor to relieve water pressure can sometimes be of help provided the volume of water so released is not excessive. If it is, continuous pumping to keep the dock dry will be necessary. On sites in which water pressures do not have to be resisted, the design is generally simpler, and sufficient strength and stiffness to spread the loads from the ships' keels over the underlying ground so as not to exceed the bearing resistance of the latter is the controlling floor-design factor.

Dry docks in shipbuilding

The use of dry docks for the building rather than the maintenance of ships is a practice that has been increasingly adopted. Both the building and the launching of a ship in these circumstances can be considerably simplified. The designs of such dry docks are no different from those hitherto described; what is possibly the largest dry dock in the world was completed in Belfast, Northern Ireland, in 1970. This dock, built along the site of a former channel between two open basins, is capable of accommodating the three Cunard liners "Queen Mary," "Queen Elizabeth," and "Queen Elizabeth 2" simultaneously and is to be used for the building of large tankers. It is spanned by a crane of 400 tons (360,000 kilograms) lifting capacity to handle large prefabricated ship sections.

Entrances. Dry dock entrances are closed by gates of different designs, of which the sliding caisson and the flap gate, or box gate, are perhaps the most popular. The sliding caisson is usually housed in a recess, or camber, at the side of the entrance and can be drawn aside or hauled across with winch and wire rope gear to open and close the entrance. The flap gate is hinged horizontally across the entrance and lies on the bottom, when in the open position, to be hauled up into the vertical position to close the dock—a process occasionally facilitated by rendering the gate semibuoyant through the use of compressed air.

The ship type of caisson gate, a quite separate vessel, floated and sunk into its final position across the entrance, is largely out of favour. Although it was comparatively easy to remove for maintenance and had the further advantage that a spare caisson could be kept in reserve in case of damage, the tie-up of capital is usually found unnecessarily expensive merely as an insurance premium.

The maximum degree of watertightness obtainable between the gate and its seating is essential if continuing and expensive operational commitments for pumping out leakage water are to be avoided. The pressure of the water outside the gate is available to provide a powerful sealing force, but special treatment of the actual contact faces is necessary to make this force fully effective. For a long time it has been held that the only satisfactory arrangement was by the use of a timber lining (generally greenheart) around the contact face on the gate, bearing against stops in the dock structure composed of granite dressed and polished to a high degree of accuracy. The increased expense of such methods and the diminishing supply of skilled labour capable of dressing the granite has led to a search for alternatives. These include such devices as the use of stainless facing bars set in concrete, in place of the dressed granite, and rubber linings on the gates themselves. While these have generally proved effective when first installed, more experience is needed to determine their durability as compared with older methods.

Keel and bilge blocks. Keel and bilge blocks, on which the ship actually rests when dry-docked, are of a sufficient height above the floor of the dock to give reasonable access to the bottom plates. Such blocks are generally made of cast steel with renewable timber caps at the contact surfaces. Individual blocks can generally be dismantled under the ship to allow access to that part of the plates, if required, and can be reassembled to take their appropriate share of the weight after the operation required has been completed. Most modern ships, particularly tankers, are of nearly square section over a large part of their middle length and can be kept upright in dry dock by the support of the bilge blocks under their bilge keels. In the most up-to-date dry docks, the bilge blocks are provided with mechanical means for traversing them across the dock and altering their height by remote con-

trol while the dock is still flooded. This arrangement permits them to be adjusted in their correct position according to the shape of the ship while the latter is still just afloat but in contact with the centre-line keel blocks. The economic advantage of this arrangement is considerable because it allows one ship to be removed and another put into the dry dock on the same opening of the gate, whereas under previous practice it would have been necessary to close the dock and pump it out to reset the bilge blocks to the known profile of the next ship. Apart from the time needed, the power consumed in pumping out a large dry dock is a considerable factor.

As a consequence of the increasing number of ships suitable for bilge docking, the use of side shores to keep hulls upright in dry dock is a rapidly dying process, and indeed the altars provided for this purpose in dry docks of more old-fashioned design are often an embarrassment to the accommodation of a modern square-sectioned ship. Frequently this situation is remedied by cutting away some altars, an operation that must be conducted with discrimination because the removal of any quantity of material from the sidewalls may have a damaging effect on their stability.

Construction. *Basic technique.* Dry docks are usually constructed in open excavation in the dry, shutting out the sea by means of a cofferdam. Sometimes it is found convenient to construct the sidewalls first, in trench, and next to remove the loose material between them, then to lay the floor in stages so as not to endanger the stability of the walls before the floor is in position to give them toe support. Extensive pumping, to keep the excavations from filling with water during construction, is generally necessary.

Keeping out the sea

In one rather unusual case, a dry dock for 240,000-ton (128,000,000-kilogram) tankers was constructed almost wholly under water because large fissures in the rock running through to the sea flooded the site beyond the capacity of any reasonable assembly of pumping equipment. The entire space required for the structure was therefore excavated to formation level by dredging, and the sidewalls were constructed first, using prefabricated concrete caissons, sunk into place and filled with concrete. The spaces between adjacent caissons were sealed by filling with concrete in the same way. Stone aggregate, to a depth of seven metres (23 feet), was then deposited between these walls and consolidated into a concrete floor by a process of grouting in which colloidal cement grout was forced under pressure between the interstices of the aggregate, subsequently setting to form the whole into concrete. A similar process across the floor at the entrance incorporated a cofferdam of interlocking steel sheetpiling, which allowed the sill and gate hinge to be constructed in the dry. The gate, of the flap variety already mentioned, was floated and stepped into place by divers after the removal of the cofferdam. Only then was it possible to pump out the main body of the dock, which was completed by laying a reinforced concrete topping over the floor in order to provide a satisfactory working surface.

Floating dry docks. Floating dry docks have the initial advantage that they can be built and fully equipped in shipyard and factory conditions, in which their construction is not subject to unforeseen hazards arising from weather and variations in the ground conditions from those anticipated during design. The floating dock can be towed to the site, moored, and made ready for operation in a comparatively short time. Expenditure on temporary works, often a large fraction of the cost of a fixed dry dock, is also avoided.

Floating dry docks are usually fully self-contained (Figure 3). The sidewalls provide much of the residual buoyancy and stability required to keep the dock afloat when it has been so far submerged to allow the entry of a ship into the docking space over the main deck. Most of the machine tools and workshop equipment required for all the normal operations of ship repair and maintenance are also housed in the walls as well as the generating plant (usually diesel driven) to supply power for the operation of the dock and its equipment. Travelling cranes, for handling material off and onto the ship, run on the tops of the sidewalls.

A floating dry dock can be moved at relatively short notice to another site, should a long-term change in shipping-traffic patterns dictate a change. This advantage may be more apparent than real because the large work force required to man it may not be so readily transferable.

From A. Amirikian in "Transactions of the Society of Naval Architects and Marine Engineers," 1957

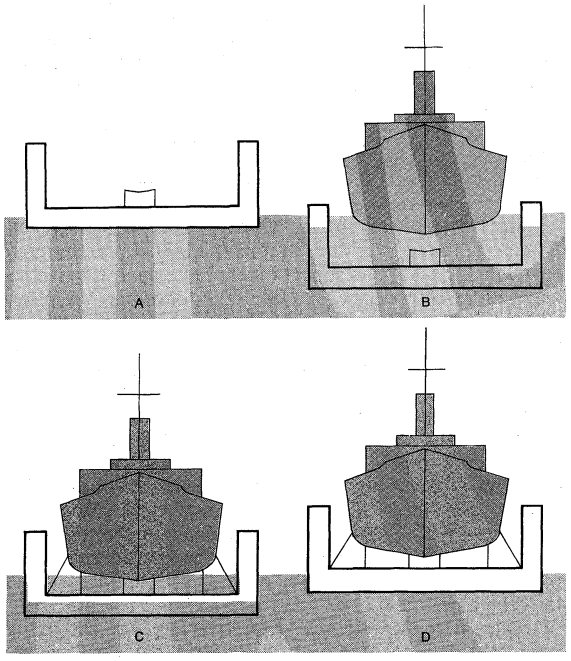

Figure 3: *Operation of a floating dry dock.*
(A) Dock afloat in its light-draft condition, with little or no water in its ballast tanks. (B) Dock submerged to its maximum draft by filling the ballast chambers; a vessel floats freely in the flooded channel. (C) Dock floor emerges from the water, and the vessel comes to rest on the support blocking. (D) All ballast is pumped out, raising the dock floor completely out of the water and providing a dry working area.

Moreover, floating dry docks tend to have large maintenance costs because the steel structure, being continually afloat, requires regular chipping and painting, as the hull of a ship does. The above-water structure presents no particular problem and can generally be given maintenance care without putting the dock out of use. The most vulnerable areas, those immediately adjacent to the waterline, can be reached by careening, a process that involves filling the water ballast tanks along one side to induce a list that lifts those on the other side part of the way out of the water. On completion, the process can be reversed for the other side.

Maintenance. Methods of underwater scaling and painting, or the use of limpet dams with which small areas can be covered with watertight enclosures inside of which men can work under compressed air, allow a limited measure of attention to be given to the bottom plating outside. Occasionally it is necessary to detach one of the sections of the dock, which is usually constructed in separate sections for this reason, and dry-docking it in the remainder, repeating the process until the whole dock has been renovated. This costly and tedious process is only resorted to for compelling reasons.

Underwater scaling and plating

To give a floating dock sufficient depth of water for submerging the docking blocks below the keel of the ship to be docked, it may be necessary to dredge a berth for it. In areas subject to heavy siltation, this dredged area will almost certainly act as a silt trap. Periodic removal of the dock from the berth to allow the latter to be redredged is an additional source of expenditure in such cases. Finally, in places where the tide range is of consequence, special mooring arrangements are necessary to restrain excessive lateral drift of the dock as the mooring chains become slack on low water.

The arrangement of keel and bilge blocks is generally similar to those described for fixed dry docks.

DREDGES, DREDGING, AND RECLAMATION

An indispensable item of equipment over a wide range of the maritime civil engineer's activities is the dredge with its ancillary units, such as hopper barges, tugs, reclamation units, and servicing craft. There are few navigable harbours or harbour approaches that do not require, at varying intervals of time, removal of deposits of unwanted material, the continuing accumulation of which can ultimately obstruct navigation. With the current trend toward larger ships, dredging is especially important.

Extensive research has been devoted to the development of dredging equipment. Through more sophisticated techniques, including, in some cases, permanent profile modification of the harbours and waterways, efforts are made to keep the need for dredging to a minimum. Model studies, mentioned earlier, can be of the greatest assistance.

Dredging. The material to be removed by dredging operations is usually derived from one of two sources or from a combination of both. In harbours at the mouths of rivers, quantities of silt are carried down in suspension and tend, partly because of the deceleration of the flow in the increased waterway available and partly because of the effects of increasing salinity, to be deposited at the mouth, usually the site of harbour works.

Estuarial silt

This process has produced areas of marked agricultural fertility, such as the Nile Delta in Egypt. While over a large time span the action is one of great benefit, in the short term it is generally a considerable inconvenience. The skillful employment of modern dredging equipment, however, has indicated possibilities of getting the best of both worlds. The other source of deposited material likely to obstruct navigation is littoral (coastal) drift, especially in areas where there is a sizable tidal range. The incoming tide frequently brings suspended material, some proportion of which settles to the bottom around the turn of the tide when the movement of water is at a minimum. In the absence of any countervailing tendency, an accumulation takes place, which again requires dredging.

For many years the workhorse of many of the world's dredging fleets has been the bucket-ladder dredge, operating a continually moving chain of open-ended shovels or scoops. At the bottom of the ladder the scoops are pushed into the face of the material, and empty themselves as they turn over at the top, the material falling into chutes that divert it into hopper barges for removal. A four-point mooring system enables the craft, and with it the bucket ladder, to be held up to the working face and, at the same time, swung sideways across it in either direction. By this means, an often remarkably level bed to the sea bottom can be closely controlled by adjusting the position of the ladder under the dredge's bottom. The positive action in filling the buckets enables such a dredge to tackle material of considerable stiffness, thereby extending its use to works of dredging and harbour development in which soils other than recently deposited silt or sand have to be excavated. Even some of the softer rocks can be removed in this way if the buckets are provided with hardened and stiffened edges and ripping teeth.

The principal disadvantage of the bucket-ladder dredge is the need for an elaborate system of fixed moorings. The area that can be covered by one placing of the moorings is limited. Continuous lifting and replacing of the moorings are not only time-consuming, but must be carried out in such a way as to offer minimum obstruction to navigation, a requirement that sometimes involves a great number of interruptions in dredging operations.

In areas in which the deposited silt is highly mobile and accumulates in considerable quantities, it can be economically removed by a suction dredge, which pumps water mixed with silt into open hoppers. By adjustment of the capacity of the hopper to the rate of flow from the pump, the water can be made to remain in the hopper long enough to deposit most of the silt. Careful design of the pumping machinery is required to assume a continuous mixture of maximum silt with minimum water.

The suction dredge

The first suction dredges generally operated from moored positions in the same way as bucket-ladder dredges, but a less elaborate system of moorings generally sufficed because the levelling of the seabed could be left to occur naturally through the mobility of the material. A marked advance was achieved by the elimination of much of the lifting and laying of moorings through the development of the trailer suction dredge. This craft has the capacity to dredge while on the move and cruises up and down the waterway or other area, sucking up silt as it goes. This operation does not eliminate all interference to navigation because a working trailer suction dredge moves more slowly than a ship under normal steerage way, but the obstruction is markedly less. The dredge's turn at the end of each sweep is usually facilitated by the incorporation of a bow side thrust propeller.

The growing tendency to use dredged material for reclamation purposes and the suitable condition for such purposes of the spoil as delivered by a suction dredge has encouraged its development. The seabeds and river bottoms in their natural state are often largely composed of relatively soft material and can be deepened by the use of suction dredges operating normally. Where rock or other hard material must be handled, conditions are favourable to the use of the suction-cutter dredge, which incorporates at the suction head a powerful rotating screw cutter that fragments the hard material. The increased dredging stresses arising from the use of a cutter require that a craft so equipped should be operated as a stationary dredge with moorings. Because such operations seldom take place in areas already under use by traffic, the obstruction problem is not often critical. Additionally, in modern equipment, the incorporation of heavy spud legs in the craft to anchor in the seabed reduces the number of separately laid moorings required.

A useful ancillary piece of equipment to all the above is the grab dredge, either self-propelled or towed to the site. Grab dredges are especially suitable for dredging close up to existing quay walls or other structures with minimum risk of damage, and the grab equipment is often capable of lifting individual boulders. Not infrequently grab dredges have value for maintenance dredging, particularly in restricted areas and with silt of sufficient mobility to level out the individual holes almost inevitably left. Although the return fall of the grab takes place with the bucket empty and is, to that extent, nonproductive, with skillful operators this element can be reduced to a minimum and, with some large craft operating four grabs simultaneously, considerable outputs can be achieved.

Dredges are characteristically designed to deliver their output either overside into attendant hopper barges or, in the case of self-propelled dredges, into hopper compartments incorporated in their own structure. These compartments are essential in the case of trailing suction dredges, but their value in other cases depends on the circumstances and the method of disposal of the spoil. When a long journey to the depositing area is involved, it is obviously more economical to leave the dredge continuously at work and remove the spoil in separate barges.

When the journey is short and the spoil is to be simply dumped, for which purpose the hoppers are provided with bottoms that fall open, then an economical work cycle between dredging area and spoiling ground, using one craft only, can frequently be established.

A special case is the side-boom dredge, which discharges straight back overside; by making the work coincide with an appropriate state of the tidal current, this arrangement secures the removal of the dredged silt by the tide's operation.

The side-boom dredge

Dredged spoil is less and less often disposed of by dumping out at sea, a practice once almost universal; instead it is used for the reclamation of land from the sea and foreshore. This process has been stimulated by the rise in the value of the land so created and by the dis-

covery that, in many instances, spoil taken out to sea frequently returns. This phenomenon has been investigated, both on hydraulic models and by mixing radioactive tracers with the dumped spoil in small quantities, permitting its subsequent movements to be followed with Geiger counters.

A variety of procedures have been developed for the combined operation of dredging and reclamation. Where the area to be dredged and the area to be reclaimed are in close proximity, as sometimes happens, the whole operation can be carried out by a single suction dredge pumping ashore through a floating pipeline. When, as is more often the case, there is a considerable distance between the two sites, transport in hopper barges is more economical. At the reclamation site, the barges can either be pumped out by a suction reclamation unit, or occasionally can dump their loads on the bottom; from there the material can be pumped ashore by the unit acting as a stationary suction dredge.

The layout of reclamation areas is a matter to which adequate scientific investigation should be devoted, covering such aspects as the adequacy and subsequent maintenance of any navigable waterways it is intended to provide through them, the design of the banks required to contain the pump spoil while the solids settle, and the relative positions of delivery and runoff points to obtain the maximum recovery of solid matter. Such schemes for reclamation, carried out in this way, can simultaneously ensure more valuable new land and improve navigation facilities.

The Delta Plan. It was noted at the beginning of this article that maritime engineering has two large objectives: improvement of transportation and reclamation and conservancy of land. Outstanding among examples of human ingenuity in the second category has been the long effort of the people of The Netherlands to keep their country, large areas of which are below sea level, habitable and productive.

The purpose of these efforts has generally been twofold, first to recover, reclaim, and retain more land for occupation; and second, to prevent the percolation of seawater into the water table of both the recovered and the original ground, which, if not prevented, would seriously reduce or even altogether destroy the value of the land for agricultural purposes. This second purpose has sometimes been described as "pushing back the salt line."

A prime example of the first purpose was the enclosure, by means of a dike some 28 kilometres (17 miles) in length, in 1926–32, of the large inlet formerly known as the Zuiderzee and, after its enclosure, renamed the Ijsselmeer. Considerable areas of this body of water have since been reclaimed by the pumping ashore of dredged sand, and the reclamation of further areas is either in hand or planned for the future. A large proportion of the area will, nevertheless, be maintained as a freshwater lake by the flow of the river Ijssel, which takes off from one of the outfalls of the Rhine, known as the Lek, or Neder Rhine, just south of Arnhem. In the 1960s it was found necessary to place a dam across the Lek just below the takeoff of the Ijssel, to divert an increased quantity of Rhine water down the Ijssel to the Ijsselmeer. The growth of shipping traffic on the canal, which connects Amsterdam with the North Sea, the locking operations of which necessarily discharge quantities of salt water into the Ijsselmeer, would otherwise tend to nullify the effects of the freshwater flow of the Ijssel.

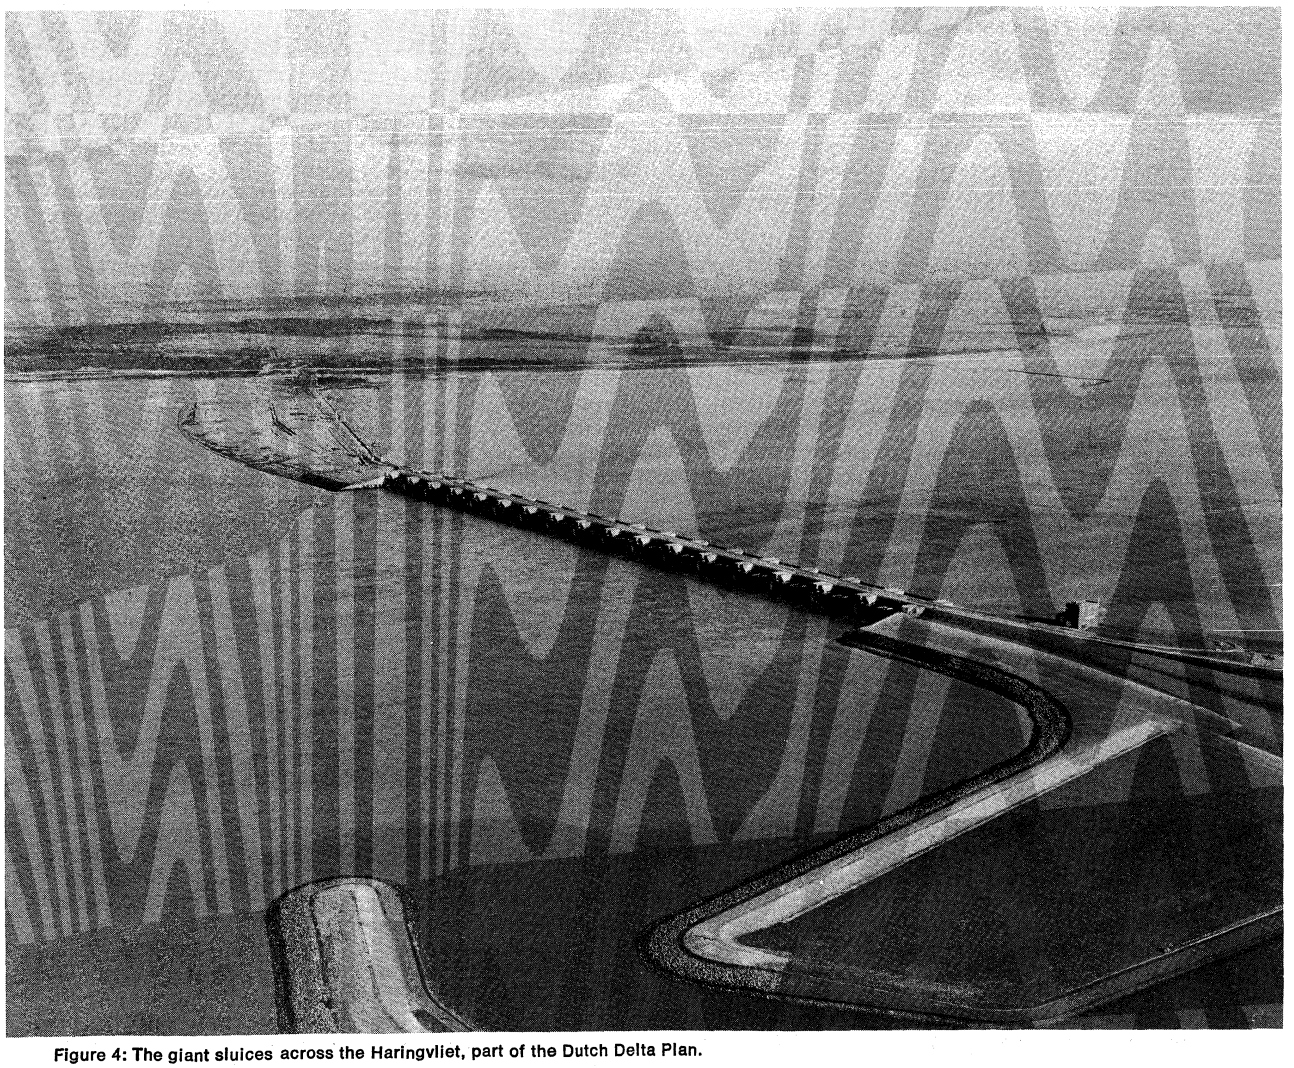

Figure 4: The giant sluices across the Haringvliet, part of the Dutch Delta Plan.

To maintain navigation in the Lek, in spite of the reduction in water flow, two further dams are provided downstream toward Rotterdam, and all three dams are capable of being opened, in the event of excessive floodwater coming down the Rhine.

Desalinization. The second purpose, that of desalinization or "pushing back the salt line," has been at the heart of the Delta Plan, one of the most imaginative civil-engineering projects ever undertaken. The incident that triggered the Delta Plan was the disastrous flooding of February 1, 1953, when the notorious North Sea surge brought tide levels higher than ever previously recorded, overtopping many of the existing dikes and causing untold damage and salt contamination of vast areas of agricultural land. The surge also caused considerable flooding and damage on the other side of the English Channel, along the east and southeast coasts of England. Statistical research suggests that tides of this level are to be expected at a frequency of at least once in 300 years.

The weak point in The Netherlands' defenses against flooding from the sea is the several deep inlets formed at the mouths of the Rhine and Maas rivers, through which the greater part of the water coming down these rivers discharges into the North Sea. Around the shores of these inlets run many miles of dikes, the maintenance of which is a constant burden and the strengthening and heightening of which to prevent a repetition of the disastrous 1953 floods represented a project of considerable magnitude.

It was considered that the most economical result would be obtained by a major operation of shutting out the sea, more or less at the main coastline, by a series of dams across the mouths of the inlets. By this means some 700 kilometres (435 miles) of dikes would be cut off from direct sea attack and reduced to a secondary function, whereas the total of the new dams that might still require a measure of maintenance is only 30 kilometres (19 miles). By conserving and controlling the vital flows from the Rhine and the Maas, the inlets themselves would be gradually transformed into freshwater lakes, thus greatly contributing to "pushing back the salt line."

A secondary effect in this direction will be an increase in the flow of freshwater toward Rotterdam, as a result of the raising of the levels in the estuarial inlets, particularly in the most northerly, the Haringvliet. This result should greatly assist desalinization in the Rotterdam area, where the penetration inland of the salt line had reached alarming proportions, as a result of the improvement in the navigational approaches to the port, effected by the construction of the channel known as the New Waterway from the Hook of Holland.

A further benefit to be gained from the structures of the Delta Plan is the great improvement in communications between the mainland and the hitherto somewhat isolated communities on the islands lying between the inlets; the new dams across the inlets will provide foundations for motor roads.

The Delta Plan construction was scheduled to take nearly a quarter of a century and the total cost represents a significant percentage of The Netherlands' national budget.

Although the authors of the plan stress that it is not properly a land-reclamation scheme (little or no extra land will be created by it), there is no doubt that many of the techniques developed for reclamation work are of the utmost value in carrying out the work, and, conversely, lessons learned in the course of the project will no doubt find useful application in future reclamation work the world over.

Thus, for the construction of the sluices through the dam across the Haringvliet, necessary to provide for escape of river water in times of flood, a working island was created in what was almost open sea, by the continuous depositing of sand on the seabed until the level rose above that of the water (Figure 4). Procedures for the rapid waterproofing of the banks so created have been brought to a high pitch of efficiency. This has been accomplished through the use of nylon carpets or asphalting by special high-speed placing machines. The former take the place of the previously well-tried practice of using fascine mattresses weighted down with stones for which labour on the scale required to cover large areas with sufficient speed is no longer available.

The closure of the final gaps in the dams, a hazardous operation because of the large volume of water rushing through the narrow remaining gap at this stage, is effected at the Delta by the use of concrete caissons floated into the gap and scuttled in position. The technique has progressed there from the use of solid-walled caissons that had the disadvantage of closing the gap suddenly, with consequent hazard, to caissons incorporating their own sluices, thus allowing the flow of water to continue until all were in place and the sluices could be safely closed.

BIBLIOGRAPHY. The Nautical Charts and the Sailing Directions issued by the Hydrographic Office of the U.S. Navy and the Sailing Directions published by the Hydrographic Department of the Admiralty give full descriptions of the harbours of the world. For U.S. harbours, see the "Port Series" and the "Lake Series" published by the Corps of Engineers, U.S. Army, and the charts issued by the U.S. Coast and Geodetic Survey.

The Corps of Engineers, U.S. Army, publishes many manuals and articles concerning particular harbours and problems of harbour design.

The *Proceedings* of the Permanent International Association of Navigation Congresses (PIANC) contain much detailed information on harbours of the world, as well as technical studies on harbour problems.

Books on this subject include: F.M. DU-PLAT TAYLOR, *The Design, Construction and Maintenance of Docks, Wharves and Piers*, 3rd ed. rev. (1949); J.F. BRAHTZ (ed.), *Ocean Engineering: Goals, Environment, Technology* (1968); J. CLAPON, *Travaux maritimes*, 2 vol. (1966–67); C.M. TOWNSEND, *The Hydraulic Principles Governing River and Harbour Construction* (1922); and A.M. MUIR WOOD, *Coastal Hydraulics* (1969).

Hardenberg, Karl von

Karl August, Fürst von Hardenberg, Prussian statesman and administrator, was mainly responsible for preserving the integrity of the Prussian state during the Napoleonic Wars. Domestically he was able to continue the reforms introduced by Karl, Freiherr vom Stein; in foreign affairs he exchanged Prussia's alliance with France for an alliance with Russia in 1813, and in 1814–15 he represented Prussia at the peace negotiations in Paris and Vienna. He vainly fought for the establishment of a constitution but gained lasting fame for his domestic reforms—the liberalization of financial, economic, and agricultural policies—and for his conduct of foreign affairs, which created the political requisites for Prussia's liberation from French rule in 1813–15.

Early years

Hardenberg's father, Christian Ludwig, a member of an

Hardenberg, engraving by an unknown artist, 1820.

aristocratic family with estates in the southern part of the electorate of Hanover in Germany, was a general. Karl August was born on his mother's estate near Brunswick, on May 31, 1750, the oldest of seven children. During the Seven Years' War (1756–63), in which Austria and Prussia fought for supremacy in Germany, his mother lived with the children in the city of Hanover. While her husband was in the field, his oldest brother, a high Hanoverian civil servant, saw to the education of the children. As was the custom, Hardenberg was tutored at home in languages, history, and geography and attended a prestigious private school in Hanover for a year (1762–63). At the end of the war his father took over his ancestral estate, Hardenberg, about 80 miles (130 kilometres) south of Hanover, where Karl August acquired his much-admired skills in shooting, riding, dancing, and music.

To prepare himself for a career in public administration, Hardenberg enrolled at the University of Göttingen in the fall of 1766. In 1768 he spent a year at the University of Leipzig, where he made the acquaintance of a number of valuable and interesting people, among them Goethe, a contemporary and fellow student; F.A. von Heinitz, the head of the Elector of Saxony's mining industry; and Christian Fürchtegott Gellert, professor of philosophy and literature, an outstanding representative of the German-Protestant version of the French Enlightenment. He had brief contacts with Goethe throughout his life. Heinitz, later Prussian minister of mines, was not only a first-rate expert in mining and metallurgy but also a highly cultured and humane man who later helped both Hardenberg and Stein to enter the Prussian civil service. Hardenberg attended lectures on archaeology, history, literature, mathematics, the natural sciences, and economics. He also took lessons in drawing and music, but his main field was law, in which Göttingen provided the best instruction in Germany—often paving the way for an appointment in the imperial civil service or in that of one of the German states.

In 1770 Hardenberg left Göttingen and entered the Hanoverian ministry of justice. In order to advance his career he set out in the summer of 1772—on the advice of King George III of England, who was also elector of Hanover—on a year's travel throughout the whole of Germany, primarily to widen his political horizons. His voluminous diary, packed with information about the lands, institutions, and people he visited, shows his remarkable powers of observation and his capacity for independent judgment. He stayed in about a dozen capitals of ecclesiastical and secular princes in the middle Rhine region and southern Germany, studied the operation of the imperial administration in a few cities, and, after a visit to Vienna, began his homeward journey via Dresden and Berlin. In Nassau he stayed with the parents of Stein, and in Wetzlar he visited Goethe. His travels afforded him an insight into the political realities of Germany before 1789 and at the same time awakened in him a preference for the North German states. In 1773 he went to England to be presented to King George III, who appointed him Hanoverian councillor.

In 1774 Hardenberg married the 15-year-old Countess Juliane von Reventlow, who bore him a son and a daughter. A wealthy girl, she was, like himself, gay and extravagant, but their similarity of dispositions doomed their marriage and they were divorced in 1788. Because his career had come to a standstill and his wife had involved him in a scandal by her liaison with the Prince of Wales, Hardenberg left the Hanoverian service and entered that of the Duke of Brunswick. There, however, he proved to be unsuccessful as head of the department of education; moreover, his personal life became the subject of public gossip, for immediately after his divorce he had married Sophie von Lenthe, who had been divorced from her husband on Hardenberg's account. He therefore gladly accepted the post of Prussian provincial minister in Ansbach-Bayreuth that was offered him in 1790, a post in which he performed splendidly. He had the knack of selecting highly capable experts and attracting talented junior executives; among the former was the naturalist Alexander von Humboldt, who was in charge of the technical improvement of the mines. All in all Hardenberg made a model Prussian province out of the two former margravates.

Entry into the Prussian service

In 1793 Hardenberg described himself as follows:

> Endowed by nature with robust health and talents, a vivacious temperament that often gave free rein to my passions, enough material means to satisfy them but also fortunate to be by nature kind-hearted and humane, imbued from childhood with the desire to become great and good for the sake of mankind, early aware of my father's wealth and the wealth that awaited me, educated in the old-fashioned way to become a man of integrity and of learning—with these attributes I entered upon the great stage of the world.

When, in 1798, he won the abiding trust of King Frederick William III of Prussia, Berlin became this stage for him. He was entrusted with the most important administrative and diplomatic tasks, (*e.g.*, serving as foreign minister from 1804 to 1806). But, his nature being what it was, "enemies, women, and debts" hounded him throughout his life. In Ansbach his second marriage had come to grief when he took his mistress, a singer of bourgeois origin, into his household. She stayed with him for over 20 years, going with him to Berlin and later to his estate in the province of Brandenburg. He married her in 1807, six years after he had been divorced from his second wife; but shortly before his death he also separated from her. In order to rid himself of some of his chronic debts he sold his ancestral estate. But forced by his family to reinvest the money in land in order not to reduce the total family holdings, he bought the estates of Tempelberg near Berlin, which he developed into a handsome private residence with a splendid library. In 1814 gifts of land from the King enabled him to expand the estate into the demesne of Neuhardenberg, and the celebrated architect Karl Friedrich Schinkel rebuilt the residence into one of the most beautiful of the neoclassic manors in the province of Brandenburg.

When Prussia lost the war of 1806–07 against France, Hardenberg, on Napoleon's orders, had to relinquish his premiership after only a few months in office. In 1810, however, when Prussia was faced with insolvency and could hardly maintain payments to France, he was the appointed Premier with far-reaching powers—this time with Napoleon's approval. Faithful to his motto, "democratic principles within a monarchic government," he continued the economic and governmental reforms that Stein had begun. He also granted full citizenship to the Jews. In foreign affairs he skillfully steered Prussia through the difficult years until 1813. Early in 1812 Prussia had had to sign a military alliance with France. After Napoleon's disastrous Russian campaign, Hardenberg preserved the appearance of the alliance while watching for a favourable moment for liberation. He advised the King to break away only when Prussia secured an alliance with Russia, which was finally concluded in 1813.

Appointment as Premier

After Napoleon's fall in 1815, however, Hardenberg's power declined. He became entangled in Prussia's constitutional controversy; his advocacy of a constitution based on his essentially liberal beliefs eventually brought him into opposition to the plans of the King. Politically, Hardenberg's last years were marked by a mood of resignation, but even in old age he remained unusually well-read and maintained a many-sided interest in science and literature. Technical progress was as fascinating to him as the arts, of which he became a well-known patron. He helped artists and architects, took part in the reconstruction of Marienburg Castle near Danzig, and unstintingly provided the funds for restoring the Berlin theatre and opera house. When the first steamboat travelled down the Elbe River, Hardenberg was one of the passengers. On his 70th birthday Goethe honoured him with a poem. He died on November 26, 1822, in Genoa.

As Hardenburg grew older, respect for his ideas increasingly declined in political circles. While patriots and reformers found him too accommodating and conciliatory, in the eyes of advocates of the return to absolutist

Assessment

rule he was too liberal. By 1822 his great diplomatic achievements and notable domestic reforms of 1810–13 had been largely forgotten. Later in the 19th century the great German historian Leopold von Ranke was to emphasize Hardenberg's achievements as a statesman, pointing out that he had preserved the Prussian state when it was on the verge of destruction at Napoleon's hands. Since then Hardenberg has been primarily remembered in that role. While the social progress achieved by his reform legislation has always been acknowledged, it has only been truly appreciated in the 20th century. The unfavourable opinions of some of his important contemporaries, such as Stein and Humboldt, cast a shadow on his personality and diminished his stature when compared to the imposing figure of Stein. Only his more recent biographers have done justice to the unique and valuable aspects of his personality.

BIBLIOGRAPHY. K.A. VON HARDENBERG, *Denkwürdigkeiten des Staatskanzlers*, ed. by L. VON RANKE, 5 vol. (1877), contains an introduction by Ranke in vol. 1 and 4; H. HAUSSHERR, *Hardenberg: Eine politische Biographie*, ed. by K.E. BORN (1963–), vol. 1 of this excellent work is the best presentation of Hardenberg's youth and political career up to 1798; P.G. THIELEN, *Karl August von Hardenberg 1750–1822* (1967), the best complete biography in existence, including an outline of Hardenberg's private life using recently discovered sources; W.M. SIMON, *The Failure of the Prussian Reform Movement, 1807–1819* (1955), an attempt at a critical general assessment, with a somewhat biassed thesis; H. HAUSSHERR and W. BUSSMANN in *Neue Deutsche Biographie*, vol. 7, pp. 658–663 (1966), a brief biography with bibliography.

Hardy, Thomas

Thomas Hardy is the foremost—and perhaps the only important—English regional novelist. His most impressive novels are set in what he called "Wessex" (in fact, southwest England), chiefly in "South Wessex" (his native county of Dorset) and derive much of their strength from Hardy's intimate knowledge of the speech, customs, and way of life of people in that part of England. They are also a conscious attempt to translate some of the themes of Greek tragedy into terms of the English novel. As a poet—and Hardy attached more importance to his poetry than to his novels—he produced several poems of concentrated, intensely realized personal feeling that are perhaps his finest literary achievement, though these comprise a relatively small part of his poetic output.

EB Inc.

Hardy.

Early years. Hardy was born on June 2, 1840, at Upper Bockhampton, Stinsford ("Mellstock" in his stories), in Dorset. He was the son of Thomas Hardy, builder and master mason, and Jemima, born Hann. Both his parents were of long-established Dorset families. The writer was the eldest of four children. Though rather delicate in childhood, by the age of eight he was able to enter the new village school at Bockhampton. After one year he left to enter a Nonconformist school at Dorchester, and when the headmaster opened the Academy, a more ambitious school in the town, Hardy went with him. This master was a talented Latinist and aroused and encouraged in Hardy a love of classical writers that was to have a marked influence on his work. Leaving school in 1856, Hardy became a pupil of an architect and church-restorer named John Hicks, who practiced in Dorchester. At this time and for some years afterward Hardy read widely with a view to taking holy orders.

In 1862 he left Dorchester for London and soon obtained a post with a well-known architect, Arthur Blomfield (later Sir Arthur), as a "Gothic" draftsman, capable of designing and restoring churches and rectories. He remained with Blomfield until 1867, when a deterioration in health compelled him to return to Dorset, where he again worked for Hicks. During his years in London, Hardy had begun seriously to write poetry: some of the poems of this period—for example, "Neutral Tones"—are among his finest and most characteristic work; it is notable that there is no line of development in Hardy's poetry from immaturity to maturity, followed by a falling-off; at any period, his best and inferior work is found mixed, and his style undergoes no significant change.

First novel

During 1867–68 he wrote his first novel, *The Poor Man and the Lady*, which was rejected, though with some favourable comment, by two publishers, chiefly on the grounds that it was too satirical and Socialistic. The novelist George Meredith, who worked as reader to Chapman and Hall, one of the publishers, advised him to attempt a novel with a purely artistic purpose and a more complicated plot—advice that he followed too faithfully in his first published novel, *Desperate Remedies* (1871).

In March 1870, Hardy was asked by a Weymouth architect, for whom he was then working, to go to St. Juliot, near Boscastle, in Cornwall, in connection with the restoration of its church. There he met his future wife, Emma Lavinia Gifford, the rector's sister-in-law; this meeting and its setting were to be re-created over 40 years later in Hardy's most poignant poems, a group known as *Veteris Vestigiae Flammae* ("Vestiges of an Old Flame").

Desperate Remedies had been published anonymously and had met with a mixed reception. In 1872 Hardy returned to London and architectural work, having meanwhile written *Under the Greenwood Tree*, which was published in May of that year. Although slight compared with the later tragic novels, it has much humour and sympathetic observation, both in the rather burlesque account of the Mellstock choir and in a delicately handled courtship. The first of the Wessex novels, it shows already how closely connected these stories are with the rhythms of the rural year.

First popular success

Hardy's next novel, *A Pair of Blue Eyes*, published serially (1872–73) in *Tinsley's Magazine*, owes its setting and certain minor details to St. Juliot and its surroundings. In 1873 he began *Far from the Madding Crowd*, first published serially (1874) and anonymously in Leslie Stephen's *Cornhill Magazine*. It was his first popular success, and he was encouraged by it to devote himself entirely to writing. It is also the first "typical" Hardy novel, for, although it has humour—not only in the treatment of the rustic characters—and what may pass for a happy ending, its scheme and general tone belong more to tragedy than to comedy.

That Hardy was obliged to publish most of his novels in serial form may well account for his somewhat detached attitude toward them; it also explains their strong melodramatic content, almost inevitable if each installment was to conclude forcefully enough to sustain the reader's interest until the next installment appeared one month later. He wrote to Leslie Stephen, during the serial appearance of *Far from the Madding Crowd*, "I may have higher aims some day . . . but, for the present, circumstances lead me to wish merely to be considered a good hand at a serial." Toward the end of his life he said that his only ambition was to have some poem in a good anthology such as Francis Palgrave's *Golden Treasury*.

Hardy married Emma Gifford in August 1874. For the first years of their married life they lived at various addresses in London and Dorset; in 1885, they settled at Max Gate, a house that Hardy had had built on the outskirts of Dorchester, where he lived for the rest of his life.

Writings of maturity. From 1878 to 1895 is the period of Hardy's greatest achievement as a novelist. During this time he published *The Return of the Native*, *The Trumpet-Major*, *The Mayor of Casterbridge*, *The Woodlanders*, *Tess of the D'Urbervilles*, and *Jude the Obscure*. In these books Hardy's stoical pessimism—based on his conception of the "Immanent Will" (to be developed most plainly in his prose-poetry drama *The Dynasts*)—and his sense of the inevitable tragedy of human life are continually apparent.

Sometimes, by his use of disastrous coincidence, Hardy gives the impression of wrenching his material to fit his outlook (for instance, the events leading to the death of Mrs. Yeobright in *The Return of the Native* and the fate of Tess's letter of confession to Angel Clare); and sometimes the tragedy topples over into melodrama (the whole episode of little "Father Time" in *Jude the Obscure*). Yet there is real tragic dignity in the story of Tess, as well as of Henchard in *The Mayor of Casterbridge*. The latter, with the gradual, relentless revelation of Henchard's past, must be more than an unconscious recollection of Sophocles' *Oedipus*, while the function of the villagers or Casterbridge townsfolk in these books is clearly to provide a commentary akin to that of the chorus in Greek tragedy. But Hardy's intimate knowledge of the Wessex countryside and of rural life and speech (somewhat stylized though the latter may be) prevent the novels from being regarded only as attempts to transplant Greek tragedy into the 19th-century English countryside.

Conflict with the conventions of Victorian morality

With *Tess*, Hardy began to come into conflict with the conventions of Victorian morality. Certain scenes had been omitted from the serial publication, and others were altered; the subtitle, "A Pure Woman Faithfully Presented," aroused resentment. That a girl who had an illegitimate baby and who was eventually hanged for the murder of the man she was living with should be treated with compassion and understanding seemed an affront to accepted moral standards. *Jude the Obscure* aroused even greater indignation: here a married man and a married woman left their respective partners, lived together, and had children—and yet the author appeared to have sympathy for them. The Bishop of Wakefield announced that he had thrown the book in the fire, and he certainly got it withdrawn from circulation by one important firm of booksellers. Yet there was little to take exception to in the ethics of these novels: all too clearly in either instance, "the wages of sin is death." Hardy's crime had been to present the sinners as unhappy human beings, rather than as monsters of depravity.

The reception given to *Jude* so disgusted Hardy that he wrote no more novels, henceforth devoting his energies to poetry, which he had always regarded as far more important than his fiction. In 1898 *Wessex Poems*, including a good deal of poetry written earlier, was published; *Poems of the Past and the Present* followed in 1901, and several more volumes appeared during the remainder of his life.

From 1903 to 1908 appeared, in three installments, *The Dynasts*, a huge drama (unperformable and, indeed, not intended for performance) of the Napoleonic Wars, written mostly in blank verse; its lighter scenes are in prose, being chiefly concerned with the attitudes of the Wessex peasantry. Impressive though the endeavour is, the achievement is not altogether successful because of the pedestrian quality of much of the blank verse. It is in *The Dynasts* that Hardy's conception of the Immanent Will, implicit in the tragic novels, is most clearly stated. Put simply, this Will is an indifferent and unconscious force "that neither good nor evil knows" and is the motive power of the universe. The results of its impulses are almost invariably disastrous. In *The Dynasts* there is an implication that it may be growing into self-consciousness: perhaps the most striking expression of this concept is in "The Convergence of the Twain," a poem written on the sinking of the "Titanic" in 1912.

Hardy's conception of the Immanent Will

In 1910 Hardy was awarded the Order of Merit. On November 27, 1912, Mrs. Hardy died. Although the marriage does not seem to have been a very happy one, Hardy's grief was deep and found expression in the summit of his poetic achievement, the *Veteris Vestigiae Flammae* group mentioned above, which includes such moving poems as "The Voice" and "After a Journey."

In 1914 Hardy married his secretary, Florence Emily Dugdale, who survived him and wrote his biography. He continued to write poetry almost up to his death on January 11, 1928. His ashes were placed in Westminster Abbey, and his heart was buried, as he had wished, in the church at Stinsford, near his birthplace.

Hardy remains—owing in some measure to interest stimulated by cinema and television adaptations of his work—one of the most widely read Victorian novelists, and his work has been the occasion of a number of critical essays and monographs. What might have pleased him more is the general recognition of his genius and importance as a poet.

MAJOR WORKS

NOVELS: *Desperate Remedies* (1871); *Under the Greenwood Tree* (1872); *A Pair of Blue Eyes* (1873); *Far from the Madding Crowd* (1874); *The Hand of Ethelberta* (1876); *The Return of the Native* (1878); *The Trumpet-Major* (1880); *A Laodicean* (1881); *Two on a Tower* (1882); *The Mayor of Casterbridge* (1886); *The Woodlanders* (1887); *Tess of the D'Urbervilles* (1891); *Jude the Obscure* (1895, dated 1896); *The Well-Beloved* (1897); *Our Exploits at West Poley* (1952).

SHORT STORIES: *Wessex Tales: Strange, Lively and Commonplace* (1888), contained "The Distracted Young Preacher," "Fellow-Townsmen," "The Three Strangers," "Interlopers at the Knap," and "The Withered Arm," to which in the 1896 edition Hardy added "An Imaginative Woman"; *Life's Little Ironies: A Set of Tales with Some Colloquial Sketches Entitled a Few Crusted Characters* (1894), included "The Fiddler of the Reels," "On the Western Circuit," "To Please His Wife," and "Wessex People"—in 1927 Hardy transferred "An Imaginative Woman" to *Life's Little Ironies*, and added "The Melancholy Hussar of the German Legion" and "A Tradition of Eighteen Hundred and Four" to *Wessex Tales; A Group of Noble Dames* (1891), including "Barbara of the House of Grebe," "The First Countess of Wessex," "The Duchess of Hamptonshire," and "The Honourable Laura"; *A Changed Man, The Waiting Supper, and Other Tales* (1913), containing "The Romantic Adventures of a Milkmaid"; *An Indiscretion in the Life of an Heiress* (1934), a reworking as a long short story of Hardy's lost, unpublished first novel, *The Poor Man and the Lady* (written 1867).

POEMS: *Wessex Poems and Other Verses* (1898); *Poems of the Past and the Present* (1901, dated 1902); *Time's Laughingstocks and Other Verses* (1909); *Satires of Circumstances: Lyrics and Reveries with Miscellaneous Pieces* (1914), later combined with *Moments of Vision, and Miscellaneous Verses* (1917); *Late Lyrics and Earlier* (1922); *Human Shows, Far Phantasies: Songs and Trifles* (1925); *Winter Words in Various Moods and Metres* (1928).

POETIC EPIC DRAMA: *The Dynasts: A Drama of the Napoleonic Wars*, pt. 1–3 (1903–08, the three parts together, 1910).

BIBLIOGRAPHY. FLORENCE HARDY, *The Life of Thomas Hardy, 1840–1928* (1962), previously issued as two volumes, *The Early Life of Thomas Hardy, 1840–1891* and *The Later Years of Thomas Hardy, 1892–1928*, more an editing of Hardy's letters and diaries than a biography, is indispensable for Hardy's life, opinions, and sources of his work; LIONEL P. JOHNSON, *The Art of Thomas Hardy* (1894), one of the first attempts at an appreciation of Hardy's art and definition of his ideas; VIRGINIA WOOLF, "The Novels of Thomas Hardy," in *The Second Common Reader* (1932), a perceptive essay on the power and excitement of the novels; D.H. LAWRENCE, "A Study of Thomas Hardy," in *Selected Literary Criticism*, ed. by ANTHONY BEAL (1961), a brilliant, though highly subjective study of the psychology of Hardy's characters; WILLIAM R. RUTLAND, *Thomas Hardy: A Study of His Writings and Their Background* (1938), valuable for the background and origin of Hardy's beliefs; LORD DAVID CECIL, *Hardy, the Novelist* (1943), attempts to relate Hardy's fiction to Elizabethan drama and 18th-century fiction; DOUGLAS BROWN, *Thomas Hardy*, 2nd ed. (1961), perhaps the best critical account of Hardy; RICHARD L. PURDY, *Thomas Hardy: A Bibliographical Study* (1954), the definitive bibliography.

(F.Ch.)

Harmony

In music, harmony can be broadly defined as the sound of two or more notes heard simultaneously. In practice, this broad definition can also include some instances of notes sounded one after the other. If the consecutively sounded notes call to mind the notes of a familiar chord (a group of notes sounded together), the ear creates its own simultaneity in the same way that the eye perceives movement in a motion picture. In such cases the ear perceives the harmony that would result if the notes had sounded together. In a narrower sense, harmony refers to the extensively developed system of chords and relations between chords that characterizes Western music.

Musical sound may be regarded as being both horizontal and vertical. The horizontal aspects are those that proceed in time such as melody, counterpoint (or the interweaving of simultaneous melodies), and rhythm. The vertical aspect is the sum total of what is happening at any given moment: the result either of notes that sound against each other in counterpoint, or, as in the case of a melody and accompaniment, of the underpinning of chords that the composer gives the principal notes of his melody. In this analogy, harmony is primarily vertical. It also has a horizontal aspect, however, since the composer not only creates a harmonic sound at any given moment but joins these sounds in a succession of harmonies that give the music its distinctive personality.

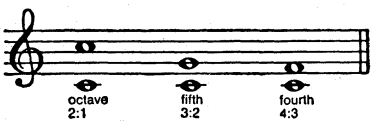
Non-harmonic music

Melody and rhythm can exist without harmony. By far the greatest part of the world's music is nonharmonic. Many highly sophisticated musical styles, such as those of India and China, consist basically of unharmonized melodic lines and their rhythmic organization. In only a few instances of folk and primitive music are simple chords specifically cultivated. Harmony in the Western sense is a fairly recent invention of limited geographic spread. It arose less than a millennium ago in the music of western Europe and is embraced today only in those musical cultures that trace their origins to that area.

This article will discuss the basic concepts of Western harmony, such as consonance and dissonance, the feelings of relative repose or tension sensed in chords; functional harmony, the theories regarding the relationships of specific chords to each other; keys, the sets of interrelated notes and chords used in harmony; modulation, the change of key; and tonality, the organization of notes, chords, and contrasting keys around a centrally important note, the tonic. This discussion will examine the development of Western harmony from its roots in the melodic music of antiquity and the Middle Ages, through the evolution of its classical form in the "common practice period" (the period of traditional Western harmony; *c.* 1650–*c.* 1900) and its disintegration in the 20th century. Finally, the article will discuss the relationship of harmony to chromaticism (use of notes not belonging to the key of a composition), dissonance, melody, and musical form, and the role of harmony in avant-garde music.

HARMONY AND TONALITY

The concept of harmony and harmonic relationships is not an arbitrary creation. It is based on certain relationships among musical tones that the human ear accepts almost reflexively, and that are also expressible through elementary scientific investigation. These relationships were first demonstrated by the Greek philosopher Pythagoras in the sixth century BC. In one of his most famous experiments a stretched string was divided by simple arithemetical ratios (½, ⅔, ¾, . . .) and plucked. By this means he demonstrated that the intervals, or distances between tones, that the string sounded before and after it was divided are the most fundamental intervals the ear perceives. These intervals, which occur in the music of nearly all cultures, either in melody or in harmony, are the octave, the fifth, and the fourth. (An octave, as from C to the C above it, encompasses eight white notes on a piano keyboard, or a comparable mixture of white and black notes. A fifth, as from C to G, encompasses five white notes; a fourth, as from C to F, four white notes.) In Pythagoras's experiment, for example, a string sounding C when cut in half sounds C, or the note an octave above it. In other words, a string divided in the ratio 1:2 yields the octave (C′) of its fundamental note (C). Likewise the ratio 2:3 (or the entire length to two thirds of its length) yields the fifth, and the ratio 3:4, the fourth. These notes—the fundamental and the notes a



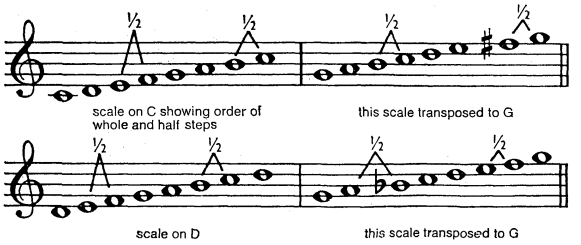
fourth, fifth, and octave above it—form the primary musical intervals, the cornerstones on which Western harmony is built.

The roots of harmony. The organized system of Western harmony as practiced from *c.* 1650 to *c.* 1900 evolved from earlier musical practices: from the polyphony—music in several voices, or parts—of the late Middle Ages and the Renaissance, and ultimately, from the strictly melodic music of the Middle Ages that gave rise to polyphony. The organization of medieval music, in turn, derives from the medieval theorists' fragmented knowledge of ancient Greek music.

Although the music of ancient Greece consisted entirely of melodies sung in unison or, in the case of voices of unequal range, at the octave, the term harmony occurs frequently in the writings on music at the time. Leading theorists such as Aristoxenus (fl. 4th century BC) provide a clear picture of a musical style consisting of a wide choice of "harmonies," and Plato and Aristotle discuss the ethical and moral value of one "harmony" over another.

In Greek music a "harmony" was the succession of tones within an octave—in modern usage, a scale. The Greek system embraced seven "harmonies," or scale-types, distinguished from one another by their particular order of succession of tones and semitones (*i.e.*, whole steps and half steps). These "harmonies" were later erroneously called modes, a broader term involving the characteristic contours of a melody, as well as the scale it used. The distinctions between the Greek scale-types can be approximated on the piano by playing a series of scales beginning on seven successive white keys and using *only* white keys (as from C to C′, from D to D′, etc. It will be seen that the scale on C begins with two whole tones (C–D, D–E) followed by a semitone (E–F), while that on D begins with one whole tone (D–E), a semitone (E–F) and a whole tone (F–G), etc. Because the particular shape of a Greek "harmony" depends on its arrangement of whole and half spaces, any harmony can be transposed; *i.e.*, duplicated at a higher or lower pitch, by using the black keys of the piano to provide the proper sequence of steps. When a melody is built using one of these "har-

Greek scales



monies," or scale patterns, the arrangement of tones and semitones of the scale helps form the distinctive musical character of the melody.

In the Greek view, each of the "harmonies" embodied a distinctive ethos, or moral characteristic. Plato refers to the Lydian and Mixolydian scales (those that the foregoing experiment would produce beginning, respectively, on C and B) as "dirgelike," while the Iastian (beginning on G) is "too relaxed." Both he and Aristotle called for an emphasis on certain scales, those of an uplifting and heroic nature, in the education of young men. A faint echo of this complex ethical view persists in contemporary scale-forms, major and minor, in which the first is often thought of as "happy" and the second "sad."

Medieval modes

Early Christian music demonstrates a similar diversity of scale patterns. As early as 560 AD, the post-Roman musician and monk Flavius Cassiodorus in his treatise "Institutiones musicae" discerned fifteen scale patterns normally used as a basis for the modes, or melody patterns, of medieval music. Cassiodorus also identifies three basic harmonies of notes sounded simultaneously: the fourth (notes in the 4:3 Pythagorean ratio), the fifth (3:2), and the octave (2:1), plus compounds of these intervals (*e.g.*, the octave plus a fifth, a ratio of 3:1). Thus, by the 6th century both scale patterns and the primary musical intervals were recognized.

By the end of the eighth century, the Christian liturgy had been codified, and a large body of chants designated for specific religious occasions had been collected by a succession of monks beginning with Pope Gregory I, whose name the collection of Gregorian chant bears. In this body of chant six principal modes can be discerned using scale patterns beginning, respectively, on the notes D, E, F, G, A, and C. Each mode also had a variant form, yielding a total of 12 modes. Lydian, Mixolydian, and other Greek names were later applied to these modes, although they began on notes different from the Greek "harmonies." The modes consisted of more than mere scale patterns; in addition, one note of the mode was the proper final note for a melody; another was the "reciting note," characteristically acted as a point around which melodies centred. The modal melodies were sung unharmonized and in a rhythmically free manner.

Harmony before the common practice period. By the ninth century the practice arose in many churches of performing portions of chant melodies with an added, harmonizing voice—possibly as a means of greater emphasis, or of reinforcing the sound to carry through the larger churches that were being built at the time. This harmonizing technique, called organum, is the first true example of harmony. The first instances were extremely simple, consisting of adding a voice that exactly paralleled the original melody at the interval of a fourth or fifth (parallel organum). Within a short time the new technique was explored in far greater diversity. Added harmonic lines took on melodic independence, often moving in opposite, or contrary, motion to the given melody. This style was called free organum. In such cases it was impossible to maintain at all times the accepted harmonies of fourth, fifth, and octave. These intervals were considered consonances—*i.e.*, intervals that because of their clear sonority, implied repose or resolution of tension. In free organum they were used at the principal points of articulation: the beginnings and ends of phrases and at key words in the text. In between occurred other intervals that were relatively dissonant; *i.e.*, they implied less repose and more tension. In the following example of free organum, dissonances are marked by asterisks. Free organum is an early example of harmonic motion from repose to tension to repose, basic to Western harmony. The emphasis on consonances at the end of compositions set the final points of arrival in strong relief and reinforced the idea of the cadence, or the finality of the keynote of a mode (on which pieces normally ended).

From the booklet edited by Gerald Abraham accompanying *The History of Music in Sound* (booklet published by Oxford University Press); examples reprinted with permission of the publisher

Until the late 14th century the attitude toward consonance, especially among continental composers, adhered largely to the Pythagorean ideal, which accepted as consonances only intervals expressible in the simplest numerical ratios—fourths, fifths, and octaves. But in England the interval of the third (as from C to E) had been in common use for some time, although it is not expressible as such a simple ratio. A kind of English organum known as gymel, in which the voices move parallel to each other at the interval of a third, existed in the late 12th century; and in the famous *Sumer is icumen in* canon of the 13th century, a remarkably elaborate piece for the time, the harmonic style is almost entirely centred on thirds. The sixth (as from E to C′), an interval closely related to the third, was also common in English music. These two intervals sounded much sweeter than did the hollow-sounding fourths, fifths, and octaves.

Rise of the intervals of the third and the sixth

By the early 15th century, in part because of the visits of the illustrious English composer John Dunstable (*c.* 1385–1453) to the courts of northern France, the third and sixth became accepted in European music as consonant intervals (prior to this time they were considered mildly dissonant). The result was an enrichment of the harmony in musical compositions.

This was a time, too, of a developing awareness of tonality, the concept of developing a composition with a definite keynote used as a point of departure at the beginning and as a point of arrival at the final cadence.

At this time there also began the tendency by composers to think of harmony as a "vertical" phenomenon, to regard the sound of notes heard simultaneously as a definite entity. Although the basic style of composition was primarily linear—*i.e.*, concerned with counterpoint—the chords that emerged from the coincidences of notes in contrapuntal lines took on a personality of their own. One phenomenon that bears out this development is fauxbourdon (French: "false bass"), or, in England, faburden. The following example illustrates English faburden of about 1300. This was a musical style in which three voices move parallel to each other; the middle voice consisted of a succession of notes in parallel organum a fourth below the top voice; the lowest voice paralleled the sequence a third below the middle voice, producing a chord such as G–B–E also known as a $\frac{6}{3}$ or first inversion chord. This was originally an English development adopted in the 15th century by continental composers seeking to enrich their harmonies. It combined the continental fondness for "pure" intervals such as the fourth (here, B–E) with the English taste for parallel thirds (here, G–B) and sixths (here, G–E).

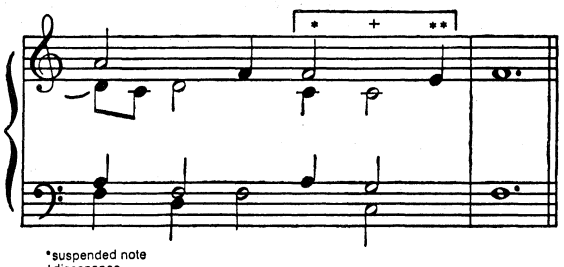
The weakening of the modes

A final phenomenon in early 15th-century harmonic practice clearly foreshadowed the end of the ancient modal system in favour of the major and minor modes of the later common practice period. The old modes were used by composers of the time and persisted to some extent until the end of the 16th century. But their purity became undermined by a growing tendency to introduce additional notes outside the mode. This was achieved either by writing a flat or sharp sign into the manuscript, or by leaving the performer to understand that he was expected to improvise accordingly. The effect of this musical ficta (Latin: "invented music"), as the technique of introducing nonmodal notes was called, was to break down the distinction between modes. A mode, it will be remembered, owes its character to its specific pattern of whole and half steps. Introducing sharps and flats upsets the mode's normal pattern by placing half steps at unusual points. In many cases the resulting change made one mode resemble another. For example, adding an F♯ to the medieval Mixolydian mode (from G to G′ on the white keys of the piano) made that mode's intervals identical with those of the Ionian mode (from C to C′ on the white keys), which in turn is identical with the modern major scale. Likewise, adding a B♭ to the Dorian mode

(from D to D′) made its intervals equivalent to those of the Aeolian (A to A′) mode, which is identical with the modern minor scale. In this way the major and minor modes gradually became predominant over the medieval church modes. The process is especially observable in the music of the late Renaissance.

New uses of dissonance

At the same time there emerged a more sophisticated attitude toward dissonance, favouring its use for expressive purposes. By the time of the Fleming Josquin des Prez (*c.* 1445–1521), the leading composer of the Renaissance, contrapuntal music had assumed a more resonant texture through the use of four-, five-, and six-part writing instead of the older three-part scoring. The increased number of voices led to further enrichment of the harmony. A typical Josquin device using harmony for expressive purposes was the suspension, a type of dissonant harmony that resolved to a consonance. Suspensions arose from the chords occurring in contrapuntal music. In a suspension one note of a chord is sustained while the other voices change to a new chord. In the new chord the sustained, or "suspended," note is dissonant. One or two beats later the suspended voice changes pitch so that it resolves into, or becomes consonant with, the chord of the remaining voices. The following illustration from Jean d'Okeghem's *Missa prolationum* shows a suspension at the cadence. The suspension, which became a standard



musical device, creates tension because the expected harmony is delayed until the suspended voice resolves. Its use as the next to last chord of a cadence, or stopping point, was favoured by composers as a way to enhance, through dissonance resolving to consonance, the sense of completeness of the final chord. The use of suspensions indicates a growing awareness both of chords as entities, rather than coincidences, that have expressive potential, and of the concept that harmony moves through individual chords toward a goal. This concept was developed in the harmony of the common practice period.

At the end of the 16th century there was an upheaval in musical style. Contrapuntal writing was frequently abandoned, and composers sought out a style that placed greater emphasis on an expressive melodic line accompanied, or supported, by harmonies. This style, called monody, brought about no marked changes in the harmonic language (the particular chords used), although such composers as the Italian Claudio Monteverdi (1567–1643) did experiment with a heightened use of dissonance toward expressive ends. The major change at this time was in the conception of harmony. The bass line became the generating force upon which harmonies were built. It was often written out with figures below it to represent the harmonies to be built upon it. From this single line—plus figures, known variously as "figured bass," "basso continuo," or "thorough bass"—the accompanying instrumentalists were expected to improvise, or "realize," a full harmonic underpinning for the melody of the topmost voice or voices. In the example below, from the continuo madrigal *Amarilli* by Giulio Caccini, the second line shows the harmonies supplied by the keyboard player. There was, thus, a polarization between the melodic and bass lines, with everything in the middle regarded as

From W.J. Starr and G.F. Devine, *Music Scores Omnibus*, Part 1 (© 1964); Prentice-Hall, Inc.

harmonic filling-in. This contrasts markedly with the older concept, in which all voices were regarded as of equal importance, with the harmony resulting from the interweaving of all parts.

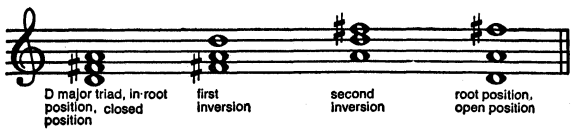
Classical Western harmony: its growth and dissolution. The approach to harmony according to which chords are purposely built up from their bass note marked the beginning of the common practice period of Western harmony. The transition began around 1600 and was nearly complete by 1650. Certain new concepts became important. These had their roots in the harmonic practices of the late Middle Ages and Renaissance and in the medieval modal system. They include the concepts of key, of functional harmony, and of modulation.

A key is a group of related notes belonging to either a major or minor scale, plus the chords formed from those notes, and the hierarchy of relationships among those chords. In a key the tonic, or keynote, such as C in the key of C—and thus the chord built on the keynote—is a focal point toward which all chords and notes in the key gravitate. This is a further development of the idea of a harmonic goal that appeared in the music of the late Renaissance, and that ultimately developed from the medieval idea that modes have characteristic final notes.

In the new system keys further assumed relationships to one another. The larger organizational system embracing keys, key relationships, chord relationships, and harmonic goals was called tonality, or the major-minor system of tonality, because the keys were built on major and minor scales. In the tonal system, given chords assumed specific functions in moving toward or away from harmonic goals, and the system assigning goals to all chords was called functional harmony. The main goal was the keynote, or tonic, of the principal, or tonic, key. Modulation, or change of key, became an important factor in composition because it allowed the composer to exploit the listener's ability to sense the relations between keys.

Rameau's theories of chords

The approach to harmony that emerged about 1650 (the bass-note approach) was soon formalized in one of the most important musical treatises of the common practice period, *Traité de l'harmonie* (1722), by the French composer Jean-Philippe Rameau (1683–1764). The crux of Rameau's theory is the argument that all harmony is based on the "root" or fundamental note of a chord; for example, D. Other notes are placed a third (as D–F or D–F♯) and a fifth (as D–A) above the root. A chord formed in this way is a triad (as D–F–A or D–F♯–A), the basic chord type of the common practice period. The third and fifth above the triad can be placed within the same octave as the root (close position) or can be spread out over several octaves (open position) in compound intervals such as an octave plus a third or two octaves plus a fifth. A triad can exist in its basic, or root position, with the root as the lowest, or bass, note (as D–F♯–A). It can also exist in inversions or rearrangements of its notes placing the third or fifth in the bass, as F♯–A–D (first inversion) and A–D–F♯′ (second inversion). Theorists after Rameau observed that inverted chords are less stable than chords in root position; at the end of a composition, for example, they do not have sufficient finality. Although Rameau's monumental work contains certain elements that later



practices tended to disprove, his writing remains the basis for the study of common-practice harmony.

By Rameau's time no vestige remained of the ancient modal system, which was replaced by 12 major and 12 minor keys beginning on each of the 12 notes of the piano keyboard (C, C♯, D, . . . A♯, B). The invention in the late 17th century of equal temperament (a tuning system) made it possible to play keyboard and other instrumental music in all 24 keys of the chromatic system, the system embracing all possible notes of the 24 scales. (Previous tuning systems made several keys sound out of tune on any one instrument.) Such a work as J.S. Bach's *Well-Tempered Clavier* was, among many things, a set of exercises to acquaint keyboard players with this newfound freedom. Equal temperament also made it possible for a composer to modulate freely from one key to another to obtain contrast in works of an extended nature. Modulation was no new invention, but it now became of prime importance.

In normal, or functional, harmony, the succession of chords is analyzed by the distance, or interval, between their roots. The most common movement from chord to chord is through "strong" intervals: fourths (as C to F), fifths (as C to G), and seconds (as C to D). A movement from one chord to another having this root relation is strong because the two chords have the fewest notes in common and therefore contrast more with each other. Movement by "weak" intervals—thirds (as C to E) and sixths (as C to the A above it)—is weaker, or less pronounced, because the two chords in this case usually share two out of their three notes; for example, C–E–G and E–G–B, or C–E–G and A–C′–E′. Similarly, modulation from one key to another in the course of a piece was most characteristically from one key to another whose keynote is a strong interval apart from that of the first key, as from C to G. Usually the modulation was to the key built on the fifth note, or dominant, of the original scale. A work in C major, for example, tended to move toward the area of G. In works in a minor key, the modulation might be to the dominant minor key (A minor to E minor, for example); or it might be to the relative major key (the key that shares the same scale notes as the minor scale but arranging them in major scale order rather than minor scale order [A minor and C major, for example]). In the second case the contrast of major and minor mode appeared to compensate for the weak modulation (A and C are a third apart).

Harmony and modulation in the 18th century

By the early 18th century these modulatory principles were well established and were made use of in musical form. In the keyboard sonatas of Domenico Scarlatti, for example, or the instrumental dance movements in Bach's partitas, the opening key is well established at the beginning of the piece. There then begins a movement to a new key, normally the dominant key. This is characteristically achieved by an emphasis on chords common to both keys (known as "pivots"), plus a strong musical statement in the new key leading to a cadence in that key. After the modulation there is a process of return to the initial key. During this process the harmonic motion tends to be more rapid, passing quickly through many chords and often including momentary diversions into many new keys, thus lending greater impact to the eventual return to the original key. Such a composition is said to be in "binary form." In binary form compositions in a minor key, there occasionally occurred an exception to the rule of return to the home key. The composer could at his option return to the tonic major, the major key built on the same keynote, or tonic, as the original minor key—A major from A minor, for example. But even in this case the harmonic goal toward the tonic note (A in this case) remained the same.

This basic modulatory scheme from tonic key to dominant key back to tonic key formed the basis of the large-scale musical forms that developed during the 18th century and persisted well into the 19th. The sonata forms of Mozart and Haydn, with their exposition, development, and recapitulation, adhere closely to this plan, often greatly expanded. Here the movement from the tonic to the dominant key or to the relative major key made up the exposition; the rapid harmonic movement en route back to the tonic made up the development; and the return to the tonic key—usually reinforced by a return of the initial thematic (melodic) material—signalled the start of the recapitulation. An optional final coda, or concluding section, further strengthened the sense of the tonal journey's having come to an end. In the large, multi-movement works from this period, there was usually a further contrast achieved by having one of the inner movements in another key, but the final movement almost invariably was once again in the same key as the first movement.

Romantic changes in classical harmony

This clear and logical system of organization seemed highly consistent with an age that took its cues from the clarity and balance of ancient classical architecture. It was not so consistent, however, with the ideals of the ensuing era of Romanticism. Already in the mature works of Beethoven, there is the beginnings of a breaking-down of the classic modulatory scheme; the opening movement of the *Waldstein Sonata*, Opus 53 (completed, 1804) for example, is built on a modulation from the tonic, C major, to the sharply contrasting key of E major, instead of the expected key of G. Much of the individual harmonic language of Franz Schubert (1797–1828) is based on his purposeful disavowal of modulation via the smooth succession of pivot chords, and his fondness, instead, for dropping suddenly into unrelated, and therefore unexpected, keys, as C major to E flat major in the opening movement of the *String Quintet in C Major*, Opus 163 (1828); C major to E minor in the opening movement of the *Symphony No. 9 in C Major* (1828), known as the *Great Symphony*.

Throughout the 19th century there was also a great increase in the use of chromatic tones—tones not belonging to the scale of a given key and that formed "foreign," sometimes dissonant, harmonies with the notes of that key. In addition to the triad, the typical chord of functional harmony, other more complex chords were used, the harmonic functions of which were extremely ambiguous to the listener. As a result the sense of clearly established tonality created by traditional harmonies began to vanish from the musical language—doubtless in line with composers' greater obsession with music and all arts as something mysterious and personalized.

By the time of the German composer Richard Wagner (1813–83), the sense of tonality as the unifying musical force showed definite signs of disintegration. For one thing, Wagner's idea of the "endless melody" led him in his late works to abjure almost completely, except at the end of acts, the full cadence that establishes tonality. A seeming approach to a cadence in *Tristan und Isolde* or the *Ring des Nibelungen* tetralogy is more often than not thwarted by a quick and unprepared switch to a sharply contrasting key and a continuation of the music in that new area. For another, Wagner's passion for complex chords subject to more than one functional interpretation made the tonality of even short passages difficult to assess.

Post-Wagnerian developments

Although Wagner's specific harmonic concepts were not universally accepted, during his time or afterward, the blurring of the tonal sense by one means or another became prevalent throughout Western music by the last decades of the 19th century. Even in the works of the Italian Giuseppe Verdi (1813–1901), whose music was regarded as the opposite pole from Wagnerian techniques, this abandonment of clear tonal outlines may be noted: the sudden changes to unrelated keys, the piling up of dissonances that leave the sense of key obscured for minutes at a time, the emergence in his late works of a continuous melodic style that avoided regular, key defining cadences. In France, the blurring of clear outlines characteristic of Impressionist painters found its musical counterpart in the music of Claude Debussy (1862–

1918), who employed such devices as the scale consisting entirely of whole tones as a means of sidestepping the tonal feeling created by traditional scales. In the music of later French composers, especially the members of the post-World War I group known as "Les Six," a common practice was polytonality, or the sounding of two tonalities simultaneously, each defined with relative clarity, but neither dominating the other. Similar polytonal methods also occur in the works of the Hungarian-born Béla Bartók (1881–1945) and the Russian émigré Igor Stravinsky (1882–1971).

The Wagnerian influence continued most directly, via the music of Gustav Mahler (1860–1911), into the serial techniques developed in the 1920s by Arnold Schoenberg (1874–1951) and his Viennese school. In Schoenberg's serialism the 12 notes of the chromatic scale are arranged into an arbitrary series, or 12-tone row, that becomes the basis for the melodies, counterpoint, and harmonies of the composition. Of these 12 notes no single note is allowed to predominate. This is in complete contrast to the predominance of the tonic, or keynote, in the music of the late Renaissance and the common practice period. Serialism thus completely and systematically obliterated traditional harmonic organization. With no single note serving as a musical goal, tonality—at least as it was known from the 15th century—ceased to be a unifying musical force. Other elements, including serialization of rhythms and tone colours as well as of notes, came to prevail.

Schoenberg's 12-tone row

CHROMATICISM IN HARMONY

Although the preceding paragraphs represent a brief outline of composers' attitudes toward harmony and tonality from the late Middle Ages to the present, there is the danger that the broad outlines may be taken as a rigid statement of standard practices by composers at any period in musical history. Actually, although these outlines remained the general framework in which composers worked, they frequently diverged from it to some extent, particularly in their use of chromatic notes (notes outside the scale of the basic key of the composition) and chromatic chords (chords containing chromatic notes).

The capacity of chromatic tones to add harmonic colour, expressiveness, and interest was apparent to composers from the beginnings of standard harmonic practice. J.S. Bach, for example, in a striking passage at the end of the "Crucifixus" of the *Mass in B Minor*, lent poignance to the verbal description of the burial of Christ by the musical device of a sudden modulation from B minor to a sharply contrasting new key, G major, that contained notes chromatic to the basic key. Mozart, too, derived much of the drive of his harmonic style from a constant use of chromaticism. A characteristic device of Mozart, for example, is his frequent use of secondary dominants to intensify harmonic movement. A secondary dominant is a chord related to the dominant; specifically, it is the dominant of the dominant. If the key is C, the dominant is G and the secondary dominant is D. Secondary dominant chords by their nature contain a note that is chromatic to the basic key. In Mozart's music a harmonic progression from tonic chord (I) to dominant chord (V) will often pass through the dominant of the dominant (V-of-V): from I to V-of-V to V. By using the secondary dominant, he expanded the harmonic range of the composition by introducing chromaticism. In his later works Mozart also came to rely more and more on the dissonant value of suspensions to create harmonic interest. The slow introduction of his *String Quartet in C Major*, K. 465 (the *Dissonant Quartet;* 1785) consists of a string of long-delayed suspensions so that the harmonic definition at any given instant is as blurred as anything in Wagner.

Although the harmonic style of the common practice period remained a basic framework, the history of music from Mozart's time to the present shows a constant increase in harmonic density, or the amount of chromaticism and frequent chord changes present. The opening bars of Beethoven's *Eroica Symphony* demonstrate the power of chromaticism to enhance the emotional effect.

Increased use of chromaticism

The first eight notes of the theme are resolutely normal in their outline, the triad of E flat major, the tonic chord of the movement. But the ensuing two notes lead violently away from this harmonic stability, with the tenth note a totally unrelated C sharp. This completely upsets the harmonic structure and gives unmistakable notice that a long, complex movement will be necessary to right the imbalance. Not until the coda of the movement, 15 minutes later, is this opening theme allowed to follow the expected harmonic outline dictated by the style of the times.

Throughout the 19th century, composers remained rooted in the basic concept of tonality, while at the same time doing everything in their power to complicate or obscure the tonal sense for the listener. Even at the present time, the large, varied, and important group of composers who are called conservative—among them, Samuel Barber (1910–), Aaron Copland (1900–), Sir William Walton (1902–), Dmitri Shostakovitch (1906–), Gian Carlo Menotti (1911–), Benjamin Britten (1913–)—adhere to the concept of tonality only as a challenge. Tonality in their works exists, in the sense that there are extended stable areas that give the impression of being in some definable key. But the intense chromaticism of current-day composition, be it conservative or radical, makes it nearly impossible for the listener to grasp the unity of a work in terms of its adherence to a clear tonal plan. Unity is achieved, rather, by melodic means, the organization of rhythms, or even of tone colour. For all practical purposes, the function of tonality as the prime unifying force in musical structures, known from the 15th through the 19th centuries, is a thing of the past.

THE ROLE OF DISSONANCE IN HARMONY

The very foundation of harmonic music has been the interplay of consonance and dissonance. Consonance can be defined as the normal range of tone combinations accepted by theorists and composers of any given time as implying repose; dissonance, therefore, refers to any sounds outside that range. From the 19th century on, as writers increasingly explored the exact effect of music on the emotions, these two terms took on the aspect of value judgments. There is a tendency to confuse consonance with concord, or sweet sound, dissonance with discord, or clashing sound. This has led to a certain amount of confusion.

Dissonance is in fact the prime element in the harmony that creates movement, and this has been recognized by composers from the dawn of the harmonic millennium. When the human ear recognizes a certain harmony as unstable within the context of a composition, it demands that this instability be rectified by the resolution to a stable harmony. Dissonance, therefore, has never been forbidden in music, for without it music would be hopelessly static. What has been clearly defined in each era has been, rather, the treatment of dissonance, the approach toward it and away from it in a smooth and logical manner so that the musical flow is of a continual tension and relaxation.

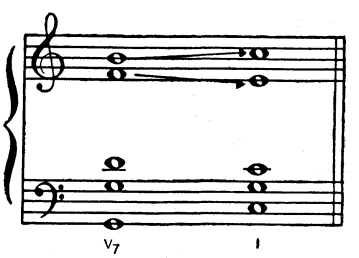
The regulation of dissonance. The notion of which specific chords and intervals constitute consonance and dissonance has altered violently from the beginning of harmony. In the earliest harmonic writing, the parallel organum of the ninth century, the accepted intervals were the perfect consonances, or those of the simplest harmonic ratios: the fourth, the fifth, and the octave. As contrapuntal movement among voices became freer, certain other combinations necessarily occurred: thirds

and sixths and, in some cases, seconds (as C–D) and sevenths (as C–B). These combinations were regarded as dissonances and were to be confined to weak beats of the musical metre; they were to be resolved, for the most part, by stepwise movement downward to the adjacent consonance. Another interval that the musicians of the modal era took great pains to avoid was the augmented fourth (the tritone, or "devil in music"), an interval containing three whole steps, as between F and B—the whole steps F–G, G–A, and A–B. This interval was considered intolerably dissonant. Primarily to avoid the forbidden, unstable harmonic relationship of the tritone, the use of accidentals (sharps, flats, natural signs) entered music and introduced chromatic tones into a mode.

Chords with a pull to cadence

By the time of Rameau, the concept of the dissonance had altered markedly. The basis of the harmony had changed, as noted above, from the perfect intervals (unison, fourth, fifth, octave) to the triad, or chord such as C–E–G, built of thirds above a root, or bass note. The tonic, or keynote, triad became the point of departure and of arrival for an entire composition and also for melodic phrases and larger sections within that composition. The harmonic movement to the cadence, a prime means of establishing points of articulation, became by the mid-18th century a more or less standard progression of harmonies subject to variation according to the composer's own powers of imagination. Preceding the tonic chord in these cadences, and pushing toward it, was the chord built on the dominant, or fifth note of the scale. This convention developed because of the nature of the dominant chord. In a dominant chord, the note a third above the root (as B in the chord G–B–D′—considering the G chord the dominant and the basic key C) is the seventh note of the scale (C, D, E . . . B). This note has a strong leading tendency toward the tonic, or keynote (here, C), because it is only a half step away from the tonic, and is thus called the leading note. Because the leading note is a member of the dominant chord, this chord also has a strong pull toward the tonic chord.

By Rameau's time it was also a common practice to enhance the pull of the dominant chord to the cadence by adding to it the note a seventh above the root of the chord (as F′, in the chord G–B–D′–F′), that note being the fourth note of the scale (C′, D′, E′, F′). Such a chord, a dominant seventh chord (V_7) contains two leading notes: the seventh of the scale, here B, with its strong pull toward the tonic and the fourth of the scale, here F′, which has a strong pull toward another of the notes of the tonic chord (in this case toward E′ in the chord C′–E′–G′), being a half step away from that note. In this way two notes of the dominant seventh chord pulled strongly toward two notes of the tonic chord. Another reason for the strong pull of the seventh chord toward the tonic is that that chord contains a tritone (in this case B′–F′). Although the tritone was less intolerable by that time than it was to medieval ears, it was still considered a particularly strong dissonance that demanded resolution. This resolution occurred when the dominant seventh chord moved to the tonic chord. In the example below a dominant seventh chord (V_7) moves to a tonic chord (I) in the key of C major. Arrows show the resolution of the tritone dissonance. The dominant seventh chord thus became one



of the basic chords in functional harmony. In addition, because it contained two dissonances (a seventh, as G–F′ in the chord G–B–D′–F′, and a tritone, as B–F′ in the same chord), it was the first instance of incorporating dissonance into a system built on the basically consonant triad. Throughout the common practice period dissonances were continually added to the basic harmonic language, so that the range of harmony and use of dissonance in late 19th-century music had expanded considerably beyond that of the early 17th century.

Music using the system of functional harmony has a flow of harmonic movement through contrasting chords and through passages from consonant to dissonant to consonant chords. If the change of chords is frequent in relation to the musical rhythm, there is said to be a rapid harmonic rhythm. Similarly, a leisurely pace of chord change is a slow harmonic rhythm. The slow or fast harmonic rhythm of a composition helps define its musical character, and by varying the harmonic rhythm within a piece a composer can create contrast, thereby defining sections of musical form.

Modulation and dissonance in the common practice period

Modulation, or change of key, was, like dissonance, increasingly explored during the common practice period. In the sonata forms that emerged as the primary musical forms of the mid-18th century, modulation from the tonic to other keys as a means of obtaining contrast became of prime importance. This musical esthetic involved not only the necessity of modulation itself but also drew much of its strength from the varying rate of modulation. Thus, the exposition, or first section, of the "normal" sonata form involves a modulation from the tonic to a nearby related key—usually the dominant, or in works in a minor key, the relative major. The development, or second section, on the other hand, depended on a rapid series of modulations, the purpose being to cast the return to the tonic in as strong a dramatic light as possible by having the stability of the tonic contrast with the instability of rapid modulation that preceded it.

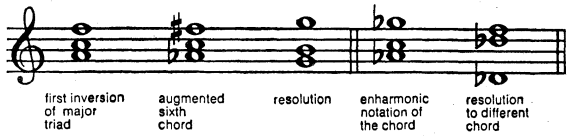
The process of modulation to many keys involved the addition of dissonant, often chromatic, notes to the basic harmonic outline of a composition. A common way of preparing for the appearance of the dominant key area in a sonata exposition was for the composer to overshoot his mark, moving temporarily to the dominant of the dominant, thereby using chromatic chords. Thus, in the transition from tonic key (C major) to dominant key (G major) in the first movement of *Symphony No. 1 in C Major*, Opus 21 (1800) of Beethoven, there is considerable emphasis on the chords of D, both major and minor, establishing D as a dominant leading to a cadence on G, the point of arrival. Much of the dissonance in music of the late classic composers is traceable to this use of secondary dominants. The tendency to move quickly through extended sequences (musical patterns repeated at higher or lower pitch) based on secondary dominant chords became a highly sophisticated technique in the mature works of Haydn and Mozart (as for example, the extraordinary sequence in the slow movement of Haydn's *Symphony No. 104 in D Major*, the *London Symphony*).

Functional harmony was based on chords built from the diatonic (seven-note) major and minor scales; chromatic notes and chords were integrated into the functional system. Although composers of this period proved remarkably adventurous in straying beyond the limits of purely diatonic harmony, their use of dissonance and chromatism was at all times both rational and functional. Chords, even though complex, normally resolved sooner or later into the chords toward which they tended, even when the composer, as in the Haydn passage cited, added unstable elements to the chord of resolution, and therefore occasioned further resolution.

Use of dissonance for harmonic colour. By the early 19th century, composers became aware that harmony could also serve another purpose: it could exist outside of a purely functional context as a means of enhancing the pure harmonic colour of a composition. The opening of the *Quintet in C Major* of Schubert provides a simple and quite early example of chords used for the sheer effect of their sound. The C major triad of the first two bars seems to swell out in the ensuing two bars into a diminished seventh chord, a chord functioning much like a dominant chord in its pull to its tonic, but built instead with a leading note as its root, as, for example, F♯, the leading note of G, on which is built a chord such as F♯–A–C–E♭. (The top and bottom notes of such a chord, here

F♯–E♭, encompass the interval of a diminished seventh, giving the chord its name.) In Schubert's quintet the particular diminished seventh chord used would normally resolve to a chord on G. Instead it simply subsides back to the C major triad of the preceding bars, so that there occurs no real harmonic movement in the opening six bars.

Nineteenth-century harmonic usage, therefore, tended to expand not only the chordal vocabulary itself but also the function of chords. In the former respect there was an increase in the use of chords the particular type of dissonance of which lent them an unstable and a functionally ambiguous quality; for example, a chord that became of prime importance as a means of thickening the harmonic sound and of blurring the exact tonality of a musical passage was the augmented sixth chord. This is an altered chord, or one built by taking a chord normally occurring in its key and chromatically altering it. In this case, two of its notes are changed by a half step. Specifically, an augmented sixth chord is built on the first inversion of a triad, as, for example, A–C′–F′, the first inversion of the triad F–A–C′. Taking the first inversion (A–C′–F′), the A is flatted and the F′ is sharpened, resulting in a chord (A♭–C′–F♯′) that is both dissonant and ambiguous in harmonic function. The ambiguity of sound is partly due to the nature of enharmonic chords, chords that sound identical but in musical notation use different notes (as G♭, identical in sound with F♯). Thus the chord A♭–C′–F♯′ may move smoothly to a chord built on G, but the identical sounding chord A♭–C′–G♭′ will progress to a vastly different chord, on D♭. Composers can thus



use such ambiguous chords to achieve unusual or expressive harmonies that blur the listener's expectations and therefore his ability to perceive key and tonality.

Dissonance and emotion in Wagner's music

The opening of Wagner's musical drama *Tristan und Isolde*, famous for its ambiguous sense of tonality, is an augmented sixth chord that resolves by way of a second dissonance to the dominant seventh chord of the key of A. This sequence is repeated at a higher pitch, here resolving to the dominant seventh chord of the key of C.

Although this passage can be explained in terms of normal harmonic analysis, it was in itself strikingly abnormal for its time. The passage occurs at the beginning of the composition, the point where a composer normally would be expected to establish his basic tonality. In addition, there is considerable doubt as to the exact nature of the resolution. The dominant seventh chord (here the chord of resolution) is itself dissonant, although less so than the augmented sixth chord. The tonality of the passage is obscured, for it is impossible to tell whether the passage is in A minor or A major. Since the notes of the scale that would give this information to the listener are missing from the passage, it is clear that Wagner does not want the listener to be sure. He wants the passage, rather, to stand for the substance of the opera itself: unrequited passion is equal to unresolved harmonies.

Other composers, too, sought out harmonic as well as melodic and rhythmic means to underscore the content of passion, restlessness, mystery, or tragedy in their scores. The unstable, ambiguous chord of the diminished seventh accompanies the appearances of the evil Samiel and his seven supernatural bullets in the opera *Der Freischütz* (*The Freeshooter*) by Carl Maria von Weber (1786–1826). Long strings of this chord, moving rapidly up and down the scale for purely colouristic purposes, also appear in climactic passages of the tone poem *Les Préludes*, by Franz Liszt (1811–86), expressing the struggle of the soul against supernatural forces. The highly embroidered piano style of Frédéric Chopin (1810–49) touched, in passing, on showers of dissonant, often chromatic tones—again used not for any exploitation of their functional value but as a spray of colour used as an overlay for a basically diatonic (nonchromatic) style, well-hidden underneath and recognizable only at the cadence.

Until the genuinely revolutionary *Tristan und Isolde* of 1865, the increase in the amount of chromaticism in the musical language of the Romantic composers was largely an enhancement of expressive detail. The diatonic (nonchromatic) basis of 18th-century functional harmony was in the main respected, as was the orderly process of modulation as a means for giving structure to large musical forms. With *Tristan* and even more markedly with Wagner's music drama *Parsifal*, one can discern the beginnings of a gradual but unmistakable dissolution of the diatonic system on which traditional harmony was based. The analysis of *Tristan*'s harmony by Rameau's principles, although possible, is simply unimportant. What matters more is the constant flow of chromaticism, of Wagner's wide variety of means—altered chords, chains of secondary dominants, and resolutions to chords that themselves prove unstable—for blurring any sense of functional harmony. Doubtless impelled by the dramatic substance of this music drama, he succeeded in evading the cadence, or coming to rest, that traditionally defined harmonic direction.

The impact of this step became apparent in the directions taken by harmony by the end of the 19th century. After Wagner, dissonance, particularly dissonance caused by chromaticism, largely ceased to function as it had in traditional harmony, and composers created their own individual, often experimental, usage of dissonance. No composer, whether he accepted *Tristan* as a masterpiece or dismissed it as madness, was left untouched by its implications.

Dissonance after Wagner. In France, where musical culture stood in some ways the direct antithesis to Wagnerism, Claude Debussy evolved his own style that succeeded, as Wagner's had, in beclouding the harmonic basis of a work either altogether or for extended periods.

Debussy's sources

Debussy was influenced by a number of sources: the Impressionist painters, who were involved with the renunciation of clear perspectives and outlines in favour of the play of light across surfaces and the effect of images only half seen; exotic music, particularly that of Indonesia; and folk music, especially the modal scales of Russia. All of these led him to a partial abandonment of functional tonality. Among the devices he used toward this end is a scale composed entirely of whole tones (as C–D–E–F♯–G♯–A♯–C′). Such a scale lacks the distribution of whole and half steps that define the character of the major and minor scales of the common practice period. Chords built from the whole tone scale are by normal harmonic analysis unstable: all possible triads are augmented (the top note is altered by being sharpened; for example, C–E–G♯ instead of C–E–G) and as a result are dissonant. The perfect fourth and fifth, the ancient cornerstones of harmony, do not exist. Because the chords to which dissonances traditionally resolve are impossible with this scale,

a work built upon it—*e.g.*, "Voiles" ("Sails"), from the first book of preludes for piano—can be said to exist without harmonic resolution and, therefore, without traditional tonality. Other Debussian devices include the regarding of the seventh chord (*e.g.*, dominant seventh, diminished seventh) as a self-sufficient harmony instead of as a dissonance that must resolve; sequences of sevenths moving parallel to each other giving the effect, in his music, of lines of harmony plus a dissonant descant (a countermelody in the highest part, or voice) blurring any real sense of traditional harmonic movement. This use of self-sufficient seventh chords was also much exploited by Maurice Ravel (1875–1937) and came, through his great appeal, into a great deal of the popular music of western Europe and America from the 1920s to the present time.

Again, as with Wagner, Debussy's methods cast their shadow over composers both influenced by and hostile to his musical style. Igor Stravinsky, who was a little of both, first mirrored some of Debussy's harmonic usage in *Le Sacre du printemps* (*The Rite of Spring;* 1913). In *Le Sacre*, chords appear, as they often do in Debussy, purely for their colouristic value, related to each other only by virtue of the rhythmic insistence in the music's patterns. Much of Stravinsky's harmonic style, however, is actually derived from much simpler elements than Debussy's. His complex chord structures often break apart to reveal two unrelated and dissonant diatonic chords sounded simultaneously. In the works of his Neoclassical period, Stravinsky reverts to a clear harmonic language reminiscent, at least as regards individual chords, of the 18th century; but in harmonic movement from chord to chord there is a noticeable difference from earlier styles. Stravinsky, even in this clear compositional style that occupied him in the 1920s and into the 1930s, tends to use these classical harmonies in isolation, for the chords move freely one to the other without their classical function.

Polytonality of "Les Six"

Similar in a sense to Stravinsky's pandiatonicism, or use of diatonic chords without the limitations of classical harmonic function, is the tendency toward polytonality in the works of the post-World War I group of French composers known as "Les Six." These composers, notably Darius Milhaud (1892–), worked for a time with simple, diatonic chords piled upon each other in a way that suggested a clash between simultaneous tonal areas, almost a kind of counterpoint of tonalities—again leading to the dissolution of any sense of a single, central key area. Some traces of polytonality also occur in the early works of Bartók, who was much taken with French influences early in his career. But Bartók did not pursue this device to any great extent later on. He turned instead to an exploration of the folk styles of eastern Europe—Hungarian and Rumanian, predominantly. His music, though harmonically dense and complex, remained rooted in tonality, with an admixture of harmonies gleaned from the modal scales of folk music.

Certain other composers, similarly obsessed with the desire to expand the harmonic vocabulary but loath to abandon the tonal system entirely, experimented with some success with synthetic scales of their own devising, and with chords built of intervals other than the third. The Russian mystic Aleksandr Scriabin (1872–1915) and the German Paul Hindemith (1895–1963) both worked extensively with chords built out of fourths (as C–F–B♭). Scriabin employed these sounds primarily in a quasi-Impressionist way, using their unusual sounds as sonorous self-sufficient units. His "mystic" chord, shown below, formed the entire basis for many of his later works. Hindemith, whose orientation was toward the Neoclassical, dealt with these chords by devising his own system of harmonic function, creating a quite successful reincarnation of the dissonance-consonance tensions of earlier composers.

The direct impact of Wagner's methods, however, was felt within the German-Austrian orbit. The restless, nonresolved chromaticism of *Tristan* was directly reflected in the late works of Gustav Mahler. In such a work as the long, slow movement that ends Mahler's *Ninth Symphony*, one feels the *Tristan* influence quite directly: the long, lyric lines move freely through a systematic evasion of cadences and through a widening range of tonalities, often reaching tonal regions far removed from the starting point. Yet Mahler, too, remained a tonal composer. So did Richard Strauss, whose overlays of dissonance in such works as *Elektra* are easily separable from a basically tonal harmonic movement.

Schoenberg's relation to Wagner

And so, in his early years, did the Viennese Arnold Schoenberg. Such scores as the string sextet *Verklärte Nacht* (*Transfigured Night;* 1899), the *Chamber Symphony in E Major*, Opus 9 (1906), and the first two string quartets are direct outgrowths of *Tristan*'s chromaticism, masking but not obliterating the tonal basis. But by 1912 Schoenberg began actively to question the importance of tonality as a musical inevitability and to accept the broader implications of Wagner's style. From then on the pileup of dissonance in Schoenberg's music became so pronounced as to make the concept of dissonance itself meaningless. In such a seminal work as the chamber cantata *Pierrot Lunaire* (1912), tonality has been put aside. And since this is so, it is no longer possible to discuss consonance and dissonance, for these concepts relate to the structure of a composition according to the harmonic principles of tonality.

Schoenberg's far-reaching musical philosophies, which were epitomized in his invention of the technique of serialism, have had a potent impact on the music of the decades following his own writing. They have also been resisted by large numbers of composers who are conveniently, if not always accurately, described as conservative. It seems likely that the conflict between tonality and atonality (*i.e.*, nontonality) will provide the dynamic dualism for musical styles in the foreseeable future.

HARMONY AND MELODY

As noted above, melody and harmony were synonymous in classical Greek theory; the term harmony referred, not to notes sounded simultaneously, but to the succession of notes, or the scale, out of which melody was formed. During classical antiquity and the European Middle Ages melodies were written that had an inner logic in terms of their scale, or mode, its important notes, and the melodic patterns associated with it. This is also true of many non-Western melodies. After the gradual evolution in Europe, through the polyphony of the late middle ages and the Renaissance, of the common practice, or classical, system of Western harmony, the inner logic of melodies was strongly affected by harmony. Because the ear can perceive harmonic patterns in certain groups of notes, even when sounded successively rather than simultaneously, melodies began to carry a strong implication of underlying harmonies. During this period there arose the conception that melody was the surface of harmony. Thus, for example, the partitas for unaccompanied violin by J.S. Bach, despite their melodic basis and lack of outright harmonic underpinning, clearly set forth their basic tonality and harmonic direction. This is achieved by a melodic style that includes frequent scale passages and arpeggiated chords (chord notes played successively, in melodic fashion, rather than simultaneously, as in a chord) that make clear to the listener the scales, harmonies, and keys belonging to the tonality of the composition. Through the 18th century and well into the 19th, melodies tended to be the bearers of their own harmonic implications. The above noted opening of Beethoven's *Eroica Symphony* represents this practice at both its height and at the beginnings of its dissolution. The opening eight notes outline an unmistakable E flat triad, and

Melody as the harmonic surface

would do so even if they were sounded unharmonized; the ensuing plunge to the unexpected C sharp likewise indicates by its mere melodic shape the harmonic unrest arising at this juncture.

Nevertheless, melody in the hands of a composer seeking a genuine expressiveness must function with some degree of independence from its harmonic underpinning. The long, expressive dissonances in the vocal lines of Romantic composers not only heighten the passion sought after in the music they also specifically represent a seeking for a heightened independence of melody from harmony.

The shift of harmonic usage in the 20th century can be viewed partly as a marked change in relationships between melody and harmony. In Schoenberg's techniques, the generating force is the 12-tone row, which is primarily a melodic sequence out of which harmonies, as well as themes, are generated. Thus, it is possible to detect a reversal of the traditional relationship, whereby harmony has become the surface—or at least the final result—of melody.

HARMONY IN MUSICAL FORM

The chief problem of composition, in any style from ancient times to the present, is the creation of a form, or structure in which the principles of unity and contrast operate in some kind of equilibrium. The listener himself enters into this process by the use of his powers of recognition and of memory.

In purely melodic, modal music the form often derives from the inner logic of the melody in terms of the important notes and melodic patterns of the mode. In polyphonic music before the common practice period musical form depended partly on the unity achieved by setting a piece in a given mode, partly on the use of musical themes, and partly on creating harmonic movement and tension toward stopping points, or cadences. During the common practice period—from Bach to Debussy—much of the creation of musical form took place through the organization of harmonies into keys and relationships between keys. Thus, the sonata forms of the 18th and early 19th centuries depended as much on the statement of a key, the movement to other key areas and the eventual return to the same key, as they did on themes and other melodic devices. The composer was likely, of course, to employ the two principles of melody and harmony simultaneously; return to the tonic key late in the course of a movement was usually reinforced by a restatement of the initial themes. In certain works of Haydn and Mozart, the listener was often thrown off course purposely by the premature return of initial themes in an unexpected key; such devices served further to enhance the drama of the genuine recapitulation or return to the main key.

By the 19th century, however, the power of harmony to suggest clear formal structures was greatly undermined by freer use of dissonance, which broke down the clarity with which a key was defined. Other customary procedures were also abandoned. Many of Schumann's songs do not return to the tonic, or home key, for the final cadence. The extended length of Wagner's music dramas, and their wide-ranging modulation, make it impossible to regard key as a unifying force. Mahler's *Ninth Symphony*, the first movement of which is in D major, ends with a movement in D flat major, and since the symphony lasts nearly 90 minutes, there seemed to Mahler to be no reason to pay any closer lip service to classical practices of unity of key. Such necessities, by the time of this symphony, had vanished from the musical language.

AVANT-GARDE CONCEPTIONS OF HARMONY

The course of harmony after Wagner followed three distinct paths. (1) Within the broad outlines of tonality, composers explored the potential of chords of far greater complexity than the traditional triad. In doing so they often allowed unstable chords such as dominant sevenths to stand as self-sufficient entities, and they greatly increased the use of ambiguous chords such as augmented sixths and diminished sevenths to thicken or occasionally to blur the sense of a stable tonality. (2) Composers broke away from the classical system of tonality by using chords that, although clearly recognizable as derived from earlier harmonic practices, resolved in other than the expected direction. Some also went further afield by substituting for the major and minor scales unusual scales such as whole tone and Gypsy folk music scales; by using chords built out of fourths; and by utilizing polytonality. (3) Composers systematically abandoned tonality through Schoenberg's technique of granting equal importance to all twelve chromatic tones, rather than allowing one tone to predominate as tonic. When this was done, the concept of a single, predominant key centre vanished entirely in favour of atonality. In such cases, the traditional duality of consonance and dissonance also disappeared.

New ways of creating harmony

Among most "progressive" composers of the 20th century, atonality has been extensively explored. By far the greatest concern among avant-garde composers has been to revive contrapuntal writing, or composition stressing the combination of independent melodic lines. This was partly a reaction against the lush harmonies and lyricism of the Romantic period. During the common practice period any counterpoint that occurred was subordinated to the principles of traditional harmony. The 20th-century obsession with counterpoint tended to sweep aside concern with harmonic relationships beyond the incidental fact that clusters of notes in counterpoint are indeed heard simultaneously. In the music of the American Charles Ives (1874–1954), for example, many skeins of fully developed atonal, contrapuntal writing pass by simultaneously, producing momentary sonorities. Such sonorities may occasionally, and quite accidentally, be identical with recognizable harmonies; but these accidental sonorities have little to do with traditional harmonic organization. Similarly, the "tone-cluster" writing of another elder American innovator, Henry Cowell (1887–1965), whereby a pianist's forearm sounds every note it can depress at once, can hardly be analyzed as functional harmony in any sense.

Other developments, too, point to the dissolution of traditional attitudes toward harmony. The aleatoric, or indeterminacy, experiments of John Cage (1912–), Earle Brown (1926–), and others, assign part of the composer's melodic, harmonic, and rhythmic events to a specific performer at a specific instance. In such music any discussion of harmonic direction is irrelevant. Most importantly, the rise of electronic music, which breaks away from any traditional scales such as might be produced on "normal" instruments, can only with the greatest stretch of the imagination lend itself to considerations of harmony.

Yet, there is a possible analogy with traditional harmony in electronic music, as its musical styles and languages tend to take shape. In the works of Karlheinz Stockhausen (1928–), one of the electronic pioneers and a composer of enormous influence among his younger colleagues, there are organizational systems emerging that point to a clear control and regulation of musical elements. The strict control of musical factors such as densities of sonority, rates of rhythmic change and of change in phrase structure, rates of change in the spread of sound in an auditorium through the use of carefully positioned and modulated loudspeakers point toward a new musical system that may possibly be analyzed in terms of a new, fundamentally different harmony.

Search for a new order

The dissolution of harmony in the "progressive" music of the 20th century was not a matter of anarchy replacing order. Actually, the common practice period is of relatively short duration against the entire history of harmony. Before Bach other rules existed. Such rules, in contrast to the later system of traditional harmony, depended not on the contrast of keys but on harmonic unity brought about by the use of a given mode. Since Debussy, similarly, harmonic styles have been dictated by new rules, or by the desire of many composers to seek out new rules. And as both the modal and the common practice systems of harmony evolved only after centuries, so is it also safe to predict that the seeming anarchy of much

of today's music represents a state of movement toward new harmonic precepts. The question at hand, moreover, is not one of the dissolution of harmony itself, for any notes sounded simultaneously produce a harmony—whether the notes be from traditional scales or from the infinity of musical pitches produceable through electronic means. The matter is, rather, the question of the uses to which these harmonies are put, and the changing relations of harmony to musical structure.

An awareness of the value of harmony as pure, expressive sound persists among all composers of the present time. Some have pursued the atonal principles toward the point where harmonic sounds are totally dissonant (which is the same as saying that they are all consonant, because the contrast between consonance and dissonance disappears). Others have written works that consist of almost nothing but static, unadorned harmony—not necessarily harmoniousness. Such a work as Terry Riley's *In C*, for example, consists basically of a sustained triad on C (lasting, at the performer's option, anywhere from 30 minutes to several hours), over which fleeting dissonances are occasionally sounded, seldom more revolutionary than an F sharp or B flat. Here again, although one is more conscious of harmony in this work than of any other musical element, the harmony itself does not move or progress in the traditional sense; the sound exists, but not its function. Here one can discuss the work as pure consonance—which is the same, for lack of harmonic contrast, as pure dissonance.

Thus, in the 20th century the concepts basic to traditional harmony began to lose their importance. In counterpoint harmonies became the incidental result of the combination of melodic lines. New experiments with unusual harmonies, such as tone clusters, functionless in the traditional sense, the lessening of the tension between consonance and dissonance, the creation of unprecedented harmonies by the use of computers, have been the result of a search for new methods of musical organization. This in turn was the natural outgrowth of the blurring and final dissolution of the harmonic system that had prevailed for over two centuries in Western music.

BIBLIOGRAPHY

General historical sources: D.J. GROUT, *A History of Western Music* (1964), is an important outline of stylistic development from ancient music to the present. Other specialized histories of specific periods include CURT SACHS, *The Rise of Music in the Ancient World, East and West* (1943); GUSTAVE REESE, *Music in the Middle Ages* (1940), *Music in the Renaissance* (1959); M.F. BUKOFZER, *Music in the Baroque Era: From Monteverdi to Bach* (1947); R.G. PAULY, *Music in the Classic Period* (1965); and ERIC SALZMAN, *Twentieth-Century Music: An Introduction* (1967). W.S. NEWMAN, *A History of the Sonata Idea*, 3 vol. (1965–69), is a comprehensive survey of large-scale musical form from the Baroque through Mahler. Selections from the actual writings of musical theorists and aestheticians from Plato through Wagner may be found in W.O. STRUNK (ed.), *Source Readings in Music History* (1950), an invaluable work.

Textbooks and theoretical works: Two works by 20th-century composers that give considerable insight into the role of all musical elements in composition are PAUL HINDEMITH, *Unterweisung im Tonsatz* (1937–39; Eng. trans., *The Craft of Musical Composition*, 2 bks., 1941–42); and ARNOLD SCHOENBERG, *Harmonielehre*, 3rd ed. (1922; abridged Eng. translation, *Theory of Harmony*, 1948). Schoenberg's formulation of his 12-tone theories may be found in his *Style and Idea* (1950). Other theoretical works that trace the fluid state of harmony since the later 19th century are ELLIOTT ZUCKERMAN, *The First Hundred Years of Wagner's "Tristan"* (1964); HENRY COWELL, *New Musical Resources* (1930, reprinted 1968); and GEORGE PERLE, *Serial Composition and Atonality*, 2nd. ed. (1968). Standard textbooks based on the theories of Rameau are WALTER PISTON, *Harmony*, 3rd ed. (1962); and ROGER SESSIONS, *Harmonic Practice* (1951).

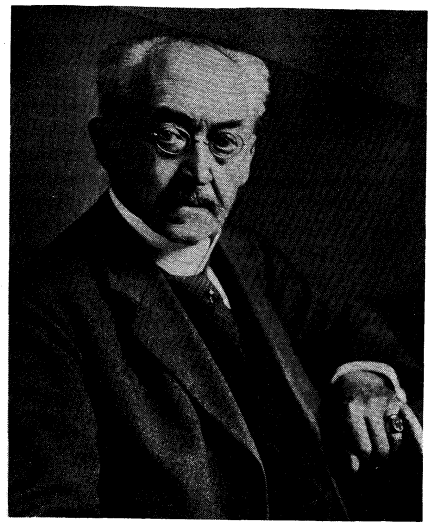
Harnack, Adolf von

Adolf von Harnack, the leading historian of the Christian Church in the late 19th and early 20th centuries, exerted a profound and long-recognized influence in modern theological and historical scholarship and in scientific endeavours.



Harnack, photographed during the 1920s.
The Bettmann Archive

Early life and career

Harnack was born on May 7, 1851, in Dorpat, Livonia (Estonia), where his ancestors had moved from Germany. His father, Theodosius Harnack (1817–89), was a professor of practical and systematic theology, first in Dorpat, then for 13 years in Erlangen, Germany, and again, until his death, in Dorpat. His chief work, dealing with the theology of Luther, is still widely read.

Adolf von Harnack was educated at the universities of Erlangen, Dorpat, and Leipzig. After obtaining the doctorate with a dissertation on a text of an early Christian heresy (Gnosticism), he became a lecturer at the University of Leipzig in 1874. Two years later, he was promoted to a professorship in church history. In 1879 he moved to Giessen and in 1886 to Marburg. From there he was called in 1888 to a professorship at the University of Berlin. Because of his liberal theological views, especially with respect to the validity of the historical Christian creeds, his appointment to the post at Berlin was opposed by the supreme council of the Evangelical Church of Prussia, but the opposition was overruled by Chancellor Otto von Bismarck and, on his advice, by the emperor William II; the latter had become emperor in 1888, the year of Harnack's appointment at Berlin.

Throughout his life, though maintaining academic appointments in theology and church history, Harnack was denied ecclesiastical posts. Nevertheless, he exercised broad influence in Protestant churches, because, through his masterful teaching and his solid learning, he won an enthusiastic following among his students, many of whom rose to positions of ecclesiastical leadership.

He also was highly effective as a historian, not only because he completely mastered the primary sources but also because he regarded himself as called upon to assume the royal function of a judge. "We study history," he said,

> in order to intervene in the course of history, and it is our right and duty that we do this, for if we lack historical insight we either permit ourselves to be mere objects placed in the historical process or we shall tend to lead people down the wrong way. To intervene in history—this means that we must reject the past when it reaches into the present only in order to block us. It means also that we must do the right thing in the present, that is, anticipate the future and be prepared for it in a circumspect manner.

Major works

In his voluminous writings, he brought to a culmination the interpretation of the Christian religion as a historical "development" as it had been taught by the earlier German biblical and historical theologians Johann Salomo Semler, Ferdinand Christian Baur, and Albrecht Ritschl. His purpose was to replace theological dogmatism by historical understanding. His chief works were *The History of Dogma* (3 vol., 1886–89; 4th ed. 1909); *The Mission and Expansion of Christianity in the First Three Centuries* (2 vol., 1902; 4th ed. 1924); *The History of Ancient Christian Literature* (3 vol.,

1893–1904). He was the chief editor of a critical edition of *The Greek-Christian Authors of the First Three Centuries* (1891–). In addition to these writings he published numerous monographs on the New Testament and on the doctrines and institutions of the ancient church. It was a signal honour that, though a theologian, he was asked to write *The History of the Prussian Academy of Sciences* in connection with the celebration of its 200th anniversary (3 vol.; 1900). Harnack revealed himself in this work as a comprehensive historian of modern learning. Indeed, he was a master of many fields of knowledge. Throughout his life, he concerned himself with the life and thought of the German Romantic poet Johann Wolfgang von Goethe (1749–1832) and devoted to him several profound studies.

His most popular book, *Das Wesen des Christentums* (1900; Eng. trans., *What Is Christianity?*, 1901, 15th ed. 1950), is a transcript of a student's stenographic record of a course of lectures, which were delivered in the University of Berlin.

In all these works it was Harnack's purpose to show how it happened that the gospel of Jesus, which in his view has nothing in common with authoritarian ecclesiastical statutes and doctrines, became embodied in the doctrines of the church. He also wanted to offer support for his conviction that if the gospel is to retain power in the modern world, it must be freed from its connection with the dogmas of God and Christ with which it became identified necessarily to survive in the Hellenistic world.

Holding three important positions at the height of his career, each one of which normally would have demanded a man's whole effort, Harnack had a profound impact on historical theological scholarship and was a major influence in the natural sciences. A professor of church history at the University of Berlin, he made important and creative contributions to historical and theological scholarship, in recognition of which he became a member of the Academy of Sciences in Berlin. In addition, he was the general director of the Prussian State Library and, after 1911, president of the Kaiser-Wilhelm-Gesellschaft (now called Max-Planck-Gesellschaft zur Förderung der Wissenschaften). Harnack secured the support of government and industry for this foundation and established research institutes in the natural and medical sciences.

Death and assessment

Harnack never left his position at the University of Berlin until he retired in 1921, at which time he was granted the title professor emeritus. He died on June 10, 1930. At the memorial service held in Berlin after his death (1930), the rector of the university characterized him as follows:

> He was of a noble aristocratic character; his outward distinction was softened by a generous, considerate, and kind disposition. In conversation, he never let one feel his superiority; on the contrary, he enhanced the self-confidence of the one who was speaking with him by rearranging in a most agreeable way whatever was said to him and putting it in such a form that the other took great delight in the thought he had expressed.

Harness and Saddlery

Harness and saddlery is the equipment for any animal used for packing, traction, or riding. "Harness" is the general term for the gear used for traction. "Saddlery" applies to articles traditionally produced by a saddler; *i.e.*, a person who makes, repairs, or sells riding saddles and related equipment, such as bridles, bits, and stirrups.

History. With the possible exception of the sail, harness represents man's first attempt to employ nonhuman power for his purposes. In pre-Columbian times, the New World knew no harness except for llamas and dogs carrying packs, dogs pulling travois on the North American plains, and dogsleds among the Eskimo. The Indian failure to develop harness may be due to the scarcity in America of animals anatomically suited to it and to the failure to observe systematically the effects of gelding (castration), which makes male animals sufficiently docile to be used for traction.

The yoke

The earliest Old World form of harness, which presupposes gelding, is the yoke resting on the withers (shoulders) of two animals, first used in the Near East, perhaps by 4000 BC, to attach a pair of oxen to a plow. By about 3000 BC the yoke was employed in Mesopotamia with onagers (Asian asses) to draw light wagons and chariots; and by about 2000 BC it was applied to horses, then newly arrived from Central Asia. Asses were used as pack animals in Egypt by 3000 BC, but there is no evidence that any animal was ridden until about 1300 BC.

The first use of the camel for labour is of very uncertain date. Presumably it is early, since the single-humped camel appears as a pack animal by 1000 BC in Mesopotamia. In the region north of the Altai Mountains, reindeer were used for traction earlier than horses, to judge from the fact that horses drawing the funeral sled of a chieftain buried at Pazyryk about 400 BC, which were sacrificed and buried with him, wore reindeer masks.

Bits. Both oxen and onagers were controlled by rings through the nose. The horse, however, appears from the beginning to have been governed normally by a bridle and bit, sometimes of bone but generally of metal. At first this was a simple bar with a ring at each end for reins, although by 1400 BC the jointed snaffle was known throughout the Near East. While there were many variations of both bar and snaffle bit, no important innovation appeared for 1,000 years; in the 4th century BC, Xenophon speaks of the curb bit. During the European Middle Ages the development of mounted shock combat demanded that the knight have absolute control of his charger, with the result that heavy and very severe curbs were produced. But no basic new idea in bits has appeared for the past 23 centuries.

Spurs. The simple prickspur is found in Celtic graves of about 400 BC. Although its use became habitual in Europe and eventually in the Americas, it seems not to have spread widely in the Orient or Africa. Rowel spurs, which replaced the single prick with a wheel of radiating points, first appeared in late 13th-century Europe.

Saddles. For at least 12 centuries after horses were first ridden, there were no saddles but only saddlecloths attached by surcingles or bellybands. These cloths were gradually supplemented by cushions or rolls that improved the rider's comfort but did not add greatly to his stability. Rigid saddles without stirrups appear in China during the Han dynasty (206 BC–AD 220) and are found in Roman Gaul in the 1st century AD, probably as an introduction from the barbarian world. The development of mounted shock combat required that the saddle become a large seat, giving maximum support to the knight. In early modern times, as shock combat in warfare and the tournament as sport went out of fashion, saddles steadily grew lighter. The decline of the saddle into the so-called English saddle of the late 19th and the 20th centuries is a sign of the technological obsolescence of the horse among those using such saddles. Herdsmen continued to use very substantial saddles.

The sidesaddle

The sidesaddle developed from an ancient packsaddle with a pannier, a board suspended on one side upon which the woman rider could rest her feet for support. By Frankish times the term *astraba* referred specifically to the footrest of such a saddle, and the word conveniently labelled the stirrup when it came from Central Asia.

During the Middle Ages and early modern times, the sidesaddle was varied in many ways from the basic device.

Stirrups. The first stirrups appeared as big-toe stirrups in India in the late 2nd century BC. These were diffused widely in the warm regions, where horsemen were barefoot, from Timor and the southern Philippines on the east to Ethiopia on the west. The wave of Indian culture that took Buddhism to China likewise carried the idea of the stirrup, which the booted Chinese, in their

chillier climate, expanded into the foot stirrup by the 5th century AD.

The foot stirrup reached Korea in the 5th century and Japan and some of the Central Asian countries in the 6th century. In 694 Muslim armies in northern Persia received the stirrup from Turkistan. Shortly afterward it was found in Byzantium, and by the early 730s it had arrived in the Frankish realm.

Before the support of the stirrup supplemented that of pommel and cantle, a mounted warrior could thrust his spear only with the strength of his own arm. With stirrups he could lay the spear at rest under the upper arm while his hand guided the blow that was now delivered by the force of his charging horse. The increase of violence was immense. Because it made possible mounted shock combat, the stirrup was the most significant invention in the history of warfare prior to gunpowder. In the early 730s Charles Martel saw the military potentialities of the stirrup, seized great areas of church lands, distributed them to retainers as endowment on condition that they serve him by fighting in the new manner, and thus instituted the feudal regime.

Invention of modern harness. The Bronze Age transfer of the yoke from oxen to onagers, horses, and similar animals was not successful for anatomical reasons: a horse or ass could be attached to such a yoke only by two straps running from the end of the yoke around the animal's neck and under its belly. The neck strap pressed on the windpipe and jugular vein in proportion to the pull of the animal, while the withers were so high a point of traction as to be mechanically inefficient. The modern harness, with its padded collar supporting rigid hames on the shoulders in a way that does not interfere with breathing or blood circulation, enables the animal to throw all its weight into pulling. It has been shown experimentally that a team of horses equipped with modern harness can pull a load four to five times heavier than it can pull with the ancient yoke harness.

Invention of the horse collar

Modern harness appears to have been introduced into Europe from Asia. China under the Hans developed a type of chariot drawn by a horse harnessed between lateral shafts, and the modern harness is depicted in frescoes of AD 500 in Kansu.

The first modern harness in Europe was probably seen about AD 800.

Animals or teams could not be harnessed tandem, or in sequence, until the 1st or 2nd century AD, when the first evidence of suitable harness is found in Gaul, Italy, and China. When this was later combined with horse collar and traces, horsepower became available for plowing and heavy hauling, although most historians believe that the use of horses in plowing was rare before the 12th century. In the 11th century the whiffletree, a horizontal transverse bar joining the two harnesses, helped to equalize the pull of traces on the load; and the pivoted front axle, known in Roman times, became common. By the 12th century the big four-wheeled wagon drawn by several teams of horses was revolutionizing land transport.

It was the ancestor of all later Western coaches and wagons, including the Conestoga wagons of the American frontier and the railroad coach (see WAGONS AND CARRIAGES; RIDING AND HORSEMANSHIP).

Modern equipment. Modern harnesses for riding and draft horses respectively are shown in Figures 1 and 2.

Bridles. The bridle, a harness of horses and mules, is a set of straps that makes the bit secure in the animal's mouth and thus ensures human control by means of the reins (see Figure 1). The upper portion of the bridle consists of the headpiece passing behind the ears and joining the headband over the forehead; the cheek straps run down the sides of the head to the bit, to which they are fastened; in the blind type of driving bridle the blinkers, rectangular or round leather flaps that prevent the animal from seeing anything except what lies in front, are attached to the cheek straps; the noseband passes around the front of the nose just above the nostrils; and the throatlatch extends from the top of the cheek straps underneath the head.

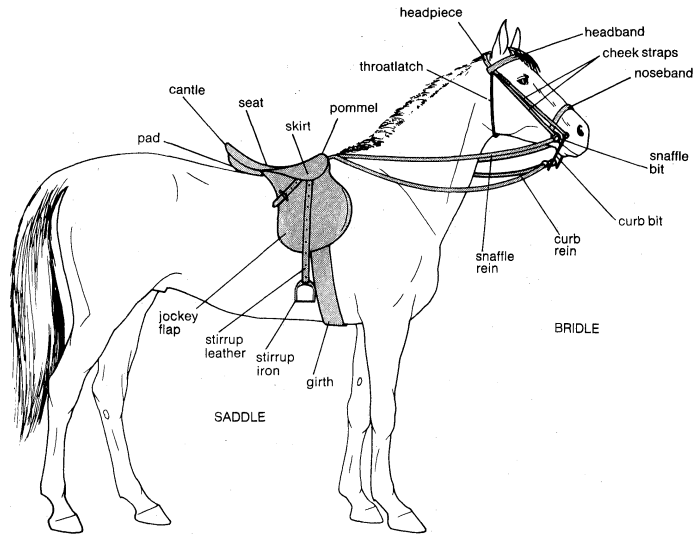

Figure 1: Nomenclature of a modern bridle and English saddle.
By courtesy of the American Saddle Horse Breeders Assoc. and W. W. Rouch & Co.

The martingale, sometimes used on riding horses, but not shown in the Figure, passes between the horse's forelegs with one end fastened to the saddle girth and the other to the head harness. It keeps the horse from throwing back its head.

The bit, the metal contrivance inserted in the mouth to which the reins are attached, is of three general types: the straight bar, snaffle, and curb. The snaffle has a jointed steel mouthpiece with straight cheek bars, the rings for the reins and cheekpieces of the headstall being fixed in the bars at the junction with the mouthpiece. The bars prevent the horse from pulling the bit through its mouth. The snaffle without bars is termed a bridoon. The curb bit is one to which a curb chain or strap is generally attached, fastened to hooks on the upper ends of the cheek bars of the bit and passing under the horse's lower jaw in the chin groove. The reins are attached to rings at the lower ends of the cheek bars, the leverage thus pressing the curb chain against the jaw. The mouthpiece of the curb bit is unjointed and in the centre commonly has a port; *i.e.*, a raised curve, allowing liberty for the tongue and bringing the pressure on the base of the horse's jaw. The curb bit and the bridoon can be used together with separate headstalls and reins, and there are many combination bits.

Saddles. The skeleton of the riding saddle is composed of the tree, or framework, the parts of which are the pommel, or head, the projection that fits over the animal's withers, and the sidebars that curve around to the back to form the cantle, or hindbow. The rigid parts are almost always covered with leather. The stirrup bars are fastened to the tree. On either side of the saddle are a leather skirt and hanging flaps to protect the rider from the mount's sweat. In saddles to be used with unbroken or unruly horses, the front of the flap is often padded to form a knee roll.

The saddles of Asia, Africa, and continental Europe tend to be heavy and high. But the English saddle, removed from all utilitarian purpose, is designed for extreme lightness for sport, racing, and fox hunting; the pommel and cantle are greatly reduced, and provision is made for clinging with the knees in jumps.

The English saddle

The saddles of Latin America and of western North America are diversified but are derived largely from equipment developed in the cattle industry of Spain during the Middle Ages. On the pommel is a sturdy metal horn to which the lariat, or lasso, is tied when cattle are being roped. The cantle is high to prevent the rider from slipping off the seat when the horse sits back on its haunches at the moment of roping. The saddle is made secure by one or two surcingles called cinches or girths; these are held to the tree rings by latigos, long leather straps. The sides and front of the stirrups are covered by

leather taps (Spanish *tapaderas*), a casing that prevents them from snagging in brush.

Harness. Many types of harness are used in different parts of the world for oxen, zebus, asses, reindeer, elephants, camels, water buffalo, yaks, and dogs. In the basic Occidental harness for horses and mules (Figure 2),

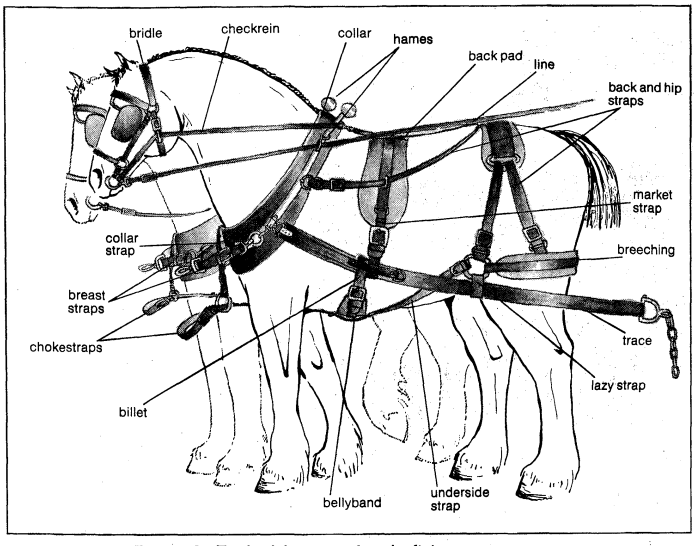

Figure 2: Typical harness for draft horses.

a leather collar, heavily padded, passes over the head and rests firmly on the shoulders; two hames, rigid curved pieces of metal, rest on this collar and are fastened at top and bottom by hame straps. To the hames are attached the traces, straps that pass along the animal's sides and are connected to the end of the whiffletree (also called whippletree, singletree, or swingletree), which is connected to the load by a centre link (see Figure 2).

When the animal is harnessed between shafts, the shafts are usually supported by a back pad; the pad is a narrow leather cushion resting on the back, attached to the shaft by straps and held in position by a girth, or bellyband, as well as by a backband and crupper, a loop strap passing under the tail. Reins pass through terrets, or rings, on the hames and pad. The other harness on the animal's hindquarters consists of the breeching, straps passing around behind the haunches to help in backing, braking, and stopping the vehicle, and the hip strap, fastened to the breeching and passing over the hindquarters.

The checkrein (bearing rein), a device sometimes used to add to the elegant arch of a horse's neck, consists of a separate bridoon bit with the reins passing through rings on the collar and then attached to a hook on the pad.

Hārūn ar-Rashīd

Hārūn ar-Rashīd, the fifth caliph of the ʿAbbāsid dynasty, though he ruled the Islāmic Empire of the caliphate from 786 to 809, when it was at its zenith, is now celebrated mainly for the colourful and romanticized picture of himself and his court in Baghdad as set out in the tales known as *The Thousand and One Nights* (*The Arabian Nights Entertainments*).

Family and early life

His father was al-Mahdī, the third ʿAbbāsid caliph (ruled 775–85). His mother, al-Khayzurān, a former slave girl from Yemen, was a woman of strong personality who greatly influenced affairs of state in the reigns of her husband and sons. The elder of these, al-Hādī, was four when Hārūn was born at Rayy, near modern Tehrān, Iran, in February 766 (or March 763). The princes were brought up in the court at Baghdad and educated in the Qur'ān (the holy book of Islām), poetry, music, anecdotes about the Prophet Muḥammad, early Islāmic history, and current legal practice. Hārūn had as tutor Yaḥyā the Barmakid, a loyal supporter of his mother. In 780 and 782 Hārūn was nominal leader of expeditions against the Byzantine Empire, though the military decisions were doubtless made by the experienced generals accompanying him. The expedition of 782 reached the Bosporus, opposite Constantinople, and peace was concluded on terms favourable to the Muslims. For this success Hārūn received the honorific title of ar-Rashīd, "the one following the right path," and was named second in succession to the throne and appointed governor of Tunisia, Egypt, Syria, Armenia, and Azerbaijan, with his tutor Yaḥyā acting as actual administrator. These moves were presumably engineered by al-Khayzurān and Yaḥyā. The two are even said to have induced al-Mahdī to make Hārūn his immediate successor, but al-Mahdī died in August 785 without officially changing the succession. Al-Hādī became caliph and Hārūn acquiesced. When al-Hādī died mysteriously in September 786, rumour suggested that al-Khayzurān was behind the death, because he had resisted her domination.

Hārūn ar-Rashīd thus became caliph on September 14, 786, succeeding to the rule of an empire reaching from the western Mediterranean to India. He made Yaḥyā the Barmakid his vizier, or chief minister. With Yaḥyā were associated his sons al-Faḍl and Jaʿfar, for the vizier at this period was not only an initiator of policy but also had attached to himself a corps of administrators to carry out his decisions. Al-Khayzurān had a considerable influence over the government until her death in 789. Thereafter until 803 the Barmakids largely controlled the empire, but the caliph was not wholly dependent on them, since certain offices of state were held by other men.

The reign was one of much internal trouble. At various times there were revolts for local reasons in Egypt, Syria, Yemen and several eastern provinces, but the central government was strong enough to quell these and restore order. Ifrīqīyah (or Tunisia), after having had a series of incompetent governors, was given in 800 to Ibrāhīm ibn al-Aghlab, who agreed to make a substantial yearly payment to Baghdad in return for semi-independent status. This was immediately advantageous to Hārūn financially but was the beginning of the loss of power by the caliphs, for the Aghlabid family continued to rule the province for over a century without interference from Baghdad, and similar status was granted to other regional dynasties. Though the revolts fill the pages of the historians, much of the empire was peaceful most of the time. This led to a great development of industry (textiles, metal goods, paper, etc.) and to an expansion of trade. The resulting prosperity made possible the concentration of vast wealth in the hands of the caliph and leading men and women of the empire.

ʿAbbāsid wealth under Hārūn

The fabulous descriptions of Hārūn and his court in *The Thousand and One Nights* are idealized and romanticized, yet they had a considerable basis in fact. Untold wealth had flowed into the new capital of Baghdad since its foundation in 762. The leading men, and still more their wives, vied in conspicuous consumption, and in Hārūn's reign this reached levels unknown before. His wife Zubaydah, herself a member of the ʿAbbāsid family, would have at her table only vessels of gold and silver studded with gems. Hārūn's palace was an enormous institution, with numerous eunuchs, concubines, singing girls, and male and female servants. He himself was a connoisseur of music and poetry and gave lavish gifts to outstanding musicians and poets. The brilliant culture of the court had certain limits, however, since, apart from philology, the intellectual disciplines were in their infancy in the Arabic world. There was also a rougher and

more sombre side. Instead of listening to music, Hārūn might watch cocks and dogs fighting. As caliph he had power of life and death and could order immediate execution. In the stories of his nocturnal wanderings through Baghdad in disguise, he is usually accompanied by Masrūr the executioner as well as friends like Ja'far the Barmakid and Abū Nuwās, the brilliant poet.

The less pleasant aspects of Hārūn's character are highlighted by the fall of the Barmakids, who for over 16 years had been mainly responsible for the administration of the empire, and who had provided the money for the luxury and extravagance of the court. Moreover, Ja'far the Barmakid had become Hārūn's special friend, so that gossip spoke of a homosexual relationship. Gossip also alleged that Hārūn had arranged that Ja'far should secretly marry his sister 'Abbāsah, on condition that he did not consummate the marriage, but that Ja'far fell in love with her, and she had a child. Whether in anger at this or not, Hārūn had Ja'far executed on January 29, 803. The other members of the family were imprisoned and their goods confiscated. Modern historians reject this gossip and instead suggest that Hārūn felt dominated by the Barmakids and may even have coveted their wealth. Moreover, diverse interests within the empire were being attracted to two opposing poles. On the one side were the "secretaries," or civil servants, many Persians, and many men from the eastern provinces; on the other side were the religious scholars (*'ulamā'*), many Arabs, and many from the western provinces. Since the Barmakids favoured the first group of interests and the new vizier, al-Faḍl ibn ar-Rabī', favoured the second, it is likely that this political cleavage was involved in the change of ministry.

The fall of the Barmakids

The struggle between the two groups of interests continued for at least half a century. Hārūn recognized its existence by assigning Irāq and the western provinces to his son al-Amīn, the heir apparent, and the eastern provinces to the second in succession, his son al-Ma'mūn. The former was son of the Arab princess Zubaydah and after 803 had al-Faḍl ibn ar-Rabī' as tutor. Al-Ma'mūn was son of a Persian slave girl and after 803 had as tutor a Barmakid protégé, al-Faḍl ibn Sahl. Hārūn has been criticized for so dividing the empire and contributing to its disintegration, for there was war between his two sons after his death; but it may well be that by making the cleavage manifest, he contributed to its eventual resolution after 850.

As vizier, al-Faḍl ibn ar-Rabī' lacked the efficiency of the Barmakids, and Hārūn's personal decisions may have had more weight. There were further successful operations against the Byzantine Empire, but in the autumn of 808, while on his way to deal personally with a serious two-year-old revolt in Khorāsān (in Iran), Hārūn fell ill at Ṭūs (near modern Meshed) and died there on March 24, 809. Al-Amīn succeeded him as caliph.

Hārūn was neither a great ruler nor a man of prepossessing character, though he was a lavish patron of the arts. He owes his fame to the wealth and luxury of his court, surpassing anything previously known, and to his place in Arabic legend.

BIBLIOGRAPHY. There is no standard biography. H. ST.J.B. PHILBY, *Harun al-Rashid* (1933), is a popular work of limited merit. More scholarly is NABIA ABBOTT, *Two Queens of Baghdad* (1946), describing the political roles of Hārūn's mother and his wife Zubaydah. The fullest account in general histories is that by P.K. HITTI in his *History of the Arabs*, 8th ed. (1964).

(W.M.W.)

Harvey, William

A leading English physician of the first half of the 17th century, William Harvey achieved fame by his conclusive demonstration of the true nature of the circulation of the blood and the function of the heart as a pump. Functional knowledge of the heart and the circulation had remained almost at a standstill ever since the time of the Greco-Roman physician Galen—1,400 years earlier. Harvey's courage, penetrating intelligence, and precise methods were to set the pattern for research in biology and other sciences for succeeding generations, so that he shares with William Gilbert, investigator of the magnet, the credit for initiating accurate experimental research throughout the world.

Harvey, oil painting by an unknown artist after an etching attributed to R. Gaywood. In the National Portrait Gallery, London.

William Harvey was born on April 1, 1578, at Folkestone, Kent. His father, Thomas Harvey, was a prosperous businessman and a leading citizen of the small town. William, the eldest of nine children, was the only one to achieve special distinction in his career, but all his brothers were successful in business or at the royal court in London and among them amassed considerable wealth.

Career as physician and scientific innovator. Little is known of William Harvey's boyhood in the Kentish countryside. During the years 1588 to 1593 he was at the King's School attached to the cathedral at Canterbury. In his 16th year Harvey entered Gonville and Caius College, Cambridge, where he was awarded a scholarship in 1593. Although Harvey attended Caius College because of its special interest in educating doctors, his training was grossly inadequate. He was absent from the university for the greater part of his last year (1598–99) because of illness—probably malaria—but had received the B.A. degree in 1597. Determined, in spite of his experience at Cambridge, to continue with medical training, he began a two-and-a-half-year course of study at the University of Padua, reputed to have the best medical school in Europe. His teacher was a celebrated anatomist, Hieronymus Fabricius ab Aquapendente, and it was in the now-famous oval Anatomy Theatre, still to be seen at the university, that Harvey first recognized the problems posed by the function of the beating heart and the properties of the blood passing through it.

Early theories of the heart and circulation

From the time of Aristotle in the fourth century BC it had been widely believed that the blood vessels contained both blood and air. Galen, the Greco-Roman physician, in the second century AD proved that the arteries contained only blood but still believed that air entered the right side of the heart from the lungs. There was a general belief that the movement of the blood was by ebb and flow, an analogy being found in the movement of the sea. Galen's view on this are difficult to assess with exactitude, but it is apparent that he, like everyone else, had no conception of a circular movement of the blood, leaving the heart by one set of vessels, the arteries, and returning to it by another set, the veins. The main propulsive force initiating this oscillatory movement was supposed to be derived from a contracting of the arterial system, rather than by a pumping action of the heart. The blood in the veins was believed to be formed in the liver, passing to the right auricle (*i.e.*, one of the two upper chambers of the heart), and from there to the right ventricle (one of the two lower chambers), to make its way through holes in the septum, or partition, to the left

side, where it met with blood from the arteries, which was mixed with air derived from the lungs. This was the extent of man's knowledge about the movement of the blood until 14 centuries later. Early in the 16th century the idea of a pulmonary circulation—that is, a circular motion of blood through heart and lungs—began to occur to some anatomists. In addition, the presence of a perforated septum was beginning to be questioned. In the middle of the 16th century a great anatomist, Andreas Vesalius, also working at Padua, first established accurate knowledge of human anatomy but was less interested in function. Several other medical investigators refined the anatomical knowledge of the heart. Realdus Columbus of Cremona, working as assistant to Vesalius, developed the idea of a pulmonary circulation, and this was made more definite by his pupil, Andreas Caesalpinus, though they still thought that the blood was distributed to the body by the great veins and their branches. Fabricius had a special interest in the anatomy of the veins and first described the system of valves found in them, but he was quite ignorant of their true function. In brief, there existed no convincing explanation of how the heart worked, and Harvey's logical mind remained unsatisfied.

His 28 months at Padua are only meagrely documented, but it is clear that he was outstanding among the students of his year. After receiving his diploma as doctor of medicine of Padua in April 1602, he returned to England. By the standards of the time he was fully trained in anatomy, the simpler functions of the human body, and in therapeutics based on the writings of Aristotle. He had had some clinical experience in the hospitals of Padua and Venice and was entitled to obtain a fellowship of the College of Physicians in London after passing through the preliminary stage of candidate for the higher qualification. At his first oral examination, in May 1603, he was given limited permission to practice medicine, but only after further examinations in April and August 1604 was he fully licensed to practice within the jurisdiction of the college—that is, in the London area.

Shortly after his return to England, Harvey married Elizabeth Browne, daughter of Lancelot Browne, physician to King James I and his queen, and a senior fellow of the college. The couple set up house in the parish of St. Martin's by Ludgate, not far from the College of Physicians; and, backed by Browne, Harvey then tried to obtain the appointment of physician to the Tower of London, where a number of distinguished men were imprisoned. Though he failed in this attempt, in 1607 he finally obtained a fellowship of the College of Physicians, which entitled him to seek an appointment as physician to one of the two great hospitals then serving London—St. Bartholomew's and St. Thomas's. It may have been through his brother John, who had obtained employment in the King's household, that early in 1609 the King gave Harvey a recommendation for an appointment at St. Bartholomew's, which was conveniently near his house in St. Martin's. He was given the post of assistant physician, and, when the physician died in the summer of that year, Harvey succeeded him. The hospital at that time had about 200 beds for patients in 12 wards, and Harvey's duties consisted in attending in the hall of the hospital on at least one day a week throughout the year to see the patients and prescribe for their treatment and at any other time when specially needed. The physician was usually expected to live within the hospital precincts, but the rule was waived for Harvey since he lived not far away. He received an annual salary of £25 with £2 extra for his livery and a further £8 since he did not use the official residence. His colleagues were three surgeons and an apothecary in charge of the dispensary.

Appointment to St. Bartholomew's

Harvey held this office for 34 years until 1643 when he was displaced for political reasons by Oliver Cromwell's party, then in power in London. These years saw the development and culmination of his active career as physician and scientific innovator. He developed a large private practice, attending many of the most distinguished citizens, including Sir Francis Bacon—and, about 1618, was made physician extraordinary to King James I, thus becoming a colleague of Sir Theodore Turquet de Mayerne, the senior court doctor. There can be no doubt that Harvey was for many years one of the most widely trusted doctors in England, although his unorthodox views on the circulation of the blood did injure his practice after their publication in 1628. Invariably courteous and regarded with affection and respect by his colleagues, he conducted his practice with common sense and honesty. Though advanced in his ideas of anatomy and physiology and scientific in his methods of research, he was inevitably conservative in his use of remedies. Very few potent drugs were known in his time, and accurate diagnosis was, more often than not, impossible, so that he never escaped from the influence of Aristotle, in whose principles he had been trained. He was the great protagonist of experimental biology but did not apply himself to this form of originality in therapeutics.

At the time of the King's last illness in 1625, de Mayerne was out of the country, and Harvey led the team of doctors in attendance. After the King's death it was rumoured that his favourite, the duke of Buckingham, had contributed to the fatal outcome by applying remedies not approved by the doctors. He was actually accused of having poisoned the King, and an inquiry was ordered by Parliament in 1626. Harvey was the most important witness of several who contributed to exonerating the Duke from any direct responsibility. Charles I, the new king, continued Harvey's appointment as his personal physician and gave him a special award for the care he had given the last King. Charles's health remained good until the day of his execution, so that he rarely had need to consult his doctor. Nevertheless, Harvey became his close friend and was always in attendance on his journeys, such as his state visits to Scotland in 1633 and 1638. The King helped Harvey's scientific researches by putting the deer in the royal parks at his disposal, and he delighted in showing the King anything of curiosity or scientific interest. At the same time, Harvey took his full share in the affairs of the College of Physicians, being constantly present at the meetings of the fellows and occupying all the official positions in the college hierarchy except that of president. His duties at court would not have allowed him to fill this position during his active years, and when it was offered to him in 1654 he was too old and ill to be able to accept. Yet it is clear from the college records that Harvey was always the man to whom his colleagues turned for advice in resolving their difficulties. The physicians at this time had precedence over the other branches of the profession, and Harvey had a prominent part in maintaining this ascendancy over the surgeons, obstetricians, and apothecaries whenever they became restive under the authority of the college.

Scientific research

In spite of Harvey's activity in medical practice and college affairs, he spent much time in scientific research from the time of his return to England in 1604 until the beginning of the Civil War in 1642. His interest lay primarily in elucidating the facts of the movement of the heart and its relation to the circulation of the blood. Fabricius at Padua had opened his eyes to the value of comparative anatomy, and he was tireless in dissecting every kind of living thing, from insects, earthworms, reptiles, birds, and mammals up to man himself. He seized every opportunity to increase his knowledge of pathology through postmortem examinations and was an acute clinical observer of his patients, not omitting their psychology. Most of his scientific papers were destroyed by parliamentary soldiers during the Civil War, so that there is now no direct evidence of his methods. On the other hand, his lecture notes used from 1616 onward survive. In 1615 he was appointed to a college lectureship intended to cover all parts of medical knowledge, though each lecturer modified the course to suit his own interests. Harvey's manuscript, now in the British Museum, was entitled "Lectures on the Whole of Anatomy." It is written in a very bad hand in mixed Latin and English, and it is incomplete, lacking any account of the skeleton, the sense organs, and other systems. The systematic anat-

omy is enlivened by many references to comparative anatomy, morbid anatomy, and clinical observations, even naming individuals whom he had treated. It is evident that he wrote these notes before he had come to any conclusions about the circulation of the blood, so that they contain nothing that seriously questioned the authority of Galen. The only reference to his novel views is on a leaf inserted some years later, probably after 1628. Harvey held this lectureship until 1656.

Discovery of circulation of the blood. It is evident from his writings that Harvey reverenced Aristotle, even though he had to dismiss some of his teachings as absurd. He also valued the views of Galen, his predecessor in experimental physiology, and enlisted his support whenever he could do so. Yet Harvey depended essentially on reasoning from his own observations and experiments for proof of his contentions. During the 12 years after 1616, Harvey may have introduced some novelties into his lectures; but, by his own assertions, he demonstrated the results of his researches to his friends privately at the college. Finally he published his book, *De Motu Cordis et Sanguinis in Animalibus* (*On the Motion of the Heart and Blood in Animals*), in 1628, a slender volume that established concisely and conclusively a new and unorthodox demonstration of the facts about the circulation of the blood. With Galen's help, he first disposed finally of the idea that the blood vessels contained air. He then elucidated the function of the valves in the heart in maintaining the flow of blood in one direction only when the ventricles contracted—on the right side to the lungs and on the left to the limbs and viscera. He proved that no blood passed through the septum, separating the two ventricles, and he explained the purpose of the valves in the larger veins in directing the return flow toward the heart. He showed that blood was expelled from the ventricles during contraction, or systole, and flowed into them from the auricles during expansion, or diastole. He proved that the arterial pulse was due to passive filling of the arteries by the systole of the heart and not by active contraction of their walls. He explained the purpose of the pulmonary circulation from the right ventricle through the lungs and back to the left auricle and ventricle. His only failure was in not demonstrating the connection of the arterial and venous systems in the tissues of the limbs by means of the smallest, or capillary, vessels. These he was unable to see, having no adequate form of microscope at his disposal. He was the first scientist to employ measurement of the content of the chambers of the heart and estimation of the total amount of blood in the body—that is, quantification.

Fame and criticism

Harvey's book made him famous throughout Europe, though the overthrow of so many time-hallowed beliefs attracted virulent attacks and much abuse from those who did not wish to believe the plain evidence of their senses. He refused to indulge in controversy and made no reply until he published a small book in 1649 answering the criticisms of a French anatomist, Jean Riolan. In this he reiterated some of his former arguments and utterly demolished Riolan's objections.

In 1636 King Charles dispatched a diplomatic embassy to the Holy Roman emperor Ferdinand II at Regensburg, Germany, in an attempt to establish the claim of his nephew, Prince Charles Louis, as Elector Palatine. Harvey was chosen as doctor to the mission and spent ten adventurous months of travel by land and water through territories ravaged by the Thirty Years' War, extending his journey by visits to Vienna, Prague, Venice, Rome, and Naples. At Nuremberg Harvey had a historical encounter with Caspar Hofmann, professor of medicine at the University of Altdorf, whom he attempted, at a public demonstration, to convince of the truth of his doctrine of the circulation. Though he did not succeed, Harvey behaved with great dignity and good temper in the face of obstinate blindness to demonstration of the facts.

At the start of the Civil War in 1642, Harvey was with the King and was in charge of the two princes, Charles and James, in the early stages of the Battle of Edgehill. When the King established his headquarters soon afterward at Oxford, Harvey remained with him and was given the position of warden of Merton College in 1645. Here he resumed his work on the development of the chick in hens' eggs and first met John Aubrey, antiquary and gossip, who afterward left a revealing account of Harvey in his *Brief Lives*. When the defeated King fled from Oxford to surrender himself to the Scots, Harvey joined him for a time at Newcastle but was forced to leave the King when he was handed over to the parliamentary army and was not allowed to go to him when he was imprisoned in the Isle of Wight. Harvey had never been much interested in politics but felt a deep personal regard for the King and after his execution in 1649 was a broken and unhappy man.

Yet two years later he published his second great book. After the publication of *De Motu Cordis*, the main achievement of Harvey's life, he had continued active research into the difficult subject of reproduction in animals. This led in 1651 to the publication of *De Generatione Animalium* (*Anatomical Excitations, Concerning the Generation of Living Creatures*, 1653) through the persuasions of his younger friend Sir George Ent, a fellow of the college. The book contains much of historical and scientific interest, but Harvey's thought was greatly influenced by Aristotle. The book is mainly concerned with the development of the chick in hens' eggs, and Harvey insisted throughout that in all living things the origin of the embryo is to be found in the egg. He investigated also the embryology of deer, rejecting Aristotle's notion that menstrual blood played any part in the formation of the fetus; he also questioned whether or not semen had any influence. Having no microscope, he could not see the spermatozoa, which were not demonstrated until 1686 by Leeuwenhoek working in Holland with stronger lenses. Harvey remained uncertain of how fecundation of the ovum was accomplished and even suggested that it was by a kind of infection resembling the origin of infectious diseases. Aristotle had originated the theory of gradual formation of the embryo, part by part, as opposed to the idea of preformation, meaning that all the parts arose in miniature at the same time. Harvey agreed with Aristotle and crystallized the belief in the term epigenesis, though to him its meaning was extremely simple compared with all that is implied by it at the present time. Aristotle believed in the principle of spontaneous generation of primitive organisms; it is probable that Harvey did not support this belief, but his statements are equivocal, and his position remains uncertain.

Harvey's brothers had been successful merchants, and their advice, coupled with his skill as a doctor and his naturally austere habits, enabled him to accumulate considerable wealth. But he had become old and ill. He had met with so much opposition and disbelief that his passionate desire to establish scientific truth was partially unsatisfied. In his last years under Cromwell's Protectorate, he was regarded as a political "delinquent" owing to his long association with King Charles and was forced to spend most of his time lodging in one or another of his brothers' houses outside London. Though he corresponded with many distinguished foreign doctors, he was reluctant to engage in any further scientific research, saw few patients, and took little part in the affairs of the College of Physicians. He showed his regard for the fellows by giving them a new college building in 1652 with a library containing his own collection of books and presumably any remaining manuscripts. This was in use for less than 14 years, being destroyed in the Great Fire of London in 1666, so that very few of his books have survived to the present day. He suffered severe pain from gout and kidney stones and described himself to a correspondent as "not only ripe in years, but also a little weary and entitled to an honourable discharge" from further scientific argument. His last illness was brief. He awoke one morning partially paralyzed and unable to speak, probably owing to a cerebral thrombosis. He died in his 80th year on June 3, 1657, probably in his brother Eliab Harvey's house at Roehampton. He was buried in the family vault at Hempstead, an Essex village 50 miles (80 kilometres) from London. In 1883 he was reburied in a marble sar-

Last years

cophagus in the Harvey Chapel there, near a marble bust by Edward Marshall. This is a lifelike image of Harvey, better, probably, than any of the existing portraits of him in old age.

Haryana

Haryana, a state of the northern region of the Indian Union, was constituted November 1, 1966, as a result of the partition of the former state of Punjab into two separate states—Punjabi-speaking Punjab and Hindi-speaking Haryana. It is bounded on the northwest by Punjab, on the northeast by Himachal Pradesh, on the east by Uttar Pradesh and the union territory of Delhi, and on the south by Rājasthān.

The reorganization of the former Punjab followed agitation by the Sikhs for a Punjabi Suba (Punjabi-speaking province); but it also met, substantially, the aspirations of the people of the Hindi-speaking region of Punjab for a Vishal Haryana (Greater Haryana). The name means "the abode of God," from Hari (the Hindu god Viṣṇu) and *ayana* (home), although it has also been suggested that the derivation may be from the word *hari* ("green"), denoting the fertility of the countryside.

The area of the state is 17,010 square miles (44,056 square kilometres). Its population in the early 1970s was about 10,000,000. The headquarters of the state government are at Chandīgarh, the modern capital of Punjab.

History. The region now known as Haryana was the birthplace of the Hindu religion and the civilization of the Indus Valley. There, the first hymns of the Aryans were sung, and the most ancient manuscripts were written. On the battlefield at Kurukṣetra, Lord Kṛṣṇa delivered to the warrior Arjuna the teachings that are contained in the *Bhagavadgītā*, venerated in India as the highest code of ethics.

The early Aryan settlers

The earliest known settlers of Haryana were Aryans. Lying athwart the route of overland invasions into India, it underwent successive waves of migration from the time of Alexander the Great (326 BC) and was the scene of many famous battles of Indian history, including the battles of Pānīpat in 1526 (at which the Mughal leader Bābur defeated Ibrāhīm Lodī to end Muslim domination), 1556 (at which the Afghan forces were defeated by the army of Mughal emperor Akbar), and 1761 (at which the Afghan shāh decisively defeated a Marāthā army, strengthening British control in Bengal) and the Battle of Karnāl in 1739 (at which Nāder Shāh of Persia dealt a blow to the crumbling Mughal Empire).

The area included in the present state was ceded to the British East India Company in 1803. In 1832 it was transferred to the then North-Western Provinces (Uttar Pradesh). In 1858 Haryana became a part of Punjab, remaining as such after the partition of India and Pakistan in 1947. The demand for a Haryana province, however, was raised even before India's independence in 1947. Lala Deshbandhu Gupta and Asaf Ali, prominent figures in the national movement, advocated a separate state of Haryana. Sri Ram Sharma, a veteran freedom fighter, had headed a Haryana Development Committee to focus attention on the concept of an autonomous state. The demand for unilingual states by Sikhs and Hindus gained momentum in the early 1960s, and Haryana became the 17th state of the Indian Union in accordance with the recommendations of the Punjab Reorganization Commission and the provisions of the Punjab Reorganization Act of 1966.

Physical geography. Most of Haryana lies on the Indo-Gangetic Plain, but in the northeast there is an extension of the low, sub-Himalayan Siwālik Hills. The state, on the whole, is flat, the average height ranging from 700 to 900 feet (210 to 270 metres) above sea level. It is drained by one perennial river, the Yamuna (Jumna), which does not flow in the state but forms its eastern border with Uttar Pradesh. There are numerous seasonal streams, the most important being the Ghaggar, which flows out of the Siwālik Hills and forms its northern border with Punjab.

Rainfall is scanty in most areas. Although the state has a system of canal irrigation, there are chronic drought-prone areas and occasional floods from the tributaries of the Yamuna and the Ghaggar. The climate is hot in summer and markedly cold in winter. The maximum temperature in summer (May–June) goes up to 114° F (46° C). The minimum temperature of 28° F (−2° C) occurs in January.

The soils are deep and fertile except in the eroded lands of the northeast and in the southwest where, bordering the Thar Desert in Rājasthān, they are sandy. Out of a total area of 10,900,000 acres, 9,600,000 acres are classified as arable. Canal irrigation is available for only about 3,200,000 acres, or a little more than one-third of the arable land.

The land, as indicated above, is mostly arid or semi-arid, and the natural vegetation, although little remains, reflects that fact, the flora of the plains resembling that of Iran, Saudi Arabia, and North Africa. The largest indigenous trees are the shisham (*Dalbergia sissoo*) and the kikar (*Acacia arabica*).

Dominance of Hindus in the population

Population. *Composition.* Haryana was constituted as a Hindi-speaking state. According to the 1971 census, out of a total population of about 10,000,000, Hindus constituted 89 percent. Other principal religious groups were Muslims (4 percent), Sikhs (6 percent), and Jains (less than 1 percent).

Languages and distribution. The principal language spoken is Hindi. The other important languages are Punjabi and Urdu.

More than 80 percent of the population is rural, living in over 7,000 villages. Only about 18 percent of the total population is classified as urban, spread over 60 cities and towns. Ambāla, together with its army cantonment, is the largest town in the state, with a population of more than 186,000. It is followed in size by Rohtak, with a population of almost 124,760. Other towns are Karnāl, Hissār, Pānīpat, Farīdābād, Bhiwāni, and Yamunānagar. The overall population density of the state is more than 590 persons per square mile.

Administration. The governor, appointed by the president of India, is the head of the state. He is aided and advised by a Council of Ministers responsible to the state Legislative Assembly (Vidhan Sabha). The 81-member assembly had its third election in less than six years in 1972. Normally, election to the assembly is for a five-year term. Political defections, however, brought about the dissolution of the first assembly, elected in 1967. A new assembly was elected in May 1968, but the ruling party decided on dissolution for a fresh mandate from the people, coinciding with assembly elections in neighbouring Punjab and several other states. The state has a common High Court with Punjab and also a common Public Service Commission that recruits all government employees.

The state is divided into seven districts—Hissār, Rohtak, Gurgaon, Karnāl, Ambāla, Jīnd, and Mahendargarh. The system of village self-government (*pañcāyat raj*) has been extended to all of the 7,039 villages. Administration,

as is the case in the rest of the country, is oriented toward development in all sectors.

Social conditions. With education getting a high priority in the development program, there has been a large quantitative expansion in school enrollment in Haryana; however, as in the northern states in general, girls' education has not made much headway. The literacy rate is lower than in the western or southern states of India. About 55,000 students attend colleges. The state has a teaching college and a residential university (founded 1956) at Kurukshetra, which also has a regional engineering college. Panjab University, in Chandīgarh, grants degrees through affiliated colleges of which there are six in Rohtak, five in Karnāl, seven in Ambāla, and four in Hissār. Hissār is the seat of the Haryana Agricultural University.

Haryana has a network of district and subdivisional hospitals and primary health centres. The Family Planning Programme is making headway. In more than half the villages, drinking water is acutely scarce. Eighteen percent of the population belonging to scheduled castes (former "untouchables") and other backward classes are covered by schemes of assistance in education and technical guidance and for housing.

Economy. The economy is agricultural and, despite its pockets of chronic drought and scanty rainfall, Haryana is one of the few states in which substantial investments in agriculture, irrigation, fertilization, and related programs embodied in India's five-year plans have made a tremendous impact. By 1972 the state had already exceeded its Fourth Five-Year Plan (1969–74) target of 4,400,000 tons of additional food grains. The spurt in food-grain production (mainly wheat) led to a significant growth in per capita income. Except in the northeast, most of the land is used for two crops annually. In addition to wheat, the principal winter crops are gram, barley, and mustard. The principal summer crops are millet, rice, maize (corn), sugarcane, and cotton. The state is also known for the quality of its bullocks and dairy cattle.

Agricultural programs

To increase agricultural production, the state has initiated a number of irrigation schemes to tap subsoil water and has undertaken several small and medium-size irrigation projects. The state has been energizing more than 20,000 tube wells (driven wells) a year to augment irrigation facilities. There are more than 77,000 such tube wells.

The state has no heavy industry; nor has it any sizable mineral resources for exploitation. Light industries, however, have been developing, especially since the late 1960s. The increase in agricultural production, especially of sugarcane and cotton, has stimulated related industries, and there were several cotton textile and sugar mills in the state in the early 1970s. Other light industries include the manufacture of farm tools, machine tools, electrical and glass goods, cement, paper, and bicycles. Industrial areas with medium- and small-scale factories and other enterprises have developed at Farīdābād and Ballabhgarh, south of Delhi (where Haryana borders Uttar Pradesh), and at Sonepat, Jagādhri, and Yamunānagar. Industrial areas are also rising up along the Grand Trunk Road from Delhi and along railways to take advantage of transport facilities.

Transport and communication. Road development has been accorded high priority in the state's development plans. These included the construction of 2,500 miles of new roads to bring the state total to 6,200 miles. Haryana Roadways, which is a nationalized transport undertaking, operates hundreds of vehicles on local and interstate routes.

The chief lines of communication are those leading to and from Delhi, particularly the historic Grand Trunk Road and the mainline of the Northern Railway between Ambāla and Delhi, which is the centre of the nation's rail, road, and airway networks.

Culture. Haryana is a land of legends, temples, historical places, and archaeological sites. Besides the Hindu pilgrim centre of Kurukṣetra, site of a bathing fair at each solar eclipse, the state has several sacred and historic sites including Karnāl, site of many events in the epic of the *Mahābhārata;* Thānesar, an early (9th–12th century) Hindu capital; and Gurgaon, capital of the Gurjara dynasty before the 10th century. Rohtak was the centre of the Yaudheya warriors in the 5th and 6th centuries. Religious centres with sacred tanks for bathing and other purposes include Agroha, Pandara, Pehowa, and Ramrah. Surajkund, an ancient centre of sun worship, has a sacred tank built in the shape of the rising sun. Pānīpat, mentioned in the *Mahābhārata,* was the scene of important dynastic battles in the 16th and 18th centuries.

The Indus Valley civilization was crystallized at Khokhra Kot (Rohtak), Naurangabad, Meham, and Agroha in Haryana. The Gurukul (University) at Jhajjar has a rich collection of ancient coins, molds, seals, inscriptions, utensils, and statues, which throw light on the life of people inhabiting the region at different periods.

The people of Haryana are simple and hardworking and have preserved their old religious and cultural traditions and customs. They hold fairs and festivals with great enthusiasm, among the most notable being the Janam Ashtami (Lord Kṛṣṇa's birthday) Fair at Bhiwāni and the Masani Fair at Gurgaon. Folk theatre and folk dancing have also been very popular. *Saang* is the most popular variety of performances with the participants—the female roles played by men—singing and dancing continuously for five to six hours. The themes are drawn from mythology or Sanskrit literature and occasionally include love lores of Punjab.

Essentially a rural state, more than 80 percent of the people live in the villages, where their principal occupation is agriculture. At the same time, the Indian army, traditionally a favourite career for young men, finds Haryana a major recruiting ground.

BIBLIOGRAPHY. R.S. SHARMA (ed.), *Haryana Directory & Who's Who: 1967–68* (1968), gives the background of the formation of Haryana state and various details of the state's economy. The *Haryana Review* (quarterly), gives useful information about the state; *Facts about Haryana* (1970), is a small statistical handbook. Both are published by the Public Relations Department, Haryana.

Ḥasan al-Baṣrī, al-

Al-Ḥasan al-Baṣrī (Abū Sa'īd ibn Abī al-Ḥasan Yasār al-Baṣrī), one of the most important religious figures in early Islām, was known to his own generation as an eloquent preacher, a paragon of the truly pious Muslim, and an outspoken critic of the political rulers of the Umayyad dynasty (AD 661–750). Among later generations of Muslims, he has been remembered for his piety and religious asceticism. Muslim mystics have counted him as one of their first and most notable spiritual masters. Both the Mu'tazilah (philosophical theologians) and the Ash'arīyah (followers of the theologian al-Ash'arī), the two most important theological schools in early Sunnī (traditionalist) Islām, considered Ḥasan one of their founders.

Ḥasan was born in Medina in AD 642, nine years after the death of the prophet Muḥammad. One year after the battle of Ṣiffīn (657), which proved to be one of the most important events in the history of Islām, Ḥasan moved to Basra, a military camp town situated 50 miles (80 kilometres) northwest of the Persian Gulf. From this base, military expeditions to the east disembarked, and, as a young man (670–673), Ḥasan participated in some of the expeditions that led to the conquest of eastern Iran. In a short time, Basra came to be more than a military post; its cultural importance in the history of Islām is based on the fact that it became the home of intense religious and intellectual activity that had profound effects on the development of later Islāmic thought.

Early career; leader in theological debates

After his return to Basra, Ḥasan became a central figure in the religious, social, and political upheavals brought about by internal conflicts with the Muslim community. The years 684–704 marked the period of his great preaching activity. From the few remaining fragments of his sermons, which are among the best examples of early Arabic prose, there emerges the portrait of a deeply sensi-

tive, religious Muslim. For Ḥasan, the true Muslim must not only refrain from committing sin, but he must live in a state of lasting anxiety, brought about by the certainty of death and the uncertainty of his destiny in the hereafter. He said: "I never saw a certainty of which there is no doubt bear a greater resemblance to a doubtful thing of which there is no certainty, than death does." The world is treacherous, "for it is like to a snake, smooth to the touch, but its venom is deadly." The practice of religious self-examination (*muḥāsabah*), which led to the activity of avoiding evil and doing good, coupled with a wariness of the world, marked Ḥasan's piety and influenced later ascetic and mystical attitudes in Islām.

Religious and political views

The enemy of Islām, for Ḥasan, was not the infidel but the hypocrite (*munāfiq*), who took his religion lightly and "is here with us in the rooms and streets and markets." In the important freedom–determinism debate, he took the position that man is totally responsible for his actions, and he systematically argued this position in an important letter written to the caliph ʿAbd al-Malik. His letter, which is the earliest extant theological treatise in Islām, attacks the widely held view that God is the sole creator of man's actions. The document bears political overtones and shows that in early Islām theological disputes emerged from the politico-religious controversies of the day. He wrote: "Oh Commander of the Faithful . . . tyranny and injustice are not from God's decree, but His decree is His command concerning goodness, justice, kindness, and generosity regarding one's relatives." His political opinions, which were extensions of his religious views, often placed him in precarious situations. During the years 705–714, Ḥasan was forced into hiding because of the stance he took regarding the policies of the powerful governor of Iraq, al-Ḥajjāj. After the Governor's death, Ḥasan came out of hiding and continued to live in Basra until he died in 728. It is said that the people of Basra were so involved with the observance of his funeral that no afternoon prayer was said in the mosque because no one was there to pray.

BIBLIOGRAPHY. With the exception of a few of his sayings, nothing from al-Ḥasan's works has been published in English translation. The most important Western-language studies are: LOUIS MASSIGNON, *Essai sur les origines du lexique technique de la mystique musulmane*, rev. ed. (1954), an examination of al-Ḥasan's place in Islāmic mysticism; HELMUT RITTER, "Studien zur Geschichte der islamischen Frömmgkeit," *Der Islam*, 21:1–83 (1933), the most detailed study of al-Ḥasan's thought—includes the Arabic text of the letter written to ʿAbd al-Malik; JULIAN OBERMANN, "Political Theology in Early Islam: Ḥasan al-Baṣrī's Treatise on Qadar," *Journal of the American Oriental Society*, 55:138–162 (1935), which also discusses the letter written to ʿAbd al-Malik; and "Hasan al-Basri," *Encyclopaedia of Islam*, new ed., vol. 3, pp. 247–248 (1966).

(D.E.)

Hastings, Warren

As the first British governor general of Bengal, Warren Hastings was responsible for consolidating British control over the first major Indian province to be conquered. In the 13 years he held office (1772–85), solutions began to be devised to such problems as how vast Indian populations were to be administered by a handful of foreigners and how the British, now themselves a major Indian power, were to fit into the state system of 18th-century India. These solutions were to have a profound influence on Britain's future role in India. Hastings' career is also of importance in raising for the British public at home other problems created by their new Indian empire—problems of the degree of control to be exercised over Englishmen in India and of the standards of integrity and fair dealing to be expected from them—and the solutions to these problems were also important for the future.

Early life. The son of a clergyman of the Church of England, Hastings was born on December 6, 1732, at a village in Oxfordshire. Abandoned by his father at an early age, he was brought up by an uncle, who gave him what was probably the best education then available for a boy of his inclinations, at Westminster School in London. Hastings showed great promise as a schoolboy and seems at Westminster to have acquired the literary and scholarly tastes that were later to give him a serious interest in Indian culture and civilization. His school days were, however, cut short by his uncle's death in 1749. He was then taken away from school and granted a writership (as the junior appointments in the East India Company were called), and in 1750, at the age of 17, he sailed for Bengal.

In 1750 British contact with India was still the monopoly of the East India Company, which was engaged in

buying and selling goods at small settlements in Indian ports. As one of the company's servants, for the early part of his career Hastings was employed in the company's commercial business. But after 1756 the outlook for both the company and its servants was radically altered. The company became involved in hostilities in India both with the French and with Indian rulers, and under Robert Clive its army was able to depose the nawab, or Indian governor, of Bengal at the Battle of Plassey in 1757. Although the company did not at this stage intend to set itself up as the actual ruler of the province, it was now so powerful that the new nawabs became its satellites. Thus, the servants, including Hastings, began to be drawn more and more into Indian politics. Hastings served as the company's representative at the court of the nawabs of Bengal from 1758 to 1761 and then on the company's Council, the controlling body for its affairs in Bengal, from 1761 to 1764. His career was cut short, however, by bitter disputes within the Council. Finding himself in a minority, Hastings resigned from the company's service and returned to England in 1765.

Servant of the East India Company

Governorship of Bengal. Short of money, Hastings sought service in India again. In 1769 he was appointed second in Council in Madras. Two years later he received his great opportunity when he was sent back to Bengal as governor in charge of the company's affairs there. Since he had last been in Bengal, the disintegration and demoralization of the normal Indian government of the province, begun after Plassey, had gathered speed; yet the company had been reluctant to create a new system in its place. In practical terms Bengal was in the power of the British, who were also virtually its legal rulers after being granted in 1765 the powers called the dewanee by the Mughal emperor. But the business of government was still conducted by Indian officials, with very limited European participation. Hastings recognized that this situation could not go on and that the British must accept full responsibility, make their power effective, and involve themselves more closely in the work of government, even if he shared his contemporaries' objections to excessive involvement. His view of the British role in India was later to be regarded as a very conservative one. He saw no "civilizing" or modernizing mission for them. Bengal was to be governed in strictly traditional ways, and the life of its people was not to be disturbed by in-

novation. To ensure good government, however, he felt that the British must actively intervene. In what was to be the most constructive period of his administration, from 1772 to 1774, Hastings detached the machinery of the central government from the nawab's court and brought it to the British settlement in Calcutta under direct British control, remodelled the administration of justice throughout Bengal, and began a series of experiments aimed at bringing the collection of taxation under effective supervision.

End of undisputed power in Bengal

Political rivalries. Hastings' period of undisputed power in Bengal came to an end in 1774 with changes in the company's government. He acquired the new title of governor general and new responsibilities for supervising other British settlements in India, but these powers had now to be shared with a Supreme Council of four others, three of whom were new to India. The new councillors, who were led by an army officer, Sir John Clavering, and included the immensely able and ambitious Philip Francis, immediately quarrelled with Hastings. Hastings' admirers have had little patience with Clavering and Francis; but it is possible to see that Francis had a genuine point of view in his opposition to Hastings and that there was still much in Bengal, even after Hastings' reforms, to shock men fresh from Britain (bribery, extortion, and other abuses of power by Englishmen, which had been so common since Plassey, undoubtedly continued). The quarrel between the new councillors and Hastings paralyzed the government of Bengal and produced a number of squalid episodes in which the newcomers, to discredit Hastings at home, encouraged Indians to bring accusations of malpractices against him, while his friends used various methods to deter such accusations. The most notorious of these episodes concerned one Maharaja Nandakumar, who made accusations against the governor general but was in his turn accused of forgery and hanged for it. Hastings was certainly not guilty of procuring a judicial murder, but recent research does suggest that he knew in advance of the counterplot against Nandakumar.

War in India. The death of Clavering in 1777 put Hastings once again in possession of full power, although Francis' opposition dragged on for another three years. It ended in a pistol duel between Hastings and Francis; the latter was wounded, and he returned to Europe. But by 1777 the energies of the Bengal government were becoming more and more absorbed in war. War against Indian states was always a likely consequence of the company's conquest of Bengal. As full participants in the unstable world created in India by the fall of the Mughal Empire, the company now found it difficult not to be drawn into the rivalries of the powers that had set themselves up in the ruins of the empire. Hastings' policy was to avoid further conquest and war but to maintain peaceful relations with neighbouring states by a series of alliances. He had, however, already taken part in one war in 1774, when he helped the company's ally on the northwestern boundary of Bengal, the Vizier of Oudh, to take over territory occupied by a people called the Rohillas; and in 1778 he became involved in war with the Marāthās, a loose federation of Hindu peoples in western and central India. Rightly or wrongly, Hastings came to believe that it was necessary for the safety of the British in India to ensure that the Marāthā leaders were friendly to the company and that he would be justified in applying military pressure to achieve this end. After the entry of France into the U.S. War of Independence in 1778, he was also confronted with French expeditionary forces in the Indian Ocean. Finally, in 1780, Hyder (Haidar) Ali, the ruler of the south Indian state of Mysore, attacked the British at Madras. War on several fronts brought out the best in Hastings, and his achievement in organizing the company's military and financial resources to counter every threat was a remarkable one. The Marāthās were brought to peace in 1782, as was Mysore in 1784, and the French were held in check until peace was made in Europe in 1783. But war stretched the company to the limit, disrupting its trade and thus antagonizing opinion at home. War also forced Hastings (or so he believed) into dubious acts to raise extra funds, two of which—the demand for a subsidy to the company from Chait Singh, the raja of Banaras, and the requisitioning of the treasures of the begums of Oudh (the mother and grandmother of the Vizier)—were to count heavily against him later.

Wartime achievements

Retirement and impeachment. It was, however, an India at peace and with British dominions fully intact that Hastings finally left in 1785. But even before his retirement the allegations of Francis and the reports of wars, whether justly or unjustly undertaken, had damaged his reputation; and the passionate moral concern about the standards of the British in India felt by Edmund Burke, the great Whig parliamentarian, had come to be focussed on Hastings. Most historians, while recognizing Burke's absolute sincerity, now feel that Burke was attempting to pin the evils of a situation on one individual and that he had chosen the wrong one. But Hastings was vulnerable on episodes such as the execution of Nandakumar and his treatment of the begums of Oudh and Chait Singh and even on some aspects of his personal finances, where he had acquired money in excess of his official allowances. In 1786, when Burke introduced an impeachment process against him (a prosecution by the House of Commons before the House of Lords), these blemishes were enough to persuade the House of Commons and in particular William Pitt the Younger, the prime minister, that Hastings ought to be sent to trial. The trial before the House of Lords lasted from 1788 to 1795, when he was acquitted. It is difficult not to regard this long-drawn-out ordeal as a serious injustice. At the most it made some contribution to the process by which standards were being laid down for the future conduct of British rule in India.

After his acquittal, Hastings lived the life of a retired country gentleman—unassuming, mild-mannered, and of scholarly tastes, as he had been during his active career. He died on August 22, 1818, at age 85.

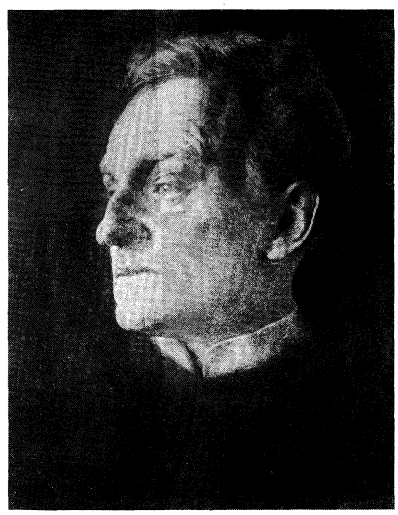
BIBLIOGRAPHY. PENDEREL MOON, *Warren Hastings and British India* (1947), is the best short account. KEITH FEILING, *Warren Hastings* (1954), is a full biography. P.J. MARSHALL, *The Impeachment of Warren Hastings* (1965), deals with the trial and the controversial episodes featured in it. For the English and Indian backgrounds respectively, see LUCY S. SUTHERLAND, *The East India Company in Eighteenth-Century Politics* (1952); and ABDUL MAJED KHAN, *The Transition in Bengal, 1756–1775* (1969). Hastings' letters may be consulted in G.R. GLEIG, *Memoirs of the Life of the Right Hon. Warren Hastings, First Governor-General of Bengal*, 3 vol. (1841). Macaulay's Essay on Warren Hastings, available in most editions of his collected essays, should still be read.

(P.J.M.)

Hauptmann, Gerhart

The most prominent German dramatist of his time, Gerhart Hauptmann established his reputation in 1889 as an exponent of Naturalism with the performance of *Before Dawn* in Berlin. This starkly Realistic tragedy, dealing with contemporary social problems, signalled the end of the rhetorical and highly stylized drama of the 19th century. Hauptmann's most celebrated works are in the Realistic style, notably, such proletarian tragedies as *The Weavers* and *Drayman Henschel*, as well as the tragicomedy *The Rats* and the satirical comedy *The Beaver Coat;* but he also produced, beginning in the 1890s, dramas in a variety of other styles: lyrical, Symbolist, historical, neo-Romantic, Neoclassical, and others. Many of these are tinged with the mystical religiosity to which he turned with advancing years. Starting in the 1880s, he also published stories, novels, verse epics, poems, essays, and autobiographical accounts, which demonstrated his extraordinary range. The unifying element of Hauptmann's vast and protean literary output is the sympathetic but by no means activist concern for human suffering: his heroes are generally passive, victims of elementary "powers." He extended this view to the concept of history in his highly controversial *Festspiel*, which commemorates the centenary of the anti-Napoleonic Wars.

Hauptmann was born on November 15, 1862, in the then fashionable Silesian resort town of Obersalzbrunn (now Szczawno Zdrój, Poland), where his father owned



Hauptmann, etching by Hermann Struck, 1904. In the Schiller-Nationalmuseum, Marbach, West Germany.

the main hotel. He enjoyed little formal education. Leaving school at 15, he tried to find himself in a variety of pursuits during the next ten years. After trying his hand at farming, he studied sculpture for nearly two years at the Breslau (now Wrocław, Poland) Art Institute and then joined his older brother Carl in Jena for a semester of studies in history, philosophy, and science. After spending the winter of 1883–84 in Rome as a sculptor, he continued his academic studies and took acting lessons in Berlin. It was at this time that he decided to make his career as a poet and dramatist. Having married the well-to-do Marie Thienemann in 1885, Hauptmann settled down in Erkner, a rural suburb of Berlin, dabbling in political, sociological, theological, and literary studies and associating with a group of scientists, philosophers, and avant-garde writers. The circle was influenced by the literary works of Leo Tolstoy, Émile Zola, and Henrik Ibsen; the philosophical writings of Karl Marx and Friedrich Nietzsche; the theological works of D.F. Strauss; and the writings of the German Darwinian zoologist Ernst Haeckel. Although he was never a doctrinaire Naturalist, Socialist, or Materialist, Hauptmann's first dramas grew out of the ferment of such ideas.

First success

In October 1889, *Before Dawn* made him famous overnight, though it had to be performed in the Freie Bühne, a private theatre club dedicated to the modern drama. Encouraged by the ensuing uproar, he wrote in rapid succession a number of successful plays on Naturalistic themes (heredity, the plight of the poor, the clash of natural science and religion), again artistically reproducing social reality and common speech, as well as nonverbal elements of communication. Most gripping and humane, as well as most objectionable to the political authorities, was *The Weavers*, a compassionate dramatization of the Silesian weavers' revolt of 1844. The following decade, the writer's most creative, was marked by marital difficulties, which ended in 1904 with a divorce; in the same year he married an actress and violinist, Margarete Marschalk (12 years his junior), four years after the birth of their son, Hauptmann's fourth. In 1901 they had moved to their newly built mansion, Haus Wiesenstein, at Agnetendorf in Silesia (Jagniąków, Poland). No longer suffering from his usual sickliness, Hauptmann spent the rest of his life here in his characteristically convivial style, summering on the Baltic isle of Hiddensee, wintering on the Italian Riviera or in the Ticino district of Switzerland, and travelling frequently to Berlin and Vienna and occasionally elsewhere (to England in 1905, to Greece in 1907, to the U.S. in 1932). The tranquillity of his life was interrupted only temporarily, in 1905–06, by his romance with Ida Orloff, a 17-year-old actress, who was to become the model of numerous elfish figures in plays and novels.

Hauptmann never became a partisan of any literary trend, receptive though he was to many of them. Although he was honoured like a national figurehead at his frequent public appearances, he tended to isolate himself somewhat from the literary and intellectual life of the time. His literary production became prolific—he dictated virtually every afternoon—but also more uneven over the years; yet it culminated in one of the most powerful dramatic works of the century, the *Atridentetralogie*, a tetralogy on the myth of the Atrides that he wrote during World War II. In addition to the literature and mythology of Greek and Germanic antiquity, in his later years he derived much of his inspiration from Shakespeare (whose *Tempest* he adapted in *Indipohdi*) and Goethe (to whom he felt a particularly close personal affinity), as well as from his own early life. He also delved into the theology and mythology of early Christianity, especially into its heretical movements. These studies have left their imprint most clearly on his philosophically ambitious visionary epic in terza rima, *Der grosse Traum* ("The Great Dream"). The autodidactic philosophical and scholarly pursuits and the syncretistic cosmological speculations of Hauptmann's later decades did, however, distract him from his spontaneous talent for creating characters that come alive on the stage and in the imagination of the reader. Not surprisingly, he was also an ingenious director of his own plays, as well as those of others.

Period of major literary productivity

Hauptmann's fame—the Nobel Prize (1912) being only one of many international honours—was unequalled, though not uncontested, until the ascendancy of Nazism, when he was barely tolerated by the regime and was denounced by émigrés for staying in Germany. Though privately out of tune with the Nazi ideology, he was politically naïve and tended to be indecisive. He died on June 6, 1946, in Agnetendorf and was buried on the isle of Hiddensee. His plays, the early Realistic ones especially, are still frequently performed, though not so often as during his lifetime.

Fame and honours

MAJOR WORKS

PLAYS: *Vor Sonnenaufgang* (1889; *Before Dawn*); *Das Friedensfest. Eine Familienkatastrophe* (1890); *Einsame Menschen* (1891; *Lonely Lives*); *Die Weber* (1892; *The Weavers*); *College Crampton* (1892); *Der Biberpelz* (1893; *The Beaver Coat*); *Hannele* (1894; later pub. as *Hanneles Himmelfahrt*; Eng. trans., *The Assumption of Hannele*); *Florian Geyer* (1896); *Die versunkene Glocke* (1897; *The Sunken Bell*); *Fuhrmann Henschel* (1898; *Drayman Henschel*); *Schluck und Jau* (1900); *Michael Kramer* (1900); *Der rote Hahn* (1901; *The Conflagration*); *Der arme Heinrich* (1902; *Henry of Auë*); *Rose Bernd* (1903); *Elga* (1905); *Und Pippa tanzt!* (1906; *And Pippa Dances*); *Kaiser Karls Geisel* (1908; *Charlemagne's Hostage*); *Griselda* (1909); *Die Ratten* (1911; *The Rats*); *Gabriel Schillings Flucht* (1912); *Festspiel in deutschen Reimen* (1913; *Commemoration Masque*); *Der Bogen des Odysseus* (1914; *The Bow of Odysseus*); *Winterballade* (1917); *Der weisse Heiland* (1920; *The White Saviour*); *Indipohdi* (1920); *Veland* (1925); *Dorothea Angermann* (1926); *Vor Sonnenuntergang* (1932); *Hamlet in Wittenberg* (1935); *Die Tochter der Kathedrale* (1939); *Die Atridentetralogie—Iphigenie in Delphi* (1941), *Iphigenie in Aulis* (1944), *Agamemnons Tod* (1948), *Elektra* (1948). The above translations can be found in *The Dramatic Works of Gerhart Hauptmann*, trans. by Ludwig Lewisohn *et al.*, 9 vol. (1912–29).

NOVELS: *Der Narr in Christo, Emanuel Quint* (1910; *The Fool in Christ, Emanuel Quint*, 1911); *Atlantis* (1912; Eng. trans., 1923); *Der Ketzer von Soana* (1918; *The Heretic of Soana*, 1923); *Phantom* (1922; Eng. trans., 1923); *Die Insel der grossen Mutter* (1924; *The Island of the Great Mother*, trans. by Willa and Edwin Muir, 1925); *Wanda* (1928); *Der neue Christophorus* (1943), fragment.

STORIES: *Bahnwärter Thiel* (1888); *Die Hochzeit auf Buchenhorst* (1932); *Das Meerwunder* (1934); *Der Schuss im Park* (1942).

VERSE: *Anna* (1921); *Till Eulenspiegel* (1928); *Der grosse Traum* (Part 1, 1942); *Neue Gedichte* (1946).

OTHER WORKS: *Griechischer Frühling* (1908), travel diary; *Buch der Leidenschaft* (1930); *Das Abenteuer meiner Jugend* (1937), autobiographical.

BIBLIOGRAPHY. WALTER A. REICHART, *Gerhart-Hauptmann-Bibliographie* (1969), is a selective listing of scholarly books and articles. Hauptmann's own archives (thousands of manu-

scripts, typescripts and letters, notebooks and diaries, many of them unpublished) are preserved in the Staatsbibliothek der Stiftung Preussischer Kulturbesitz, West Berlin. The Schiller-Nationalmuseum, Marbach-Neckar, West Germany, holds a sizable collection of primary and secondary materials (exhibition catalog: *Gerhart Hauptmann: Leben und Werk*, 1962) as does the Deutsche Akademie der Künste, East Berlin. 5,000 volumes of Hauptmann's library are preserved in the Märkisches Museum in East Berlin; 4,000 volumes in the Staatsbibliothek der Stiftung Preussischer Kulturbesitz; and 1,000 volumes in Hauptmann's house in Kloster on the isle of Hiddensee, East Germany.

Editions and Correspondence: Das Gesammelte Werk, series 1, 17 vol. (1942–43), series 2, drafts and unfinished works, not published. The more comprehensive 11-volume centenary edition, *Sämtliche Werke*, ed. principally by HANS EGON HASS (1962–73), contains previously unpublished completed works and substantial selections from drafts and unfinished writings. There is no edition of the correspondence; the letters to and from Ida Orloff are included in *Gerhart Hauptmann und Ida Orloff* (1969).

Biography and comprehensive appreciation: C.F.W. BEHL and FELIX A. VOIGT, *Chronik von Gerhart Hauptmanns Leben und Schaffen* (1957); HUGH F. GARTEN, *Gerhart Hauptmann* (1954), in English; KARL S. GUTHKE, *Gerhart Hauptmann: Weltbild im Werk* (1961); EBERHARD HILSCHER, *Gerhart Hauptmann* (1969); HANS DAIBER, *Gerhart Hauptmann, oder der letzte Klassiker* (1971).

Studies of phases, themes, groups of works, and problems: FELIX A. VOIGT and WALTER A. REICHART, *Hauptmann und Shakespeare*, 2nd ed. (1947); SIEGFRIED H. MULLER, *Gerhart Hauptmann and Goethe* (1949); RALPH FIEDLER, *Die späten Dramen Gerhart Hauptmanns* (1954); MARGARET SINDEN, *Gerhart Hauptmann: The Prose Plays* (1957); LEROY R. SHAW, *Witness of Deceit: Gerhart Hauptmann As Critic of Society* (1958); FREDERICK W.J. HEUSER, *Gerhart Hauptmann: Zu seinem Leben und Schaffen* (1961); *Hauptmann Centenary Lectures*, ed. by K.G. KNIGHT and F. NORMAN (1964); FELIX A. VOIGT, *Gerhart Hauptmann und die Antike* (1965).

(K.S.G.)

Havana

One of the great historic cities of the New World, Havana (Spanish La Habana) is the capital of the Republic of Cuba and its major economic, political, and cultural centre. Its core, Old Havana, still contains carefully preserved remnants of the colonial period, when Havana was the leading Spanish stronghold in the Americas and, for a time, the greatest port of the Western Hemisphere. Contemporary Havana, which includes also the modern city and its suburbs, has undergone a radical transformation since the Cuban Revolution of 1959, when it was essentially a developed, even overgrown city in an underdeveloped country. A major current goal of the government is to redress this imbalance.

The capital is located toward the western end of the northern coast of the island of Cuba. In an administrative reorganization of the country in October 1976, the boundaries of the city were extended and 15 municipalities within the new city limits were created. Thus, in the later 1970s Havana was the home of more than 1,900,000 persons, about 20 percent of the national total, concentrated in 286 square miles (740 square kilometres), less than 0.5 percent of the national territory.

The harbour

The city is located on the west side of a classic example of a "bottleneck" harbour, the narrow entrance of which, 270 yards wide and 1,500 yards long (250 by 1,400 metres), leads to a broad interior bay divided into the smaller bays of Marimelena, Guasabacoa, and Atarés. The city is crossed by the slow-moving Río Almendares, which enters the sea between the old cities of Marianao and Havana. Havana's most notable topographic feature is a limestone ridge some 200 feet (60 metres) high, which penetrates the city from the east, parallel to the coast, and terminates at the bay entrance in the heights of La Cabaña and El Morro. This same relief feature reappears in the hill occupied by the Universidad de La Habana (University of Havana) and the Castillo del Príncipe (Prince's Castle) and extends southward across Marianao. Other low hills include the Castillo de Atarés and those dotting the historic neighbourhoods of El Cerro, Jesús del Monte, and La Víbora.

Climate

The city's climate, tropical yet mild, is tempered by the location of the island in the belt of the trade winds and by the warm Gulf Stream offshore; occasionally in winter a cold front from the North American mainland brings cold northwest winds (the Norte) that temporarily displace the usual mild onshore breezes. Relative humidity averages 78 percent, and rainfall averages about 73 inches (1,850 millimetres) annually, falling largely in the May to October rainy season. Average temperature is 79° F (26° C), varying by only about 9° F (5° C) throughout the year. (For information on related topics, see LATIN AMERICA AND THE CARIBBEAN, COLONIAL; CUBA; and CUBA, HISTORY OF.)

History. *Foundation and early growth.* The city of Havana was founded in the southern part of the province of the same name by the Spanish colonizer Diego de Velázquez de Cuéllar in 1515. The first location may have been either on the site now occupied by the little town of Surgidero de Batabanó, or nearby, where the Río Mayabeque flows into the sea. Its inhabitants later moved to the northern coast in search of better climatic conditions, then began to shift toward the city's present position, finally establishing themselves at the port of Carenas, today the port of Havana, around 1519.

Because of its geographic position, Havana was a port of call for Spanish ships travelling between the colonies in America and the Iberian Peninsula. As a result, the primitive village slowly evolved from a group of rustic houses into a city of stone structures, including churches and public buildings, with carefully planned paved streets and public squares.

In 1538 the city was attacked, and in 1555 it was plundered, by French buccaneers. Philip II of Spain in 1589 ordered the erection of the two forts, La Punta and El Morro, at the entrance to the passage leading to the harbour, to reduce the danger from pirates.

In 1656 the construction of a defensive city wall began, with important consequences, both military and structural. Within the walls the area now known as Old Havana (La Habana vieja) developed, and, though it has been constantly modified, it retains many characteristically colonial buildings as well as the original crooked streets. The walls made Havana the leading Spanish stronghold in America, a status soon reflected in the designations "Key to the New World" and "Rampart of the Indies," titles assigned the city by the Spanish crown. In 1607 Havana had officially been named the island's capital by royal decree, though it had occupied this position in practice since 1553.

English occupation

The 18th and 19th centuries. In 1762, during the Seven Years' War, after bloody battles around the capital the English captured it. Their occupation lasted only 11 months, after which the city was returned to Spain in exchange for the territory of Florida. The brief occupation bestowed important benefits on the island's landholders: the English reduced some of the limitations on foreign commerce and eliminated the monopoly held by the Real Compañía de Comercio (Royal Commerce Company). On their return, the Spanish had no alternative but to continue the policies established by the English. In 1765 Havana became a free port for commerce with Spain, leading to a period of economic prosperity, which in turn consolidated the power of the nascent Cuban aristocracy.

The city's original population was remarkably heterogeneous; in addition to its customary inhabitants, it accommodated transient soldiers, sailors, clergy, merchants, and ordinary travellers who often had to spend many months in the city waiting for the last ship of the fleet to arrive so that in convoy—the so-called Fleet System, for protection against pirates—they could safely make the return voyage to Spain. There were some 50,000 persons in Havana toward the middle of the 18th century, including the population of the suburbs that were already appearing outside the wall. The third most heavily populated city in the Americas at that time, it was also the New World's most important port in terms of volume of commercial transactions.

The city continued to grow during the 19th century but

El Vedado section of Havana.
Sovfoto

was no longer merely a place of transit. It had begun to export sugar, coffee, tobacco, and rum, and its economic health was reflected in further growth of the suburbs. In 1817 the tobacco monopoly was suppressed, and a year later free commerce with other countries was authorized.

The 20th century. The city's growth continued in the 20th century, especially to the west and south, and Havana became a striking, modern city, with wide avenues and large buildings. This urban growth and concentration, disproportionate to the rest of the country, was accompanied by the creation of an incipient industrial base that has been insufficient, however, to absorb the surplus work force emigrating to the capital from rural areas. Since the revolution in 1959, attempts have been made to reverse this flow of population.

Layout and architecture. As noted above, the capital first developed within its walls but soon began to expand outward into suburban neighbourhoods. The city had already greatly exceeded its original walled boundaries by the 19th century, and its subsequent growth has been primarily toward the west and south, with increasingly more distant areas being integrated into the urban nucleus. The city's expansion to the east was facilitated by the construction of an 875-yard (800-metre) tunnel under the entrance to the bay, permitting the creation of such new suburban neighbourhoods as Habana del Este in a previously inaccessible area. Contemporary Havana is thus an urban, political, and administrative unit comprising the old cities of Havana, Marianao, Regla, Guanabacoa, Santiago de las Vegas, and Santa María del Rosario.

Composition of metropolitan Havana

Some of the city's most imposing architecture is located around the Plaza de la Revolución (Revolutionary Square, formerly the Plaza Cívica); the monument to José Martí, the "apostle of independence," in the centre, is surrounded by such modern public buildings as the Centro del Gobierno Nacional and buildings housing the Central Committee of the Communist Party of Cuba, as well as the Armed Forces, Interior, Communications, and Construction ministries, the Biblioteca Nacional (National Library), the Junta Central de Planificación (or Juceplan; Central Planning Board), and others. In the centre of the city, imposing in style although less modern in architecture, are the buildings housing the Academia de Ciencias de Cuba (Academy of Sciences of Cuba, the former National Capitol), the Museo de la Revolución (Museum of the Revolution, in the old Presidential Palace), the Centro Asturiano (Asturian Centre) and the Centro Gallego (Galician Centre), founded as clubs by Spanish immigrants, and the Palacio Aldama.

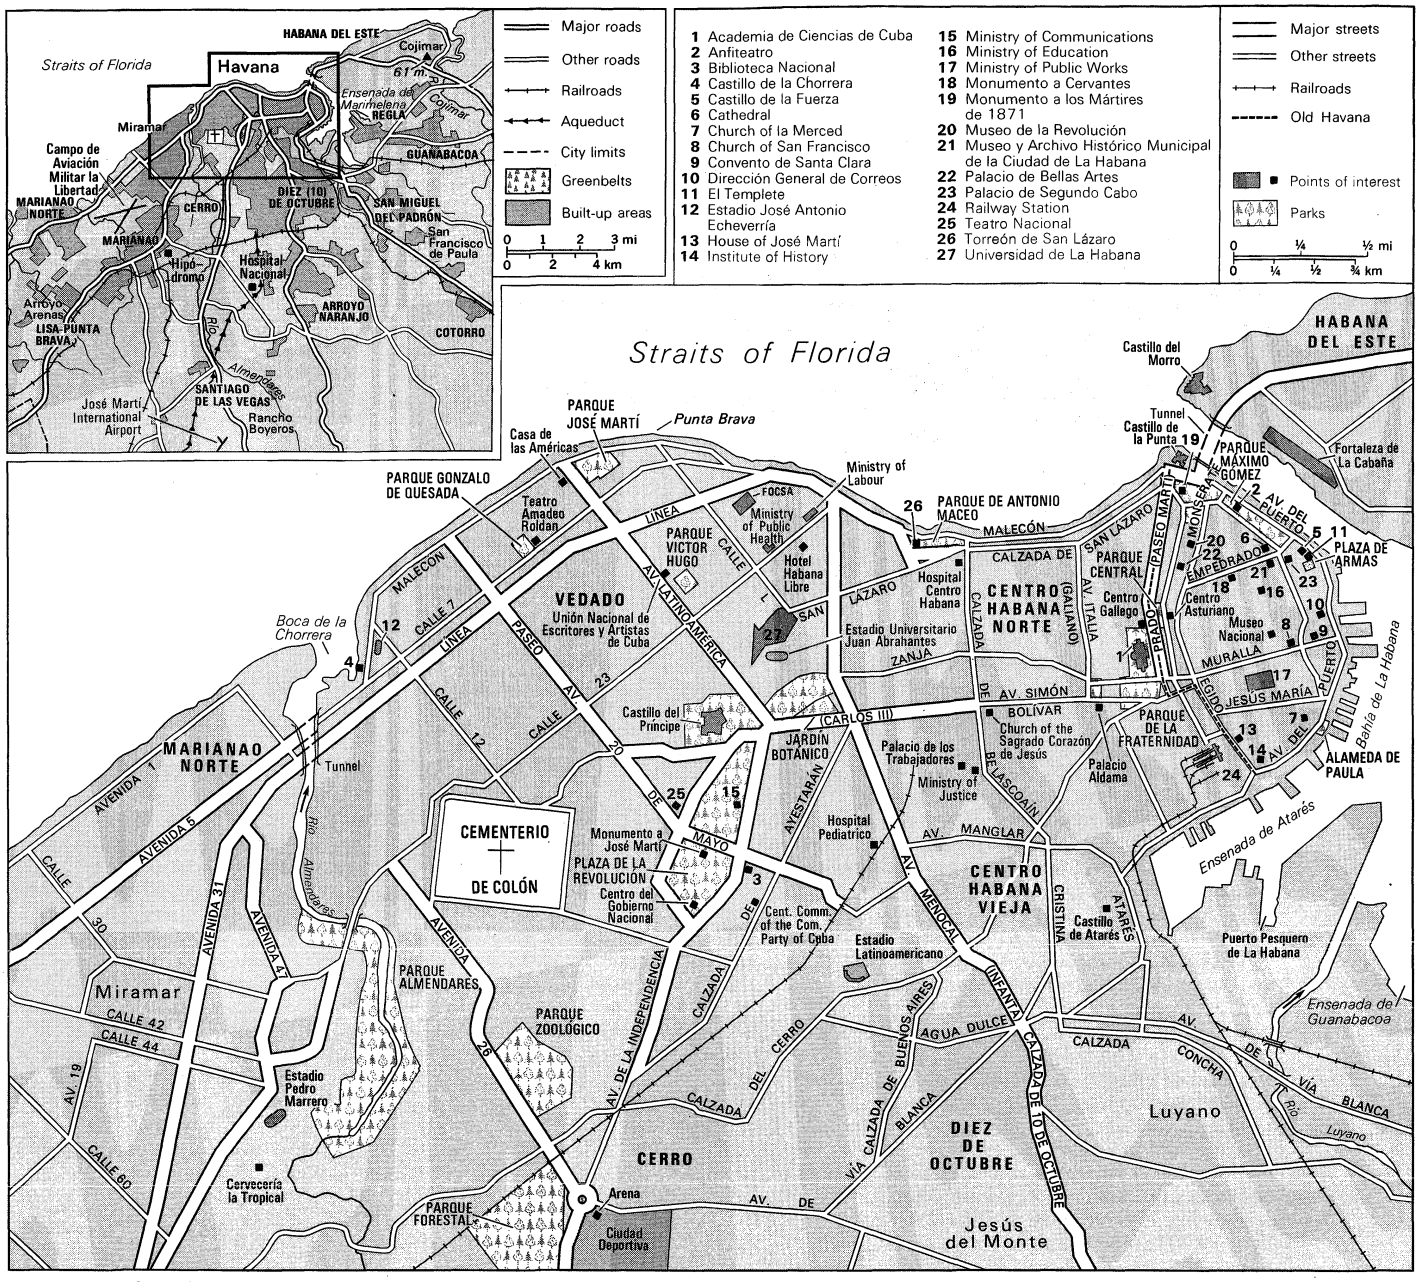
Old Havana, the original urban nucleus next to the port, is characterized by history-laden buildings in pure colonial style. Among the most outstanding of these is the Palacio de los Capitanes Generales (Palace of the Captains General), completed in 1793; from 1902 this accommodated the first presidents of the republic and later was the home of the Ayuntamiento (City Council). After the revolution it was restored to its former architectural magnificence and now houses the Museo y Archivo Histórico Municipal de la Ciudad de La Habana, the city's historical museum and archives. Old Havana also contains the Palacio del Segundo Cabo (*i.e.*, of the former second-ranking military chief of the province), also restored and now the seat of the Consejo Nacional de Cultura (National Council of Culture), and El Templete.

The architectural heritage of Old Havana

Other outstanding architectural features are those fortresses built for the city's defense, such as the Castillo del Morro, or Morro Castle (to which was subsequently added the lighthouse that guides ships to the port of Havana, a famous symbol of the city), the Fortaleza de La Cabaña, the Castillo de la Punta, the Castillo de Atarés, the Castillo del Príncipe, the Torreón de San Lázaro, the Castillo de la Chorrera, and the Castillo de la Fuerza, a monumental fortress perhaps built on the city's original site. The last named is the oldest colonial military building in the Americas, having been rebuilt between 1565 and 1583 on the site of a fortress built in 1538 on the orders of the colonizer and explorer Hernando de Soto. Havana's ancient ruined walls are still visible, as are many other buildings bearing witness to the colonial city's military power.

Old Havana also contains such fine colonial churches as the late 18th-century cathedral; the church of San Francisco, finished in 1575 and reconstructed 1731–37 (now housing the central post office); and the Convento de Santa Clara, built in 1644 and protecting within its great interior patio some of the city's earliest houses and streets.

Other fine architecture may be found in El Vedado (The Park), an area of the city characterized by large, modern buildings. Outstanding among these are the Hotel Habana Libre, the structure known for its builders as FOCSA (Ferrocarriles Occidentales de Cuba, Sociedad Anónima), the medical insurance building, the Sugar Industry and



Central Havana.

External Commerce ministries, and the Instituto Cubano de Radiodifusión (Cuban Broadcasting Institute) building. The Cementerio de Colón (Columbus Cemetery) contains many important historical monuments.

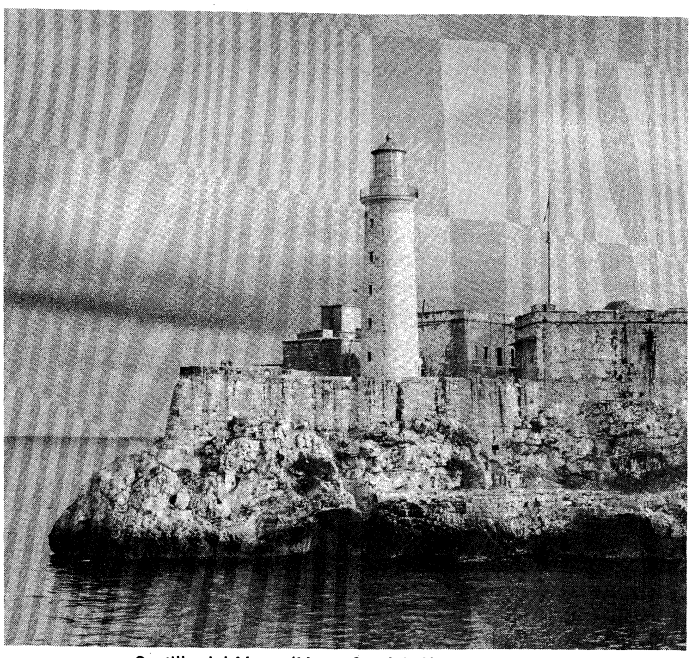
The city has numerous parks, notably the Parque Central; the Alameda de Paula next to the port; the Plaza de Armas, completed in 1792; the Parque de la Fraternidad, formerly the Campo de Marte; and the Plaza de la Revolución, as well as the Antonio Maceo and Máximo Gómez parks and the park of the Mártires de la Revolución (Martyrs of the Revolution).

Traffic flow is facilitated by many first-class avenues. These include the Malecón, an avenue extending several miles from the port entrance and along the coast to the outlet of the Río Almendares, where it enters a tunnel beneath the river and emerges at Avenida Quinta (Fifth Avenue) of Miramar. Another very long avenue is Línea, in El Vedado, which crosses this entire section and then passes through the same tunnel under the river to Marianao Norte, where it becomes another avenue crossing the entire residential area and proceeding miles farther to a junction with an avenue completely encircling the urban perimeter. Other avenues and streets include the Paseo de José Martí (formerly the Prado), which follows the old wall, and the Avenida del Puerto, the Calzada de Belascoaín, Calzada del Cerro, Calzada de Galiano, and Avenida de la Independencia (formerly Boyeros). Multiple housing units, constructed after the revolution to house former residents of the city's slum areas, add a major new element to the urban landscape.

The avenues

The people of Havana. The reorganization of Cuba in October 1976 extended Havana's city limits to what was formerly the boundary of the metropolitan area; the area within these boundaries was divided into 15 municipalities, replacing the six divisions into which the former metropolitan Havana had been divided. The city's present constituent parts are: Arroyo Naranjo, Centro Habana Norte, Centro Habana Vieja, Cerro, Cotorro, Diez (10) de Octubre, Guanabacoa, Habana del Este, Lisa-Punta Brava, Marianao, Marianao Norte, Regla, San Miguel del Padrón, Santiago de las Vegas, and Vedado. With 6,650 inhabitants per square mile, it is also Cuba's most densely populated area. Metropolitan Havana's birth rate approximates 20.2 per 1,000, its death rate 8.4, and its infant mortality rate 39.8.

The population of Havana, like that of the rest of Cuba,



Castillo del Morro (Morro Castle), Havana.
Gus Parras

is very heterogeneous. Its people include whites, who are basically descendants of the Spaniards; blacks, descendants of former slaves; and mestizos (of mixed ancestry). In the 19th century there was an immigration of Chinese to the island; in the first half of the 20th century, an influx of Spaniards, as well as Italians, French, and Germans; and, after World War II, Jews from central Europe. The city's population has increased steadily since its founding: 51,307 inhabitants were recorded in 1791; 96,304 in 1811; 184,508 in 1841; 253,418 in 1899; 363,506 in 1919; 542,522 in 1931; 676,376 in 1943; 1,880,700 in 1958; and 1,751,216 in 1970. In 1975 the population of 1,900,000 occupied an area nearly 100 square miles (260 square kilometres) larger than the area within the boundaries of 1970.

Population growth

In the 20th century, Havana's population increases in periods of economic crisis, when masses of landless farmers come to the capital seeking employment. Statistics indicate that when the sugar industry (Cuba's principal economic activity) is flourishing, the rural population grows at a more rapid rate than that of Havana, and that the reverse occurs in periods of economic crisis. This demographic rhythm has become less pronounced since the revolution, a result of government policy to develop other parts of the country and alleviate excessive metropolitan growth.

Economic life. The Cuban government is attempting to take advantage of the capital's existing infrastructure (*i.e.*, its technical and administrative resources and the competence and relative abundance of its work force), which is the nation's most developed, but only in those activities where its economy complements that being developed in the rest of the country. By the late 1960s, Havana had more than 885,000 inhabitants of working age, of whom almost 550,000 were economically active; some 290,000 were housewives; some 44,000 were nonworking students; and the rest were engaged in other forms of housework or were not working. The active labour force was divided into production (about 374,000) and services (155,000). Within the first group, industrial workers numbered 133,000; agricultural, 57,000; commercial, 64,000; transportation, 46,000; and construction, 46,000. In services, the two largest sectors (each with almost 40,000 workers) were education and health. More than 12,000 persons were self-employed.

Havana is Cuba's most important industrial, importing, and distributing centre, with a considerable part of the manufacturing and processing industries of the country concentrated in its environs. The different branches include the food processing industry, with numerous factories and a wide range of products; shipyards, devoted primarily to building various kinds of fishing boats; and the automotive industry, notably the construction of medium-sized urban and rural buses. Beverages and liquors produced include liquors and rums. Textile manufactures include knitted fabrics and ready-to-wear clothing, while the leather and footwear industry produces boots and shoes. Other activities include those associated with electric power plants; gasworks; fertilizer plants; printing (especially of books of all kinds); paper manufacturing; furniture and packaging; metallurgy; a wide range of pharmaceutical and chemical products including perfumes, soaps, detergents, plastics, and stock feed; and petroleum refineries supplying the greater part of the country's demand. The quality products of the tobacco industry, notably Havana cigars, have brought Cuba world fame. The fishing industry is particularly notable; the building of the Puerto Pesquero de La Habana (Havana Fishing Port), with all its auxiliary installations, together with the constant growth of the fleet itself, led to a quadrupling of the fish catch over the 1960s.

Expansion of the fishing industry

Most of Cuba's imports and an appreciable amount of its exports pass through the port of Havana; the total tonnage handled now exceeds the port's effective unloading capacity, making larger installations a necessity.

Since 1967, the larger part of the population of the city has been involved, directly or indirectly, in the development of the Cordón de La Habana (Havana Cordon, or Green Belt), a belt of 71,530 acres (28,948 hectares), 60 percent of it arable. In this vast sector, plantains (*plátanos*) and root crops (manioc, *malanga*, yams, and so on) are produced for home use as well as for the urban domestic market; crop failures in this labour-intensive agriculture have been largely eliminated by the use of irrigation systems. Crops from perennials, such as coffee, citrus fruits, mangoes, soursops, and guavas, are also harvested. Many people engage in dairying, poultry production, and pig raising. New roads, new urban nuclei for workers, and additional plants for processing such products as coffee and fruits all have aided in the dispersion of population.

Political, governmental, and social institutions. Havana is the political, administrative, and cultural centre of Cuba. It is the seat of the revolutionary government and of the Central Committee of the Communist Party of Cuba, as well as of all state bodies directing governmental tasks, including 31 ministries. Judicial power resides in the Tribunal Supremo Popular, divided into four chambers. Other important government organizations include the Central Planning Board (Junta Central de Planificación, or Juceplan), the agency charged with the central planning of the economy and with allocation of resources; the National Institute of the Tourist Industry (Instituto Nacional de la Industria Turística, or INIT); the National Fisheries Institute (Instituto Nacional de la Pesca, or INP); the National Institute of Agrarian Reform (Instituto Nacional de Reforma Agraria, or INRA); and several other bodies concerned with sport and recreation, technology, forestry, and agriculture. All these agencies are directly under the national Council of Ministers.

Government-sponsored mass organizations also play an important role in public life in the contemporary city and in the country. Paramount is the Partido Comunista de Cuba (PCC; Communist Party of Cuba), the only political party and the organizing and directing force of all the elements of the Cuban government. The Unión de Jóvenes Comunistas (UJC; Communist Youth Organization) is for young persons between the ages of 14 and 27; it absorbed the National Federation of University Students, important in student affairs before the revolution. An adjunct of the UJC is the Pioneros (Pioneers), for children between the ages of 7 and 14. The Federación de Mujeres Cubanas, or FMC (Federation of Cuban Women), founded in 1960, and other organizations also help advance the ideals of the revolution.

Mass organizations

The Committees for Defense of the Revolution (Comités de Defensa de la Revolución, or CDR) are a particu-

larly distinctive feature of present-day Cuban life. Their members—estimated to include almost 25 percent of the national population—are organized by districts throughout the country, and their chief function is to watch for counter-revolutionary activities on the part of their neighbours and report them to the national security apparatus; they are referred to by hostile critics as neighbourhood spy rings. They serve other functions as well, including public health and Marxist indoctrination of the public.

All these bodies are interconnected in their functions, and their objective is continued transformation of Cuban society. As the Communist authorities emphasize, increasing mass participation in what is regarded as an ever changing revolutionary process makes new forms of organization and new institutions necessary.

Services. Havana is the centre from which communications radiate to the rest of Cuba, a particularly disadvantageous situation in view of the length and narrowness of the island.

Transportation

Havana was the first city in all of Latin America to possess a railroad, a line inaugurated in 1837 between Havana and Bejucal. Railroads link Havana with the provincial capitals and other major cities. The city is also connected with the rest of the country by bus routes. The José Martí International Airport (Aeropuerto Internacional José Martí) provides flights to the principal Cuban cities and links the capital with foreign centres.

There is heavy traffic within the city itself, consisting almost exclusively of buses, which transport more than 900,000,000 passengers annually. There are also taxi services at hospitals, hotels, bus and railway terminals, and the airport. The port of Havana is visited by ships of many nations; shipping services are also available to and from Cuban ports.

The city maintains the usual modern urban services. The telephone service is well developed, and public telephones are free. The capital contains 10 radio stations, most of which broadcast to the entire country, and 14 shortwave stations broadcasting cultural, entertainment, musical, and news programs. Two television channels transmit a variety of programs; an educational television channel operates from the José Antonio Echevarría University City.

The city has 10 general hospitals, 26 clinics, and supplementary specialized clinics and dispensaries. A notable feature is the 100 or so nurseries (*círculos infantiles*), with about 20,000 children under five years of age enrolled by the end of the 1960s.

Commercial and service establishments include some 6,000 food distribution centres, almost 1,500 for industrial products, and more than 4,000 cafeterias and restaurants, as well as numerous hotels. A student and worker dining room service, with more than 3,400 establishments, supplies free meals to students and very low-priced meals to workers.

Cultural life and recreation. Spanish is spoken in Havana, as in the rest of Cuba, for Spain was the country's most important cultural influence. The capital is prominent in national cultural life. There are numerous centres

Education

of instruction in the city, outstanding among them being the University of Havana (Universidad de La Habana), which has about 54,000 students and an international reputation. In addition, there are some 2,400 educational centres of various types, with a total enrollment of almost 325,000 students; primary schools alone account for 200,000 students. Education has been given high priority since the revolution, initially with a campaign to eradicate illiteracy. By the start of the 1970s, emphasis had shifted to experiments with new methods and forms aimed at giving more students exposure to a university education. All education is directed by the national government.

Mass cultural activities are primarily under the direction of the National Council of Culture (Consejo Nacional de Cultura, or CNC). They include theatrical events, activities for children, literary functions, and many activities for hobbyists. Attendance at public exhibitions of various kinds is high.

Havana is the home of the Ballet Nacional de Cuba (National Ballet of Cuba), which, together with its first star, Alicia Alonso, has achieved continuous successes in its performances at home and abroad. The Havana Symphony Orchestra offers regular concerts, and there are numerous other musical groups performing for the public, with annual attendance approaching 500,000. Classes in ballet, modern dance, theatre, painting, sculpture, and music are available.

Literary activities in the city are encouraged by contests held by such government-sponsored institutions as the National Union of Writers and Artists of Cuba (Unión Nacional de Escritores y Artistas de Cuba, or UNEAC) and the House of the Americas (Casa de las Américas), the latter being international in character, and also by the University of Havana. The city has some 16 libraries, and the National Library (Biblioteca Nacional), with 351,000 cataloged volumes, is outstanding. Film making in the city is under the supervision of the Cuban Institute of Cinematographic Art and Industry (Instituto Cubano del Arte e Industria Cinematográfica, or ICAIC); its distinguished products, with a documentary emphasis, have won international recognition. Film projection equipment mounted on vehicles offers free programs in schools, parks, hospitals, factories, and farms.

Scientific research in the city is stimulated and coordinated by the Academy of Sciences of Cuba and other related institutions. These include the National Centre of Scientific Research (Centro Nacional de Investigaciones Científicas, or CNIC) and the Cuban Institute for Research into the Derivatives of Sugarcane (Instituto Cubano de Investigaciones de los Derivados de la Caña de Azúcar, or ICIDCA).

Newspapers

There are two newspapers in Havana, both official organs: *Granma*, the voice of the Central Committee of the Communist Party of Cuba (named for the yacht that carried Fidel Castro and his followers to Cuba in December 1956), and *Juventud Rebelde* ("Rebel Youth"), speaking for the Young Communist Organization. There are numerous popular magazines, most of which are distributed nationally and a few of which circulate throughout Latin America. Publications from other Communist countries are available on newsstands.

By the late 1960s, the city had almost 1,000 separate sports installations. Important centres are the Ciudad Deportiva (Sports City), containing the offices of the National Institute of Sports, Physical Education and Recreation (Instituto Nacional Deportes, Educación, Física y Recreo, or INDER) and noted for its architectural beauty and its large capacity (16,000). The Latin-American Stadium (Estadio Latinoamericano) has a capacity of 58,000, and the Juan Abrahantes University Stadium (Estadio Universitario Juan Abrahantes; capacity 10,000), with multiple installations, and the Pedro Marrero Stadium (Estadio Pedro Marrero; capacity 15,000) are also important. All sporting events are free to the public. Havana has also been the site of several international sporting events, including chess and fencing championships.

The city possesses a large and very popular zoo, the Parque Zoológico, and an aquarium containing the principal tropical marine species. On the right bank of the Río Almendares, in the Miramar section, the Parque Almendares is a well-equipped recreation area for children and adults. Also noteworthy are the social clubs located on the beaches bordering the city, which provide facilities for water sports and also include restaurants, cafeterias, and dance halls.

BIBLIOGRAPHY. Basic historical works are EMILIO ROIG DE LEUCHSENRING, *La Habana: apuntes históricos*, 2nd ed., 3 vol. (1963–64); JULIO LE RIVEREND, *La Habana: biografía de una provincia* (1960) and *Historia económica de Cuba*, 2nd ed. (1965); and MANUEL MORENO FRAGINALS, *El Ingenio*, vol. 1, *La Habana* (1964). ANTONIO NUNEZ JIMENEZ, *Geografía de Cuba*, 3rd ed. (1965); and the ACADEMIA DE CIENCIAS DE CUBA, *Atlas nacional de Cuba* (1970), give a general survey of the urban characteristics, boundaries, and demography of Havana. Economic life is covered in detail in the Cuban economic section of the *Economía y desarrollo* (1970–).

(I.E./R.E.Cr./Ed.)

Hawaii

A group of volcanic islands in the central Pacific Ocean, Hawaii was characterized by the American Mark Twain as "the loveliest fleet of islands that lies anchored in any ocean." It became, in 1959, the 50th state of the United States of America.

By the early 1970s, it was economically vigorous, with diversified agriculture and manufacturing; strategically important to the global defense system of the United States; a Pacific Basin transportation and cultural centre, often called "the Crossroads of the Pacific"; and a major tourist mecca. Hawaiian activities gaining in national and international importance by the early 1970s include research and development in oceanography, geophysics, astronautics, satellite communications, and biomedicine.

The capital city of Honolulu, on the island of Oahu, is 2,397 miles from San Francisco to the east, and 5,293 miles from Manila, in the Philippines, to the west. For information on related topics, see the articles PACIFIC ISLANDS; OCEANIA, HISTORY OF; UNITED STATES; and PACIFIC OCEAN.

THE HISTORY OF HAWAII

The early Hawaiians

The first Hawaiians are thought to have reached the islands by canoe about AD 400, and for nine centuries such contacts continued with other parts of Polynesia, notably Tahiti. Powerful classes of chiefs and priests emerged and established themselves, as did internecine conflicts not dissimilar to the feudal struggles in Europe, with complicated land rights contributing to the disputes. The early Hawaiians lacked a written language, and their culture was entirely oral, rich in myth, legend, and practical knowledge especially of animals and plant life. The material life of the islands was hampered by the lack of metal, pottery, or beasts of burden, but there was great skill in the use of wood, shell, stone, and bone, and the huge outrigger canoes were technical marvels. Navigational methods were well developed, and there was an elaborate calendar. Athletic contests encouraged warrior skills.

European discovery. Capt. James Cook, the English explorer and navigator, is regarded as having made the first European discovery of Hawaii, first landing at Waimea, Kauai Island, on January 20, 1778, returning the following year to meet his death in an affray with a number of the local inhabitants at Kealakekua Bay, Hawaii.

The initial discovery was followed by a period of intermittent contact with the West during which the remarkable Kamehameha I, utilizing European military technology and weapons, emerged as an outstanding Hawaiian leader, seizing and consolidating control over most of the island group. For 85 years thereafter, monarchs ruled over the Hawaiian Kingdom. In the early years of the 19th century, the American whaling fleet took up the practice of wintering in Hawaii, and the islands were visited with mounting frequency by explorers, traders, and adventurers. Capt. George Vancouver had introduced livestock to the island in 1794. In 1820 the first of 15 companies of New England missionaries arrived. By midcentury there were frame houses, horse-drawn vehicles, schools, churches, taverns, and mercantile establishments. A written language had been introduced, and European and American skills and religious beliefs—Protestant and Catholic—imported; Hawaiian culture was irrevocably changed.

Establishment of United States dominance. Political manoeuvring between United States, British, and French consuls and naval forces caused uncertainty in the governmental situation. The foundations of constitutional government were nevertheless laid down with the promulgation, by Kamehameha III, of a Declaration of Rights (June 7, 1839), an Edict of Toleration (June 17, 1839), and a written constitution (October 8, 1840). This step forward—made under missionary influence—was followed by formal avowals of Hawaiian independence by the United States, Britain, and France. The ambitions of these powers continued unabated, however, with a succession of overt and covert diplomatic moves, culminating in the signing of a reciprocity treaty with the United States in 1875. Hawaiian kings continued to attempt to preserve their peoples' culture and society, but the turbulent second half of the 19th century was to witness, by the joint annexation resolution of Congress in 1898, the final establishment of United States domination. This status was confirmed by the establishment of a territory on June 14, 1900.

The period until 1940 was to see a great growth in population, the development of a modern economy based on the production of sugar and pineapples for consumption on the mainland, and the growth of transport and military links. Movements for statehood, based in part on the fact that Hawaii had to pay United States taxes without corresponding legislative representation, began to make themselves heard. The Japanese attack on Pearl Harbor, on December 7, 1941, precipitated not only Hawaii but the United States as a whole into the conflict of World War II, and the islands witnessed an upsurge of military activity and a sometimes controversial curtailment of civil liberties. The post-1945 period was marked by further economic consolidation and a long constitutional path to statehood, a status finally achieved in 1959.

THE NATURAL AND HUMAN LANDSCAPE

The natural environment. *Surface features.* The state actually consists of the tops of a chain of submerged volcanic mountains that form eight major islands and 124 small islets, stretching in a 1,500-mile crescent from Kure Island in the west to the island of Hawaii in the east, with a combined land area of 6,425 square miles (16,641 square kilometres). With the exception of Midway, a United States naval reservation near the western end of the archipelago, the leeward coral atolls and central lava islets, forming a total of only 3.2 square miles, are in the Hawaiian Islands National Wildlife Refuge.

Islands comprising Hawaii

The eight major islands at the eastern end of the chain are, from west to east, Niihau, Kauai, Oahu, Molokai, Lanai, Kahoolawe, Maui, and Hawaii. The volcanic activity that molded the island landscapes has long since become dormant, with the exception of the volcanoes of Mauna Loa and Kilauea on the easternmost and largest island, Hawaii, where spectacular eruptions and lava flows take place from time to time. The highest Hawaiian mountains are Mauna Kea and Mauna Loa, reaching 13,796 feet (4,205 metres) and 13,677 feet (4,169 metres) above sea level, respectively.

There is little sign of erosion in the geologically young areas, where the terrain is comparatively domelike and the volcanic craters are clearly defined. In the contrasting older areas, during the glacial age, the mountains were shaped and eroded by ice and by the action of sea, rain, and wind. Their aspects thus include sharp and craggy silhouettes; abrupt, literally grooved cliffs pocked with caves; deep valleys; smoothed saddle areas; and coastal plains. The powerful Pacific surf, churning and crashing against the fringing coral shelves and the lava shorelines, has carried minute shells onto the shore and reduced coral and large shells to sand, creating the state's famous expanses of beach.

Soils and drainage patterns

Volcanic ash, gravel, rotted vegetation, crumbling lava, and windblown sand and dust all help to make up the alluvial, residual, and organic soils found in various depths and densities in valley floors, the regions between mountain ranges, and along the shores. Oxidation of iron causes a ubiquitous, bright-red soil and rock strata. The iron content is, however, insufficient for smelting, and there are no coal or oil deposits.

As the topography is generally abruptly descending or sloping, there are few surface collecting basins or lakes. Excess rainfall seeps through porous mountain areas to collect in subterranean chambers and layers retained by less permeable lava and ash beds or is prevented by underlying salt water from seeping to the sea. The resultant artesian water supply is tapped by man in many places, for use in irrigation and also for human consumption.

Where rainwater has converged in high mountain

pockets and then plunged great distances, it has dug deep pools at the foot of the falls, overflowed, and cut streams downward in its pursuit to the sea. Some streams and small rivers meander and wind through wide valleys to lowlands and debouch concisely into the ocean or disperse themselves into swampland.

Climate. Though Hawaii lies in the earth's tropical zone, its climate is temperate. The Pacific anticyclone, a large atmospheric eddy located northeast of Hawaii, is the generator of prevailing trade winds from the northeast, which are cooled by their journey over the ocean. The ocean is, in effect, a natural air-conditioner.

The average temperature in Honolulu is 71.9° F (22.2° C) in the coolest month and 78.4° F (25.8° C) in the warmest, with extremes from 57° F (14° C) to 88° F (31° C) having been recorded. Average water temperatures off Waikiki Beach, near Honolulu, range from 75° F (24° C) in late February to 79° F (26° C) in late September. Mountainous regions are considerably cooler, especially during the winter months, when there can be frost; temperatures as low as 14° F (−10° C) have been recorded on the summit of Haleakala, on Maui, and winter snows frequently blanket the crests of Mauna Kea and Mauna Loa, on Hawaii.

Rainfall variations throughout the state are dramatic. Mt. Waialeale, on the island of Kauai, is probably the wettest spot in the world, with an annual rainfall of 486.1 inches. The driest area in the islands is at Puako, on the island of Hawaii, where the average annual rainfall is only 9.46 inches. The average yearly rainfall in Honolulu is 23.9 inches, and, in Hilo, it is 136.62 inches.

As moisture-laden air is carried over the islands, most frequently by the trade winds, it is apt to condense, form cloudcaps, and dissipate against the shores and mountains of the windward coasts, which are therefore more lush in foliage than the leeward coasts.

Plant and animal life. The seeds of endemic plant species were carried to Hawaii by birds, riding winds, or moving in currents and tides, bringing about extensive forestation, shrubbery, and grasslands where soil and precipitation were favourable. From the time of the first Polynesian settlement to the present day, a tremendous variety of food and ornamental plant life from many parts of the world has been introduced. Food plants grown commercially or in backyards for home consumption include sugarcane, pineapples, papayas, bananas, mangoes, guavas, lichee, coconuts, avocados, breadfruit, macadamia nuts, limes, passion fruit, taros, and tamarinds. Nearly all varieties of common garden vegetables are raised in the islands, and flowers abound all year.

The effects of isolation on natural life

Endemic birds, long isolated from others of their kind, have taken on certain characteristics of their own. These include the Hawaiian goose (nene), the Hawaiian stilt, and a variety of small forest birds. Some species have become extremely rare, but as the result of an increased environmental awareness, great strides have been taken in recent years to preclude their extinction. Seabirds nest in profusion on the western islands of the archipelago and to a far lesser extent among the major eastern islands. There has been considerable importation of birdlife during the last 100 years. Quantities of mynas, sparrows, cardinals, and doves inhabit the trees in both urban and country areas. Every fall the small golden plover make an awe-inspiring, nonstop 3,000-mile flight from Alaska to Hawaii, where they spend the winter, together with ducks from Alaska, Canada, and the northwestern United States.

Most forms of common domestic animals and poultry are raised on farm and beef ranches, and a large percentage of Hawaiian households keep dogs and cats as pets. What wild-animal life there is consists of mongooses, rats, frogs, toads, and, in the more remote regions of some of the ranches, deer, pigs, sheep, and goats. The Hawaiian insect population is multitudinous, and marine life abounds in Hawaiian waters.

Patterns of settlement. Agricultural and fishing activities bring about extensive and scattered rural settlement, ranging from tiny fishing villages far off the main roads, scant clusters of small houses in isolated valleys, solitary farm and ranch houses, to large coastal and upland villages and plantation and ranch towns.

The older houses in the smaller villages are largely single-family, raised, frame structures, with corrugated-iron roofs. Plants of native origin skirt the foundations of houses, and the yards are informally planted with fruit and flower trees. In all but the very small villages, there are a school, markets, post office, firehouse, and at least one church. The day's activities traditionally begin early and end early, following the sun. The life-style of the rural people appears to be simpler and less sophisticated than that of the urban populations, who are exposed to constant and varied activity, and the country dwellers tend to retain more of the speech patterns and customs of their distinctive ethnic backgrounds.

Village and urban life

During the 1950s and 1960s, Hawaii experienced a building boom of such magnitude that the configuration of entire towns was altered. The most graphic example of this was in the city of Honolulu, where construction of 20- and 30-story buildings gave the city, once sprawling and low, a thrusting, many-levelled skyline. On Oahu, erstwhile vacation or agricultural towns have become expansive residential areas for commuters to Honolulu and Pearl Harbor.

Urban settlement once consisted almost entirely of single-family dwellings, individual business houses and shops, small markets, and three- or four-story hotels; but, with the increase of resident and touring population during the preceding two decades, Hawaiian towns and cities were, by the early 1970s, building more and more high-rise apartment houses, hotels, and business establishments, with the traditional individual shopkeepers becoming absorbed into the complexes of shopping centres and supermarkets.

The planned city, a new housing concept in Hawaii, is gathering momentum in the 1970s and is being carried out in areas that were previously open spaces or given over to agriculture.

Throughout the state there are large hotels and resort complexes, creating communities that are not without colour in themselves.

New construction throughout the state is thriving, and thus the physical aspect of Hawaii, in terms of the landscape under human settlement, continues to undergo considerable change.

THE PEOPLE OF HAWAII

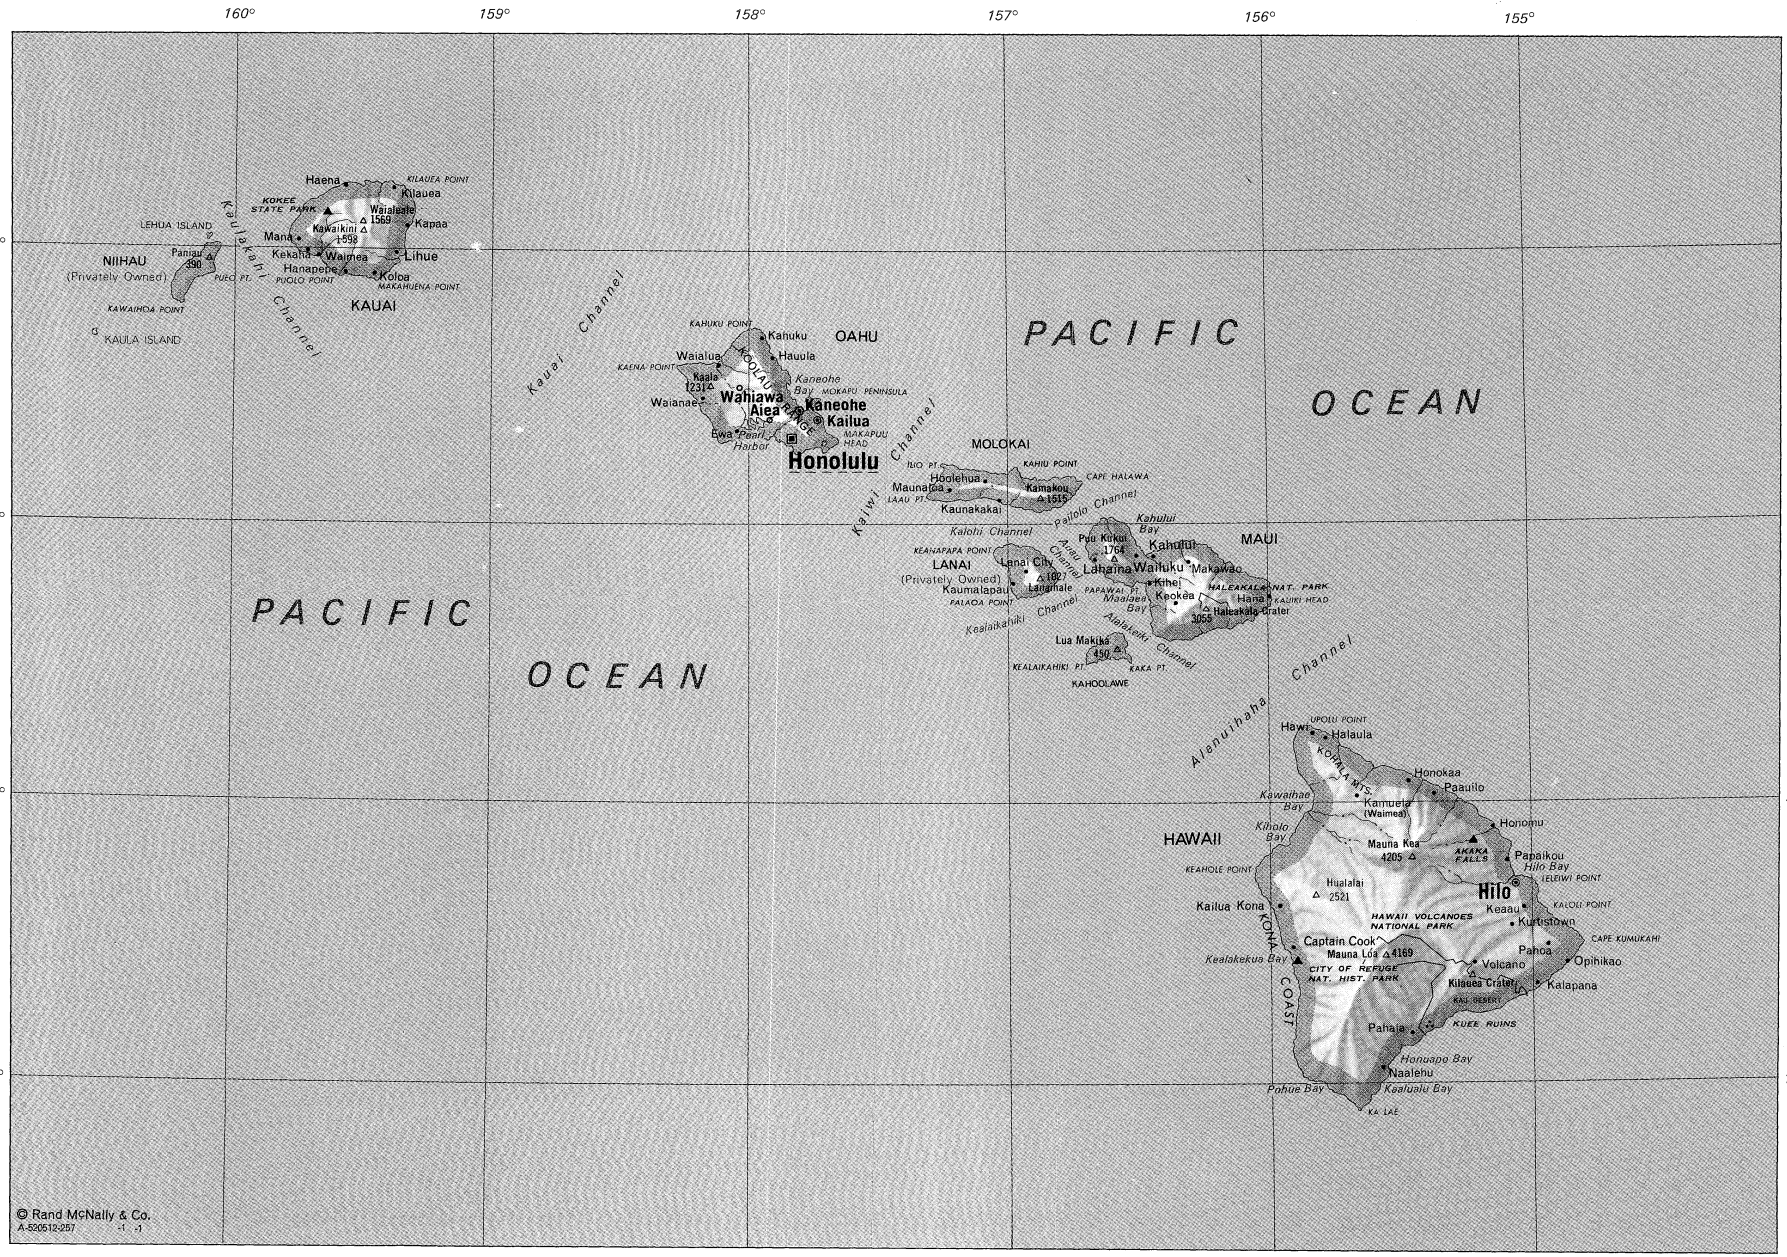
Ethnic origins. Most anthropologists feel that the original settlement of Hawaii was by Polynesians who migrated northeast from the Marquesas Islands perhaps as early as AD 400, to be followed by a second wave of immigration from Tahiti in the 9th or 10th century. Once having established themselves in Hawaii, the Hawaiians had no further need for supplies from their old homeland and underwent centuries of isolation. Although there remained close resemblance in linguistics, physical characteristics, and general customs and life-styles between the Hawaiians and their Polynesian relatives, a degree of racial individuality evolved.

The original Hawaiians were a brown-skinned people of large stature, highly skilled in fishing and farming, who adhered to an extremely rigid and strict system of laws set down by their chiefs and the priests. They worshipped and feared a group of gods not unlike, in character and power, the ancient Greek deities of Olympia.

The first recorded contact between the Hawaiians and the people of the European world took place in 1778, when the English explorer James Cook came upon the islands. During the ensuing four decades, the influence of further European and American explorers, adventurers, trappers, and whalers stopping for fresh supplies at Hawaiian islands was to have a profound effect.

Impact of the cultural mix

Contact with men of totally different cultures, with a belief in only one god substituted for fear of swift punishment from vengeful gods, eventually caused a spiritual revolution among the Hawaiians. In a series of defiant acts led by members of the royal family, the basic beliefs of the Hawaiian religion were undermined, the priests were overthrown, and by 1820—the year



HAWAII

Size of symbol indicates relative size of town • ○ ◉ ▣

Elevations in metres

when the first company of Christian missionaries arrived from America—Hawaiians were experiencing something of a religious void. Loss of faith in the old gods, intense interest and curiosity about the ways of the people of America and Europe, avid interest in learning to read and write, and a desire for spiritual identity caused a swift adoption of Christianity on the part of the Hawaiians. By the mid-19th century, the Hawaiian kingdom was largely a Christian nation. It has been estimated that the population of the Hawaiian Islands at the time of Captain Cook's discovery was approximately 300,000. Virtually disease free, this population had no natural immunity to the diseases introduced from both west and east and fell easy prey to venereal disease, cholera, measles, bubonic plague, and leprosy, all of which contributed to the decimation of the native peoples.

It is recorded that in 1853 the population of the Hawaiian kingdom consisted of 70,036 native Hawaiians, 983 part-Hawaiians, 1,687 Caucasians from Europe and the United States, 364 Chinese, five Filipinos, and 62 people of other racial extractions, making a total of 73,137 people.

The racial and religious makeup of Hawaii has undergone dramatic change since then. Thousands of settlers from the Pacific Basin—primarily from China, Japan, Korea, and the Philippine Islands—as well as immigrants from Europe and from America, carried their own customs, languages, and religions into the Hawaiian way of life. Today, they and their descendants now far outnumber the descendants of the original Hawaiians.

The contemporary population. In 1970 there were 16,591 live births in Hawaii, a 21.5 rate per 1,000 civilian resident population, and 4,216 deaths, a 5.5 rate per 1,000 civilian resident population, indicating the large natural rate of increase in the state. In the ten years between 1960 and 1970, 140,000 American civilians and 30,000 persons from foreign countries, largely the Philippines, moved to the state, while only 123,000 residents moved away. This, too, contributed to population growth. There is also a continuous influx and outflow of military personnel and their dependents, linked closely to the American presence in Southeast Asia.

The majority of the state's 769,000 people reside on the island of Oahu, with 325,000 in the city of Honolulu proper and 305,000 in outlying districts, making a total of 630,000 residents. As there are vast areas of Oahu devoted to agriculture and forest reserve, the majority of the population actually resides in high-density clusters. The high birth rate and continuing influx from the mainland United States and from foreign countries lead statisticians to expect the population to pass the million mark in the not too distant future.

Linguistic diversity

Linguistically, Hawaii is English speaking. Although Hawaiian, formerly a major means of communication, is all but extinct, it remains alive in place-names and street names and in songs, and the local residents liberally sprinkle their speech with words and phrases from the traditional language. A pidgin English, differing from standard English in both word usage and inflection, is spoken throughout the state in varying degrees of richness, while some of the older immigrants from Japan and China continue to speak their native tongues. As Filipinos continue to move to Hawaii, their language, too, is frequently heard in the state.

THE STATE'S ECONOMY

On the national scene, Hawaii ranks between 38th and 45th among the United States in terms of personal income, farm products sold, value of manufacturing shipments, retail sales, and bank deposits. Its cost of living and personal income per capita are among the highest.

Resources and power. Since Hawaii has no significant mineral deposits, its only natural resources are its temperate climate, water supply, soil, vegetation, and surrounding ocean and rock, gravel, sand, and earth quarried for use in construction and landscaping. Electric power is supplied throughout the state by a small number of power companies operating oil-powered steam and diesel generators. Certain military installations and some private institutions generate their own power, and a small amount of hydroelectric power is generated on the islands of Hawaii and Kauai.

Agriculture. Although the largest source of income to the state of Hawaii is the federal government, primarily through defense expenditures amounting to over $650,000,000 per year at the start of the 1970s, and while tourism annually attracts over 1,000,000 visitors to the state, with gross expenditures of more than $500,000,000, agriculture remains the backbone of the local economy.

Sugar and pineapples are the principal crops, the plantations maintaining high yields through the use of sophisticated irrigation systems and planting and harvesting machinery. Hawaii produces 40 percent of all of the canned pineapple consumed in the world. There is extensive diversified agriculture, livestock, poultry, and dairy production, together with some lumbering and commercial fishing. Approximately half of the commercial fish catch is aku (skipjack tuna).

Manufacturing. Hawaii has more than 600 companies engaged in diversified manufacturing. Heavy-manufacturing plants, using raw materials for the most part imported from the United States mainland, include an oil refinery that produces a variety of petroleum products and chemical compounds, a steel mill manufacturing reinforcing bars, two cement plants, a concrete-pipe plant, and an aluminum-extrusion plant. Most building lumber is imported from the mainland. Eighty garment manufacturers, largely situated in Honolulu, produce printed fabrics and apparel bright with colours and designs inspired by the local flora and marketed locally, nationally, and abroad.

A wide variety of Hawaii-grown foodstuffs are bottled, canned, jarred, or packaged in the state; sold in local grocery stores; and exported to the mainland. These include Oriental and Hawaiian food specialties, tropical fruit juices, jams and jellies, candies, coffee, macadamia nuts, and various alcoholic beverages.

Foreign trade. Exports to foreign countries are largely in the form of sugar, canned pineapple, garments, flowers, and canned fish. Major foreign imports are fuel, vehicles, food, and clothing.

Management of the economy. By mid-1969, some 13,000 corporations and partnerships were registered to do business in Hawaii, and 51 percent of the land in the state was owned by private individuals or corporations, although the state itself, holding 39 percent of the land, was the largest single landowner. State and county governments hire a larger number of employees (nearly 40,000) at a higher wage scale than do most of the other states. Hawaii is the regional headquarters of the federal government, which owns 10 percent of the land in the state and employs 34,700 persons.

State and private interests

Taxation. By the 1970s, annual fiscal tax collections by federal, state, and county governments totalled almost $1,000,000,000, with nearly two-thirds in federal taxes, almost a third in state taxes, and the remainder in licenses and fees from the four counties making up Hawaii's local government system. There are no municipal governments or incorporated villages. State taxes are collected under a centralized tax system. The chief sources of revenue are a general excise tax, corporate income taxes, and real property tax.

Trade unions. Major Hawaiian industries are unionized, as are many service and construction industries. The largest union in the state, and one with a turbulent history, is the International Longshoremen's and Warehousemen's Union.

Economic prospects. Economic policies, influenced by and relative to the economic state of the country and the world, tended toward the conservative at the start of the 1970s. Investments, by Hawaii-based financiers in the mainland United States and abroad, increase yearly, as further outlets for economic energy are located, and investment in Hawaii by mainland and foreign capital is on the increase. Within the confines of the state, a certain mood of cautiousness regarding overextension prevails, in sharp contrast to the headlong development, particularly in construction, characteristic of the decade of the

Movements of capital

1960s. Governmental budgets indicate increasing allotments for public housing and recreation and for the preservation of the environment.

A major economic problem in Hawaii is the high cost of living due in large part to Hawaii's insularity and dependency on imports. Transportation costs are included in the purchase prices of nearly all consumer goods. As population increases, it finds housing difficult to acquire and when acquired, by purchase or lease, disproportionately expensive when compared with housing costs in many of the mainland states. Prospects for the economic future in the light of views expressed by both private and governmental study groups are optimistic. A major Hawaiian goal is said to be to bring the economy out of the growing pains of the 1950s and 1960s and, hopefully, into a more secure maturity.

It has been suggested that this may be accomplished by limiting permitted encroachment by urban development on agricultural lands. Carefully planned housing, located in communities in which, in addition to high-rise, high-density dwellings, the single-family home gives way to cluster housing around recreational areas, is indicated as one solution to the shortages and expense associated with urban housing. Finally, an increase in the quantity and variety of manufacturing is envisaged for the entire decade of the 1970s.

TRANSPORTATION

Shipping. Ocean surface transportation is Hawaii's lifeline. Consumer goods and raw materials are brought to Hawaii, and Hawaiian goods are exported in freighters, tankers, container ships, and barge "sea trains." Gigantic, high-speed cranes load and unload the containers.

The importance of Honolulu Harbor

Honolulu Harbor, with its extensive docks, warehouses, and storage sheds, is the focal point of Hawaiian shipping, handling over 8,000,000 tons of incoming cargo and nearly 5,000,000 tons of outgoing cargo annually. A large percentage of the cargo ships ply between Hawaii and California ports, a few between Hawaii and the East Coast of the United States via the Panama Canal, and others from western Pacific ports. Around-the-world passenger ships carry approximately 28,000 passengers through Honolulu every year, and passenger liners from the West Coast of the United States alone bring 38,000 visitors to the islands annually. Tug-pulled barges and small freighters transport goods from Honolulu to the outer islands, returning with agricultural crops and livestock.

Air transport. The majority of voyagers to and from Hawaii travel by air, as do nearly all interisland passengers. The Honolulu International Airport, on Oahu, and the General Lyman Field at Hilo, on Hawaii, are the state's two civilian airports capable of serving large-jet traffic. There are 12 smaller airports among the islands and a number of small private airfields. Military authorities maintain a number of airports throughout the state. About 80 cargo planes come in from the east each month, with over 40 from the west, bringing an annual 78,000,000 tons of cargo into the state and departing with in excess of 42,000,000 tons. There are two interisland air carriers.

Roads. Throughout the state, there are 3,529 miles of roads, most of them following the lowland contours, circling the islands along or near the shorelines, and only crossing islands between mountain ranges. In addition, there are many spectacular mountain roads zigzagging down cliff faces. On Oahu two tunnels bring traffic from the heads of two valleys behind Honolulu through the Koolau Mountain Range and out into the windward, or northeastern, side of the island. Hawaiian roads range from narrow country tracks to an eight-laned divided freeway, which crosses the city of Honolulu.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. Hawaii is governed by a state constitution that was originally adopted in 1950, was amended in 1959, at the time of admission to statehood, and further amended at the constitutional convention of 1968. The governor and lieutenant governor, elected for concurrent terms of four years, must be members of the same political party. The only other elected members in the 17 departments of the executive branch are the members of the Board of Education. Hawaii's bicameral legislature consists of a Senate, with 25 elected representatives from eight senatorial districts, serving four-year terms, and a House of Representatives, consisting of 51 members elected from 25 districts for two-year terms. The state judicial system consists of a Supreme Court, four circuit courts, and 27 district courts, a family court, and a land court.

Executive, legislative, and judiciary

Hawaii's governmental structure is unique in the United States in that it is limited to two levels of government: the state and the four counties, each with a mayor and a council. There are no separate municipal governments.

The political process. Primary elections are held in October and general elections in November. Party competition is intense in Hawaiian politics. During the first half of the century, the Republican Party remained dominant, but party success at the polls began to seesaw somewhat after this, and the Democratic Party has captured a majority of House, Senate, and council seats in recent years.

Military influence. Hawaii holds a strategic position in the defense system of the United States. Pearl Harbor, a vast shipyard for repair and overhaul, is home port to many naval ships. It serves as a training base for Polaris submarine and antisubmarine warfare forces. The headquarters of the commander in chief, Pacific, and of the Fleet Marine Force, Pacific, are at Camp H.M. Smith. The major army, Marine Corps, and air force bases are Schofield Barracks, Ft. Shafter, Ft. De Russy (a rest and recreation centre for personnel fighting in Asia), Corps Hickam and Wheeler air force bases, and the Kaneohe Marine Corps Air Station. In addition, there are military installations, camps, and airfields of varying sizes throughout the state. The total of approximately 116,000 United States military personnel and their dependents are stationed or home ported in Hawaii, a fact not without significance in the local economy and social life.

Social conditions. The minimum wage under Hawaii's Wage and Hour Law, at the start of the 1970s, was $1.60 per hour. Agricultural workers in Hawaii were more highly paid than those in most of the mainland states, receiving an average of $2.37 an hour, with other wage earners obtaining an average of between $1.97 and $3.43 an hour. Federal and county employees are among the most highly paid in the country.

The per capita annual income of $4,530 at the start of the 1970s was higher than the national average, although living costs, as has been noted, were among the highest in the country. Hawaii's high health standards are generally reflected in the vital statistics. Expectation of life at birth is approximately 72 years, among the highest in the nation. Hawaii is free of most tropical diseases, smallpox, and rabies.

Hawaii enjoys a unique reputation as a place in which the population, stemming from many different roots, has created a harmonious society; a degree of social division takes place, following the patterns of ethnical and cultural backgrounds, but the groups tend to appreciate and enjoy the variations of other such groups. As in other parts of the United States, poverty and wealth coexist, sometimes in startling contrast.

Education. Hawaii's school system provides educational facilities from nursery school through the Ph.D. level. By the 1970s, there were 217 public schools below the college level, with an enrollment of almost 180,000 and over 7,000 classroom teachers. Well over 100 private schools added over 30,000 students to the total enrollment. At the college level Hawaii has the University of Hawaii, five smaller private colleges, and a state-established system of five two-year community colleges. By the 1970s, nearly 60,000 full- and part-time students were attending colleges and universities. Private business, technical, and specialized schools provide further educational facilities and opportunities.

Higher education

A unique educational institution is the Center for Cultural and Technical Interchange Between East and West,

commonly referred to as the East–West Center. A project of the federal government, it is housed at the Manoa campus of the University of Hawaii and annually provides specialized and advanced academic programs and technological training to 600 students, from countries in Asia, the Pacific, and the United States.

Public Services. There are 31 hospitals in the state and nearly 1,000 licensed doctors. A state department of health maintains hospitals, health centres, clinics, care centres, and nursing services. Annual public welfare costs at the start of the 1970s exceeded $50,000,000, which came from state and federal government funds. The Hawaiian Homes Commission controls the transfer of land use to qualified persons of Hawaiian racial origin for homesteading.

CULTURAL LIFE AND INSTITUTIONS

The cultural milieu. Hawaii's cultural milieu, the result of overlay after overlay of varied cultural groups, is rich in its admixture. The force of the original culture remains highly evident, although the Hawaiian race has become diminished and diluted through death and intermarriage.

Vestiges of American culture in the New England tradition remain, as do the traditional cultures of the early Asian and Filipino immigrants. With the advent of fifth-, sixth-, and seventh-generation descendants of Asian and Caucasian immigrants and the massive influx of Americans from all parts of the country, the cultural overlays have melded to form a uniquely Hawaiian culture.

Uniqueness of Hawaii's cultural heritage

Interest in the arts is high in this state, which has produced distinguished artists, photographers, and theatrical and musical performers. Appreciation of classical, modern, and experimental art forms is manifest in attendance figures at galleries, concerts, legitimate-theatre performances, and museums. Many ethnic groups preserve the traditions of their ancestors or combine or modify music and dance forms. In addition, islanders very literally keep in step with whatever dance forms are currently popular in the nation as a whole and make a distinctive contribution to the music of the times.

Cultural institutions. An assortment of cultural and scientific institutions in Hawaii provides a wide variety of opportunity for the appreciation and understanding of the fine arts, history, traditions, and sciences. The Bernice P. Bishop Museum, founded in 1889 in Honolulu, is a research centre and museum dedicated to the study, preservation, and display of the history, sciences, and cultures of the Pacific and its people. The Honolulu Academy of Arts, often called the most beautiful museum in the world, houses a splendid collection of Western art, including works by the late 19th- and early 20th-century masters of modern art: Monet, van Gogh, Matisse, Gauguin, and Picasso. Its collection of Oriental art is also one of the finest in the Western world. The University of Hawaii art, music, and drama departments contribute to the expanding cultural life of Hawaii, while the state has several legitimate-theatre organizations, professional and amateur. The 80-member Honolulu Symphony Orchestra performs 100 concerts a year in Honolulu and on the other major islands and 300 educational concert demonstrations. Its home is the Honolulu International Center, a municipal theatre–concert-hall–arena complex, where touring opera companies and ballet troupes and musical artists of international renown also perform. Honolulu's Chamber Music Society gives a concert series each year. The active art, music, and drama departments in Hawaiian schools and colleges and the innumerable students receiving private instruction in the arts also contribute toward the maintenance and growth of Hawaii's cultural life.

The performing arts

Press and broadcasting. In the city and county of Honolulu, two daily newspapers and several specialized weekly and semiweekly papers are published in English, and there are also two daily papers in Japanese and English and two daily papers in Chinese. Honolulu papers are delivered daily by air to the other islands. A daily paper, a biweekly paper, and two weekly papers are published on the island of Hawaii, and a biweekly paper is published on Maui. There are 28 radio stations and 12 television stations in the state.

Problems and prospects. Long famed for its beauty, Hawaii had, by the 1970s, also acquired distinct national and international stature as a Pacific cultural, transportation, economic, and scientific centre. At that time, the state's future appeared to be one of continued growth in production, manufacturing, investment, foreign trade, agricultural, scientific exploration and research, population, and visitor services, with the government and the private sector utilizing imaginative modern methods and concepts to bring about successful development and continued change while preserving the environment and the unique pattern of Hawaiian life.

BIBLIOGRAPHY. Since Captain Cook penned his journal at the time of his discovery of Hawaii for the Western world, the islands have been the source material and inspiration for hundreds of writers from many nations; the complete bibliography is vast.

An understanding of the insular nature of the state, its geographical reference to the Pacific, and its topography and still-active volcanoes are basic to an understanding of present-day Hawaii as well as its history. HAROLD THORNTON STEARNS, *Road Guide to Points of Geologic Interest in the Hawaiian Islands* (1966), is especially valuable for its descriptions of points of interest along the roadside, maps, statistical tables, and a glossary of volcanic terms. See also GORDON A. MACDONALD and DOUGLASS HOPWOOD HUBBARD, *Volcanoes of the National Parks in Hawaii*, 3rd ed. rev. (1965).

PETER H. BUCK, *Vikings of the Sunrise* (1938, reprinted 1959), covers Polynesian migration in the Pacific by a noted anthropologist. Fact, legend, and myth brought to the written word are a mine of information, passed by memorization through generations, about the early Hawaiians. MARTHA BECKWITH, *Hawaiian Mythology* (1940), is scholarly and valuable.

Personal journals from the late 18th and early 19th centuries form a major source of information regarding life in Hawaii. Outstanding are ARCHIBALD CAMPBELL, *A Voyage Around the World, From 1806 to 1812*, 3rd ed. (1822, reprinted 1967), one of the best accounts of life in Hawaii before any significant settlement by non-Hawaiians; and LAURA FISH JUDD, *Honolulu: Sketches of Life in the Hawaiian Islands from 1828–1861* (1880, reprinted 1966), an excellent documentary by the wife of an American medical missionary.

Good histories include ALAN GAVAN DAWS, *Shoal of Time: A History of the Hawaiian Islands* (1968), one of the best single-volume histories of Hawaii; ANDREW W. LIND, *An Island Community* (1938, reprinted 1968), an excellent in-depth study of the racial migrations of Hawaii and subsequent race relations; and RALPH S. KUYKENDALL and A. GROVE DAY, *Hawaii: A History, from Polynesian Kingdom to American State*, rev. ed. (1961), another good history of the period covered.

Descriptions of flora and fauna include LORRAINE E. KUCK and RICHARD C. TONGG, *Hawaiian Flowers and Flowering Trees* (1958); MARIE C. NEAL, *In Gardens of Hawaii*, new and rev. ed. (1965), the latter containing a plant guide as well as legends; and GEORGE CAMPBELL MUNRO, *Birds of Hawaii*, rev. ed. (1970), the best illustrated guide to Hawaiian birds.

THE AMERICAN INSTITUTE OF ARCHITECTS, HAWAII CHAPTER, *A Guide to Architecture in Honolulu, 1957* (1957), illustrated; and RUTH L. HAUSMAN, *Hawaii: Music in Its History* (1968), are two good books on the arts.

JEAN SCOTT MacKELLAR, *Hawaii Goes Fishing* (1956, reprinted 1968), is a very readable book about different methods of fishing; THOMAS EDWARD BLAKE, *Hawaiian Surfboard* (1935, reprinted 1961), includes stories of surfing and instructions; PETER L. DIXON (ed.), *Men and Waves: A Treasury of Surfing* (1966); BEN R. FINNEY and JAMES D. HOUSTON, *Surfing, the Sport of Hawaiian Kings* (1966), a history and guide; RICKY GRIGG and R. CHURCH, *Surfer in Hawaii* (1963), places to surf and instructions; JOHN MELVILLE KELLY, *Surf and Sea* (1965), a good complete guide, including an explanation of the tides and currents that create waves; and H. ARTHUR and M.C. KLEIN, *Surf's Up! An Anthology on Surfing* (1966), are all recommended books on sports in Hawaii.

Hawthorne, Nathaniel

Nathaniel Hawthorne was the first American writer to produce a distinguished body of fiction so clearly reflecting American experience, particularly that of 17th-century New England, that one cannot imagine its having been produced in another culture with a different history.

Hawthorne was born on July 4, 1804, in Salem, Massachusetts, where his ancestors had lived since the 17th century. The first Hathorne (Nathaniel added the *w* to the name when he began to write) was a magistrate who had sentenced a Quaker woman to public whipping. He had acted as a staunch defender of Puritan orthodoxy, with its zealous advocacy of a "pure," unaffected form of religious worship, its rigid adherence to a simple, almost severe, mode of life, and its conviction of the "natural depravity" of "fallen" man. According to an apocryphal family legend, a later Judge Hathorne, presiding during the witchcraft trials of 1692, was supposed to have brought down upon himself and his descendants the curse, uttered by a woman he sentenced to death, "God will give you blood to drink."

Cursed or not, the Hathornes declined in prosperity and prominence during the 18th century, while other Salem families were growing wealthy from the lucrative shipping trade with China. When Nathaniel's father—a ship's captain—died during one of his voyages, he left his young widow, Elizabeth Manning Hathorne, without means to care for her two girls and young Nathaniel, aged four. She moved in with her affluent brothers, the Mannings. Hawthorne grew up in their house in Salem and, for extensive periods during his teens, in Raymond, Maine, on the shores of Sebago Lake. He returned to Salem in 1825 after four years at Bowdoin College, in Brunswick, Maine. Unlike his classmate Henry Wadsworth Longfellow, who was soon to become a popular American poet, Hawthorne did not distinguish himself early. Instead, he spent nearly a dozen years in what he would later refer to as his "dismal third-floor chamber," reading and trying to master the art of writing fiction.

Early work. In college Hawthorne had excelled only in composition and had determined to become a writer. Upon graduation, he had written a novel, *Fanshawe*, which he published at his own expense—only to decide that it was unworthy of him and to try to destroy all copies. The novel was an amateurish blend of the popular mode of supernatural melodrama and Hawthorne's college moods and experiences. Hawthorne, however, soon found his own voice, manner, and subjects; within five years of his graduation he had published such impressive and distinctively "Hawthornesque" stories as "The Hollow of the Three Hills" and "An Old Woman's Tale." By 1832, "My Kinsman, Major Molineux" and "Roger Malvin's Burial," two of his greatest tales—and among the finest in the language—had appeared. "Young Goodman Brown," perhaps the greatest tale of witchcraft ever written, appeared in 1835.

First short stories

Increasing success in placing his stories—first in newspapers, then in Christmas "gift-book" annuals, and finally in magazines—brought him slight fame (most of his early work was unsigned and pseudonymous) but hardly any money. Writing, he became convinced, was not a "career" in America in the 1830s. Unwilling to depend any longer on his uncles' generosity, he turned first to editorial hackwork in Boston and then to a job in the Boston Custom House, where by frugal living he managed to save some money. Finally, he became a shareholding member of the agricultural cooperative Brook Farm, in West Roxbury, Massachusetts, where he dreamed of earning a living by manual labour while still having enough time to write. Even when his college friend Horatio Bridge had financially guaranteed the publication of his first signed book, *Twice-Told Tales*, in 1837, the work had brought gratifying recognition but no dependable income. By 1842, however, Hawthorne's writing had brought him a sufficient income to allow him to marry Sophia Peabody, a Salem neighbour to whom he had been engaged for several years, as well as to realize his dream of being just a writer.

Life in Concord. The young couple rented the Old Manse in Concord and began a three-year period that Hawthorne would later look back on as the happiest in his life.

The presence of some of the leading social thinkers and philosophers of his day, such as Ralph Waldo Emerson, Henry Thoreau, Bronson Alcott, and Ellery Channing in Concord, made the village the centre of the new philosophy of Transcendentalism—a school of thought that encouraged man to transcend the materialistic world of experience and facts and become conscious of the pervading spirit of the universe and the potentialities for human freedom. But despite his new-found contentment, Hawthorne identified with the Puritans enough to write such anti-Transcendentalist sketches as "The Celestial Railroad" and "Earth's Holocaust" during the Concord years. When his Transcendentalist neighbours paid calls, he and Sophia were gratified but he had little to say to them. Artists and intellectuals never inspired his full confidence, but he thoroughly enjoyed the visit of his old college friend and classmate Franklin Pierce, later to become the 14th president of the United States. A happy man, Hawthorne thought, would have no questions to ask of Emerson, who seemed to him to dismiss natural evil and human guilt too easily. Though his writing of the Concord period was generally lighter in tone than his earlier sombre tales of Puritan history, Transcendentalism touched him only lightly.

Reaction to Transcendentalism

Mature novels. A growing family and mounting debts brought an end to his idyllic life in 1845, and the Hawthornes returned to Salem where Nathaniel became surveyor of the Custom House. Salem was declining as a port, and the job was essentially a political sinecure with minimal duties. Nevertheless, Hawthorne did no writing beyond book reviews during the more than three years of his tenure. When the next presidential election brought a new administration to power, he lost the job; but in a few months of concentrated effort he produced his masterpiece, *The Scarlet Letter*. The bitterness he felt over his dismissal is apparent in "The Custom House" essay prefixed to the novel. The work also reflects the grief he felt at his mother's death—in the unrelieved sombreness of the story of two lovers kept apart by the ironies of fate, their own mingled strengths and weaknesses, and the Puritan community's interpretation of moral law, until at last death unites them under a single headstone. The cemetery, the prison, and the rose compete for symbolic dominance, but the cemetery has the last word. Hawthorne decided the work was not "representative" of him and resolved to make his next book a happier one.

Sombre or not, the work sold far better than any of his books yet had, well enough to renew his hope of being able to live by writing alone. His dismissal from the Custom House job had become a partisan cause célèbre across the country, a fact that no doubt greatly helped the book's sale. Sales were further stimulated by the condemnations of the novel's sympathetic treatment of an adultress by certain reviewers in religious publications.

Bitter about his dismissal and determined to leave Salem

forever, Hawthorne decided that the mountain scenery of the Berkshires in western Massachusetts would be conducive both to concentrated writing and to that lighter mood he wished to achieve in his new romance. He settled in Lenox and began work on *The House of the Seven Gables*, the story of the Pyncheon family, who for generations had lived under a curse until it had been removed at last by love.

The 18 months he spent in Lenox were, at first, a happy and productive time for Hawthorne. Some five months of steady writing in the fall and winter of 1850–51 produced the new romance, and its favourable reception cheered and encouraged Hawthorne. His publisher now saw him as a "valuable property" and continually pressed him for new works, to which Hawthorne responded with two new editions of *Twice-Told Tales* and two books for children designed to make the past seem as vividly present to their readers as it did to Hawthorne.

Friendship with Melville

The friendship he formed in the Berkshires with the author Herman Melville, although important for the younger writer and his work, was much less so for Hawthorne. Melville praised Hawthorne extravagantly in a review of his *Mosses from an Old Manse*, comparing him with Shakespeare in depth of meaning. He also dedicated *Moby Dick* to Hawthorne and wrote some of his *Piazza Tales* in a manner that owed much to the symbolic writing he had first discovered in Hawthorne's tales. But eventually Melville came to feel that the friendship he so ardently pursued was one-sided. Later he was to picture the relationship with disillusion in his introductory sketch to *The Piazza Tales* and depicted Hawthorne himself unflatteringly as "Vine" in his long poem *Clarel*.

Hawthorne's final months in "the little red house" at Lenox found him increasingly discontented. Deciding that he preferred to be near the coast rather than in the mountains after all, he moved his family to another temporary residence, this time in West Newton, near Boston. There he quickly wrote *The Blithedale Romance*, based on his disenchantment with Brook Farm, as well as another book for children. Then he purchased and—urged on by his wife—extravagantly redecorated and remodelled Bronson Alcott's house in Concord, the Wayside, hoping apparently to recapture something of the idyllic contentment of the earlier Concord period. But *Blithedale* was disappointingly received and did not produce the income Hawthorne had expected. He was hoping for a lucrative political appointment that would bolster his finances; in the meantime, he began writing the kinds of books he could produce quickly and that would make money. Two more works for children and a campaign biography of his old friend Franklin Pierce resulted.

Consulship in Liverpool

When Pierce won the presidency Hawthorne was, in 1853, rewarded with the consulship in Liverpool, Lancashire, a position he hoped would enable him in a few years to leave his family financially secure. (He was now 48 and already anticipating an early death, as his first college-day protagonist Fanshawe had.)

Last years. The remaining 11 years of Hawthorne's life were, from a creative point of view, largely anticlimactic. Though the official duties as consul, which terminated in 1857, left him a great deal of free time, he found himself unable to write any new work of fiction, filling his notebooks instead with descriptions of places visited on sight-seeing trips. A year and a half of sightseeing in Italy similarly swelled the notebooks, but they were full of his anxiety over serious family illnesses and the tedium of museum visiting. Determined to produce yet another romance, he finally retreated to a seaside town in England and quickly produced *The Marble Faun*. In writing it, he drew heavily upon the experiences and impressions recorded in the Italian notebooks to give substance to an allegory of the Fall of man, a theme that had usually been assumed in his earlier works but now received direct and philosophic treatment.

Back in the Wayside once more in 1860, Hawthorne found American summers unbearably hot and the winters unpleasantly cold. Although he devoted himself entirely to his writing, he was unable to make any progress with his plans for a new novel. The drafts of unfinished works he left are mostly incoherent and show many signs of a psychic regression, already foreshadowed by his increasing restlessness and discontent of the preceding half dozen years. He managed to draw upon his English notebooks for a sensitive and moving book of English sketches, *Our Old Home*, to complete a magazine piece called "Chiefly About War Matters," and finally to begin *The Dolliver Romance*, which starts off in something very like the manner of the early tales. Some two years before his death he began to age very suddenly. His hair turned white, his handwriting changed, he suffered frequent nosebleeds, and he took to writing the figure "64" compulsively on scraps of paper. He died in his sleep on May 19, 1864, in Plymouth, New Hampshire, on a trip in search of health with his friend Pierce.

Assessment

Hawthorne's work initiated the most durable tradition in American fiction, that of the symbolic romance that assumes the universality of guilt and explores the complexities and ambiguities of man's choices. His work directly influenced that of Melville, Henry James, Flannery O'Connor, and Robert Penn Warren, among others, and analogues of his manner and his vision may be found in William Faulkner's works and that of many other writers. His greatest tales and *The Scarlet Letter* are marked by a depth of psychological and moral insight seldom equalled and never surpassed by any American writer.

MAJOR WORKS

NOVELS: *Fanshawe, a Tale* (1828); *The Scarlet Letter* (1850); *The House of the Seven Gables* (1851); *The Blithedale Romance* (1852); *The Marble Faun: Or, the Romance of Monte Beni* (British title, *Transformation*, 1860). (UNFINISHED NOVELS): *Septimius Felton* (1872); *The Dolliver Romance, and Other Pieces* (1876); *Doctor Grimshawe's Secret* (1883); *The Ancestral Footstep* (1883).

STORIES: *Twice-Told Tales*, including "The Gray Champion," "The Gentle Boy," "A Rill from the Town Pump," "The Great Carbuncle," "Sights from a Steeple," and "Dr. Heidegger's Experiment" (1837); 2nd enl. ed., including also "The Celestial Railroad" (1842); *Mosses from an Old Manse* (1846); *The Snow-Image, and Other Tales* (1851; also published as *The Snow-Image, and Other Twice-Told Tales*, 1852). (STORIES FOR CHILDREN): *Grandfather's Chair* (1841); *Famous Old People* (1841); *Liberty Tree* (1841); *Biographical Stories for Children* (1842); *A Wonder Book for Girls and Boys* (1851); *Tanglewood Tales for Girls and Boys* (1853).

BIOGRAPHY: *Life of Franklin Pierce* (1852).

AUTOBIOGRAPHICAL: *Our Old Home: A Series of English Sketches* (1863); *Passages from the American Note-Books of Nathaniel Hawthorne* (1868); *Passages from the English Note-Books of Nathaniel Hawthorne* (1870); *Passages from the French and Italian Note-Books of Nathaniel Hawthorne* (1871).

BIBLIOGRAPHY. NINA E. BROWNE, *A Bibliography of Nathaniel Hawthorne* (1905, reprinted 1967); BUFORD JONES, *A Checklist of Hawthorne Criticism, 1951–1966* (1967); *Hawthorne's Works*, "Riverside Edition," 12 vol. (1904); *The Centenary Edition of the Works of Nathaniel Hawthorne* (in progress); N.H. PEARSON (ed.), *The Complete Novels and Selected Tales of Nathaniel Hawthorne* (1937); HENRY JAMES, *Hawthorne* (1879), the earliest critical study, still valuable; RANDALL STEWART, *Nathaniel Hawthorne: A Biography* (1948), still definitive, though it lacks insight into Hawthorne's inner life; HYATT H. WAGGONER, *Hawthorne: A Critical Study*, rev. ed. (1963); R.H. PEARCE (ed.), *Hawthorne Centenary Essays* (1964); FREDERICK C. CREWS, *The Sins of the Fathers: Hawthorne's Psychological Themes* (1966); B. BERNARD COHEN (ed.), *The Recognition of Nathaniel Hawthorne* (1969), a collection of representative critical responses from the earliest to the present.

(H.H.W.)

Haydn, Joseph

Closely linked to the flowering of classical music in his 18th-century Austria, Franz Joseph Haydn, after experimenting with various stylistic trends prevailing in his youth (the pompous and complex idiom taken over from the preceding Baroque period; the light and gay *style galant*, a style distinguished by formal elegance and clarity imported from Italy and France; and the strongly emotional and expressive *Empfindsamkeit*, or "sensitive style," preferred by North German composers), eventually achieved his own distinctive musical identity by us-

ing some elements of all three styles simultaneously. From the age of nearly 50 onward, he wrote his greatest works, which display a classical synthesis of seemingly incompatible characteristics. Inspiration and heartfelt expression were as important to him as the work of an alert intellect. He established a well-balanced mixture of cheerful folk song elements and serious, at times even tragic, moods. Haydn was significantly helped by the younger composer Wolfgang Amadeus Mozart, who at first accepted the older man's guidance and later enthusiastically collaborated with him.

Haydn, portrait by Thomas Hardy, 1791. In the collection of the Royal College of Music, London.

Haydn is often called the father of the symphony and of the string quartet. Although the statement is in the nature of an oversimplification, works of this kind having existed before him, he did endow the two forms with an artistry and significant content that secured for them a high place within musical literature. His last two oratorios, his great symphonic masses, as well as some of his piano works, songs, and concerti stand on an equally high level. Beethoven was strongly indebted to Haydn, and in the 19th century such composers as Franz Schubert, Johannes Brahms, and Anton Bruckner all were to build on foundations erected by him.

Early years. Haydn was born on March 31, 1732, in Rohrau, a village in eastern Austria near the Hungarian border. War was anything but a rarity in the district, and Haydn's ancestors had suffered from invasions by the Turks and by Hungarian raiders. Stubborn tenacity and resourcefulness were needed to survive under such conditions, and these were qualities inherited by Haydn. His parents, like their forefathers, were humble people; his father a wheelwright, his mother, before her marriage, a cook for the lords of the village. Joseph, their second child, revealed, to everybody's surprise, unusual musical gifts, and the parents were at a loss how to provide the proper type of education for him. The problem was solved when a cousin, serving as a school principal and choirmaster in the nearby city of Hainburg, offered to take the boy into his home and train him. The parents, seeing no other way, agreed; and thus Joseph, not yet six years old, left home, never to return to the parental cottage except for rare, brief visits.

Education at Hainburg and Vienna

From a professional point of view, the move to Hainburg was an important one. The boy sang in the church choir, learned to play various instruments, and obtained a good basic knowledge of music. In other respects, life at Hainburg was less satisfactory. The cousin was poor and his modest salary hardly sufficed to support a growing family. Joseph was not given the love and care a child needs; as he later reported, he received "more floggings than food." But he was able to take such disadvantages in his stride; his nature was endowed with wiry resilience and a contented disposition.

A decisive change in his life occurred when Haydn was eight years old. The musical director of Saint Stephen's Cathedral in Vienna had observed the boy on a visit to Hainburg and invited him to serve as chorister at the Austrian capital's most important church. Haydn's parents accepted the offer with delight, for it secured for their son a thorough musical training and relieved them of all financial cares while he boarded at the choir school. Thus, in 1740 the eight-year-old moved to Vienna full of expectation of the glorious experiences in store for him. He stayed at the school for nine years, acquiring an enormous practical knowledge of music by constant performances but, to his disappointment, receiving far too little instruction in music theory. The pattern of life in Hainburg seemed to repeat itself. Again he had to work hard to fulfill all his obligations as a chorister; again he was badly fed and sometimes suffered, as he reported, from "ravenous hunger." Gradually his voice deteriorated; when it broke, the cathedral choir had no use for him. Seizing on the pretext of punishing a practical joke committed by the high-spirited youth, the director had him expelled from the choir school.

With no money in his pocket and three ragged shirts and an old coat as his only possessions, Haydn at 17 was left to his own devices. He found a refuge for a while in the humble garret of a fellow musician and supported himself "miserably" with odd musical jobs, performing at dances and serenades, playing the organ at Sunday services, and teaching at very modest fees. Hand in hand with these activities went an arduous course of self-instruction through the study of musical works—notably those of Carl Philipp Emanuel Bach (1714–88)—and of leading manuals of musical theory. A fortunate chance brought him to the attention of the successful Italian composer and singing teacher Niccolò Porpora (1686–1768), who accepted him as accompanist for voice lessons and, in return for this as well as for his services as a valet, corrected Haydn's compositions.

Thanks to tremendous persistence and unflagging energy, Haydn made progress. He was eventually engaged to teach some aristocratic pupils and introduced by them to the music-loving Austrian nobleman Karl Joseph von Fürnberg, in whose home he played chamber music. For the instrumentalists there he wrote his first string quartets, a form that he cultivated throughout his professional career, composing some 80 works in this genre.

In 1758 Haydn received his first steady appointment. Through the recommendation of Fürnberg he was engaged as musical director and chamber composer by the Bohemian count Ferdinand Maximilian von Morzin, who resided most of the time in his country estate of Lukaveč in western Bohemia. Haydn had an orchestra of about 16 musicians at his disposal, and, for this ensemble, he wrote his first symphony, the other musical form in which he pioneered. These first attempts in the field of instrumental composition were still conventional in character, yet a certain freshness of melodic invention and sparkle marked them as the work of a future master.

Bohemian post with Count von Morzin

The first period of Esterházy patronage. Haydn did not stay long with Count von Morzin, as financial difficulties forced his patron to dismiss the orchestra. Before long he was invited to enter the service of Prince Pál Antal Esterházy, who had heard his works at Count von Morzin's castle. The Esterházys were one of the wealthiest and most influential families of the Austrian empire and boasted a distinguished record of supporting music and art. Prince Pál Antal had a well-appointed orchestra performing regularly in his sumptuous castle at Eisenstadt, a small town some 30 miles from Vienna. As his aged music director was ailing, the prince had vision enough to appoint the relatively unknown Haydn as assistant conductor. The contract concluded on May 1, 1761, informs us about the new appointee's duties. While church music was still entrusted to the director, three other spheres of activity were assigned to Haydn: to conduct the orchestra and coach the singers (which meant almost daily rehearsals); to compose the greatest part of the music required; to do administrative work by serving as music librarian, supervisor of instruments,

and chief of the musical personnel. Haydn carried out these duties extremely well and even managed to find time to supervise the work of the copyists of music and to tune his own keyboard instruments. His service as chief of personnel revealed tact, good nature, and skill in dealing with people. He exerted himself to support his subordinates against other officials on the Prince's staff, and, thanks to his friendliness and his sense of humour, he managed to maintain good relations with staff and employers. The musicians loved and respected their "Papa," as they nicknamed him.

"Papa" Haydn

In 1766 Haydn became musical director at the Esterházy court. He raised the quality and increased the size of the Prince's musical ensembles by appointing many choice instrumentalists and singers. His ambitious plans were supported by Prince Miklós, who, on the death of his brother in 1762, had become head of the family and maintained his leadership for 28 years. A passionate and discriminating music lover himself, he was able to appreciate Haydn's contributions and created an atmosphere beneficial for the development and maturing of his music director's art. Miklós "The Magnificent," as he was usually referred to, loved splendour and display. Having admired Versailles in France, he decided to match it by a creation of his own. At enormous expense he built in 1766 the splendid castle of Esterháza, situated in the western part of Hungary. Every night a performance of a German play or of an Italian opera would be offered in the palace theatre. Haydn, in addition to his other staggering duties, was in charge of all operatic activities. He not only selected, rehearsed, and conducted operas by other composers but contributed more than a dozen musical works of his own. No lesser person than Empress Maria Theresa of Austria testified to the high level of operatic performance achieved in the Esterházy theatre. She was once overheard saying, "When I want to hear a good opera, I have to go to Esterháza," a verdict that was not gratifying to the musicians of Vienna.

Operas

Some of Haydn's operas, such as the hilarious *La canterina* (*The Songstress*) of 1767 and *Lo speziale* (*The Apothecary*) of 1768, are musical comedies; other stage works, such as *L'isola disabitata* (*The Deserted Island*) of 1779 and *Armida* of 1784, are of a serious character. Most significant are those operas in which Haydn succeeded in combining comic and serious elements by conjuring up gay characters contrasted with more earnest-minded ones. One of his last and most successful works for the stage, *Orlando paladino* (*Knight Roland*) of 1782, bore the fitting subtitle of "drama eroicomico" (heroic–comic drama). Even when performing operas by other composers, Haydn made adaptations to render them suitable for the personnel of the Prince's theatre. Following the common practice of the time, he often added arias of his own to works by other composers, which were display pieces for the singers and added additional sparkle to the work performed.

In addition to his operatic duties, he composed symphonies, string quartets, and other chamber music. The Prince was a passionate performer on the baryton, and Haydn provided for his patron more than 150 compositions featuring this now obsolete cello-like instrument.

Haydn seems to have enjoyed his busy life and served Prince Miklós for nearly 30 years. Living in the country was no hardship for him. He loved hunting, fishing, and other outdoor activities. Nor did he feel cut off from the cultural world, for travelling dramatic troupes often brought works by eminent writers to Esterháza, and he frequently visited Vienna in the Prince's retinue.

Friendship with Mozart

On these occasional visits a close friendship developed with Mozart. The fact that Mozart was 24 years younger than Haydn did not matter. They felt inspired by each other's work. Mozart declared that he had learned from Haydn how to write quartets and dedicated a superb set of six such works to his "beloved friend." Haydn's music, too, shows in various details the impact of his young friend's idiom. The mature composer was by no means set in his ways; he was flexible and receptive to new ideas, an admirable trait in an artist who had already won wide recognition.

Unlike Mozart, Haydn became internationally famous in his own lifetime. His works were performed throughout Europe and were published in Austria, Germany, Holland, France, and England. He received official commissions from many European music lovers. The city of Cádiz in Spain, for example, commissioned *The Seven Last Words* for a Good Friday service; the king of Naples requested compositions for the lira organizzata, a hurdy-gurdy (wheel fiddle) with a built-in tiny pipe organ; and the *Paris Symphonies* (numbers 82–87) were composed between 1785 and 1786 for the French capital.

The success of Haydn's professional career was not matched in his personal life. The girl he loved entered a convent, and her parents induced Haydn, who had just obtained his position with Count von Morzin, to espouse the elder sister. The decision proved disastrous for his realization of a pleasant, peaceful home. No children were born to the couple. Haydn's wife, two years his senior, was quarrelsome and bigoted. She did not understand music and showed no interest in her husband's work. It was reported that her expression of disdain went to the extremes of using his manuscripts for pastry linings or curl papers. As a result the composer was not insensitive to the attractions of other women, and for years carried on a love affair with Luigia Polzelli, a young Italian mezzo-soprano in the Prince's service.

Unhappy marriage

English period. In 1790 Prince Miklós died. His son, Prince Antal, did not care for music and dismissed most of the court musicians. Haydn was retained, however, and continued to receive his salary. No duties were required of him, enabling Haydn to do whatever he pleased. But after such a long time at the Esterházy court, the composer was eager to try a different way of life. He, therefore, considered seriously two tempting offers that were made as soon as his availability was generally known. First, the king of Naples urged him to accept an invitation extended several years earlier to visit his court; second, a violinist and concert manager, Johann Peter Salomon, arrived from England and commissioned, at excellent financial terms, six new symphonies and 20 smaller compositions to be conducted by the composer himself in a series of orchestral concerts in London sponsored by Salomon. Haydn, moreover, was to compose a new Italian opera for the King's Theatre in London, for a fee of £300. Haydn felt far more attracted by the English than by the Italian invitation. He felt it would be a great experience to work with a large, excellently trained orchestra and to live in one of the great musical centres of the 18th century. Furthermore, he would no longer have to submit to the rigid etiquette of the Esterházy court and continually be reminded of his subservient position.

First visit to London

Undeterred by the dire warnings of his friends, including Mozart, he left for London. What the prospect of the visit to England meant to him may be realized when one considers that though 58 he had yet to travel beyond the borders of Austria. On New Year's Day, 1791, he arrived on British soil, and the experience of the following 18 months proved as rewarding and stimulating as he had anticipated. The many novel impressions, the meeting with eminent musicians, the admiration bestowed on him had a powerful impact on his creative work. The symphonies written for the first and second visit to London represent the climax in his orchestral output. One admires their virtuosity of instrumentation, the masterly treatment of musical forms, the freely flowing melodic inspiration, and the sense of humour that endeared the works so much to the British audiences. Their popularity is reflected in the various nicknames bestowed on them (*Surprise, The Clock, Military, Drum Roll*). As Haydn conducted the works himself, he exercised, in the words of the great contemporaneous British musicologist Charles Burney, "an electrical effect on all present and such a degree of enthusiasm as almost amounted to frenzy." The opera he composed fared less well because the King's Theatre, for which it was commissioned, was refused the license to perform such works. Haydn, however, suffered no financial loss, and the event seems not to have greatly disturbed him.

In England Haydn was feted by famous men as well as by royalty. In July 1791 Oxford University awarded him the honorary degree of Doctor of Music. He performed at the residences of the Prince of Wales and the Duke of York. His diary describes visits at which he was "gloriously entertained," and references to beautiful women he met at such occasions are anything but rare. Sixty years old, his face pitted by smallpox, with a large aquiline nose, and too-short legs, he remained attractive to women admirers.

In spite of his great success, Haydn was forced to submit to one of the artistic contests fashionable at the time. A rival music organization, which had failed to induce Haydn to join them, engaged a young pupil of his, one Ignaz Pleyel, to conduct its concert series. A vicious campaign was started emphasizing Haydn's advanced age and the pupil's expertise, but it was to no avail; Haydn could report that he had "kept the upper hand." The concerts he conducted, consisting largely of his own works, continued to be a series of triumphs.

In June 1792 Haydn left London for Germany, as Prince Esterházy wanted the famous composer in his retinue at the coronation of the emperor Francis II in Frankfurt am Main. On his journey he stopped at Bonn where the 22-year-old Beethoven was introduced to him, and it was arranged that the young composer should move to Vienna to receive the aged master's instruction. On July 29 Haydn arrived in Vienna where he was able, thanks to his considerable earnings in England, to buy a pleasant house in the suburb of Gumpendorf. This dwelling still stands today and is the site of a Haydn museum.

Second visit to London

The composer did not stay in Vienna for long, however. His English admirers urged him to visit London once more, and in January 1794 he left the Austrian capital to return to England until August 15, 1795. Again he won great acclaim. Various members of the royal family made efforts to keep him in England, but Haydn declined, because a change had occurred in the leadership of the Esterházy family. Miklós II, the new head of the princely house, was eager to restore the former orchestra under Haydn's direction, and the composer felt compelled to accept the assignment. The duties he now undertook would, of course, not be as burdensome as previously. Moreover, the Prince's intention to spend the winter months in Vienna provided a strong incentive. Although Haydn had to separate from the many friends he had made in London, he could look back on the period spent in England as a profitable one. His trunks bulged with no less than 768 pages of music he had written in that hospitable country, and the musical stimulus and the financial rewards for his labour had been gratifying.

The late Esterházy and Viennese period. In 1791 Haydn had attended the Handel Commemoration at Westminster Abbey in London. He was deeply moved by the superb rendition of Handel's masterly oratorios and by the veneration with which they were received by the English audience. Deciding to compose in this musical genre, he was able to obtain a suitable libretto, allegedly prepared for Handel himself. After settling in Vienna and resuming his duties for Prince Esterházy, Haydn started work on the oratorio *The Creation*, the text of which had been translated into German by Baron Gottfried van Swieten. The libretto was based on the epic poem *Paradise Lost* by England's foremost 17th-century poet, John Milton (1608–74) and on the Genesis chapter of the Bible. Composing the oratorio provided Haydn with a truly congenial task. He was a deeply religious man who throughout his long career had contributed Latin masses of great beauty for the Roman Catholic Church. In the oratorio he could express his gratitude to God in a work with German text and at the same time depict in music the beauties of nature that so greatly delighted him. The years devoted to this task were among the happiest in Haydn's life. He felt uplifted and in communion with the divine spirit. In April 1798 the oratorio had its first performance in a princely palace and produced a profound effect. As a critic wrote: "Three days have gone since that enrapturing evening . . . still the mere memory of all the flood of emotions then experienced constricts my heart." Before long a public performance took place with equal results, and, henceforth, *The Creation* was again and again performed with great success, the proceeds going, at the composer's request, to charitable institutions.

Oratorios

This encouraged Haydn to produce another oratorio, which absorbed him until 1801. A British text, the poem *The Seasons*, by the Scottish poet James Thomson (1700–48), was again chosen for the libretto and translated by van Swieten. Though of limited poetical value, the adapted work allowed him to compose delightful musical genre pictures of events in nature. This second oratorio was also triumphantly successful, both at court, where the Austrian empress sang the soprano solos, and in public performances.

Haydn's late creative activity, however, was not confined to the oratorio. The six masses written for his patron Esterházy are among the most significant works of this kind from the 18th century. He continued to compose magnificent string quartets and, in 1797, he gave to the Austrian nation the stirring song "Gott erhalte Franz den Kaiser" ("God Save Emperor Francis"). It was used for more than a century as the national anthem of the Austrian monarchy and as the patriotic song "Deutschland, Deutschland über alles" ("Germany, Germany above all else") in Germany. It is heard today under many titles as a Protestant hymn in the English-speaking countries. The song was so beloved that Haydn decided to use it as a theme for variations in one of his finest string quartets, the *Emperor Quartet*, Opus 76, No. 3.

Honours bestowed

Not surprisingly, honours from various parts of Europe gladdened the composer in his last years. Stockholm, Amsterdam, St. Petersburg, and Paris made him an honorary member of their music associations and the French capital had, after the premiere of *The Creation*, a gold medal engraved in Haydn's honour. Nor did Austria lag behind. In the village of Rohrau, Haydn's birthplace, a monument was erected to its famous son, and Haydn had the gratification of seeing it. The city of Vienna conferred on him the great golden Salvator Medal and named him an honorary citizen. Particularly notable was the Vienna concert of 1808 in celebration of Haydn's 76th birthday. *The Creation* was performed by eminent musicians in the presence of the ailing composer, carried in on an armchair and seated amid jubilant exclamations among members of the high nobility. Poems were read in his honour, applause shook the hall, and on Haydn's departure Beethoven knelt down and kissed the hands of his former teacher. This was Haydn's last public appearance. Henceforth, conditions in Vienna prevented such outings and undermined the little strength still left to the aged artist. Austria faced the Napoleonic armies in 1809—devastating battles were fought and Vienna was bombarded, a cannon ball falling near Haydn's residence. Napoleon, however, eventually placed a guard of honour outside Haydn's house.

In these turbulent days a moment of joyful respite was granted to the invalid. A French officer called and, professing admiration of Haydn's music, gave a rendering of an aria from *The Creation*, which allegedly made the composer shed happy tears. Soon afterward the singer fell in battle. Haydn survived him by only a few days, dying on May 31, 1809. At the official obsequies, members of the French army joined forces with the municipal militia to form a line before the catafalque. Vienna's cultural elite and high-ranking French officers paid solemn tribute to the genius who had given so much to the musical world.

Reasons for contemporary success

The success achieved by Haydn in his lifetime is often attributed to his slow development, enabling music lovers to progress step by step in their understanding of his aims; his long life endowed with creative power up to old age; and, most of all, his attunement to the spirit of the times. Haydn was a true representative of the age of Enlightenment. His positive, optimistic approach to life, his striving for balance between the work of the intellect and the flow of emotions; his sense of moderation, lead-

ing to the avoidance of strongly discordant moods, found superb expression in his music and thus gave his contemporaries the kind of music they were able to appreciate. Music lovers also found irresistible the nobility and deceptive simplicity of his idiom, sparked by delightful outbreaks of humour. In the 19th century the ideals of the Enlightenment no longer were prevailing. The age of Romanticism liked to probe dark and complex moods; morbidity seemed attractive, and emphasis was laid on conjuring up ambivalent emotions in music. To this epoch the gaiety and naturalness of Haydn's idiom seemed to be rather philistine and people patronized "good old papa Haydn," whose works were, as a matter of fact, hardly known. In the 20th century there was a re-evaluation of his work; and the outstanding intellectual nature of his thematic elaborations, the originality of his modulations, and the artistry and superb craftsmanship of his orchestration were again appreciated.

MAJOR WORKS

Instrumental music

SYMPHONIES: 106 symphonies, including *No. 6 in D Major* (*Le Matin;* completed, 1761); *No. 7 in C Major* (*Le Midi;* 1761); *No. 8 in G Major* (*Le Soir;* 1761); *No. 45 in F Sharp Minor* (*Farewell;* 1772); *No. 49 in F Minor* (*La Passione;* 1768); *No. 83 in G Minor* (*La Poule;* 1785); *No. 84 in E Flat Major* (1786); *No. 88 in G Major* (1787); *No. 92 in G Major* (*Oxford;* 1789); *No. 94 in G Major* (*Surprise;* 1791); *No. 96 in D Major* (*Miracle;* 1791); *No. 100 in G Major* (*Military;* 1794); *No. 101 in D Major* (*The Clock;* 1794); *No. 102 in B Flat Major* (1795); *No. 103 in E Flat Major* (*Drum Roll;* 1795); and *No. 104 in D Major* (*London;* 1795).

CONCERTI: 3 concerti for violin; 2 concerti for cello; 11 keyboard concerti; *Symphonie concertante* for violin, oboe, cello, bassoon, op. 84 (1792); *Horn Concerto* (1762); 5 concerti for two lire organizzate (hurdy-gurdies with small built-in organ pipes; 1786); *Trumpet Concerto* (1796).

OTHER ORCHESTRAL WORKS: Various overtures, divertimenti, marches, and dances.

STRINGS: About 79 quartets, including some 20 early works; 6 in op. 17 (1771); 6 in op. 20 (1772); 6 in op. 33 (1777–81); op. 42 in D minor (1785); 6 in op. 50, dedicated to Frederick William II of Prussia (1787); 7 in op. 51 *Die Sieben Worte des Erlösers am Kreuze* (*Seven Words of Our Saviour on the Cross*, originally an orchestral work, string quartet version 1787, vocal version 1796); 6 in op. 54 and 55 (1788?); 6 in op. 64 (1790); 6 in op. 71 and 74 (1793); 6 in op. 76, dedicated to Count Joseph Erdödy (1797); 2 in op. 77, dedicated to Prince Lobkowitz (1799); op. 103 (1803); various string trios, duos, and divertimenti for 3 instruments.

OTHER COMPOSITIONS FOR STRINGS: 126 trios for baryton (cello-like instrument with additional sympathetically-vibrating metal strings under the fingerboard), viola, and cello; 41 piano trios.

PIANO: 54 sonatas; *Variations in F Minor* (1793); various separate movements.

Theatre music

OPERAS: About 16, including *La canterina* (1767); *Lo speziale* (1768); *Le pescatrici* (1770); *L'infedeltà delusa* (1773); *L'incontro improvviso* (1775); *Il mondo della luna* (1777); *L'isola disabitata* (1779); *La fedeltà premiata* (1780); *Orlando paladino* (1782); *Armida* (1784); and *L'anima del filosofo* (composed 1791).

Other vocal music

ORATORIOS: *Die Sieben Worte* (*The Seven Last Words;* 1796); *Die Schöpfung* (*The Creation;* 1798); *Die Jahreszeiten* (*The Seasons*, 1801).

MASSES: 13 masses, including *Missa Celensis* (1782); *Missa in tempore belli* in C major (*Paukenmesse*, 1796); *Missa St. Bernardi de Offida* in B flat major (*Heiligmesse*, 1796); *Missa in angustiis* in D minor (*Nelson Mass*, 1798); *Mass in B Flat Major* (*Theriesienmesse*, 1799); *Mass in B Flat Major* (*Schöpfungmesse*, 1801); *Mass in B Flat Major* (*Harmoniemesse*, 1802).

OTHER CHURCH WORKS: 2 Te Deums (both in C major; one from the 1760s, one *c.* 1800); *Stabat Mater* (1767); *Ave Regina* in A major (*c.* 1756); 3 Salve Reginas (E major, 1756; E flat major, *c.* 1770; G minor, 1771); various offertories, motets, and arias.

SONGS: 12 canzonettas (in English, 1794–95); about 34 German songs; 13 partsongs; various arias for other composers' operas.

CANONS: 10 sacred (*The Holy Ten Commandments*) and 46 secular.

BIBLIOGRAPHY. ANTHONY VAN HOBOKEN, *Joseph Haydn: Thematisch-Bibliographisches Werkverzeichnis*, vol. 1 (1957), lists the instrumental compositions; the second volume dealing with the vocal works is in preparation. The largest number of Haydn's autographed scores is owned by the National Library Széchényi in Budapest, Hungary. H.C. ROBBINS LANDON, *The Collected Correspondence and London Notebooks of Joseph Haydn* (1959), is a sensitive translation of all Haydn letters known. Biographical and critical studies include: VERNON GOTWALS (trans.), *Joseph Haydn: Eighteenth-Century Gentleman and Genius* (1963), a translation of the two earliest biographical sketches of the life of Haydn, both based on information received from the composer himself; KARL and IRENE GEIRINGER, *Haydn: A Creative Life in Music*, 2nd rev. ed. (1968), a biography first published in a German version in 1932 now expanded and updated; ROSEMARY HUGHES, *Haydn* (1950), a compact biography of the composer; and H.C. ROBBINS LANDON, *The Symphonies of Joseph Haydn* (1955), a basic investigation of the composer's symphonic output.

(K.G.)

Headache

Headache in one form or another probably is man's most frequently troublesome symptom, affecting nearly everyone at some time in his life and inflicting recurrent discomfort on perhaps one person out of ten. Headaches vary widely in their intensity and in the seriousness of the underlying conditions that cause them, and there is no necessary correlation between the severity of the pain and its cause. Pain is an individual matter—a biological danger signal initiated by tissue injury, carried along fairly specific nervous system pathways, but ultimately experienced according to the psychological endowment and past experience of the sufferer. The understanding of headache, therefore, requires an awareness of the mechanisms that cause head pain and of the fact that different genetic and emotional backgrounds produce very different individual responses to tissue injury of similar intensity.

Mechanism of headache. Most headaches occur because specific pain-sensitive structures in or around the head are overstimulated or damaged. Some of these are inside the skull, or intracranial; the remainder are in the tissues surrounding or covering the skull, or extracranial. Extracranial structures are by far the more common sources of recurrent headache.

Intracranial headache

Intracranial headache results when the arterial blood vessels at the base of the brain become excessively distended (as during fever, "hangover," or a severe and sudden attack of high blood pressure), or when an inflammation or hemorrhage surrounds these same arteries and their adjacent meningeal tissues (as during an attack of meningitis or a cerebral hemorrhage). Intracranial headache also can occur if a tumour or some other space-taking mass displaces certain of the large veins or other tissues inside the skull (the brain itself is not sensitive to pain). Intracranial headaches are usually of recent origin, particularly if they are severe, and often begin abruptly; only rarely do they last throughout the waking hours, and they usually change in character with a change in posture. Most headaches from brain tumour are felt in a particular part of the head, especially when they first begin. Intracranial causes of headache almost always produce associated abnormalities that the physician can detect by physical examination or laboratory tests.

Extracranial headache

Extracranial headaches have six major sources:

1. Painful dilatation and distention of the extracranial arteries that supply the surface tissues of the head. This category includes migraine and many "tension" headaches.
2. Sustained contraction of skeletal muscles about the face, scalp, and neck. This includes most psychologically associated "tension" headaches as well as those associated with excess fatigue, orthopedic difficulties of the neck, and simple eyestrain.
3. Distention, inflammation, or destruction of pain-sensitive tissues in the nose, paranasal sinuses, eyes, ears, and teeth. Headache from these sources is accompanied by objective signs of active disease.

4. Specific neuritis or neuralgias such as trigeminal neuralgia, all of which have very specific and predictable pain patterns.

5. Direct injuries, infections, or growths involving the extracranial tissues. Head pain following trauma is often a complex matter, since it can herald troubles as serious as a blood clot on the brain or as medically trivial as a desire for greater financial compensation after injury.

6. Rare inflammatory diseases of the cranial arteries.

More than 90 percent of all headaches result from distention of extracranial arteries or from sustained contraction of face and neck muscles, and accompany feeling states of frustration, resentment, anxiety, fatigue, or depression. Thus the individual's life situation and emotions are particularly important in the genesis of headache, both because disturbed feeling states initiate changes in arteries and muscles that cause pain, and because the presence of pain is often particularly threatening to emotionally troubled persons. Usually psychological factors important in the genesis of headache actually induce hurtful tissue changes. Only rarely does headache develop as a delusion for which no responsible tissue abnormality exists.

Migraine. Migraine is a paroxysmal disorder in which vascular headache is combined with several other bodily disturbances, including periodic changes in water balance and in autonomic nervous system function. Attacks may occur daily or as infrequently as once a year. Characteristically, patients with migraine have initial symptoms that precede headache by as much as an hour and are believed to be due to constriction of selective intracranial arteries: there may be illusions of flashing lights, loss of vision, or transient defects in speech or body movement. As a rule, the early symptoms subside in 10 to 30 minutes and are followed by severe, throbbing headache located over one or the other temple or occipital region. Less commonly the headache is bilateral or generalized. During the attack, bright lights hurt the eyes and many patients have nausea and vomiting. Dilation of one or more extracranial arteries causes this early painful stage. If the headache persists for more than a few hours, secondary painful contraction sets in in scalp and neck muscles, compounding the early symptoms. In typical cases, the attack lasts 12 to 24 hours or more unless relieved by vasoconstrictor and analgesic drugs early in its course.

Initial symptoms of migraine

The underlying cause of migraine is unknown. The illness occurs in families with an incidence suggesting an autosomal dominant inheritance (*i.e.*, the defect is transmitted by a nonsex chromosome; only one of the two genes involved in the trait need be transmitted). At one time or another, various investigators have attempted to link migraine to allergy, epilepsy, or other conditions, but the evidence has been unconvincing. Recently, several studies have suggested an abnormality in the regulation of serotonin, a chemical involved in transmitting impulses in the brain. The observed chemical changes in patients with migraine, however, have not always been consistent, and the evidence has not yet led to any change in treatment, which consists of using vasoconstrictor and analgesic drugs during the attacks and psychological guidance for the patients between attacks. Persons with migraine are characteristically perfectionistic, self-demanding, hard-working, and inflexible. They commonly set impossibly high standards for themselves and, less often, for others. When affected persons come to understand these feelings and realize the fatigue and resentment they engender in themselves, they are often able to establish more realistic ways of approaching life. Headaches tend to decline in frequency at the same time.

Cause of migraine

Medical significance of headache. The medical significance of headache varies widely as the causes themselves range from relatively minor emotional difficulties to illnesses as serious as brain tumour. Any headache that is recent in onset, different from previous patterns, or altered in quality requires close and careful medical evaluation.

ANTHONY, and H. HINTERBERGER, "The Control of Cranial Arteries by Humoral Mechanisms and its Relation to the Migraine Syndrome," *Headache*, 7:93–102 (1967), an experimental paper providing evidence that links the chemical serotonin to the genesis of migraine headache; F. SICUTERI, "Vasoneuroactive Substances in Migraine," *Headache*, 6:109–26 (1966), a review of pharmacological factors that affect blood vessels in migraine, and a presentation of the hypothesis that vascular headache is related to changes in the body's indole-peptide metabolism.

(F.P.)

Healing Cults

William James held that the basic element in religion is the cry "Help! Help!" This cry might be addressed to a god or to a religious specialist; it might arise out of a physiological disorder or a sense of sin and transgression. Many would hold that the most important function of religion has been that of healing—the diagnosis of the cause of evil and mental and physical sickness, and the development of techniques for its cure. From the earliest Neolithic evidence for trepanning (operating on the skull) to the techniques of the contemporary "new" religions of Africa, Melanesia, and Japan, from the shaman's hut to the big city revival hall, healing and religion have been inextricably interrelated. Rarely can a religious leader succeed unless he can heal; no religion has survived that does not heal.

Every religious tradition engages in healing and restorative activities, especially in the use of blessings, exorcisms, and purificatory rites. In almost every religious tradition there is some form of blessing; *i.e.*, a ritually repeated formula, often accompanied by gestures, that invokes the supernatural powers to protect the devotee and to grant him health, safety, and prosperity. As the verbal expression of a wish that good may befall someone and that evil may be averted, the blessing appears in a variety of religious contexts: therapeutic (designed to heal), apotropaic (designed to avert evil), and, especially, contexts in which hope and protection are expressed. Objects (*e.g.*, charms and amulets) may also be blessed and perform similar protective functions for their possessor.

Blessings, exorcisms, and purificatory rites

Many religious traditions associate illness with evil spirits that take possession of either a person or a place. They must be expelled by a series of complex incantations and actions most usually performed by a specialist.

Illness is frequently viewed as the result of ritual or moral transgression. To set things right, rituals of purification are required to remove the taint of the offense, procedures for confession alleviate the guilt of the offense, and acts of expiation or repentance restore the proper relationship with the offended power. Most religious traditions also preserve stories of gods, heroes, or holy men who were particularly adept at healing; and many religious traditions maintain hospitals and utilize various procedures for the care or visitation of the sick.

Although every religious tradition and functionary is concerned with healing (either in the physiological sense of curing disease or in the extended sense of overcoming transgression) and with restoring the world to its presumptive proper state, some movements have been so dominated by these concerns that they have come to be called healing cults. These are usually local and limited in membership; and they either become a schismatic group, a "new" religion, or are absorbed within a larger tradition.

TYPES OF HEALING CULTS

Shrine cults. Pilgrimage to a sacred place and devotion before a sacred object is a major means of religious healing. From earliest times, healing and healing cults have been associated with springs and other sources of water. An ancient Indian Vedic source says: "The waters are indeed healers; the waters drive away and cure all illnesses" (*Atharvaveda*, 6.91.3). Water—as the source of life in many myths, as that which is an absolute necessity for existence, and as that which cleanses—is the most

Water and other shrines

all-encompassing means of restoring health. As in the spa-therapy (bathing in mineral waters) of contemporary health resorts, so thermal and mineral springs were conceived to be curative in ancient times. There is evidence of Neolithic and Bronze Age devotion at the sites of a variety of such springs in western Europe (*e.g.*, Grisy and Saint-Sauveur in France; Forlì, Italy; Saint Moritz, Switzerland). Every country in which they occur has healing traditions associated with such springs. In ancient Greece the most famous shrines were at Thermopylae and near Aedepses; they were sacred to Heracles, the legend being that they were created for his refreshment after his labours. In ancient Rome, the springs at Tibus and the hot sulfur wells of Aquae Abulae were well known. In the Middle East, Callirrhoe, where Herod attempted to find relief from his fatal illness (Josephus, *Antiq.* XVII.6.5), was perhaps the best known; in ancient Egypt many of the temples dedicated to Asclepius (the Greek god of medicine) are adjacent to mineral springs; Muslim traditions identify several hundred springs as having healing powers. There is relatively little cultic activity at such springs; one simply goes to them and bathes when ill.

More elaborate cultic practices surround those sources of water that have been the scenes of epiphanies (manifestations of deities or sacred beings), or in which divinities are believed to dwell. The power of the divine presence or blessing, it is believed, charges the waters with healing abilities. The most famous Western example of this type of shrine is that at Lourdes in France where the Virgin Mary is believed to have appeared to one Bernadette Soubirous in a series of visions in 1858 and to have indicated a miraculously flowing stream that would heal the ill. A number of other European water shrines are associated with epiphanies of Mary (*e.g.*, the Shrine of the Madonna of the Baths at Scafati, Italy). Because of his association with water, many streams and wells are believed to have healing powers on the feast of the Conception of St. John the Baptist. More frequently, however, it is minor local water spirits (nymphs, water serpents, etc.) or wells and streams blessed by saints or other holy men to which devotion is made and from which healing is expected after immersion. A special, but universal, belief is the faith in the efficacy of bathing in certain streams for the restoration of fertility to barren women.

Certain great landmark rivers, the scene of both civic cults and private devotions, are believed to have general therapeutic and apotropaic powers. By immersion in the Euphrates (Iraq), the Abana, the Pharpar (in Damascus, Syria), the Jordan (Israel), the Tiber (Italy), the Nile (Egypt), or the Ganges, Jumna or Saravatī (all in India), one might be cured of disease, purified from transgression, or protected against future disorders.

These same basic features—unusual natural characteristics, scenes of epiphanies, locations associated with the life or the burial place of holy men, or great national landmarks—are present in each variety of healing shrines (*e.g.*, those associated with sacred trees, stones, or mountain peaks).

Healing cults centred around sacred organizations. As in the case of various monastic orders throughout Europe that have as their primary function the care of the sick (*e.g.*, the Knights Hospitallers, the Augustinian Nuns, the Order of the Holy Ghost, and the Sororites Order), healing has frequently been delegated to certain groups. Among these are special classes of priests (*e.g.*, the Akkadian Āshipu or Kalū priests, the Greek Asclepiads); religious castes (*e.g.*, various Brahmin groups in India, the Vaidya caste in Bengal); secret societies (*e.g.*, the Midēʻwiwim type groups among the American Indians—such groups can be highly specialized, for among the Sia Indians there are eight societies: one specializes in treating burns, one in ant bites, etc.); or dynasties of healers who trace their knowledge back to the gods (*e.g.*, the Physicians of Myddvai in Wales, who have been active herbalists for more than five centuries). The formation of such groups has been and is in part due to the priests' services at shrines and their possession and manipulation of certain sacred objects and relics that are the sources of the priestly charisma (supernatural power) of office. Most prominent are those priests who serve in the cults of healing deities (*e.g.*, Asclepius, Hygieia in Greek religion) or at shrines devoted to healing saints (*e.g.*, St. Cosmas and St. Damian in Christianity). The tendency to concentrate healing activities in specialized sacred organizations is also due to the length of training required to master the arts of healing, the need for special equipment and libraries, and the expense of maintaining such facilities—all of which may be readily borne by settled religious communities. Thus, many important religious leaders have also been physicians (*e.g.*, Mani, Moses Maimonides) and the origin of hospitals in both East and West is linked to religious orders.

Specialized healing societies and healers

Healing cults centred around individual healers. Healing may be accomplished by those who possess powers due to their office, such as priests and kings. More frequently, however, individuals are believed to cure by means of a special gift or sacred commission. They are holy men, and one means by which their sacrality is manifested is their power to heal. This power may be revealed in a vision; it may be sought after; or it may be accidentally discovered that an individual possesses such abilities.

Almost every religious founder, saint, and prophet has been credited with the ability to heal—either as a demonstration of or as a consequence of his holiness. In every culture there are also specialists who frequently have gone through extraordinary initiations that confer curative powers upon them. These individuals (*e.g.*, shamans, "medicine men," "folk doctors") may fill a cultural niche alongside certain religious groups, fulfilling their functions when circumstances so require. Some work within an established religious tradition but concentrate their energies primarily upon healing (*e.g.*, well-known Christian faith healers of the 19th and 20th centuries, such as John of Kronstadt; Chlodwig Karl Viktor, Fürst zu Hohenlohe-Schillingsfürst; Leslie Weatherhead; Edgar Cayce; and Oral Roberts). Others have founded their own religious communities that maintain a focus on healing (*e.g.*, Phineas P. Quimby and the New Thought movement; Mary Baker Eddy and Christian Science; the various independent churches of Africa; the Spiritist and Hallelujah movements among the Carib peoples in Brazil).

THE NATURE OF ILLNESS AND TECHNIQUES OF HEALING

The various practices of religious healing may be divided into three groups according to the varying views of the origin and nature of illness. The method of cure is determined by what is believed to be the cause of illness in a particular case.

Diseases related to spiritual powers. The first group assigns the cause of disease to the actions of various spiritual powers. Deities and demons, according to this view, in the beginning of creation acted in a universal way so that the forces of disease and death were unleashed, and the narrative of their actions is given in myths of origin. Usually, however, the action is specific and is directed against an individual.

Demon possession, object intrusion, and soul loss

In demon possession, the demon or spirit enters into the body of the afflicted individual, either obviously—manifesting itself in erratic behaviour—or secretly. In the latter case the healer must first determine, usually through some form of divination, that the sick person has in fact been possessed and also the identity of the spirit that possesses the individual. The spirit will then be driven out by various means: expelled through exorcistic techniques; purged by the use of herbs or other concoctions; removed surgically by opening the means for its egress; or transferred by magical means to another person, animal, or object.

Closely related is the notion that illness is caused by a spirit manifested in the form of a foreign body (usually a small stone) in the patient. Hence, it is believed, re-

moval of the object by exorcism, purgation, or surgery will restore health.

Illness is also believed to be caused by the loss of soul—the seat of vitality—most usually during sleep when the soul is believed to leave the body and wander. Many misadventures are possible: the soul may be captured by demons; it may come under the influence of a hostile magician; or it may simply lose its way. A specialist (usually a shaman) is required to retrieve the soul by means of magical flight or do combat with hostile powers in order to win its release.

Diseases related to human maleficence. The second group locates the cause of disease in the maleficence of other men. While witchcraft, in this view, may adopt the techniques of possession, object intrusion, or soul stealing to cause disease, the initiative comes from a human being who has special power because of his relation to the supernatural world. In curing, divinatory techniques are most important in order to determine the identity of the witch. Once this is accomplished countermagic, exorcism, or forms of placation will negate the baneful influence and restore health.

Diseases related to the afflicted individual. The third group places responsibility for illness on the afflicted individual. The sufferer, either consciously or unconsciously, has neglected a religious obligation or violated a sacred prohibition, and is thus punished through illness. If unconsciously, divination is required to learn the nature of the offense. Confession, expiation, and repentance will lighten or eliminate the effects of the transgression. In some religious traditions illness is seen as either an illusion or the result of lack of knowledge about the nature of the human condition. Curing is accomplished through enlightenment bestowed by a prophet or saviour.

EVALUATION

The assessment of healing cults remains a difficult problem. Some of the illnesses are psychosomatic in origin, some of the techniques are physiologically effective (*e.g.*, close to half of the herbs used in curing ceremonies are medically active); but such interpretations do not do justice to the religious power of these cults. They stem from and are a response to a profound and universal diagnosis of the human condition—man is weak and there are deep anomalies in his situation. By describing, mapping, interpreting, and organizing those elements in human experience that resist man's control and understanding, these cults aid man to understand himself and his world, and to live in it.

BIBLIOGRAPHY. There is no recent, reliable survey of this topic. The articles on "Disease and Medicine" and "Health and Gods of Healing," in J. HASTINGS (ed.), *Encyclopaedia of Religion and Ethics*, vol. 4, pp. 723–772, vol. 6, pp. 540–556 (1908–27), remain the best overall treatments. G.H.T. BUSCHAN, *Über Medizinzauber und Heilkunst im Leben der Völker* (1941), is a rich collection of material primarily drawn from primitive practices and contains a full bibliography. F.E. CLEMENTS, "Primitive Concepts of Disease," *University of California Publications in American Archaeology and Ethnology*, 32:185–252 (1932), is the classic study of primitive theories of the origin of disease. CLAUDE LEVI-STRAUSS, *Structural Anthropology*, ch. 9–10 (1963), provides a model of the serious anthropological interpretation of the "truth" of primitive healing practices. H.E. SIGERIST, *A History of Medicine*, vol. 1 (1951), surveys primitive and ancient Near Eastern medical practices; W.A. JAYNE, *Healing Gods of Ancient Civilizations* (1925), is most useful for Greco-Roman cults. D. MCKENZIE, *The Infancy of Medicine* (1927); and G.G. DAWSON, *Healing: Pagan and Christian* (1935), are informative, anecdotal descriptions of early Western and Christian folk medicine. WILLIAM JAMES, *The Varieties of Religious Experience: A Study in Human Nature* (1902), contains much documentary material on modern Christian healing cults and is the most profound treatment of the religious role and function of healing.

(J.Z.S.)

Health, Human

Health, like the weather or fortune, may be good or bad and is variously defined. It may be thought of as the extent of an individual's continuing physical, emotional, mental, and social ability to cope with his environment. René Dubos frames the problem succinctly in "Determinants of Health and Disease" (Britannica Perspectives, vol. I, p. 281; 1968):

> The all-inclusive and consequently vague meaning of the word health can be traced all the way back to its Anglo-Saxon root, which means "hale," "sound," "whole." Irrespective of precise medical criteria, the experience of feeling healthy has always consisted in being able to function well physically and mentally and to express the full range of one's potentialities. The preamble of the charter of the World Health Organization attempts to convey this utopian ideal in the following words: "Health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity." Health so defined is a utopian state indeed.

Definitions of health

Within this framework, good health for the librarian, the artist, or the department store clerk, for example, might be quite different from good health for the logger or the farmer or the steelworker. Such a definition has its drawbacks. The librarian, for instance, may be a rather fragile individual who stays "well" within the ordinary environment of his or her existence but succumbs to a heart attack from heavy shovelling after a snowstorm; or a sea-level dweller may move to a new home in the mountains, where the atmosphere has a lower content of oxygen, and suffer from shortness of breath and anemia until his red blood cell count adjusts itself to the altitude. Thus, even by this definition, the conception of good health must involve some allowance for change in the environment.

Bad health can be defined as the presence of disease, good health as its absence—particularly the absence of continuing disease, because the person afflicted with a sudden attack of seasickness, for example, may not be thought of as having lost his good health as a result of such a mishap. The same might apply to a pregnant woman, perfectly healthy in the afternoons and evenings but suffering from morning sickness a few hours each day.

Actually, there is a wide variable area between health and disease. Only a few examples are necessary to illustrate the point: (1) It is physiologically normal for an individual, 15 to 20 minutes after eating a meal, to have a high blood sugar content. If, however, the sugar content remains elevated two hours later, this condition is abnormal and may be indicative of disease. (2) A "healthy" individual may have developed an allergy, perhaps during early childhood, to a single specific substance. If he never again comes in contact with the antigen that causes the allergy, all other factors remaining normal, he will remain in that state of health. Should he, however, come in contact with that allergen, even 20 or 30 years later, he may suffer anything from a mild allergic reaction—a simple rash—to severe anaphylactic shock, coma, or even death, depending upon the circumstances. (3) An apparently healthy individual may imbibe a relatively large amount of alcoholic beverage. After the alcohol reaches certain levels in his bloodstream he exhibits certain behavioral changes, and his condition is referred to as intoxication. During this period, and usually the morning after, he cannot be considered as being in good health. He may regain his normal health in a few days or less; but frequent repetition of this performance, or daily ingestion of large amounts of alcohol, even when no apparent behavioral or hangover effects are noted, insidiously convert a condition of good health to bad health—sometimes irreversibly. Thus it can be seen that, unlike disease, which is frequently recognizable, tangible, and rather easily defined, health is a somewhat nebulous condition, difficult to define and never in a state of perfection—*i.e.*, one can be "really sick" but never "perfectly healthy."

Moreover, physical condition and health are not synonymous terms. A seven-foot-tall basketball player may be in excellent physical condition (although outside the range of normality for height) but may or may not be in good health—depending, for example, on whether or not he has fallen victim to an attack of influenza. The one-

Table 1: Normal Values for Human Blood

characteristic or property	range of normality	chemical component	range of normality*
Volume	7–9% body weight (about 5 quarts)	Glucose (blood)	80–120
pH (acid–base measurement)	7.35–7.45	Serum protein (total)	5.9–7.5 g
Red blood cells	4,500,000–5,500,000 per cu mm	Albumin–globulin (Alg) ratio (plasma)	1.3:1–2.9:1
White blood cells	5,000–10,000 per cu mm	Fibrinogen (plasma)	290–500
Platelets	200,000–400,000 per cu mm	Nonprotein nitrogen (blood NPN)	25–40
Hemoglobin content	14–16 g per 100 ml	Blood urea nitrogen (BUN)	8.0–20
Hematocrit	47 ± 5%	Uric acid (blood)	3.2–5
Colour index	0.9–1.1	Cholesterol, total (serum)	130–250
Volume index	0.9–1.1	Iodine, protein-bound (blood)	4.0–8.5μg
Bleeding time	1–3 min	Sodium (serum)	312–342
Coagulation time	5.5–12.5 min	Potassium (serum)	14–21
Specific gravity (25° C)	1.05–1.06	Calcium (serum)	8.5–11.5
Relative viscosity (38° C)	4.7	Phosphorus, inorganic (serum)	2.5–4.0
Sedimentation rate	0–20 mm (first hour)		
Prothrombin time	10–15 sec		

*Values except where indicated are milligrams per 100 millilitres.

armed gymnast, the colour-blind skater, or the pianist born blind—all may be in good health; but are they in good physical condition? Again, this depends upon definitions, and definitions vary.

Moreover, factors relating to specific physical fitness may complicate the estimate of a particular person's state of health. Specific physical fitness is the possession of the physical attributes and ability to function that are required for a job or situation that is particularly taxing. Physical strength, endurance, ability to work without oxygen in brief bursts of activity, ability to consume adequate oxygen for taxing efforts that take a longer time, ability to make sudden changes in posture, ability to move quickly, accurately, and with agility—these all are qualities that might be required in particular situations. A person who had been "in perfect health" in one environment might suddenly seem unhealthy if he were confronted with a new job or a new situation that made demands upon him not previously encountered.

There are further problems in settling upon a definition of human health. A person may be physically strong, resistant to infection, able to cope with physical hardship and other features of his physical environment, and may still be considered unhealthy if his mental state, as measured by his behaviour, is deemed unsound. What is mental health? Some say that a person is mentally healthy if he is able to function reasonably well. Others hold that a person is healthy mentally if his behaviour is like that of a majority of his fellows. A third group makes comparisons with an ideal. According to these physicians mental healthfulness may be approached but not attained. The originating of this attitude is attributed to Sigmund Freud, who is quoted as saying, "A normal ego is like normality in general, an ideal fiction." Still another concept stresses the changes in a person's behaviour that take place with the passage of time as criteria of his mental health.

In the face of this confusion, it is most useful, perhaps, to define health, good or bad, in terms that can be measured, can be interpreted with respect to the ability of the individual at the time of measurement to function in a normal manner and with respect to the likelihood of imminent disease. These measurements can be found in tables of "normal values" printed in textbooks of clinical medicine, diagnosis, and other references of this type. When an individual is given a health examination, the examination is likely to include a series of tests. Some of these tests are more descriptive than quantitative and can indicate the presence of disease in a seemingly healthy person. Such tests include the electrocardiogram to detect some kinds of heart disease; electromyogram for primary muscle disorders, liver and gall bladder function tests; and many types of X-ray techniques for determining disease or malfunction of internal organs.

The health examination

Regarding the changing pattern of health from primitive times, Dubos wrote:

> In the course of evolution, as his characteristic structural, physiological, and mental equipment gradually emerged, ancient man developed the fitness to resist environmental threats, those dangers emanating from cosmic forces, food shortages, microbial parasites, wild animals, or human competitors.
>
> Most of the skeletal remains found in Paleolithic and Neolithic sites are of vigorous adults essentially free of organic diseases at the time of death. Human remains of more recent origin provide further evidence of primitive man's ability to resist harsh natural conditions, at least until he is exposed to influences of Western civilization. A large burial ground from a period preceding Captain Cook's discovery of the Hawaiian Islands was recently excavated in Honolulu; the skeletons recovered from the site had healthy teeth and strong bones with powerful muscle attachments. Apparently life on the Hawaiian Islands was compatible with health and vigour even under the primitive conditions of pre-European settlements. Similar discoveries made in other parts of the world validate the legend of the healthy, happy savage appearing in accounts of primitive life written by 17th- and 18th-century explorers.
>
> Recent medical surveys of contemporary African, American Indian, and Australian tribes give us even more convincing evidence that health and vigour can be achieved under primitive conditions in extremely harsh climates. During the 1960s, Western physicians, biologists, and anthropologists studied the Meban Negroes of East Africa and the Chavanté Indians of the Brazilian Mato Grosso in their own undisturbed environments. The Meban and Chavanté tribes live in isolated primitive villages, with limited food resources, under difficult climatic conditions and out of contact with Western technology or medicine. Men in both tribes were found to be extremely vigorous and of magnificent physique. They were essentially free from dental caries, high blood pressure, cancer, and other degenerative diseases so common in civilized, prosperous countries.

Other tests give numerical results (or results that can be assigned numerical values—such as photometric colour determinations) that can be interpreted by the examiner. These are physical and chemical tests, including blood, urine, and cerebral spinal fluid analyses. The results of the tests are compared with the normal values; and the physician receives clues as to the health of his patient and, if the values are abnormal, for the methods of improving the health.

A major difficulty in the interpretation of test results is that of biological variability. Almost without exception these normal values for variables are means or adjusted means of large group measurements. To give these values significance—hence the frequent use of the word

Table 2: Normal Values for Human Urine

property or constituent	range of normality (grams)*
Acidity	slightly acid
Colour	pale yellow to amber
Specific gravity	1.0025–1.025
Amount	1.25–1.5 litres
Urea	18–32
Uric acid	0.5–0.75
Creatinine	0.35–0.45
Ammonia	0.5–15.0
Nitrogen, total	9.5–16.5
Sulfur, total	1.0–3.5
Phosphate	1.95–3.75
Chloride	10–15
Sodium	2.5–7.0
17-Ketosteroids	
Male	.005–.027
Female	.005–.015
Solids, total	45–75

*Quantitative values, unless otherwise indicated, are grams in a 24-hour sample of urine from an average adult; variation may be wide depending on dietary intake.

standard rather than normal in describing them—they must be considered as lying somewhere near the centre point of a 95 percent range; *i.e.*, the so-called ordinary range or, with reservations, the range from normal to the upper and lower borderline limits. Thus, the 2.5 percent below the lower limit and the 2.5 percent above the upper limit of the 95 percent range are considered areas of abnormality or, perhaps, illness. Some areas have wide 95 percent ranges—blood pressure, for example, may vary considerably throughout the day (*e.g.*, during exercise, fright, or anger) and remain within its range of normality.

Other values have ranges so narrow that they are termed physiological constants. An individual's body temperature, for example, rarely varies (when taken at the same anatomical site) by more than a degree (from time of rising until bedtime) without being indicative of infection or other illness.

Table 3: Normal Values for Human Cerebrospinal Fluid

property or constituent	range of normality (mg per 100 ml CSF)*
Volume	90–150 ml
Specific gravity	1.006–1.008
Colour	clear, colourless
pH (acid–base measurement)	7.35–7.70
Freezing point	−0.6–0.5° C
Pressure	70–80 ml mercury
Solids, total	850–1,700
Protein, total	12–43
Chloride	420–450
Sodium	500–545
Nonprotein nitrogen	12–30
Cells	0–10 per cu mm

*Quantitative values, unless otherwise indicated, are milligrams per 100 millilitres of CSF.

In the accompanying tables may be found a selection of ranges of normality that are frequently used in physical and clinical diagnosis and in health examinations. In general, values are calculated averages for adult males and nonpregnant, nonlactating females.

For conditions in which values are higher or lower than the range of normality, see BLOOD DISEASES; CEREBROSPINAL FLUID; DIAGNOSIS; DISEASE, HUMAN; ENDOCRINE SYSTEM DISEASES AND DISORDERS; EXCRETORY SYSTEM DISEASES. (W.Sp.)

Health and Disease, Economics of

Health economics is the study of the use of resources for health services and the effects of health and ill health on the economy. Health economists attempt to measure the quantity and economic effects of health services for a given period and how these services are financed. They also study the economic effects of different types of health-service organization and payment systems; the efficiency with which resources are deployed; and the effects of disease, the cure of disease, and standards of health on individual and national production.

Health resources. The resources used in health services consist of (1) buildings, such as hospitals, nursing homes, health centres, clinics, surgeries, offices, dispensaries, shops where health goods are sold, and factories where health goods are made; (2) personnel, such as physicians, dentists, opticians, pharmacists, auxiliaries—such as medical assistants and medical aides, who may diagnose and treat and auxiliaries who provide treatments normally under medical direction (for example, physical therapists, speech therapists, radiographers)—nursing staff, research staff, teachers of the health professions, and the administrative, secretarial, and domestic staff who service health institutions; and (3) materials and equipment, such as pharmaceuticals, nonprescription drugs, dressings, X-ray equipment, surgical and scientific instruments, uniforms, and hospital food.

Many of the goods and services used in health services are used for other purposes as well—for example, food and domestic labour. The precise border of the health "industry" can only be defined by considering the purpose for which particular resources are used. Sunglasses, tonics, and mineral water, for example, may or may not be used or consumed for health purposes. There is no internationally accepted definition of pharmaceuticals; the scope of pharmaceutical preparations that can be obtained only on the prescription of a physician varies among the different countries of the world. Even the precise scope covered by the term hospital is not the same in different parts of the world. Many countries have residential institutions—which may or may not be called nursing homes, infirmaries, or hospitals—that provide care both for those requiring continuous nursing and medical supervision and those who need only welfare care; *e.g.*, the aged and mentally retarded.

EXPENDITURE ON DIFFERENT TYPES OF SERVICE

Categories of health expenditure

Health-service expenditure can be subdivided into capital expenditure—expenditure on buildings (new construction and conversion) and the purchase of durable goods for health purposes—and current expenditure. Current expenditure includes expenditure for (1) personal health services, including all curative, preventive, and promotive services given to identifiable individuals (such services can be given inside or outside a hospital, and can be received by inpatients, ambulatory patients, or patients in their own homes); (2) nonpersonal public health services, to promote a healthy environment, the benefits of which accrue to individuals not readily identifiable; and (3) teaching and research.

A study organized by the World Health Organization of the United Nations, the latest study of this scope that is available, attempted to ascertain expenditure on health services in different countries in as comparable a form as possible. The study was for the year 1961 or the nearest year for which information could be made available. Data from this study are used in the tables and diagrams in this article. Table 1 shows current expenditure (whether financed collectively or privately) on health services in 13 countries. About one-half of the expenditure on health services was channelled through hospitals, though the exact proportion varied considerably between countries.

About one-half of the expenditure (ranging from 37 percent in Czechoslovakia to about 60 percent in the United Kingdom) on personal health care was for staff. The earnings of medical and dental staff represented about 16 percent of health expenditure in the United Kingdom and nearly 28 percent in Canada. Expenditure on nursing personnel was about one-seventh of expenditure in both countries. Expenditure on medicaments was about 18 percent of expenditure in Canada and 9 percent in the United Kingdom.

Table 1: Percentage Distribution of Expenditure on Health Services
(1961 or nearest year)

	personal health services		nonpersonal public health	teaching and research
	through hospitals	outside hospitals		
Australia	43.7	52.9	1.9	1.5
Canada	42.7	54.5	1.0	1.8
Ceylon (Sri Lanka)	50.0	43.9	4.5	1.7
Czechoslovakia	47.7*	43.6	2.4	6.3
Finland	59.9	35.9	2.5	1.7
France	40.7	55.8	1.7	1.6
Israel	45.3	50.0	1.6	2.7
Poland	39.9*	53.2	2.8	4.1
Sweden	52.9	42.4	1.2	3.5
Tanganyika	44.8	50.2	4.3	0.8
U.K.	51.4	44.3	1.9	2.1
U.S.	36.2	56.9	0.3	4.6
Yugoslavia	40.7	49.9	3.9	3.0

*Including balneological institutions (health baths).
Source: Brian Abel-Smith, *An International Study of Health Expenditure*, 1967. Further qualifications to the above data are fully set out in that volume.

Capital expenditure on health services (excluding that on factories making medical goods and the construction of offices by private practitioners) normally amounts to between 3 percent and 12 percent of health expenditure in different countries. In most but by no means all countries, the bulk of the capital expenditure goes for hospitals.

FINANCING HEALTH SERVICES

The right to receive medical service. Public health measures to protect the environment (for example, the control of food, water, and the disposal of sewage) have to be collectively financed; this function is normally performed by government (central, regional, or local). Similarly, medical research has to be collectively financed. In both cases this is justified by economists on the ground that the benefits are expected to accrue to society as a whole and that these social benefits are greater than the benefits that go to individuals and for which individuals might be willing to pay. Similar arguments are used to support the case for collective provisions to contain and treat communicable diseases. The benefit from the treatment of a person suffering from communicable disease is not confined to the individual being treated, but extends to all for whom the risk of infection is reduced.

The special problems of financing health services stem from the growing belief that people ought to receive medical care for humanitarian reasons, regardless of their ability to pay. The preamble to the Constitution of the World Health Organization states, "The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being." Many countries have attempted to provide for this right to medical care by legislation. In some countries, the question of whether medical care should be provided as a legal right or as a privilege is still not resolved. In others, it would involve a high proportion of national resources to attempt to provide comprehensive health services. Indeed, resources may be inadequate to secure adequate levels of nutrition.

The question of medical care as a legal right or a privilege

Inability to pay for medical care is not of the same character as inability to pay for such other necessities as food and shelter. Though the total incidence of sickness may be predictable for society as a whole, sickness, like unemployment, is for the individual an unpredictable risk that can stop the flow of earnings. While provision for unemployment can be made by a cash allowance that is related to previous earnings or that provides or secures a subsistence or minimum level specified for the particular country or area, a standard weekly or monthly cash benefit cannot ensure that any bills for medical care can be paid. This is because the expenditure required per day or week to meet medically determined need can vary enormously according to the nature of the illness or injury.

The problem of ensuring that the whole population is in a position to purchase the medical care that physicians recommend has become more and more acute, because, although levels of living have been rising in many countries, the possible useful expenditure on medical care per unit of time has been rising much faster, largely because of the growth in medical knowledge and the development of more and more expensive diagnostic and treatment procedures.

Thus, families with modest savings and moderate incomes—families that would not be regarded as poor or indigent—may, nevertheless, be unable to pay for the medical care of a family member. Hence the use of the term medically indigent to describe people who normally can pay their way but cannot afford to bear the extraordinary costs of illness. Some countries have a higher income level of eligibility for health and medical care under public assistance or relief programs than is used to provide for ordinary living expenses. Criteria used to define medical indigence vary widely. Much depends on the extent to which medical costs are related to the capacity to pay and on the level of living of the particular country or community, quite apart from the policies and sources of income of the public authority providing for the indigent.

The history of financing health services. Many societies once responded to the problem of medical indigency by the provision of services on a charitable basis. In Europe and America, hospitals and dispensaries were endowed by public subscription or by religious bodies to provide medical services for the poor. The physicians working part time in such hospitals gave their services or received a nominal payment. Soon after they were founded, some such hospitals in the United States began to take paying patients, whom the physicians billed for their services. It was not until the 1890s that the extensively developed voluntary hospitals for acute disease in England opened beds for paying patients.

In other countries (for example, Sweden and the Soviet Union), government played a major role in developing hospitals. In general, governments have tended to make larger and earlier provision of hospital facilities for mental illness and infectious disease than for acute sickness. There was a clear advantage for the rest of the public if the infectious and the insane were isolated in hospitals, quite apart from the treatment provided for the individuals with these afflictions.

In the case of physician care, the physician has long been considered to have an obligation to provide for the poor. This obligation has led to the acceptance by many societies of the physician's right to discriminate in his fees—to charge the rich more than those with middle and low incomes. As other solutions to the problem of providing for the medically indigent have been developed, it has been questioned whether the continuation of price discrimination of this kind can still be justified.

In Spain, an early solution to the problem of paying medical bills was for the physician to receive regular payments from local inhabitants in return for his provision of services as required. Informal physician-run insurance also developed in The Netherlands and in some other countries, but, in most of Europe, informal and, later, formal health insurance was developed most extensively under the control of local consumer or occupational groups. The origin of this mutual insurance can be traced back to the early guilds, medical clubs, and benefit and friendly societies. Local or occupational sick funds and friendly societies became extensively developed in Germany, Denmark, The Netherlands, the United Kingdom, and other countries by the end of the 19th century. Gradually the arrangements were formalized and developed under national-health-insurance legislation, starting in Germany in 1883 and extending to other European countries during the 20th century.

Informal health insurance

A fourth solution to the problem of making available the services of physicians to poorer people was by the employment of physicians by the government. There is a long tradition of employment of government medical officers in Sweden to work in designated districts, and the system was also introduced in Russia under the tsars. The developing countries of Africa and Asia have also gener-

ally provided for the needs of the medically indigent—the majority of the population—by providing health care in and out of hospitals by a national or regional comprehensive service employing salaried physicians. This service often is available to private patients also, but in most such countries the more affluent section of the population obtains the bulk of its health services through private arrangements. National- or state-planned services, available to the whole population, are the pattern in eastern Europe. In the Union of Soviet Socialist Republics, the long tradition of government hospitals and government clinics was extended by the Communist regime in the interwar period, and a health service run by the government has been adopted by eastern European governments influenced by the Soviet Union.

Since 1948 the United Kingdom has provided a national health service, offering comprehensive services to the whole population either free or subject to nominal charges, and most hospitals were taken into public ownership at that time. Physicians' services outside the hospitals are provided by generalist physicians who are not employees of the government but have contracted to provide services to designated patients registered with them. A small private sector of hospital care continues in Britain—largely financed by voluntary insurance.

In nearly all countries of the world, the majority of hospital beds are owned by government. The main exceptions are Canada, The Netherlands, and the United States. In the latter, most hospitals for the mentally ill are run by public authorities, but most hospitals for other patients are controlled by nonprofit corporations.

ASSESSING PAYMENTS

Physicians' services. *Fee for service.* Under private practice, the physician normally bills the patient for each service he has performed (such as an office call, home visit, injection, or operation). This system of remuneration is currently used under most voluntary and national health-insurance systems. In most cases elaborate lists of services, with a designated fee for each service, have been negotiated with the profession by the insurance system. Usually the negotiated fee represents the total that the physician can claim for the service, whether (as is usually the case) he makes his claim direct to the insurer or whether he claims from the patient, who in turn is reimbursed in whole or part by the insurer. In some countries (for example, in Sweden), however, physicians (or certain classes of physicians) are free to bill the patient with an addition to the fee he receives from the scheme. In the United States, there is no negotiated fee under Medicare (compulsory health insurance for the aged) or Medicaid (the program for the medically indigent). The physician is free to charge his customary fee.

Types of fee for service

One difficulty with fee-for-service payments is that the physician may encourage unnecessary visits and perform services that are not strictly necessary. Regulations and provisions within fee structures are used to limit the effect of this type of incentive. In France, Switzerland, and The Netherlands, control physicians are employed by the sick funds to detect and disallow or recommend disallowance of claims by physicians. In the Federal Republic of Germany (West Germany), this function is performed by the profession itself. While at first sight, fee for service would suggest greater freedom for the physician, in practice there tend to be more controls under health-insurance schemes than in other systems of remuneration.

Problems in fee-for-service payments

When all or part of the fee falls on the patient, some persons postpone seeking treatment. Persons with low incomes may also postpone treatment under a system of total reimbursement, because of the lack of ready cash to finance the bill that is awaiting settlement. It has been suggested that a fee-for-service system leads to inadequate attention to preventive medicine. When fees are standardized under compulsory-insurance systems, there is no clear incentive for work of superior quality. While the better physicians can be expected to attract more patients (if patients are aware of their superior skill), in so far as more time is required to provide good care, the physician tends to receive lower rewards.

Salary. Public-health physicians throughout the world are generally paid on a salaried basis. This system of remuneration is also the pattern for nearly all physicians in eastern Europe and most physicians in Israel and in the health services of most of Asia and central and southern Africa for the general population.

In most countries in western Europe, separate specialist physicians work in the larger hospitals to whom generalist physicians working in the community transfer the care of patients who are admitted. These hospital physicians are generally paid on a full-time or part-time salaried basis. Part-time salaries are extensively used for hospital physicians in Spain and Latin America.

In theory, salaried payment could lead to lack of diligence in caring for patients, brusque behaviour, and poor attendance, but much depends on the extent of commitment and supervision. The possibility of promotion based on merit within a hierarchical salaried structure can be an effective incentive to painstaking work. Difficulties are greatest when a part-time salary is paid and the physician spends the rest of his time in private practice, which is more highly remunerated.

Capitation. Capitation is a fee paid normally to an out-of-hospital physician for offering services to a patient for a period of time (*e.g.*, a quarter year or a year). The payment is made whether the patient does or does not need to use the services of the physician during the period. The rate of capitation may be reduced when a physician's list exceeds a particular figure.

This system of payment is used under compulsory health insurance in Italy, The Netherlands, Spain, and the United Kingdom. In the latter, a higher capitation fee is paid for a person over age 65, in view of the greater need for medical care. The generalist physician also receives certain flat-rate allowances, which do not vary with the size of his list of patients, and a few fees for specific services (preventive services, maternity cases, and out-of-hours calls).

In theory, capitation payment could lead to less than diligent care. In addition, there is a clear incentive for unnecessary referral to specialists. In both Italy and The Netherlands, this aspect is closely examined by officials of sick funds and may lead to complaints to the local medical association. On the other hand, capitation payment creates an incentive for preventive care and encourages continuity of generalist care.

Incentive for preventive care

Capitation is used in some programs in the United States as a payment by the insurer to a medical group for comprehensive health care. The medical group may make other types of arrangement for the remuneration of physicians working in the plan.

Case payment. Under private practice a physician may make a quotation per case; for example, for the total care of a maternity case. The fee might cover care while the patient is in the hospital and checkups afterward.

Case payment has also been used as a system of paying generalist physicians under health insurance. It differs from capitation in so far as payment is made only for those patients actually treated. It developed in the Germanic countries in the 19th century and still survives in parts of Austria. In general, this system has been replaced by fee-for-service remuneration.

The case method is also used for specialists in The Netherlands. While they are paid on a fee-for-service basis for technical, surgical, and similar defined procedures, they collect case payments for the routine care of ambulatory patients and hospital inpatients.

Payments for hospital care. The most widely used system of charging for hospital care is by the length of stay in the hospital. Charges are generally calculated per day of residence. When the physicians are in a salaried relationship to the hospital, it is common for the charge to cover all services provided, including those of physicians. When a physician is not in a salaried relationship with the hospital, he generally submits a separate bill for his services, per case or per item of service. Thus a hospital patient may receive bills from several physicians if he has needed the services of more than one specialty. In a profit-oriented hospital system, the daily charge may

cover only the charge for the room and basic nursing and food. All other items may be billed separately (*e.g.*, such items as special nursing, use of the operating theatre, pathological tests, X-rays, pharmaceuticals, blood transfused, and special diet).

SOURCES OF PAYMENT OF COSTS

Funds for payment of costs may come from indirect or direct payments.

Indirect payments. *Government.* Government sources of funds include expenditure from all government agencies, whether central, state, or local, or those made by the health or other departments or from special funds belonging to government or statutory bodies. All charges and fees paid by the recipient of services provided by government agencies are classified as payments by recipients (see below).

Compulsory social insurance. Compulsory social insurance covers all payments for goods and services, irrespective of the original source of the money (but excluding fees or charges), under an official compulsory scheme; the right to benefit is limited in principle to persons for whom obligatory contributions have been paid (either by themselves or by others) and whose possession of private means does not offset the right to benefit. Such schemes may be designated as sickness, invalidity, or maternity insurance or as workman's compensation.

Other agencies. Other indirect sources of payment are voluntary insurance funds, including nonprofit and profit-making insurance; voluntary subscriptions and charitable funds; grants from outside the country; and other corporate funds.

Types of voluntary insurance

Insurance is regarded as voluntary even when membership is a condition of employment. Contributions from the government as an employer for its employees are counted as private insurance. Voluntary insurance includes (1) nonprofit insurance, which covers voluntary social insurance and insurance that may be operated by friendly societies, mutual-benefit societies, trade unions, and any other bodies that are non-profit-making, and (2) profit-making insurance, which covers all private profit-making carriers and includes cash payments made for the reimbursement of medical costs.

Voluntary subscriptions and charitable funds are moneys contributed in such a way that the contributor himself has no right to benefit from the fund contributed. Also included in this category is any income from endowments.

Grants from outside the country include grants received from foreign governments under aid programs, from international agencies, and from trusts and individuals abroad. Many developing countries receive extensive help from international agencies and missions.

Other corporate funds include services provided in kind by employers for their employees.

Direct payment by recipient. All nonreimbursed payments, charges, and fees falling upon individuals in return for which health services were received are included in this category.

The percentage of funds estimated to have been contributed from these four main sources of funds for years approximating to 1961 in 17 countries are shown in Table 2.

INTERNATIONAL COMPARISONS OF HEALTH EXPENDITURE

Because prices of health goods, levels of remuneration for those working in health services, and the types of services provided under different health systems may differ substantially, it is not possible at present to make meaningful comparisons of the quantity of health services in different countries. Moreover, such comparisons lack meaning without some consideration of quality, which is particularly hard to define in this field.

It is possible, however, to make comparisons of the proportion of each country's total resources that is used in the health sector. These comparisons relate health-service expenditure in each country to the gross national product or national income of that country. Comparisons of this kind involve distortions if the relationship between health prices and earnings and other prices and earnings differ

between countries. In Figures 1 and 2 the percentage of national income devoted to total and to indirect current expenditure on health services (excluding investment in plant) are plotted against per capita national income in United States dollars. On the whole, the countries with higher levels of income tend to spend a higher proportion of their national income on health services, but there are interesting variations. Chile and Israel stand out as high spenders for their level of income. The United Kingdom is a low spender for its level of income.

Figures for indirect expenditure are more meaningful for developing countries, where the private sector involves only a small minority of the population. Figure 2 shows a slightly closer relationship between indirect expenditure and level of income.

Financing by local government

Among the high-income countries, those with multiple systems of financing health services seem to spend more than those with centralized health-service systems. In Scandinavian countries, local government plays a major role in financing health services. In continental western Europe and now Canada, compulsory insurance is the major system for financing health services. In the United States, voluntary insurance plays a major role, but the role of the public sector has increased in recent years.

Value for money. It does not follow that those countries that spend the most on health services necessarily provide either the largest amount of care or provide care of the highest quality or have the highest standard of health. High spending may be caused by relatively high remuneration for the professions involved, by lavish services enjoyed by a few while the needs of others (for example, the rural population or the minority groups) are relatively neglected, by high levels of profit (for example, for insurers or suppliers of medical goods—notably pharmaceuticals), by heavy administrative costs, or by duplicated and underutilized facilities.

A special feature of the medical-care market is that the consumer is in a poor position to assess the quality of care that he is given, quite apart from the comfort and courtesy with which it is delivered. As the consumer is not well equipped to assess the product he is purchasing, he can demand efficiency among suppliers of medical services only to a limited extent. The services that he needs may be largely selected by his physician, but the latter may have a regular association with a particular local health facility and may be neither well placed nor motivated to obtain the most favourable price, as distinct from desirable care, for his patient. If the bulk of the cost is paid by a third party, much depends on the extent to which the latter uses or is in a position to use bargaining power to monitor the quality of care and thus to promote the efficient use of health resources, to prevent unnecessary services, and to steer patients toward facilities that provide the greatest value for money.

The most expensive part of the medical-care system is the hospital. If care out of hospital has to be paid for, and care in hospital is free or nearly free, there will be incentives for patients to overuse the hospital, even though less expensive care in other types of institutions or in the community may be no less efficacious. The knowledge, incentives, and powers of patients, physicians, and financing agencies can all have important implications on the efficiency with which health resources are used.

Trends in cost. It might be expected that providing extensive health services and making them available to the whole population would in time reduce the amount that needs to be spent because of the general improvement in the health of the population; for example, the great reduction in the incidence of infectious diseases in the more developed countries (particularly with regard to tuberculosis since World War II) has undoubtedly led to substantial savings in expenditure on persons with these diseases.

Nevertheless, most developed countries are steadily spending more on health services—both absolutely and as a proportion of their total resources. In the 1950s it appeared that such countries devoted roughly an additional 1 percent of their total resources (gross national product) to health services over the decade. To this rule the United Kingdom was an exception, but it achieved about this rate of increase in the later 1960s.

Expenditure on personal health care in Canada has risen steadily, from 3.1 percent of gross national product in 1957 to 4.9 percent in 1969. In the United States, total health expenditure rose from 3.5 percent of gross national product in 1929 to 6.6 percent in 1968. Projections suggest that the proportion of health expenditure may rise to between 8 and 9.8 percent of gross national product by 1980. If present trends continue, there may be several countries that devote a tenth of their total resources to health services by the end of this century.

Rising expenditure on health care

Three main reasons can be identified for the growth in health expenditure. The first is demographic. Older people consume more health services than younger people. Thus, part of the increase in health expenditure is caused by the changing age structure of the population. People who would have died relatively young from an infectious disease are living to become victims of the degenerative diseases of old age, many of which are costly to treat. The second reason arises from the fact that health services consist to a large extent of personal care given by physicians, nurses, and others. While mechanization can reduce the labour requirement in certain areas of the health sector, the scope for labour saving is much more limited than in manufacturing industry. Third, and most important of all, the expansion of medical knowledge, new pharmaceuticals, and new treatment procedures, from transplants to kidney machines, have greatly extended the range of care that physicians can provide for the individual patient. These new techniques, both of diagnosis and of treatment, have greatly increased the staff and equipment needed to care for the average hospital patient, and it is in this sector of health services that costs are rising most rapidly. Expenditure on all hospitals in Canada, for example, rose from 1.8 percent of gross national product in 1957 to 3.1 percent in 1969.

BIBLIOGRAPHY. H.E. KLARMAN, *The Economics of Health* (1965), provides a useful introduction to the application of basic economic principles to the health service. J. HOGARTH, *The Payment of the General Practitioner* (1963), describes how general practitioners are paid under European health insurance systems and the development of and debates concerning these systems. W.A. GLASER, *Paying the Doctor* (1970), covers hospital doctors as well as general practitioners and discusses the effects of systems of remuneration. B. ABEL-SMITH, *An International Study of Health Expenditure* (1967), makes comparisons of health expenditure, both public and private, in 29 countries. H.M. and A.R. SOMERS, *Doctors, Patients and Health Insurance* (1961), is still a basic text that describes comprehensively the dilemmas of medical care in the United States; while the Canadian ROYAL COMMISSION ON HEALTH SERVICES, *Report*, vol. 1 (1964), performs a similar function for Canada.

(B.A.-S.)

Health and Safety Laws

The protection of public health and safety has been one of the first and most important objectives of government and law. In primitive cultures and in Western civilization until the Middle Ages, public health usually was protected in a negative way by either isolating or destroying the diseased in order to protect the healthy. Modern public-health laws, social legislation, and preventive medicine have been largely the products of scientific advancements of the 19th and 20th centuries.

The interests of the individual and of society in health and safety find expression in the orders of executives, the ordinances and statutes of legislatures and councils,

and the decisions of courts and administrative bodies. That such interests are among the most important values is suggested by the deference that courts have shown for legislative and executive formulations of health and safety policy. In the United States—*e.g.*, even during periods when courts wielded their power of judicial review to unprecedented degrees and readily substituted judicial preference for legislative judgment—health and safety laws were subject to milder scrutiny than measures involving, for example, economic experimentation. The common law at times gave priority to health and safety matters over property rights and economic interests.

Hazardous undertakings and the creation or maintenance of dangerous conditions or objects have long been a basis for special classification. English doctrine has imposed strict liability for the escape of dangerous substances, and the concept of nuisance has been construed to cover such cases in other jurisdictions.

Health and safety implications of the common law

The common law created an implied warranty of fitness for human consumption in the sale of foodstuffs, and liability for deleterious products today may be based on the fact of sale rather than on negligence in processing or failure to inspect. Summary procedure and something less than the due process usually required may be invoked when health authorities or fire marshals act to cope with emergencies, and both the police power of the state and the power of eminent domain may be utilized to protect or promote public health and safety.

During the 1960s measures to promote public health and safety proliferated. In the United States, Congress for the first time undertook to establish safety standards for automobile manufacturers; and dangers occasioned by atomic reactors, radioactive isotopes (unstable, radiation-emitting forms of substances), and related devices or substances led to the enactment of amendments to the Atomic Energy Act. Pollution-control legislation became widespread, as did efforts to prevent child abuse. Laws governing the voluntary and involuntary commitment of addicts were enacted in several jurisdictions.

During the same decade, there was increased international activity in the promulgation and implementation of health and safety laws as a result of programs sponsored by the World Health Organization and meetings and conventions on international harm occasioned by environmental pollution. With regard to the latter, the emphasis was on private liability under international law for harm done by pollution.

HISTORY

In addition to isolation of the sick, principles of hygiene and sanitation were developed by many preliterate peoples. Presumably, whenever these matters were deemed to be of sufficient social concern, they received the coercive sanction of law, as well as the informal sanctions of custom or religion. The preservation of peace and order, the conservation of manpower, and a desire to prevent offenses that may provoke the wrath of the gods against the community have been among the immediate objectives of law that may be included under the general title of public-health and safety laws. They have been the forerunners of what is termed the police power of the modern state.

The history of health and safety laws has been determined in large measure by the influences of religion and science and by political and economic forces. A public concern with the health problems of community life, the control of communicable diseases, and improvement of environmental and sanitary conditions, such as the provision of food and water, medical care, and sewerage and drainage facilities, may be found in varying degrees in primitive, ancient, and modern societies. Moreover, religious and health objectives may be inextricably intermingled, as, for example, in dietary laws, the rules of hygiene, and precautions against contagion specified in the Old Testament, prohibitions against consanguineous marriages, and the merging of functions in priests and shamans. In the Western world there was a close relationship, if not identity, between church and state until the Reformation, and for centuries virtually all literate men were clerics, which meant that most scientific knowledge was in their hands and subject to church control.

Intermingling of health and religious objectives

Early influences. The emphasis of the early church upon spiritual matters and the belief that disease and death are the wages of sin long stood as major obstacles to a positive program for public health and social reform. On the other hand, the church and its religious orders did establish and maintain institutions for relieving travellers, the sick, and widows. Such institutions included that founded by Basil the Great in AD 370 at Caesarea. Pope Leo XIII's encyclical *Rerum Novarum* (1891) and Pope Pius XI's *Quadragesimo Anno* (1931) were most important for the social-reform movement of the 19th and 20th centuries. (Concerned with social and economic reform, the *Rerum Novarum* expressed approval of legislation to protect labour and ensure its receiving a just reward. This position was reaffirmed by the *Quadragesimo Anno*.) It is only since the Industrial Revolution that cleanliness has been officially promoted.

The Middle Ages, about 500 to 1500, saw a decline from the standards of hygiene and sanitation of classical Rome. Although the world is greatly indebted to the Greeks for principles of personal hygiene and to the Romans for the development of public sanitation, there are records of elaborate programs in even more ancient times. Ruins in the Indus Valley and at Harrapa, in the Punjab, reveal that building codes were in effect and that sanitation engineering was far advanced as early as 4000 BC. Egyptian ruins dating from the Middle Kingdom (2100–1700 BC) include bathroom facilities and sewerage systems, as do those of the Incas in the New World. In addition to the formulation of principles of hygiene, the Greeks were responsible for the first attempt to show a causal relation between environmental factors and disease. The book in the Hippocratic collection known as *Airs, Waters and Places* served for over 2,000 years as the basic text on epidemiology and helped to sustain the miasmatic (contaminating-atmosphere) theory of disease until use of the microscope led to the discovery of microbes and the beginning of bacteriology. The Romans saw a relation between swamps and malaria, devised crude respirators to protect workers from dust, in the 2nd century instituted a public medical service, built sewerage systems and public baths, and engineered 14 great aqueducts. They also built the first hospitals and codified and administered health laws. Officials were appointed to maintain the banks of the Tiber, to guard the aqueducts against pollution, to inspect and maintain sewers, to destroy impure foodstuffs, to check weights and measures, and to regulate public baths, brothels, and burial grounds. Justinian I, when one of the worst plagues in history came to Byzantium in 532, set up quarantine posts and required certificates of health for admission to that city.

Contributions of Greeks and Romans

Middle Ages. Upon the disintegration of the Roman Empire, there was a general decline of urban culture and with it an abandonment of public-health measures. Byzantium became the cultural and medical centre for Europe, and from there Greco-Roman medical knowledge spread to the Arab world, while, in the West, health problems were still dealt with largely in terms of magic and religion. During medieval times some of the larger monasteries had proper water supplies and heating and ventilation facilities, but smaller buildings did not; and most medieval cities had a chronic problem in trying to provide sufficient supplies of nonpolluted water and in protecting the public from disease. During the Middle Ages in England the common-law concept of public nuisance provided a means for relief against some flagrant cases of pollution of water supply, as did the common-law crime of malicious mischief; and, in both England and on the Continent, ordinances and statutes were enacted to outlaw some of the most prevalent threats to public health. For example, Douai, France, in 1271, Augsburg, Germany, in 1453, and Rome, in 1468, forbade tanners to wash animal skins on the banks of streams, dyers to pour dye residue therein, and the public from washing clothes at a river that served as a source of water supply. Early

in the 15th century several German cities forbade the construction of hogpens facing the street. In 1185 the streets of Paris were paved to help keep the city clean. London from 1309 had ordinances dealing with the disposal of sewage and offal, and Milan from the 14th century had statutes regulating cesspools and sewers. Most of these ordinances and laws, however, were only sporadically enforced and tended to become dead letters.

Pure-food laws of Middle Ages

The health measures that received the most conscientious enforcement during the Middle Ages were those pertaining to the sale of adulterated or contaminated food and those providing for quarantine in the case of epidemics. Municipal authorities in many places policed the fairs and marketplace to protect purchasers of food. Inspection was practiced, and detailed regulations were enforced. For example, Augsburg in 1276 ordered meat that was not freshly slaughtered to be sold at a special stand, and the Florentines forbade the sale on Monday of meat that had been on sale the previous Saturday.

Although epidemics were regarded by many as a punishment for man's sin, the transmissibility of certain diseases was well-known during the Middle Ages and had been for centuries. The historian Thucydides had vividly portrayed an epidemic during the second year of the Peloponnesian War. Between the plague during the reign of the emperor Justinian (AD 543) and the Black Death (1348), there were a large number of plagues, involving such diseases as leprosy, bubonic plague, smallpox, diphtheria, measles, influenza, sweating sickness, and lesser diseases. The medieval urban dweller lived in constant fear of epidemics, and, when leprosy reached serious proportions in the 13th and 14th centuries, quarantine laws were rigidly enforced. At the beginning of the 13th century, in France alone there were about 2,000 leprosariums, and in all of Europe the number probably exceeded 19,000, although many sick persons were admitted who did not have leprosy.

Regulations for leprosy and bubonic plague

The third Lateran Council, in 1179, promulgated detailed rules to govern the commitment of lepers. The experience with lepers was carried over when the Black Death (bubonic plague) killed thousands of workers in the 14th century. Persons suspected of having the disease were required to report to local authorities, who examined them; if the patients were found to have the plague, they were isolated, as were all those who came into contact with them; food and necessities were provided; the dead with their personal effects were buried outside the city, and the place where they had died was fumigated. Venice, the chief port for trade with the Orient, usually is credited with originating the pattern of quarantine procedure that was in effect during the Middle Ages, and other seaports also established observation stations and isolation hospitals.

In England from the 12th to the 15th century, more than 720 hospitals were established, 217 of which were for lepers. At the beginning of the 14th century, Paris had about 40 hospitals and at least an equal number of leper houses. During the latter part of the Middle Ages, cities and guilds took an active part in founding and maintaining hospitals.

Later history. *Europe.* By the close of the Middle Ages, medicine and public health had fallen under local governmental control. Regulations protecting the water supply from pollution were supplemented by provisions dealing with street cleaning, garbage disposal, and the like, all of which collectively might be called sanitary codes. Physicians and surgeons were required to follow rigid codes and set fee schedules. In addition, writings on nutrition began to appear, and public bathhouses were licensed. When syphilis became widespread, early in the 16th century, the first control measures were directed against prostitutes.

The attempt to deal with public-health problems on a municipal basis was far from successful. Inland cities were all but defenseless against the spread of disease from the seaports. In the larger cities, moreover, the administration of particular ordinances was delegated to various boards, commissions, and officials, a situation that resulted in a crazy quilt of sanitary committees.

Colonial America. Colonial America followed the pattern of utilizing inspection and quarantine for communicable diseases and enacting sanitation legislation. An account by George Percy, John Smith's successor as governor of Virginia, regarding the settlement of Jamestown, Virginia, describes the "cruell diseases, Swellings, Fluxes, Burning Fevers" and famine that afflicted that colony. Almost half of the 100 or more Pilgrims who landed at Plymouth, Massachusetts, in 1620, died within three months after arrival. During the winter before the Pilgrims' arrival, an epidemic had reduced the numbers of Indian warriors of New England from 9,000 to a few hundred. Inoculation was brought to the Colonies by Zabdiel Boylston and Cotton Mather and later was regulated by colonial legislatures. As early as 1647, ships from the West Indies were quarantined in Boston Harbor; and in 1663, during a smallpox epidemic, New York regulated entry into its city by travellers from contaminated regions. Abatement of public nuisances seems to have been in the hands of local authorities throughout most of the 17th century, but a South Carolina statute of 1692 forbade swine running at large in the city of Charleston and directed all persons to cut noisome weeds in and about the lots and streets. During the same year the Massachusetts General Assembly empowered selectmen and justices to assign locations for slaughterhouses and places for the testing of tallow and the currying of leather. Charters granted by William Penn to Philadelphia and Chester, Pennsylvania, in 1701 conferred power upon mayors and magistrates to abate nuisances. Detailed quarantine regulations were enacted in Massachusetts in 1701. The first American health board was appointed in Baltimore in 1793, and by 1797 there were similar boards in New York and Massachusetts.

Early quarantine measures in Colonies

Influence of the Industrial Revolution. The Industrial Revolution occasioned a tremendous increase in urban population, and slum conditions became acute in many manufacturing areas. The first English attempt at slum clearance was in London in the 1760s, when many timbered buildings were pulled down and replaced by brick structures, and streets were paved, drained, and lighted. In addition to disease and slum conditions, the urban population faced poverty and frequent unemployment. The Elizabethan Poor Laws imposed on the individual parish the duty to provide relief, including medical relief, for the indigent.

SOCIAL REFORM

By the beginning of the 19th century in England and on the Continent, the interrelationship between poverty, disease, physical environment, and crime had become apparent, and the view that such conditions were neither inevitable nor irremediable was gaining ground. To the Rationalists of the Age of Reason, a scientific approach to social problems would provide the answers. Industrialists such as Sir Robert Peel and Robert Owen and physicians such as Sir John Simon and Thomas Southwood Smith joined the social-reform movement under the leadership of Jeremy Bentham and Edwin Chadwick. Royal commissions investigated and reported, studies were made, statistics were compiled, and, beginning in the 1830s, social legislation was enacted.

The gathering of statistics

An integral part of the social-reform movement was the compilation and publication of statistics that afforded a factual basis for legislative and other investigations and reports that were an essential prelude to legislation and served to create a demand for reform by informing the public of existing conditions. William Farr was perhaps the greatest medical statistician in the 19th century, but the father of political arithmetic was William Petty, a 17th-century physician, scientist, and economist, who urged the collection of numerical data in such areas as population, education, diseases, and revenue. Petty's friend John Graunt wrote the first important study of health statistics, in 1662. In Germany the philosopher Gottfried Wilhelm Leibniz recommended statistical investigations of health problems and in the 1680s published several essays on the urgent need for

vital statistics. Leibniz' work was carried on and furthered by his contemporary Veit Ludwig von Seckendorff, who is credited with having developed for Germany the public-health philosophy that later was systematized by Johann Peter Frank and enacted into law by Bismarck. Sweden was the first country, however, to require nationwide reporting of vital statistics, legislation having been passed in 1748, in accord with the recommendations of Pehr Elvius, mathematician and secretary of the Swedish Academy of Science.

In England, the first national census took place in 1801. In the United States, Massachusetts was the first state to establish a bureau of labour statistics. The first important study of public health was the 1845 report of John Griscom, city inspector for the New York Board of Health. During the same year the National Institute of Washington undertook a survey of the nation's health. The first state health department was created in Massachusetts in 1869. Several other states followed the Massachusetts example within the next few years.

In the second half of the 20th century, the compilation of vital statistics was regarded as a matter of general public importance. Almost all of the health, safety, and welfare laws that were passed in the 19th and in the first half of the 20th century were based on factual studies and statistical reports.

EARLY LEGISLATION

Europe. There were but few examples of social or health legislation on a national scale before the 19th century. In order to check the high rate of infant mortality and for reasons of public morality the British Parliament passed a series of gin acts, which, in an act of 1751, gave control of licensing to magistrates; and perhaps the first example of social insurance was an act of 1757, "for the relief of coal-heavers working upon the river Thames," that required the employer to deduct sums from employees' wages for a fund from which benefits would be paid in case of sickness, invalidity, old age, or death. Because of its abuse by employers, however, this early insurance plan was abolished in 1770; it was revived in 1792, when a similar act was passed providing for trustees to manage the fund. The Health and Morals of Apprentices Act, sponsored by Sir Robert Peel, was enacted in 1802 to improve the conditions of child labour in the cotton mills. Although this legislation was largely ineffective, it did establish the government's interest in industrial conditions and led to agitation for child-labour laws in other industries and countries.

19th-century social legislation in England

A reformer, Edwin Chadwick, who was convinced that people were poor because they were sick, was a prominent figure in both the commission that reported on the Poor Laws in 1834 and the commission that reported on public health in 1844 and 1845. As secretary of the poor-law commission he wrote the famous *Report . . . on an Inquiry Into the Sanitary Conditions of the Labouring Population of Great Britain*, which was published in 1842. These reports eventually were embodied in legislation and established national supervision of health, safety, and social problems. The Factory Act of 1833 was the immediate forerunner of modern industrial legislation, and the Liverpool Sanitary Act of 1846 provided for health officers and borough engineers for that city. The Nuisances Removal and Diseases Prevention Act and the Baths and Washhouses Act, passed the same year, were preludes to the Public Health Act of 1848. The first general housing acts were passed under the sponsorship of Lord Shaftesbury in 1851.

Movements similar to that which brought about the rise of social legislation in England gained momentum in Germany and France. Johann Peter Frank, German pioneer in public health, ambitiously undertook to systematize all existing knowledge on the subject and to devise detailed codes of hygiene for enactment. Frank, because of his broad scholarship, was one of the first to urge international regulation of health problems and creation of a national health authority to coordinate matters within the country. A proposal made at this time was the creation of "medical police" to make and enforce health and safety regulations. In France, during the Revolution, the Constituent Assembly, on the motion of Joseph-Ignace Guillotin, created a Comité de Salubrité (Health Committee). In 1793 and 1794 a national system of social assistance, including medical care, was passed. Both France and Germany thus became committed to the proposition that government has a positive duty to promote the health, safety, and welfare of workers. In 1883–84, when Bismarck's national social insurance program for workers was enacted (including sickness insurance, industrial-accident insurance, maternity-care benefits, and benefits or pensions for disability, old age, and death), Germany provided the inspiration and established the model for subsequent social legislation elsewhere in Europe and in America.

United States. In the United States the same patterns that led to English legislation are also evident, though English social legislation generally antedated its U.S. counterpart by at least a generation, and the U.S. doctrine of judicial review slowed down development. Early in the 19th century there was considerable support for maximum-hour laws to protect women and for restrictions upon child labour. A few industrial states passed such laws, but there was no effective enforcement because of fear of competitive disadvantage. Massachusetts, for example, in 1842 enacted a child-labour law, and in 1848 Pennsylvania prohibited the labour of children under the age of 12 in certain mills and limited the hours of work to ten unless there was a special contract. The latter provision was nullified when special contracts became customary, and, since in any event the statutory sanction was only a $50 fine, the statute had little effect. As early as the 1830s some industrialists suggested national legislation to regulate child labour and hours of work. Until after the U.S. Civil War, state social legislation was regarded as constitutional, and a judicial position that social legislation violates the due-process clause or impairs the obligations of contracts did not gain currency until about the 1890s.

Early child-labour laws in United States

Congress enacted only a few pieces of social legislation before the 20th century. In 1798 a federal plan of state insurance for disabled seamen based on a 20-cent-per-month deduction from wages was established, and in 1870 the deduction was increased to 40 cents. In 1878 the National Quarantine Act was enacted; it empowered the surgeon general to enforce port quarantines. In the following year the National Board of Health was established.

RISE OF INDUSTRIAL MEDICINE

In the past, most regulation on behalf of the worker has been an expression of religious conviction, such as the duties imposed upon the master in Deuteronomy, or a reflection of the ancient concept that a ruler is supposed to be a father to his people. During the Middle Ages the craft guilds regulated working conditions in detail. Rothari, king of the Lombards, in 643 ordered that bodily harm caused by accidents to builder's labourers should be compensated. The Ordinance of Labourers, in 1349, and the Statute of Labourers, in 1351, enacted in order to negate the economic bargaining power of the survivors of the Black Death, impaired the mobility of the workers, as did the settlement laws that were part of the Poor Laws after 1601. Since workers in England were not free to travel about to seek other jobs, humanitarian impulses alone furnished an incentive to improve their lot. Of greater direct importance were decrees issued by Queen Elizabeth I in England and Jean-Baptiste Colbert and Sébastien Le Prestre de Vauban in France to regulate working conditions.

14th-century regulation of labourers

Industrial medicine, the enactment of factory laws and safety laws, and, eventually, the expansion of workmen's compensation acts to include occupational diseases in their coverage were a direct application of the new Enlightenment. The founder of industrial medicine was Bernardino Ramazzini, professor at Modena and Padua, Italy, who in 1700 published his book *De morbis artificum diatriba* ("Treatise on the Diseases of Artisans"), which examined the relation between disease and pov-

erty. Before and after Ramazzini there were reports on industrial health, such as a pamphlet by one Ulrich Ellenbog in 1473 "on the poisonous wicked fumes and smoke" that afflicted goldsmiths, a treatise on the diseases of miners by Georgius Agricola in 1556, one by Percivall Pott in 1775 on the diseases of chimney sweeps, and a comprehensive study of industrial disease and poverty by Charles Turner Thackrah in 1831. The latter study was relied upon by social reformers.

Liability in industrial accidents. Common-law principles in England and the United States generally placed the cost of industrial accidents on the injured worker in the vast number of cases. To recover in a suit against his employer, the employee had to prove that the master either was personally at fault or had violated a nondelegable duty. Moreover, the injured worker had to overcome the defenses of contributory negligence, the legal presumption that the worker knew and had assumed the risks of his work, and the fellow-servants rule, which meant that if the injured man had himself been careless for his own safety or knew or should have known of the danger or was hurt because one of his fellow workers was negligent, then the employer was not liable for damages. Although the courts recognized that certain nondelegable duties were assumed by the employer, such as an obligation to provide a reasonably safe place to work and reasonably safe machines, tools, and appliances, kept in a reasonably good state of repair, and the issuing of safety rules and warnings of dangerous conditions, nonetheless a violation of such duties did not result in employer liability if one of the common-law defenses was applicable. Most significant, the common-law defenses frequently barred employer liability even though the employer had violated a health or safety statute or ordinance, as when the employee knew of the existing conditions and was said to have assumed the risk.

Difficulty in obtaining compensation for injury

In England in 1880 Parliament enacted the Employers' Liability Act, which modified the defense accorded by the fellow-servants rule but left untouched the defenses of contributory negligence and assumption of risk and required that there be negligence by the employer or a supervisory employee for the worker to maintain suit against his employer. This act was ineffective because English courts construed it so as to permit employees to contract away their rights under the act. In other words, employees were forced to assume the risks of their work as a condition of their employment. German compensation-insurance laws enacted under the sponsorship of Bismarck in 1884 set the pattern for future legislation, and Parliament's Workmen's Compensation Act of 1897 was modelled on its provisions, as were the later United States statutes (see below).

In the United States before 1880, five states had enacted statutes that made railroads liable to employees upon the same basis as they were liable to strangers. Georgia enacted such a law in 1855 and Montana Territory in 1873.

Between 1885 and 1910 most states enacted some kind of employer-liability law, either trying to abrogate some of the common-law defenses or to impose safety inspection and regulation upon hazardous industries. In 1906 Congress enacted the first federal Employers' Liability Act, which covered railroad workers, but that act was held unconstitutional because employees not engaged in interstate commerce were included within its purview. The second Employers' Liability Act was passed by Congress in 1908 to remedy this defect and subsequently was upheld as constitutional. In effect, these railroad statutes abrogated the common-law defenses but required the existence of negligence for recovery. For example, contributory negligence by the employee diminished the amount of recovery had against his negligent employer, and assumption of risk remained a good defense until abolished by amendment in 1939.

Employers' Liability acts of 1906 and 1908

Workmen's compensation. In the United States, despite temporary setbacks and, for a time, strict judicial construction, workmen's compensation acts came to be enacted by each state. Additional congressional legislation covering occupations related to federal commerce, such as those of stevedores and longshoremen, were passed. All but a few states came to include occupational diseases, as well as accidents, as a basis for recovery when either arose out of and in the course of employment. Also, such acts have been extended beyond so-called hazardous industries to include most industrial and commercial enterprises.

PUBLIC WELFARE

Public assistance, unemployment compensation, and social insurance of various kinds became the subjects of national legislation in Europe in the 19th century and in the United States in the 20th. Until Poor Laws were enacted in England at the start of the 17th century, care of the indigent usually had been a matter for church charity or mutual aid by people of the same occupation. The Jews made and enforced regulations for the relief of the poor and regarded charity as a duty. Charlemagne ordered his counts to care for the poor at their own expense and made them *advocati* ("protectors") of the distressed. This action marked the beginning of secularization and regulation of charity in Europe; gradually, poor relief was abandoned as a general function of the church and was assumed by the parish. From ancient times people in the same social class or occupation banded together in friendly societies that arranged burials, financial help where needed, and benefits in case of sickness or widowhood. In time these societies expanded beyond a particular calling, and in England at the beginning of the 19th century they had a membership of 1,000,000 out of a total population of 9,000,000. They were almost as numerous in Holland and Belgium. Neither public nor private assistance, however, was adequate for the problems created by great depressions and chronic unemployment, and a national responsibility for the care of the sick and the poor was repeatedly urged. Sir Thomas More in his *Utopia*, which appeared at the beginning of the 16th century, had advocated public-health measures, social insurance, social security, and public housing. "Freeborn John" Lilburne, pamphleteer for the so-called Leveller movement during the Puritan revolution, called for a comprehensive program of government action to cope with social problems. Daniel Defoe, in his *Essay Upon Projects*, at the end of the 17th century proposed many reforms, including social insurance; and Denis Diderot, in his *Encyclopédie*, in the article on hospital, outlined a public-assistance scheme, including old-age insurance and medical care.

Mutual benefit societies

England. England finally eradicated the last traces of its Elizabethan Poor Laws in 1948 by the enactment of the National Assistance Act, which eliminated the old concepts of parish responsibility, primary family responsibility, and rules as to settlement and removal. Even before World War I, the National Health Insurance Act of 1911 had introduced the principle of state responsibility for the payment of sickness benefits to workers during illness and for the provision of some forms of medical care on a basis of compulsory insurance. Near the end of World War II and immediately after its close, Parliament also passed the National Insurance Act (1944), the Family Allowances Act (1945), the National Health Service Act (1946), and the National Insurance Act (1946). A report by Sir William Beveridge in 1942, experience with prior legislation, and postwar conditions in general combined to provide a favourable political climate for a comprehensive national welfare system.

United States. *Federal legislation.* Although the Department of Health, Education, and Welfare was created in 1953, most social legislation continued to be based on federal–state cooperation rather than on national action alone. For example, such acts as the Sheppard-Towner Act of 1921 (Maternity and Infancy Act), the National School Lunch Act of 1946, and Title V of the Social Security Act are based on federal–state cooperation, the federal government extending grants-in-aid and setting standards and the states administering the programs. There has been a steady trend toward adoption of the insurance principle as a basis for social legislation.

Federal–state cooperation

It was not until the Depression of the 1930s that public assistance, unemployment compensation, social-security benefits, and an integrated program of welfare legislation had been enacted for the nation as a whole. The Social Security Act of 1935 and the Fair Labor Standards Act of 1938 were perhaps the most significant pieces of social legislation enacted by Congress under its authority to regulate interstate commerce and matters affecting such commerce.

Beginning in 1937 the Supreme Court upheld the validity of such legislation, overruling prior decisions that had held that Congress has no authority to abolish child labour or to regulate wages and hours. The separation-of-powers doctrine was viewed by the court as exacting due deference for the legislative and executive judgment and determination of public policy, and the court declined to substitute its economic and social predilections for those of Congress. Most important, certain powers reserved to the states or to the people under the 10th Amendment were held to be no limitation whatsoever upon federal power granted by the Constitution. The court also permitted state legislatures to experiment with social legislation unless a federal statute or power had pre-empted the field. Sociological jurisprudence had replaced the laissez-faire commitment that had dominated the Supreme Court from the 1890s to 1937.

Although health, safety, and welfare legislation, whether enacted by Congress or by the states, was, in the second half of the 20th century, regarded as a legitimate exercise of the police power of government, there yet remained many issues as to substance and procedure that might arise under such laws. The principal limitation upon an attempted exercise of federal power was that some basis therefore must be found in the Constitution.

Powers of local boards

States' powers. State courts determine the constitutionality of state legislation under state constitutions. Historically, health regulations have presented numerous issues, including problems as to the delegation of authority by the legislature to health officials, the specification of sufficient standards to guide administrators so that an arbitrary discretion is not assigned, the reasonableness of rules and regulations promulgated by officials, and the reasonableness of legislative classification. Usually, courts have not reviewed the judgment of health officials with legal authority to exercise discretion, and private persons have not ordinarily been able to hold officials personally liable for action taken in good faith within the scope of their authority.

State health officials utilize many methods of regulation, including inspection, destruction of private property to prevent the spread of contagion or to abate a nuisance, closing of public places, disinfection and sterilization, vaccination, and quarantine. Compliance with orders may be sought by injunctions or the imposition of fines. Some states do not require health officials to give notice and to provide a hearing before taking summary action if the statute does not specify such procedure, a condition that places a heavy burden on the citizen who cares to challenge the validity of the action in a subsequent legal proceeding. In 1967 the United States Supreme Court, reversing a prior decision, held that health inspectors must first obtain a warrant before forcing their way into a private dwelling or place of business. The state may act under either its power of eminent domain or its police power. Generally, if it exercises eminent domain, just compensation is due; such is not the case for an expression of police power. A person who negligently or deliberately infects another with a contagious disease may be held accountable for damages, at least if there was no consent to such contact.

LEGISLATION

Food and drug laws. One of the most important areas of health legislation is that pertaining to adulteration. Both Athens and Rome had laws to prevent the adulteration of wine, and England from the time of Henry III—the 13th century—prohibited the adulteration of certain foods. Parliament from time to time passed statutes prohibiting the adulteration of such commodities as tea, cocoa, and beer, and in 1872 it enacted the Adulteration of Food or Drink Act, which had general application to foodstuffs; it provided for inspection and analysis of samples and for a £50 fine for the first violation and six months imprisonment at hard labour for a second offense. After that time, additional statutes were passed to plug loopholes and to correct judicial construction, culminating in the comprehensive Food and Drug Act, 1955.

Laws against adulteration of foods and drugs

In the United States an act prohibiting the adulteration of drugs was passed by Congress in 1848, and in 1890 a similar statute regarding food was passed. Between 1880 and 1906 there were 103 bills introduced in Congress to control interstate traffic in food and drugs, but none were enacted until the Pure Food and Drugs Act of 1906 was signed by Pres. Theodore Roosevelt.

Difficulty was encountered in the enforcement of the act because of the definitions given to such terms as adulteration, the narrow construction given by the courts, and the "distinctive-name" exemption that permitted a manufacturer who adopted a distinctive name for his article to ship what he pleased. Moreover, the sanctions of a maximum fine of $200 for the first offense and $300 or a year's imprisonment or both for subsequent offenses, as well as the seizure provisions, did not prove to be successful deterrents.

Except for minor amendments, the 1906 act and similar state legislation remained in effect until the Federal Food, Drug and Cosmetic Act of 1938 was passed after the tragic death, in 1937, of at least 73 persons who had taken a drug known as Elixir Sulfanilamide. (Existing legislation did not prohibit the distribution of poisonous or dangerous drugs.) The 1938 act, within the limits of the commerce power, prohibits foods dangerous to health and also prohibits foods, drugs, or cosmetics in insanitary or contaminated containers. Enforcement of the act was given to a Food and Drug Administration, and inspection stations were set up in several large industrial cities.

In addition to the 1938 Federal Food, Drug and Cosmetic Act, state legislation was important in covering food and drugs outside the scope of the federal act because of its limitation to interstate commerce. Of jurisprudential significance is the fact that under both the federal law and the statutes of some states it is not essential that there be a specific criminal intent for conviction. It may be enough that the manufacturer or processor intended to ship the articles in question even though he neither knew nor had reason to know that there was a violation.

The international tragedies that occurred in 1961 when thalidomide, taken as a sedative by pregnant women, caused gross malformations in their offspring led to the 1962 amendment of the Food and Drug Act and a 1966 memorandum of the Surgeon General that drastically altered the law as it pertains to clinical investigations and human experimentation. Earlier, the Nuremberg Code on the use of human subjects for medical research had some moral influence, but there was a dearth of law. The change, in effect, added a requirement to the law that subjects or patients must be informed that they are to receive an experimental drug.

Safety laws. The enactment of safety legislation has been contemporaneous with the passage of workmen's compensation acts and public-health laws. In this area, however, education and the activities of voluntary groups have almost completely overshadowed legal developments. There has been an intensive safety movement in the 20th century, and safety codes have been devised by engineers for various industries. At the outset humane industrialists who realized that safe working conditions are an asset to the business, particularly if the factory comes under workmen's compensation laws, promoted accident-prevention campaigns by imposing safety rules in plants. In the United States, cities and states at an early date required inspections of steam-power boilers, and, later, building inspectors, fire marshals, and elevator inspectors exercised municipal authority. Mine safety was a subject for legislation in many coal-producing

states; the Safety Appliances act for railroads, originally passed in 1887 and expanded and amended in 1893, 1903, 1910, and 1920, was the first significant federal statute. The Walsh–Healey Public Contracts Act of 1936 required government contractors to comply with the health and safety laws of the state in which the contract is being fulfilled. During and since World War II it has been one of the most important statutes because it reinforces state laws that otherwise might be ignored. For the most part, state safety laws have been strictly enforced only in a few industrial states that have provided a sufficient number of inspectors. The United States Department of Labor and, since 1953, the Department of Health, Education, and Welfare are both concerned with certain aspects of the general problem of industrial safety. Federal Coal Mine Inspection acts, passed in 1941 and 1952, require inspection and reports, empower the director of the Bureau of Mines to forbid miners to enter dangerous portions of a mine, and specify detailed rules concerning roof support, ventilation, equipment, fire protection, and other safety matters.

Walsh–Healey Public Contracts Act

Before workmen's compensation acts were securely established as constitutional around 1920, most state safety acts relied upon inspection and indirect enforcement through civil litigation in damage suits brought by injured workmen. After 1920, when damage suits all but ceased because most workmen were limited to compensation claims, administrative boards with power to make rules, investigations, and reports and to seek injunctions became the mode of enforcement. In a few states—*e.g.*, Washington—educational standards of safety, as well as rules dealing with safe working conditions, were, in the early 1960s, issued by the supervisor of safety. Statutes that provide for apprenticeship systems, limit the hours of work, or require rest periods may be classified as safety laws because of their bearing on accident prevention. The constitutionality of safety laws in the second half of the 20th century was usually upheld unless there was a showing of arbitrary action in a particular situation, and such regulations typically were enforced by inspection plus criminal or administrative sanctions. In addition to laws pertaining to industrial safety, there are statutes concerning regulation of traffic; inspection of theatres, schools, and other public places; highways and sidewalks; public carriers; bathing beaches; and fire prevention.

INTERNATIONAL EFFORTS

International concern about health and safety has been expressed in the writings of public-health pioneers such as Johann Peter Frank; in international conventions, such as that held in Paris in 1851; and in health organizations within the framework of the League of Nations and the United Nations (UN). The preamble to the constitution of the World Health Organization (WHO) provides that "an informed opinion and active co-operation on the part of the public are of the utmost importance in the improvement of the health of the people"; it further declares that every individual has a fundamental right to the highest attainable standard of health. The World Health Organization is committed to the principle of mutual aid in dealing with social and health problems, and its work is supplemented by and correlated with the activities of such other United Nations agencies as the United Nations Children's Fund, the Food and Agriculture Organization, the International Labour Organisation, and the United Nations Educational, Scientific and Cultural Organization (UNESCO).

Private organizations have also laboured in the field of international health and safety problems. The International Association of Industrial Accident Boards and Commissions has promoted safety codes, and the Rockefeller Foundation has sponsored major international health work. Numerous international conferences have been held to promote health and safety. Mohammed Ali, ruler of Egypt, called a conference in 1833 to discuss quarantines and international hygiene; the International Association for the Legal Protection of the Poor was organized in Paris in 1900; and the International Labour office was organized at Basel, Switzerland, in 1901. The Bern (Switzerland) conferences of 1905, 1906, and 1913 drew up international conventions prohibiting the use of white phosphorus in the manufacture of matches and the employment of women or of children under 16 on night work and limiting their hours of work. President Truman's Point Four program included technical assistance on health matters, and many underdeveloped nations received help from the United States and other governments in an effort to eliminate various preventable diseases that had been eradicated in Europe and the United States in the 19th century. Other nongovernmental agencies prominent in the international health and welfare fields include the International Red Cross and League of Red Cross Societies, the Save the Children Fund, and the Society of Friends.

International conferences

International trade in radioactive materials led to treaty regulations governing consignments. The first convention on the subject, signed by 16 nations belonging to the Organization for European Economic Co-operation (later the Organisation for Economic Co-operation and Development) in 1959, permitted the level of financial protection to be set by any nation at a minimum amount of $5,000,000. In 1961 the International Atomic Energy Agency, composed of 81 nations, issued Regulations for the Safe Transport of Radioactive Materials, and these were amended in 1964. The basic purpose of the regulations was to control and limit the risks of irradiation and radioactive contamination that radioactive materials may present in the course of transport; there are specifications as to shielding, distance and duration of exposure, proper containment, adequate labelling and marking, and precautions against a fissile chain reaction.

The Brussels convention of 1962 established licensing for nuclear-propelled ships, and the Inter-American Nuclear Energy Commission later promulgated regulations for the Pan-American trade in radioactive materials. Also in the 1960s the first steps were taken in Europe toward regional cooperation in protecting the human environment, and meetings were held between the United States and Canada to abate and control transboundary pollution. A specific matter of international concern was the conference called by the Inter-Governmental Maritime Consultative Organization (IMCO), which met at Brussels in 1969 and prepared international conventions relating to oil-pollution casualties on the high seas and civil liability for such damages. In these and other meetings, there was increasing reliance upon the sanction of imposing liability under international law for environmental damage caused by industry and commerce.

RECENT DEVELOPMENTS

During the late 1960s and early 1970s, widespread concern about radiation hazards, air and water pollution, and poisons used in control of plant and animal pests led to legislation in these areas.

In the Union of Soviet Socialist Republics, for example, a law enacted in 1969 established safety standards with respect to production, processing, application, storage, and transport of natural or artificial radioactive substances and of other sources of ionizing radiation (with the exception of ultraviolet radiation). In the United Kingdom, legislation concerning radiation included establishment of a National Radiological Protection Board. In Belgium a law was enacted against assigning workers declared unfit for exposure to ionizing radiations to jobs involving such exposures. In the United States the Radiation Control for Health and Safety Act of 1968 authorized the formulation of standards to control the emission of radiation by electronic products and compelled compliance with these standards by manufacturers who produce such devices and ship them in interstate or foreign commerce. Moreover, the Bureau of Radiological Health of the Food and Drug Administration promulgated regulations covering performance standards for television sets and medical X-ray equipment. Other countries that enacted laws on radiation hazards included Canada, Iceland, the Republic of the Philippines, Ceylon, the German Democratic Republic, Hungary, and Italy.

U.S.S.R. law on radioactive materials

Laws designed to prevent pollution of water or air were enacted in many countries, including Canada, Denmark, France, the Dominican Republic, and Malta. The Bulgarian measure, for example, enacted in April 1969, prescribes that projects for the utilization of water must include safeguards against contamination of surface water and groundwater, must protect mineral and medicinal waters from contamination, and must not do injury to agriculture, forestry, or fisheries. In the United States the 1955 Air Pollution Control Act had left the responsibility of pollution control to the state and local governments, and the Clear Air Act of 1963 had repeated that states' right principle but had authorized interstate compacts, such as that established for New York and New Jersey. In 1967 the federal government intervened more actively into the air-pollution problem by the enactment of the 1967 Air Quality Act, which directed the Department of Health, Education, and Welfare to establish air-quality-control regions throughout the country, to devise standards, and to notify affected areas. By 1970 some 40 states had enacted air-pollution statutes, usually setting up boards or commissions to establish air quality and emission standards. The federal Environmental Protection Agency also was established to enforce and implement the Clean Air Act of 1970.

Fear of contamination of food and fodder by pesticides elicited laws on the subject in a number of countries. In Algeria such a law was specifically directed at the use of mercury compounds on plants. The Australian law concerned a wider range of substances—insecticides, fungicides, herbicides, and vermin destroyers.

Other individual health measures established during this period included acts concerned with food hygiene, control of communicable disease, training of health workers, prevention or control of drug dependence, and control of the manufacture of pharmaceutical products and the testing of new drugs. In 1966 in the United States, for example, a regulation was established by the Food and Drug Administration that directed physicians, except in unusual circumstances, to obtain the written consent of patients before using investigational drugs.

National Traffic and Motor Vehicle Safety Act

One piece of controversial safety legislation enacted during this period was the United States National Traffic and Motor Vehicle Safety Act of 1966, which set mandatory standards for all new cars beginning with the 1968 models and gave the Secretary of Commerce the responsibility of carrying out research, testing, development, and training as to safety features in automobiles. The manufacture or sale of substandard motor vehicles or equipment was proscribed. The act applied, however, only to new cars and equipment.

In December 1969 a fundamental health code was enacted in the Union of Soviet Socialist Republics. The first of the nine main divisions of this law is concerned with the principles of organization of public health in the Soviet Union and with the jurisdictions of the Union and of its constituent republics in the field of health. Other main divisions of the act deal with (1) the practice of medicine and of pharmacology; (2) providing protection to the people with respect to sanitation and the control of communicable disease; (3) therapeutic and prophylactic care; (4) maternal and child health; (5) treatment at sanatoriums and health resorts and organization of leisure activities, tourism, and physical culture; (6) expert medical evaluation of working capacity and of matters concerning forensic medicine and forensic psychiatry; and (7) supplying of drugs and of prosthetic devices. The final section of the law specifies that, when provisions of treaties into which the Soviet Union has entered conflict with Soviet law or the laws of the constitutional republics of the Soviet Union, the provisions of the treaties shall take precedence.

FRAZER, *A History of English Public Health*, 1834–1939 (1950), the standard English work on the public-health movement of the 19th century; FRANK P. GRAD, *Public Health Law Manual* (1965), a handbook on the legal aspects of public-health administration, principally designed for health officers and administrators; D.W. CLARK and B. MACMAHON (eds.), *Preventive Medicine* (1967), a textbook with chapters written by 39 authors—lawyers, doctors, and health administrators; COLIN FRASER BROCKINGTON, *World Health*, 2nd ed. (1968), both a history and a synthesis of current views on health questions; *Public Health in the Nineteenth Century* (1965); E. HAROLD HINMAN, *World Eradication of Infectious Diseases* (1966), a monograph that considers the origins of eradication efforts, the nature of such programs, their progress to date, and the future outlook for their success; W. HOBSON (ed.), *The Theory and Practice of Public Health*, 3rd ed. (1969), a textbook designed to cover the community aspects of medicine and to give basic information to those working in the field; L.S. GOERKE and E.L. STEBBINS, *Mustard's Introduction to Public Health*, 5th ed. (1968), a textbook designed to introduce students to concepts and principles of public health and to contemporary modes of community health organization and practice.

Health care: ANNE R. SOMERS, *Health Care in Transition: Directions for the Future* (1971), a significant survey of the trends in health care and the direction it is taking; *Hospital Regulation: The Dilemma of Public Policy* (1969); NATHAN HERSHEY, "Compulsory Personal Health Measure Legislation," *Public Health Report 341* (1969), a discussion of a variety of legislative enactments (of four states), including a review of a number of court decisions.

Special health and safety problems: PETER D. LOWES, *The Genesis of International Narcotics Control* (1966); RUTH FOX (ed.), *Alcoholism: Behavioral Research, Therapeutic Approaches* (1967); LAWRENCE LADER, *Abortion* (1966); "Cigarette Advertising and the Public Health," *Columbia Journal of Law and Social Problems*, 6:99 (1970); "Automobile Design Liability; Larsen v. General Motors (391 f 2d 495) and Its Aftermath," *University of Pennsylvania Law Review*, 118: 299–312 (1969).

Food, drugs, and cosmetics: Food, Drug, Cosmetic Law Journal, a monthly publication covering statutes, decisions, and developments in this field; H.A. TOULMIN, JR., *A Treatise on the Law of Foods, Drugs, and Cosmetics*, 2nd ed., 4 vol. (1963), a treatise covering statutes and amendments and their legislative history; RICHARD HARRIS, *The Real Voice* (1964), a journalistic account of politics and the drug industry with emphasis on the Kefauver committee investigation; DAVID CAVERS, "Administering That Ounce of Prevention: New Drugs and Nuclear Reactors," *West Virginia Law Review*, 68:109–135, 233–262 (1966).

Pollution and environmental control: SIDNEY EDELMAN, *Law of Air Pollution Control* (1970), a comprehensive discussion of law up to date of publication; "Symposium: The Environment and the Law," *Hastings Law Journal*, 22:467–830 (1971), see especially J. STEVENS, "Air Pollution and the Federal System: Responses to Felt Necessities"; "Toward a Constitutionally Protected Environment," *Virginia Law Review*, 56:458–486 (1970), an examination of theories that could justify judicial recognition of the constitutional right to healthful environment.

Regulation of medical practice: ROBERT C. DERBYSHIRE, *Medical Licensure and Discipline in the United States* (1969), an analysis of the practical aspects of medical licensure in the United States today; RICHARD H. SHRYOCK, *Medical Licensing in America, 1650–1965* (1967), on the evolution of the medical licensing system as we know it today; IRVING LADIMER and ROGER W. NEWMAN (eds.), *Clinical Investigation in Medicine: Legal, Ethical and Moral Aspects, an Anthology and Bibliography* (1963), a full treatment of legal and ethical problems involved in human experimentation and the use of novel medical procedures; A.M. and B.L. SADLER, "Transplantation and the Law: The Need for Organized Sensitivity," *Georgetown Law Journal*, 57:5–54 (1968).

Protection from radiation: GERALD L. HUTTON, *Legal Considerations on Ionizing Radiation* (1966).

International problems: COLIN FRASER BROCKINGTON, *World Health*, 2nd ed. (1968); WORLD HEALTH ORGANIZATION (WHO), *International Digest of Health Legislation* (quarterly), in English and French; ARTHUR LARSON, *The Law of Workmen's Compensation*, 2 vol. (1952, 1971 suppl.); REED DICKERSON, *Products Liability and the Food Consumer* (1951); WILLIAM L. PROSSER, *Handbook of the Law of Torts*, 4th ed., ch. 17 (1971).

(H.H.F.)

Heat

Heat is energy that is transferred from one body to another as the result of a difference in temperature. If two

bodies at different temperatures are brought together, energy is transferred—*i.e.*, heat flows—from the hotter body to the colder. The effect of this transfer of energy usually, but not always, is an increase in the temperature of the colder body and a decrease in the temperature of the hotter body. A substance may absorb heat without an increase in temperature by changing from one physical state (or phase) to another, as from a solid to a liquid (melting), from a solid to a vapour (sublimation), from a liquid to a vapour (boiling), or from one solid form to another (usually called a crystalline transition; see PHASE CHANGES AND EQUILIBRIA). The important distinction between heat and temperature (heat being a form of energy and temperature a measure of the amount of that energy present in a body) was clarified during the 18th and 19th centuries.

HEAT AS A FORM OF ENERGY

Because all of the many forms of energy, including heat, can be converted into work, amounts of energy are expressed in units of work, such as joules, foot-pounds, kilowatt-hours, or calories. Exact relationships exist between the amounts of heat added to or removed from a body and the magnitude of the effects on the state of the body. The two units of heat most commonly used are the calorie and the British thermal unit (BTU). The calorie (or gram-calorie) is the amount of energy required to raise the temperature of one gram of water from 14.5° to 15.5° C; the BTU is the amount of energy required to raise the temperature of one pound of water from 63° to 64° F. One BTU is approximately 252 calories. Both definitions specify that the temperature changes are to be measured at a constant pressure of one atmosphere, because the amounts of energy involved depend in part on pressure. The calorie used in measuring the energy content of foods is the large calorie, or kilogram-calorie, equal to 1,000 gram-calories.

Heat capacity

In general, the amount of energy required to raise a unit mass of a substance through a specified temperature interval is called the heat capacity or the specific heat of that substance. The quantity of energy necessary to raise the temperature of a body one degree varies depending upon the restraints imposed. If heat is added to a gas confined at constant volume, the amount of heat needed to cause a one-degree temperature rise is less than if the heat is added to the same gas free to expand (as in a cylinder fitted with a movable piston) and so do work. In the first case, all the energy goes into raising the temperature of the gas, but in the second case, the energy not only contributes to the temperature increase of the gas but also provides the energy necessary for the work done by the gas on the piston. Consequently, the specific heat of a substance depends on these conditions. The most commonly determined specific heats are the specific heat at constant volume and the specific heat at constant pressure. Relationships between heat capacities and molecular structure of gases are covered in the article GASEOUS STATE. The heat capacities of many solid elements were shown to be closely related to their atomic weights by the French scientists Pierre-Louis Dulong and Alexis-Thérèse Petit in 1819. The so-called law of Dulong and Petit was useful in determining the atomic weights of certain metallic elements, but there are many exceptions to it; the deviations were later found to be explainable on the basis of quantum mechanics (*q.v.*).

It is incorrect to speak of the heat in a body, because heat is restricted to energy being transferred. Energy stored in a body is not heat (nor is it work, as work is also energy in transit). It is customary, however, to speak of sensible and latent heat. The latent heat, also called the heat of vaporization, is the amount of energy necessary to change a liquid to a vapour at constant temperature and pressure. The energy required to melt a solid to a liquid is called the heat of fusion, and the heat of sublimation is the energy necessary to change a solid directly to a vapour, these changes also taking place under conditions of constant temperature and pressure.

Air is a mixture of gases and water vapour, and it is possible for the water present in the air to change phase; *i.e.*, it may become liquid (rain) or solid (snow). To distinguish between the energy associated with the phase change (the latent heat) and the energy required for a temperature change, the concept of sensible heat was introduced. In a mixture of water vapour and air, the sensible heat is the energy necessary to produce a particular temperature change excluding any energy required for a phase change.

EARLY THEORIES AND OBSERVATIONS

Despite the fact that early man made use of the effects of heat and surely recognized differences in temperature, it has been only in relatively recent times that man has understood that heat is energy and, in particular, energy being transferred. The earliest evidence of man's use of fire comes from caves occupied by Peking man about 500,000 years ago. Early man's fire served two main purposes: warming the body and giving light during hours of darkness. It is not known whether Peking man was able to make fire himself, but later man produced fire by percussion (flint), friction (two pieces of wood), and even by gas compression, although the details of these phenomena were not understood.

Before the 5th century BC, much progress was made in science and technology in Egypt and Mesopotamia, but heat and temperature remained undefined. Despite the lack of understanding of its nature, heat has been used to produce and work metals suitable for tools since the beginning of civilization. Copper, tin, and lead were the first metals to be smelted from natural ores, probably before 4000 BC. Silver and bronze (an alloy of copper and tin) came into use later (3000–2200 BC), followed by brass in the Roman period (500–50 BC). Iron was used from about 1200 BC. Glass was also produced, with transparent glass being made from about 1500 BC. The Egyptians produced a turquoise-blue glaze that required delicate temperature regulation in firing.

Greek philosophers. Much of early philosophy was directed toward explaining the universe and its origin. Aristotle believed in four elements proposed by earlier philosophers: Earth, dry and cold; Water, moist and cold; Air, moist and hot; Fire, dry and hot—and believed that they were different forms of the same substance. In Aristotle's view each element occupied its own sphere in the universe, and one element might be transformed into another: the formation of steam by boiling water could be described as Water (cold moist) + Fire (hot dry) → Air (hot moist) + Earth (cold dry). Aristotle finally added a fifth element representing the heavens—ether, from a word meaning "to glow."

Aristotle's elements

Philon of Byzantium (*c.* 100 BC) and Heron of Alexandria (*c.* AD 100) studied the flow of liquids and gases. Philon described an instrument for the demonstration of the expansion of air. This device may have been used as a thermometer, one of the earliest known.

Heron invented the first steam turbine as a toy. Water was heated to boiling in a caldron by an external fire. The steam was fed to a pivoted globe having two exhaust jets. As the steam left the jets it caused the globe to rotate.

It is apparent that the study and use of heat had not progressed greatly. As previously stated, Peking man had used fire for warmth and light about 500,000 years ago; the use of fire for smelting copper occurred prior to 4000 BC; Empedocles of Agrigentum proved the corporeality of air (*c.* 450 BC); Philon demonstrated the expansion of air (*c.* 100 BC); and Heron built a toy reaction steam turbine (*c.* 100 AD); yet, the real nature of heat and combustion processes remained unknown, and the use of heat to produce work was not yet achieved.

The alchemists. The alchemists appeared about AD 100–300, seeking ways of turning other metals into gold. The pursuit of methods for changing one substance into another came to be called "khymeia" probably from the Greek word *khymea*, meaning "to fuse or cast a metal." In the 8th century, Arabic scholars turned their attentions to *al khymea*. Alchemists began the first systematic investigation of metals and developed chemical analysis in a limited fashion. A woman alchemist, Maria the Jewess, is believed to have invented the first distillation apparatus in the 1st or 2nd century AD, in Alexandria. The discovery

of a number of new materials constituted the major contribution of the alchemists.

The investigations of Roger Bacon

One notable exception to the alchemists was the English scholar Roger Bacon, who was a proponent of experimental investigations together with the use of mathematics as a method of interpreting nature. Bacon made an extensive study of lenses and mirrors and in 1269 predicted the automobile, the airplane, and motorized ships, but he apparently did not work directly in the area of heat. Alchemy persisted into the 17th century, with chemistry being a medical art or mystical science. The name alchemy began to fall into disrepute, even though some of the mystical concepts of alchemy were retained by more serious investigators, who began to call themselves "chymists."

Early chemists. In 1661 the English natural philosopher Robert Boyle published *The Sceptical Chymist*, a book credited with making chemistry an empirical science. Boyle rejected the Aristotelian concept of the elements and defined an element as a substance that cannot be broken up into two or more apparently simpler substances or built up from simpler substances. Copper was therefore an element, but bronze was not. In 1805 another English scientist, John Dalton, in advancing the modern atomic theory, defined an element by suggesting that all matter is made up of atoms and that each element is composed of atoms of one characteristic type. He worked out the first table of atomic weights based on experimental data. Boyle's contributions were not confined to the recognition of the elements. He studied air at ordinary temperatures and concluded that the pressure of the air was inversely proportional to the volume if the temperature was held constant. In 1787 a French physicist, Jacques-Alexander-César Charles, studied several gases and stated that at a fixed pressure, raising the temperature by one Celsius degree (1.8 Fahrenheit degrees) increases its volume by 1/273 of the volume it occupies at 0° C (32° F). Combined, the laws of Boyle and Charles become the perfect gas law, relating pressure, volume, and temperature of a gas. In 1802 another French chemist, Joseph-Louis Gay-Lussac, showed that air and other available gases (nitrogen, oxygen, hydrogen) "expand equally with the same degree of heat"; *i.e.*, that their coefficients of expansion were the same. This fact, which is true only of perfect gases, was used in the design of gas thermometers.

THERMOMETRY

The concept of temperature as hot or cold was long known, but a method for measuring it accurately was not available during Boyle's life. Galileo is credited with making an air thermoscope that consisted of a glass bulb containing air, connected to a glass tube of small bore, which dipped into a bowl of coloured liquid. When cooled, the air in the bulb contracted, and the liquid moved up the glass tube; when heated, the air expanded and the liquid moved down. The stem was marked in gradations, but the readings were affected by changes in atmospheric pressure as well as temperature. The principle of operation of this instrument was similar to that of Philon. Ferdinand II, grand duke of Tuscany, is said to have developed the first sealed liquid-in-glass thermometer, probably in 1641; the liquid used was alcohol. The idea of representing hot and cold numerically was familiar to physicians. In the 2nd century AD, the Greek physician Galen suggested a temperature scale based on boiling water and ice. Arab and Latin physicians developed a scale of 0–4 degrees of hot or cold, but they had only the senses for measurement. In the 17th century, thermometers based on the expansion and contraction of air or of water were used for measuring body temperature. The temperature of the human body was taken as one of the fixed points on these temperature scales. In 1688, in France, a physicist named Guillaume Amontons proposed to measure temperature by the variations in pressure of a fixed mass of gas contained in a constant volume. He defined absolute zero as the temperature at which the gas pressure goes to zero. He used a tube of mercury to measure pressure variations. In 1701 Sir Isaac Newton suggested that the temperature scale should be zero for the freezing point of water and 12 for the human body. In 1714 a German–Dutch physicist, Gabriel Daniel Fahrenheit, proposed that a freezing mixture of ice and salt should be the zero point and that the human body temperature be made 96 to give a greater number of degrees on the scale. Fahrenheit showed that the freezing point and the boiling point of water at a fixed pressure are constant. In 1724 Fahrenheit suggested that these two fixed points be used for defining the temperature scale (zero was still the ice–salt mixture and human blood 96), and the fixed points were established as 32° F (freezing point) and 212° F (boiling point) on the scale that bears Fahrenheit's name. With these fixed points, blood temperature was found to be 98.6° F. Fahrenheit greatly improved the accuracy of the thermometer by using mercury as the fluid in a sealed glass tube. The centigrade ("hundred step")—now called the Celsius—scale was suggested by a Swedish astronomer, Anders Celsius, in 1742. On this scale, the freezing point of water is zero and the boiling point of water is 100°.

Galileo's air thermoscope

All the thermometers mentioned so far depend upon the fact that gases and liquids generally tend to expand upon heating. Other properties that change with temperature can be employed in the construction of thermometers. Electrical resistivity is such a property, used in platinum resistance thermometers for accurate determinations of temperatures between −183° and 630° C (−297° and 1,170° F). The emission of electromagnetic radiation from hot objects is the basis of the optical pyrometer, a device used for measuring high temperatures (above about 1,000° C).

Modern thermometers

The German physicist Thomas Johann Seebeck discovered in 1821 that an electromotive force exists in a circuit composed of two dissimilar metals when the junctions of the metals are at different temperatures. Such devices, called thermocouples, have been thoroughly developed for use in measuring temperatures and are the basis of an internationally recognized scale of temperatures between 630.5° and 1,060° C (1,167° and 1,940° F; see THERMOMETRY.)

DEVELOPMENT OF THE PRINCIPLES OF THERMODYNAMICS

Although other sciences had made considerable progress as early as the 7th century, physics and chemistry, which form the foundations of thermodynamics (the study of the relations between heat and other forms of energy), were still in a primitive stage. Jan Baptista van Helmont, a Flemish physician and alchemist, performed the following experiment: he watered the shoot of a young willow tree with rain for a period of five years; he then weighed the shoot and concluded that the increase in weight was due to water alone, since that was all he had fed it. It appeared to him that water could transform itself into wood and, hence, into fire and ashes. Van Helmont also believed that water could be turned into metal with the help of a "seminal spirit" or alkahest. In his studies on combustion and fermentation, van Helmont was led to make a distinction between air and the products of these processes, which he called "gas" after the Greek word *chaos*, although he still used the name *spiritus sylvestris* as well. He made a distinction between flammable and nonflammable gases. He called the gas from burning charcoal gas "carbonum" (carbon dioxide or carbon monoxide). Only the names gas and alkahest were adopted by his contemporaries. During the 17th century, the chymists were primarily interested in studies involving the use of salts as part of the search for the universal solvent. They made experiments using black powder (antimony sulfide) or nitre (potassium nitrate) with combustible substances. The influence of these studies seems to have led to the belief that nitre was the universal solvent and that combustion and respiration were due to the actions of a "nitro-aerial spirit." Although the English physicist Robert Hooke adhered to this barren concept, he showed a better understanding when, in 1665, he wrote, "Heat is a property of a body arising from the motion or agitation of its parts; and therefore whatever body is thereby touched must necessarily receive some

part of that motion, whereby its parts will be shaken." This idea is similar to that which later formed the basis of the kinetic theory. Boyle was one of the first experimentalists to examine the role of air in combustion; he invented a pneumatic pump, which he and Hooke constructed and with which they were able to obtain a vacuum in which a flame was extinguished and no animal could survive. Boyle believed that there was a special agent called volatile nitre in the air that gave air its special qualities.

Phlogiston theory. The studies of chemists continued in the field of reactions of acids and bases, in particular, and led to the corpuscular concept of matter—*i.e.*, that matter is composed of indivisible and immutable particles. In 1697 a German physician and chemist, Georg Ernst Stahl, proposed the phlogiston theory. Stahl was influenced by the work of another German physician-chemist, Johann Joachim Becher, who had proposed earlier that all minerals are made up of three components in various amounts—*terra pinguis* (sulfur), *terra mercurialis* (mercury), and *terra lapida* (saline constituent)—and that all natural substances contained *terra pinguis*, which was lost on combustion. It was this concept that Stahl built upon: he postulated a weightless element, phlogiston, present in all combustible material. Substances that burned well were rich in phlogiston, and those that did not burn did not because they contained no phlogiston. Stahl explained rust in much the same way: the greater the amount of phlogiston in a given metal, the more readily it will react to form the metal oxide. Stahl visualized the phlogiston particles as escaping in the presence of air. Most interesting was Stahl's explanation of why an increase in weight occurred on the formation of a metal oxide although the phlogiston had left the metal, not entered it. Stahl argued that phlogiston was weightless and that the metals, in losing the phlogiston, became more concentrated and dense. Later, he suggested that the weight increased because air filled the vacuum left by the escaping phlogiston. The phlogiston theory was accepted universally and became not only the explanation of combustion and oxidation in general but also the principle describing the chemical and physical properties of all bodies.

The caloric theory. In 1760, 63 years after Stahl proposed the phlogiston theory, Joseph Black, a Scottish chemist, introduced the caloric theory. He stated ". . . heat is evidently not passive; it is an expansive fluid, which dilates in consequence of the repulsion subsisting among its own particles." Black considered this fluid, caloric, to be indestructible and believed that when a body was heated, it accumulated caloric, and when the body cooled, it lost caloric. Black defined the unit of quantity of heat as the amount of caloric fluid needed to raise the temperature of a given body, a unit of temperature or the amount of caloric lost when cooled one degree of temperature. This quantity of heat was called the "capacity for heat" of the body. Black also introduced the concept of latent heat, the amount of energy needed to melt ice at constant pressure and temperature. He demonstrated that the melting of a fixed mass of ice requires a constant quantity of heat. His contribution was an important one because he distinguished between heat and temperature. The caloric theory was believed as late as 1824. Radiant heat was also studied but was not readily adapted to the caloric theory and so was thought to be related to light as invisible light. The notion of phlogiston died out after 1783, when Antoine-Laurent Lavoisier explained the essentials of respiration and combustion. The concept of electricity as a fluid lasted the longest, with Benjamin Franklin's support. What was still missing was a concept of energy that would include heat, light, magnetism, electricity, chemical energy, and work. The conservation of matter had been suggested by Newton's views, and Lavoisier assumed it for all chemical reactions: "nothing is created in the operations either of art or of nature, and it can be taken as an axiom that in every operation an equal quantity of matter exists both before and after the operation." The principle of the conservation of energy was longer in coming. A Dutch physicist and astronomer, Christiaan Huygens, developed the concept of kinetic energy. That mechanical energy is always conserved was proved by several workers. Hermann von Helmholtz, a German physiologist and physicist, in 1847 showed that the sum of the kinetic and potential energies in a system of particles is constant. In 1843 an English physicist, James Prescott Joule, calculated the numerical relationship between a quantity of electricity and the quantity of heat produced by it.

Heat as a fluid

Conservation of energy

Gases and combustion. Important to the progress in understanding combustion was an understanding of gases. In 1772 Daniel Rutherford, a Scottish chemist, formed "fixed air" and "phlogisticated air" by burning a candle in a closed container until the candle went out. He removed the fixed air by bubbling the air through a solution of lime and noted that the portion of air that remained was essentially the same as the original air in its physical properties but that it would not support combustion. This "phlogisticated air" was nitrogen, although Rutherford did not realize it. The English chemist Joseph Priestley discovered oxygen in 1774: he put mercury calx (mercuric oxide) in a glass container and heated it with sunlight, using a lens. Mercury was formed in the upper portions of the glass container. Priestley thrust a smoldering splinter of wood into the container, and it burned brilliantly, more so than in ordinary air. Priestley called this gas "dephlogisticated air"; Lavoisier named it "vital air" or "oxygène."

Lavoisier and another French scientist, Pierre-Simon, marquis de Laplace, repeated earlier work and stated that water was composed of equal weights of inflammable air and vital air. Lavoisier had already heard of Priestley's results and was led to heat mercury in a limited supply of air. The mercury and container were covered with red spots and scales of mercuric oxide, and the original volume of air had decreased, leaving what was called mofette (mephitic air, mainly nitrogen). The mercuric oxide was collected and heated, and the volume of air was recovered as vital air or oxygen. Lavoisier concluded that air was a mixture of vital air and mephitic air and that phlogiston was not necessary in combustion, because combustion was a chemical combination with vital air. In 1756 a Russian chemist, Mikhail Vasilyevich Lomonosov, also rejected the theory of phlogiston, because metals increase in weight on oxidizing.

In 1852 Joule and Thomson made another important contribution to thermodynamics by showing that, on expansion, certain gases cooled, an effect that has since been applied in liquefaction of the so-called permanent gases and in design of refrigerating and air-conditioning systems. Nitrogen and oxygen were liquefied in 1883. In 1892 the Scottish physicist and chemist Sir James Dewar developed a vacuum-insulated vessel for storing fluids at very low temperatures, and in 1898 he produced liquid hydrogen in bulk quantities. In 1908 helium was liquefied. In 1783 Lavoisier and Laplace designed the first practical ice calorimeter, a device for measuring a quantity of heat by determining the weight of ice it caused to melt, which was perfected by a German chemist, Robert Bunsen, in 1870. This was replaced by Marcellin Berthelot's calorimeter, which measured the quantity of heat by the rise in temperature of a given mass of water.

Mechanical equivalent of heat. An American–British physicist, Sir Benjamin Thompson, count von Rumford, using a horse-turned machine for boring cannons in the military arsenal at Munich, was "struck with the very considerable degree of heat which a brass gun acquires, in a short time, in being bored; and with the still more intense heat (much greater than that of boiling water, as I found by experiment), of the metallic chips separated from it by the borer. . . ." Thompson designed an apparatus in which a blunt borer was forced against the bottom of a hollow metal cylinder and was rotated by machinery operated by horses. The cylinder was enclosed in a box containing about two gallons of water. The temperature had risen 47° F at the end of an hour, and after two and a half hours the water boiled. In a report to the Royal Society of London in 1798, he said,

It is hardly necessary to add, that any thing which any in-

sulated body, or system of bodies can continue to furnish, without limitation, cannot possibly be a material substance; and it appeared to me to be extremely difficult, if not quite impossible, to form any distinct idea of anything, capable of being excited, and communicated, in the manner the heat was excited and communicated in the experiments, except it be motion.

From the result of this experiment, Thompson calculated an equivalence between the heat generated and the mechanical energy expended. Between 1840 and 1849, Joule refined these measurements by measuring the temperature rise in water churned by a paddle driven by a descending weight.

In 1799 in England, a chemist named Sir Humphry Davy, interested in friction, used a clockwork to make a metal wheel turn against a wax-coated metal plate. The wax was melted even though the entire system was held below freezing. In addition, he rubbed two pieces of ice together, again keeping the ice below freezing, yet the ice melted. The caloric theory failed to explain these results, and Davy concluded that heat was kinetic in nature, a form of motion. When Dalton suggested the atomic theory in 1803, he still supported the caloric theory. According to his theory, atoms were in contact in liquids and solids but far apart, surrounded by caloric, in gases.

The first law. A German physicist, Julius Robert Mayer, also measured the mechanical equivalent of heat; more importantly, he suggested that energy is perfectly preserved if all its forms are included. This "law of conservation of energy," essentially the first law of thermodynamics, was not immediately accepted. In 1847 Helmholtz presented the conservation of energy in much the same terms as Mayer.

The conversions of work into heat shown by Thompson, Joule, and Davy had been preceded by demonstrations that heat could be converted into work. A French physicist, Denis Papin, demonstrated in 1681 that, when water is heated in a closed vessel, enough pressure is generated to raise the lid of the container. Using this principle, Papin designed the first steam engine in 1687 and a second, much improved version in 1707. About the same time, the English engineers Thomas Savery and Thomas Newcomen built steam-operated water pumps for use in coal mines. The Scottish engineer James Watt improved this engine and developed the much superior expansion engine in 1763.

Invention of the steam engine

Carnot's heat engine. Another proponent of the equivalence of mechanical energy and heat, although he still accepted the caloric theory, was the French physicist Sadi Carnot, who published his classic paper, *Réflexions sur la puissance motrice du feu et sur les machines propres à développer cette puissance*, in 1824; in it he defined work (as weight lifted through a height) and set forth the concepts that later became known as the second law of thermodynamics. Carnot made a study of a theoretical heat engine (a mechanical device that transforms heat into work) and concluded that every such engine requires a source of heat and a receiver (sink), at a lower temperature, to which part of the heat is rejected. Carnot's ideal heat engine operates in cycles of four processes. In the first process, heat is taken from the source at constant temperature while a fluid in the engine expands and does work on the surroundings; in the second process, the fluid expands further, doing additional work without absorbing additional heat, and cooling to the temperature of the sink. In the third process, the fluid in the engine contracts while heat flows from it to the sink at constant temperature and work is done upon the fluid by the surroundings; in the fourth process, no heat is transferred while further work is done upon the fluid, compressing it back to its original volume and pressure and heating it back to its original temperature, that of the heat source. The engine is now in the same state as it was at the beginning of the first process. The amount of work done by the engine during the first and second processes is greater than the amount of work done upon the engine during the third and fourth, and the amount of heat rejected to the sink is less than the amount taken from the source. The difference between the amounts of heat taken from the source and rejected to the sink is equal to the net amount of work done by the engine. Carnot likened his heat engine to a waterwheel, in which work is obtained from a fall of water from a high level to a low level: in his heat engine there is a "fall" of heat from a high-temperature source to a low-temperature sink. Most important, Carnot's theory showed that for a fixed amount of heat added to the engine, there was a fixed amount of work the engine could do and that for optimum conditions this amount of work depended only on the temperatures of the source and receiver—*i.e.*, the ratio of the amounts of heat rejected and added can be mathematically expressed in terms of the temperatures of the sink and source. (Lord Kelvin later used this relationship to devise the absolute temperature scale that bears his name.) In addition, Carnot showed that a reversible engine operating between a source at a given high temperature and a sink at a low temperature has an efficiency that cannot be exceeded by any other engine working under the same temperature conditions. His heat engine remains the model of the most efficient engine to this day.

The second law. The work of Carnot was continued by (among others) a German theoretical physicist named Rudolf Clausius and, in Scotland, a mathematician and physicist, William Thomson, Lord Kelvin. In 1850 Clausius stated the second law of thermodynamics in essentially the following manner: "Heat cannot pass spontaneously from a body of lower temperature to a body of higher temperature." In 1851 Lord Kelvin stated the second law in a different but, as was subsequently proved, equivalent fashion: "It is impossible to construct an engine which would extract heat from a given source and transform it into mechanical energy, without bringing about some additional changes in the bodies taking part." In 1865 Clausius introduced the concept of entropy (a thermodynamic quantity related to the tendency of a process to occur spontaneously) and developed many of the important consequences of the second law using this quantity; in particular, he proposed that the energy of the universe is constant but the total entropy of the universe always increases. By this time, then, the foundations of classical thermodynamics had been formulated in the first and second laws.

Entropy

In 1882 Helmholtz observed that the maximum work that can be done by chemical forces is expressed by the decrease in what he called the "free energy," now called the Helmholtz function. He concluded that if the free energy of a system is maintained at constant temperature and volume is a minimum, then the system is in thermodynamic equilibrium. A Dutch physicist, Heike Kamerlingh Onnes, defined the thermodynamic function enthalpy, which Josiah Willard Gibbs, a physicist in the United States, used in defining what he called the "free enthalpy," now called the Gibbs function. Gibbs showed that his function is a minimum for a system at equilibrium when the temperature and pressure are held constant. In 1906 in Germany, the physical chemist Walther Nernst stated that theorem now called the third law of thermodynamics: if a chemical change occurs between pure crystalline solids at absolute zero, there is no change in entropy.

The molecular basis of heat. The fact that heat is energy that is transferred from one body to another by virtue of a temperature difference, with that heat flowing from hot to cold, is now universally accepted. Attempts to explain thermal energy in terms of molecular motion can be traced to a Swiss mathematician, Daniel Bernoulli, who in 1738 explained Boyle's law by the assumption that at constant temperature the mean velocity of the particles in a gas remains constant. The kinetic theory of gases was developed in the 1850s. In 1859 a Scottish mathematician and physicist, James Clerk Maxwell, amplified Bernoulli's concept, derived a law of distribution of velocities, and found an expression for the viscosity of gases using the concept of the mean free path, the distance between two consecutive collisions of a molecule. In Austria, Ludwig Eduard Boltzmann, a physicist, further extended this work and in 1877 redefined entropy in terms of probability. In 1902 Gibbs published a study

relating thermodynamic properties to statistical principles, using a very general approach, not restricted to gases. Earlier, in 1900, the German physicist Max Planck had presented his concept of the quantum of energy, and modern statistical thermodynamics was begun (see THERMODYNAMICS, PRINCIPLES OF).

Heat transfer. Since heat is energy in transition, some discussion of the mechanisms involved is pertinent. There are three modes of heat transfer, which can be described as (1) the transfer of heat by conduction in solids or fluids at rest, (2) the transfer of heat by convection in liquids or gases in a state of motion, combining conduction with fluid flow, and (3) the transfer of heat by radiation, which takes place with no material carrier. The flow of heat in metal bars was studied analytically by the French mathematician Jean-Baptiste-Joseph Fourier and measured by the French physicist Jean-Baptiste Biot in 1816. The conductivity of water was first determined in 1839; the conductivity of gases was not measured until after 1860. Biot formulated the laws of conduction in 1804, and Fourier published a mathematical description of this phenomenon in 1822. In 1803 it was found that infrared rays are reflected and refracted as visible light is, and, thenceforth, the study of thermal radiation became part of the study of radiation in general. In 1859 a physicist in Germany, Gustav Robert Kirchhoff, presented his law of radiation, relating emissive power to absorptivity (see SPECTROSCOPY, PRINCIPLES OF). An Austrian, Josef Stefan, established the relationship (now called the Stefan–Boltzmann law) between the energy radiated by a blackbody and the fourth power of its temperature. Boltzmann established the mathematical basis for this law of radiation in 1884. It was in the study of radiation that Planck arrived at the concept of the quantum. Understanding of heat transfer by convection was developed during the period 1880–1920, although an equation describing such processes had been suggested by Sir Isaac Newton in 1701.

Conduction, convection and radiation

APPLICATIONS

Refrigerators and air conditioners. Modern air conditioning and refrigeration use the cooling effect of the expansion of gases but also use the effect of latent heat (*i.e.*, the heat rejected in condensation and the heat added in evaporation of the refrigerant). The basic components of a refrigeration system are a compressor followed by a condenser; then an expansion device, which can be a valve, a capillary tube, an expansion engine or an expansion turbine; and finally an evaporator. (For details see HEATING, VENTILATING, AND AIR CONDITIONING.)

Reciprocating steam engines. As was previously mentioned, the first steam engine was developed by Denis Papin in 1690, made practical for pumping water by Savery in 1698, and improved by Newcomen in approximately 1712. The principle was to lead steam into a cylinder, condense it with an outside coolant, and let the resulting vacuum suck a piston into the cylinder. Newcomen's engine, modified somewhat, was unrivalled until 1765, when Watt introduced the separate condenser. In 1782 Watt patented two other important changes, making the piston double-acting (the piston is driven alternately in each direction) and letting the steam expand against the piston by cutting off the flow of steam instead of letting the steam flow continuously. Many improvements of the basic design of the steam engine were introduced later, including the use of higher pressures (Watt's engine used steam at only two to three pounds per square inch [0.1 to 0.2 kilogram per square centimetre] above atmospheric pressure), higher speeds, and lighter parts. By 1900 the more efficient steam turbine had made the reciprocating steam engine obsolete in stationary power plants, but, in the third quarter of the 20th century, reciprocating engines using steam or other fluids were receiving renewed interest for possible use in automobiles. (For details see STEAM POWER.)

Turbines. If the steam engine is replaced by a steam turbine, the cycle of changes in the pressure, volume, and temperature of the steam is called a Rankine cycle, after the Scottish engineer William J.M. Rankine. Two major modifications have been made in the use of the steam turbine to improve the efficiency. The first of these is to have two turbines, one operating at high pressure and the second at low pressure, returning the steam to the generator for reheating after expanding in the high-pressure turbine. The reheated steam is then sent to the low-pressure turbine. The second modification involves the concept of regeneration (*i.e.*, an exchange of heat within the system). In a regenerative cycle, steam is bled from the turbine or turbines and led to a feedwater heater to preheat the water going to the steam generator. The function of the steam generator is the same whether the fuel is a fossil fuel or a nuclear one. In order that the entire plant not be radioactive, a nuclear power plant must have an intermediate fluid, heated by the nuclear reactor, that produces the steam in the generator.

Another type of turbine power plant, used in aircraft, employs an open cycle, the exhaust gases leaving the turbine not being returned to the compressor. Air is partially compressed in the inlet to the compressor and fully compressed by the compressor itself. Fuel is added, and combustion takes place before the gases enter the turbine. The exhaust gases expand through a nozzle after leaving the turbine. In a jet engine, the turbine provides power to drive the compressor, and the difference between the exit and inlet velocities provides the thrust for the aircraft. In a turbo-prop engine, the turbine also provides power to drive a propeller (for details see TURBINE and JET ENGINE).

Jet propulsion

Internal combustion engines. When Papin was investigating the use of steam for power, he also tried using the explosive power of gunpowder in a piston–cylinder device. This concept, suggested by Christiaan Huygens, was the predecessor of the internal combustion engine. The first such engines using the burning of gas as the power source were much like steam engines. The gas was introduced into the cylinder and then ignited by some external mechanism. The pressure resulting from the combustion acted on the piston, causing it to move. One such engine used an electric spark to ignite the combustible mixture of gas and air. In 1862 an engine designed to operate on four strokes was patented but was not built before the patent lapsed, and the cycle is known as the Otto cycle, after Nikolaus August Otto, a German inventor, who in 1878 revived the four-stroke engine with its important idea of compressing the combustible mixture before ignition and produced a gas engine using this principle.

The Otto four-stroke engine

Since gas was not available everywhere, efforts were made to develop an engine that would operate using oil. Many of the first oil-fuelled engines operated on the Otto cycle. The oil was first atomized, mixed with preheated air to vaporize the oil, and then this mixture was drawn into the cylinder. In 1892, in Germany, Rudolf Diesel patented a cycle in which fuel is added after the air has been compressed. The combustion occurs spontaneously because the air is hot enough after compression to ignite the fuel.

In 1885 Gottlieb Daimler, another German inventor, developed the surface carburetor, which permitted the use of gasoline as a fuel in the Otto cycle. The Otto cycle is still the most frequently used cycle for gasoline engines, the Diesel cycle for oil engines.

In 1878 the Scottish engineer Sir Dugald Clerk developed the two-stroke cycle, in which the intake and compression strokes are combined and the expansion and exhaust strokes are combined. The cycle is used primarily for fuel-injection or Diesel engines. Another internal combustion engine of interest is the Wankel, or rotating combustion, engine. In the Wankel engine, three cyclic processes proceed simultaneously in three separate chambers formed by an essentially triangular rotor in a nearly elliptical stator. The steps occurring are intake and compression, combustion and expansion, and exhaust. (For details see DIESEL ENGINE and GASOLINE ENGINE.)

Nuclear power plants. The power-producing portion of a nuclear plant is the same as in any modern high-pressure, high-temperature steam power plant. The major difference lies in the source of heat added to the feedwater to produce the high-temperature steam. In general, the nuclear reaction heats an intermediate fluid, which in

turn heats the feedwater. In experimental reactors the fluid may be liquid sodium, but commercial units use boiling water or pressurized water. (For details see NUCLEAR REACTOR.)

Other power sources. The desire to find new and lightweight sources of power has led to the investigation of many direct energy conversion devices. Three such devices are briefly described.

The fuel cell may be considered an electric battery in which both the fuel and oxidizer are continuously replaced. In the fuel cell, the chemical energy is not converted to heat but directly into electrical energy.

With the development of semiconductors, thermoelectric generators and refrigerators became possible. In the generator, heat is added to the system at a high temperature and removed by a cooling system at a lower temperature. Because of the temperature difference across the semiconductors, a current flows. The opposite effect is observed in the refrigerator, in which power is supplied, causing a current to flow that in turn produces the temperature difference. The effects upon which the operation is based are called the Seebeck effect (see above *Thermometry*) and the Peltier effect. In 1834 the French physicist Jean Peltier observed the reverse of the Seebeck effect: the passage of current through a junction of two dissimilar conductors produced a heating or cooling effect depending on the direction of the current. Lord Kelvin found a third effect, namely, that the flow of current in a conductor with a temperature gradient produces heating or cooling depending on the direction of flow. He also developed the relationship between the three effects (for details see BATTERIES AND FUEL CELLS; ELECTRIC POWER; THERMOELECTRIC DEVICES).

Heat Exchanger

The heat exchanger is a device in which heat from a hot fluid is transferred to a cold fluid; the temperature of the hot fluid decreases and that of the cold fluid increases. Heat exchangers are manufactured in many different designs and are used extensively in various technologies—for instance, in steam and nuclear power plants, in gas turbines, in heating and air-conditioning, in refrigeration, and in the chemical industry. More recently, special types of heat exchangers have been developed for artificial satellites and space vehicles. Heat exchangers are given different names when they serve a special purpose. Thus boilers, evaporators, superheaters, condensers, and coolers may all be considered heat exchangers.

PRINCIPLES OF OPERATION

The basic operation of a heat exchanger may be discussed with the help of a simple type shown in Figure 1. This exchanger is constructed from two pipes in a concentric arrangement. Inlet and exit ducts are provided for the two fluids. In the sketch the cold fluid flows through the inner tube and the warm fluid in the same direction through the annular space between the outer and the inner tube. This flow arrangement is called parallel flow. In it heat is transferred from the warm fluid through the wall of the inner tube (the so-called heating surface) to the cold fluid. The temperature in both fluids varies as shown in the lower part of Figure 1. The temperature of the warm fluid decreases from t_{w1} to t_{w2}, and the temperature of the cold fluid increases from t_{c1} to t_{c2}. The amount of heat Q that is transferred from one fluid to the other per unit

Parallel flow arrangement

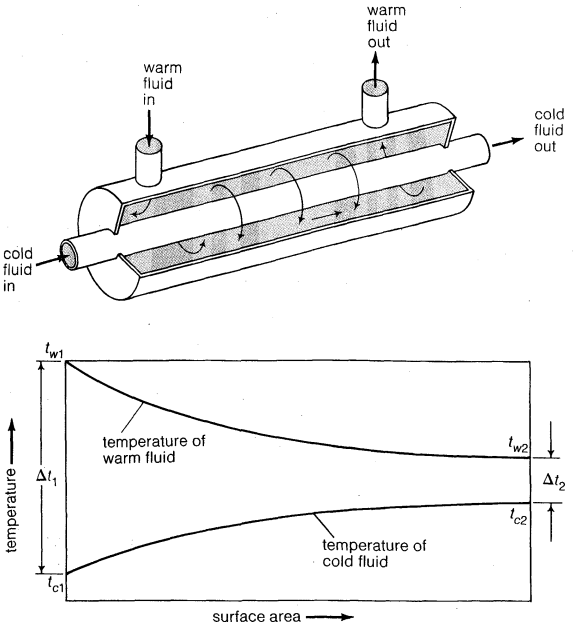

Figure 1: (Top) Operating principle of a parallel-flow heat exchanger and (bottom) changes in fluid temperatures that take place therein (see text).

of time, called heat flow, can be calculated from the following equation:

$$Q = mc\,(t_2 - t_1) \qquad (1)$$

This equation states that the heat flow Q (in kilowatts [kW]) can be obtained by multiplying the mass per unit time of fluid m (in kilograms per second [kg/sec]) by the specific heat c of the fluid and by the temperature increase $t_2 - t_1$ of the fluid from the entrance to the exit of the heat exchanger (in degrees Centigrade). The specific heat is a property of the fluid involved. For example, it has to be entered with the value 1 for air and 4.18 for water into equation (1). The amount of heat leaving the warm fluid must be the same as the amount of heat received by the cold fluid. The mass flow and the temperature increase for the cold or the decrease for the warm fluid can therefore be entered into equation (1). The heat exchanger may have to be designed, for example, to increase the temperature of a prescribed mass per unit time m_c of the cold fluid from t_{c1} to t_{c2}. Entering these values into equation (1) then determines the heat flux Q which has to be transferred in the heat exchanger. This value will be needed in the following discussion to calculate the heating surface of the exchanger. It is sometimes preferred to express the heat flux in thousands of calories per hour (kcal/hour). The corresponding value can be obtained by multiplying the heat flux Q in kW, obtained from equation (1), by 860.

Counterflow arrangement

The temperature difference Δt_1 between the fluids at the entrance of the heat exchanger decreases to the value Δt_2 at the exit, as illustrated in Figure 1. A heat exchanger is operated in counterflow when the flow direction of one of the fluids is reversed. The counterflow arrangement has the advantage that the exit temperature t_{c1} of the colder fluid can be increased beyond the exit temperature t_{w2} of the warm fluid. In addition, a smaller surface area is required in counterflow than in parallel flow to transfer the same amount of heat. This is so because the mean temperature difference Δt_m in the counterflow heat exchanger, for a given heat flux and prescribed inlet temperatures, is larger than in the parallel-flow exchanger.

The heating surface of the heat exchanger can be obtained from the equation:

$$A = \frac{Q}{U\Delta t_m} \qquad (2)$$

The equation indicates that the required surface area A (in square metres [m²]) is obtained by dividing the heat

flux Q obtained with equation (1) by the overall heat transfer coefficient U (to be discussed later) and the mean temperature difference Δt_m (in degrees Centigrade).

Larger heat exchangers utilize a bundle of tubes through which one of the fluids flows. The tubes are enclosed in a shell with provisions for the other fluid to flow through the spaces between the tubes. Fluid flowing outside the tubes can be directed either in the same direction as or counter to the effective flow in the tube bundles (see Figure 2). In the latter arrangement, parallel or counter flow

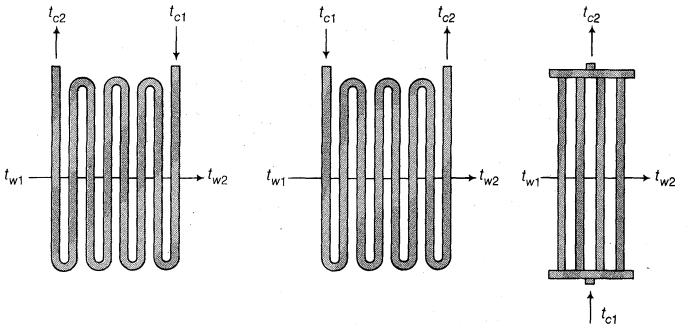

Figure 2: (Left) Counterflow, (centre) parallel flow, and (right) crossflow in tubular heat exchangers (see text).

can be approximated in the way shown in Figure 2. In another arrangement, the cold fluid is distributed in such a manner that it flows in parallel through the tubes forming the heating surface and is then collected by a header. This arrangement creates a cross flow, as shown schematically in Figure 2. In nuclear reactors fuel rods may replace the tubes, and the cooling fluid flowing around the rods removes the heat generated by the fission process. In a similar way, rods containing electric resistance heaters may supply heat to the fluid passing through the exchanger between the rods.

MECHANISM OF HEAT TRANSFER

The mechanism of heat transfer from the hot to the cold fluid must be considered. For this purpose, attention may be focussed on local conditions determining transfer from the warm to the cold fluid. Several physical processes are involved in this transfer. One of the basic laws of thermodynamics states that heat by itself always flows in the direction of decreasing temperature. In the heat exchanger, a temperature drop Δt_f is required to transport the heat from the bulk of the warm fluid to the heating surface. Another temperature drop Δt_w is needed to transport the heat through the wall between the warm and cold fluids, and yet another Δt_f to move the heat from the surface of this wall into the bulk of the cold fluid. Figure 3 illustrates the temperature variation just described.

Heat conduction

The physical process that causes the heat to flow through the solid wall from one surface to another is called heat conduction. It has to be visualized in a specific way: each atom of the wall passes on its energy to the neighbouring atoms of lower temperature, handing heat energy from the hot side of the wall to the cold side. The temperature drop required to produce this heat flux depends on the thickness of the wall, its surface area, and its thermal conductivity. The heat flux produced by a temperature difference Δt_w between the two surfaces of the wall can be calculated by the following equation:

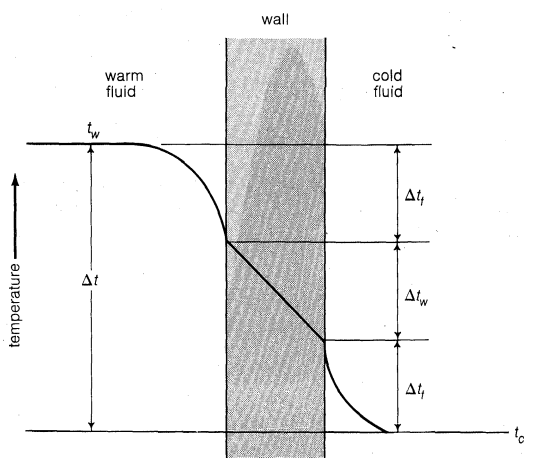

Figure 3: Heat flow from a warm fluid to a cold fluid through a conducting wall (see text).

$$Q = \frac{k}{s} A \Delta t_w \qquad (3)$$

The equation states that the heat flux Q (in kW) is obtained by multiplying the thermal conductivity k (a measure of the ability of a material to conduct heat) by the area of the heating surface A of the heat exchanger (in m^2), by the temperature difference Δt_w (in degrees Centigrade), and then dividing by the thickness s of the wall (in m). In a heat exchanger it is desirable to decrease the temperature drop so that a smaller overall temperature difference results. This can be achieved by reducing the wall thickness and by selecting a material with a high thermal conductivity. Metals have high values of k, and the magnitude of the thermal conductivity is roughly proportional to the electrical conductivity. In other words, metals that are good electrical conductors are also good conductors of heat. The following values of k may be used in equation (3) for materials that are frequently used in heat exchangers: 0.38 for copper, 0.2 for aluminum, and 0.04 for steel.

Heat transfer from a fluid to a solid surface takes place partially by conduction. It is supplemented, however, by a process in which the fluid carries heat along as it moves through the heat exchanger. This process is called convection and depends on the nature of the flow. There are two types of flow that occur in nature. In one type, called laminar, the fluid particles move along in a smooth way side by side. In turbulent flow conditions, waves and vortices are continuously formed and destroyed again. Superimposed on the mean flow, these vortices cause a continuous mixing of fluid particles. Whether the flow through a tube is laminar or turbulent depends on the tube diameter, on the velocity of the fluid, and on fluid viscosity. The flow tends to be laminar when the velocity is low, the tube diameter is small, and the viscosity is large. Laminar flow is encountered in oil coolers, for example, because oil has a high viscosity. Heat exchangers for liquids like water or for gases usually operate with turbulent flow. The heat transfer from the bulk of the fluid to the tube wall in laminar flow results mainly from conduction and is then described by an equation similar to equation (3). Consequently, it is determined by the conductivity of the fluid and by the tube diameter. Liquids have considerably larger heat conductivity values than gases and thus transfer heat more readily. Liquid metals have especially large heat conductivity values and are for this reason used in engineering applications in which large amounts of heat have to be transferred at small temperature differences. Some new designs of nuclear reactors use liquid metals as heat transfer media.

In turbulent flow, the mixing process described previously constitutes a third mechanism that transfers the heat from the bulk of the fluid to the wall. It is understandable that this process depends strongly on the velocity of the fluid. Heat transfer in turbulent flow is therefore larger than in laminar flow.

The following equation is used to calculate the heat transfer in a fluid for either laminar or turbulent flow:

$$Q = h A \Delta t_f \qquad (4)$$

The heat transfer coefficient

According to this equation, the heat flux Q (in kW) is obtained by multiplying a parameter h, called heat transfer coefficient, by the heat transfer area A (in m^2), and by the temperature difference Δt_f between the bulk of the fluid and the wall in either the warm or the cold fluid. Values for the heat transfer coefficient depend on the parameters that have been mentioned above and can be determined by fairly involved calculations. Ranges commonly encountered can be mentioned here. In air, for

instance, values that have to be introduced into equation (4) range between 0.01 and 0.1 and in water between 0.5 and 5. These values indicate that much larger heat transfer surfaces are required to transfer the same amount of heat in a gas than in a liquid. Correspondingly, it is advantageous to provide a larger heat transfer surface on the gas side of a heat exchanger than on the liquid side. This is done by equipping the tubes with fins on the side of the surface that is exposed to the gas flow. Much effort has been directed toward improving manufacturing processes for such finned surfaces.

The overall heat transfer coefficient U required in equation (2) is obtained from the equation:

$$\frac{1}{U} = \frac{1}{h_w} + \frac{s}{k} + \frac{1}{h_c} \qquad (5)$$

in which h_w and h_c denote the heat transfer coefficients for the warm and cold fluids, respectively, and s and k have the same meaning as in equation (3).

The temperature drop in heat exchangers increases occasionally with time when some material is deposited from the fluids on the surfaces of the heat transfer walls. This "fouling process" degrades the performance of the heat exchanger and may necessitate periodic cleaning to restore it to the original performance.

TYPES OF HEAT EXCHANGERS

Specific heat exchangers had to be developed for satellites and space vehicles. These vehicles operate in a vacuum; therefore heat cannot be transferred by conduction or convection. Here, heat transfer has to be effected by another process called thermal radiation. This mechanism of heat transfer, used in such heat exchangers, is the same as the process by which the Earth receives energy from the Sun. Energy transfer by radiation is especially effective at high temperatures. In engineering devices operating at high temperatures, like steam boilers or gas turbines, heat transfer is caused by radiation added to the conductive and convective heat transfer.

Optimizing heat exchangers

In designing a heat exchanger for a specific purpose, the initial cost resulting from the weight of the heat exchanger, the material used, and the required labour must be balanced against the operating cost of the power required. Power, usually in the form of electrical energy, has to be expended to overcome the pressure drop of the fluids in the heat exchanger. Much thought has been given to the problem of optimizing heat exchangers. In general, it has been found that small tube diameters and small clearances between the tubes reduce the initial and the operating costs. Designers of heat exchangers are constantly striving to develop more effective surface configurations. A wavy shape, for instance, was found to be more effective than straight fins. In this way, compact heat exchangers have been created.

Regenerative heat exchangers. A different type of heat exchanger, conventionally referred to as a regenerative heat exchanger, is constructed from a porous material through which the warm and the cold fluids are ducted alternately. The heat is stored in the porous material—the matrix—during the time the warm fluid passes through and is released from the porous material to the cold fluid when the latter fluid passes through. The matrix can be formed in a multitude of ways from screens, fibres, or other elements. Nonmetallic materials, like ceramic and glass, have also been used. The surface area per unit volume can be made very large by providing many passages with small dimensions. This leads to very compact heat exchangers. The alternate flow of the two fluids can be controlled by valves that at the proper time open and close the inlet and exit ducts for the two fluids, or the heat exchanger can be designed in such a way that the matrix rotates through the passages of the two fluids. Such heat exchangers, introduced by a Swedish engineer, F. Ljungstrom, were used frequently, beginning around 1930, in steam power plants. The compact size of this heat exchanger makes it desirable for gas turbines that power automobiles, airplanes, or other vehicles. Still to be overcome in its development is the need for effective and durable seals between the rotating matrix and the ducts for the two fluids.

Heat pipes. A heat exchanger of a different kind has recently stimulated much attention. Called the heat pipe, it is used to transport heat over relatively large distances with the temperature difference kept as small as possible. The heat pipe consists of a hollow tube closed at both ends and partially filled with a liquid that boils at a desired temperature. One end of the tube is immersed in the warm region, and the other in the cold region. The objective is to transfer heat through the pipe from the warmer to the colder region. The process may be visualized by assuming that the tube is in a vertical position with the lower end immersed in the warm region. The liquid fills the lower end of the tube and starts boiling when the temperature of the warmer region exceeds the evaporation (or boiling) temperature of the liquid. The accumulation of vapour increases the pressure at the lower end of the tube. This forces the vapour upward, where it condenses since the temperature of the colder region is below the evaporation temperature. The condensed liquid runs down along the inner surface of the tube, due to gravity. In this way a steady circulation of the fluid is maintained. Heat is required to evaporate the liquid. This heat of evaporation is removed in the boiling process from the hot region. The same amount of heat is released when the fluid is condensed and is transferred to the cold region. Consequently, circulation of fluid causes transport of heat from the warm to the cold region.

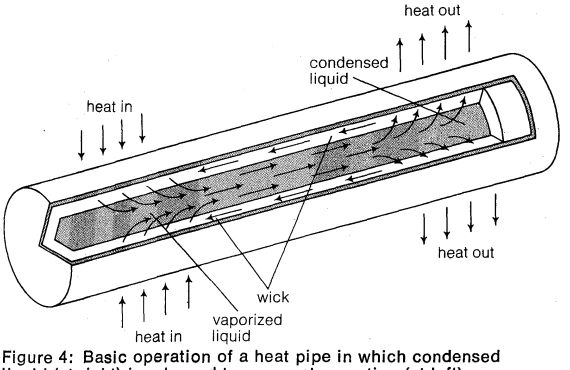

Figure 4: Basic operation of a heat pipe in which condensed liquid (at right) is returned to evaporator section (at left) by means of a wick.

Schmidt's experiments

Development of the heat pipe. Experiments conducted by a German engineer, E. Schmidt, in 1939 demonstrated that this mechanism for transporting heat is especially effective if the working fluid is close to its critical point. In 1960 he reported that a tube filled with ammonia or carbon dioxide near its critical point transfers an amount of heat per unit time that is more than 4,000 times larger than the amount of heat transferred by a solid rod of copper with the same dimensions and at the same temperature difference between the hot and cold regions.

A device of this kind can only operate in a vertical position, with the hot region located below the cold region. This limitation was eliminated through an improvement conceived by R. Gaugler at General Motors Corporation in 1942. He incorporated a wick or porous matrix covering the inside wall of the tube into the design, as shown in Figure 4. Because the wick contained many capillary passages, capillary action transported the liquid through the wick from the cold to the hot end of the tube, regardless of the direction in which it was oriented. This capillary action may be illustrated by an experiment in which a small diameter glass tube is held in a vertical position with its lower end immersed in water. The water rises in the tube to a level that is higher than that of the water surrounding the tube. The forces of attraction between the inner tube surface and the water surface—a capillary action—are able to overcome the force of gravity and lift the water in the tube above the surrounding liquid level. The height to which the water rises is greater, the smaller

the diameter of the tube. When the tube is heated in such a way that water evaporates from its surface, the water level in the tube is maintained by a continuous inflow through the lower tube end. In this way, a continuous flow of liquid through the tube is generated. Exactly the same process occurs in the wick of the heat pipe where the working fluid continuously evaporates at the hot end of the wick. Capillary forces continuously replace the evaporated liquid. The circulation of the fluid in the pipe occurs in such a way that a pressure difference in the vapour causes the vapour to flow from the warm to the cold end of the tube. Capillary forces return the liquid through the wick.

Heat pipe in space power plants

Since the device conceived by Gaugler did not become widely known, G.M. Grover, at Los Alamos Scientific Laboratory, described it again in 1963. He gave it the name "heat pipe," suggesting that it be used to transport heat in power plants for space vehicles. The effectiveness of the device derives from the fact that only small temperature differences are required to move the heat through the tube wall. Additionally, the transport of heat with the vapour requires almost no temperature difference. In this way, very large quantities of heat can be transported over considerable distances with very small temperature differences. In one such device, for instance, a heat flux in the amount of 11 kW was transported by a heat pipe with 2.5 centimetres diameter and 69 centimetres length, with a temperature difference so small that it was difficult to measure. By comparison, a temperature difference of 40,000° C would be required if a rod of copper (one of the best thermal conductors) with the same dimensions were used to transfer the same amount of heat. The hot end of the rod would thus have had a temperature much greater than the surface temperature of the sun, even though the other end was at room temperature. Obviously the copper rod would have evaporated long before the high temperature could have been reached.

This ability to transport very large quantities of heat with small temperature differences is the main feature characterizing the heat pipe. The device has other desirable features as well. For instance, the heat pipe operates whether the heat at the warm or cold end is transferred to a large or small surface area. When heat is concentrated at one location, it can be removed through a heat pipe and distributed over a large region. This feature has become important in the effort to miniaturize electronic equipment. In such equipment heat is generated as a by-product; the heat pipe makes it possible to remove a large amount of heat from the interior and transport it to some place where it can easily be removed by a cooling air stream. Consequently, electronic equipment can be constructed in very compact form. The fact that heat can be transported through the pipe with very small temperature differences suggests its application in cases where a uniform temperature of an engineering device is desirable. The heat pipe has thus been found useful in space flight. It eventually operates at a nearly constant temperature regardless of the amount of heat, large or small, it has to transfer per unit time. It can be used, therefore, to keep temperatures in various devices constant in time even when the amount of heat that has to be removed varies.

Limitations of heat pipes. On the other hand, a specific heat pipe has certain limitations for its operation. Each wick has a maximum amount of liquid flow that it can transport. This prescribes an upper limit for the amount of heat that such a pipe can transport per unit time. When the liquid at the warm end of the pipe evaporates, vapour bubbles are created at the tube surface and separate when they have reached a certain size. The density of the vapour bubbles at the surface increases as the amount of heat transferred per unit area and time increases. It finally reaches a condition in which the bubbles combine to form a continuous vapour film blanketing the surface. This condition, called the boiling crisis or burn-out condition, has to be avoided since vapour is a very poor conductor of heat. As a consequence, the temperature of the tube material may increase to values that cannot be tolerated. The boiling crisis then determines an upper limit for the amount of heat that can be transferred from the warm region to the heat pipe per unit area and time. The maximum temperature at which the heat pipe can operate is determined by the fact that the pressure of the fluid inside the pipe increases with temperature, because the evaporation temperature depends on pressure. An upper limit is then given by the pressure that the walls of the tube can withstand. Nevertheless, heat pipes can be designed to operate in a wide temperature range from below 0° C up to around 2,000° C. This is accomplished by proper choice of the liquid that the pipe contains and the material of which the pipe is manufactured. Methanol, acetone, water, fluoridated hydrocarbons, mercury, lithium, lead, bismuth, and a range of inorganic salts have been used as working fluids; the tube itself has been made of glass, ceramic, copper, stainless steel, nickel, tungsten, molybdenum, tantalum, and various alloys. Wicks have been constructed of sintered, porous materials, woven mesh, fibre glass, longitudinal slots, and combinations of these structures. An interesting example of a specialized application is a heat pipe in which both the pipe and the working fluid are electrically nonconducting. With such construction, a heat pipe can be used in an electrical device to transfer heat from locations where the electric potential exceeds 5,000 volts. The physical size and configuration of heat pipes can vary widely.

The heat pipe has become a unique and versatile heat transfer device with its range of applications seemingly unlimited.

BIBLIOGRAPHY. A.P. FRAAS and M.N. OZISIK, *Heat Exchanger Design* (1965), is intended to help practicing engineers design heat exchangers but should also be useful for the layman. The book describes heat-exchanger types for various engineering applications, fabrication techniques, fluid flow, heat transfer, stress considerations, testing of heat exchangers, and design calculations. Extensive tables of required properties and relations for design analysis are appended. W.M. KAYS and A.L. LONDON, *Compact Heat Exchangers* (1958), presents an introduction to heat-transfer and pressure-drop analysis, but is useful for engineers only. Tables and diagrams present test results for a large number of surface configurations of compact heat exchangers. G.Y. EASTMAN, "*The Heat Pipe*," Sci. Am. 218:38–46 (1968), discusses physical processes in a heat pipe and its operation in terms understandable to the layman. The advantages as well as the limitations are described and many applications are mentioned. Useful illustrations supplement the text.

(E.R.G.E.)

Heating, Ventilating, and Air Conditioning

Heating, ventilation, and air conditioning are all aspects of environmental engineering, a recent concept embracing all aspects of the engineering of buildings, such as structure, drainage, acoustics, and internal transportation. The concept of environmental engineering takes cognizance of the fact that all elements of building are interrelated. The heat produced by lighting, for instance, affects the need for air conditioning, calling for ducts, which in turn affect the design of the structure.

The present article is confined to buildings, but the subject may be extended to cover mobile vehicles, such as motor coaches, aircraft, ships, railway trains, spacecraft, and submarines, each having highly specialized requirements. Heating, ventilating, and air conditioning in the present context may be defined in general terms as the control of the environment within enclosed spaces. Apart from comfort, many industrial processes depend on a controlled atmosphere; thus, this branch of engineering covers a considerable range of applications. Heating is concerned with raising the temperature of the thermal environment. Ventilating is concerned with the supply of fresh air and removal of air that is vitiated, polluted, or contaminated. Air conditioning may include the functions of heating and ventilating but in addition is concerned with lowering of temperature of the thermal environment, raising or lowering of humidity, and purifying

the air by removal of dust, bacteria, and other airborne matter.

History. Making fire was among man's earliest achievements, and doubtless wood formed the earliest of fuels, first in caves, as remains of Stone Age hearths show, and later in mud and turf enclosures.

The discovery that charcoal could be made from wood to produce a fuel without smoke seems to have been an early step toward progress in places where only moderate warmth was needed, such as China, Japan, and the shores of the Mediterranean.

The invention of the fireplace

Another evolution was the flue or chimney, first as a simple aperture in the centre of the hut roof and later rising from the fireplace, invented in Europe in the 13th century. Smoke and fumes no longer pervaded the living space.

Stoves, far less wasteful of heat than fireplaces, appear to have been used first by the Chinese about 600 BC. They can be traced through Russia and into Germany and in the European countries generally, where they are still used today, often as a focus of family life. The stove crossed the Atlantic to the United States, where Benjamin Franklin in 1744 invented an improved design, the forerunner of the traditional potbellied stove.

The first scientific refinement of the fireplace seems to be attributable to the physicist Benjamin Thompson, count Rumford, toward the end of the 18th century. His aim was to improve the efficiency of the open fire by the use of lumps of fireclay and by a canopy, both designed to increase the amount of radiant heat. Because his ideas were not accepted, however, a gross fuel waste has continued up to the present day.

Heating by a fire outside the space to be heated, now described as central heating, appears to have been invented by the Lacedaemonians of Greece, who first used heated floors. The Great Temple in the city of Ephesus (350 BC) is believed to have been heated by flues laid in the floors, using lignite as fuel.

The Greeks perceived the advantages of central heating, but it was the Romans who became the supreme heating engineers of the ancient world with their hypocaust system. The floor was raised on pedestals, or *pilae*, and the hot gases from a furnace were guided into the underfloor space, from which they rose through hollow terra-cotta tubes embedded in the walls. Such systems are to be found throughout Europe wherever Roman culture flourished. In Italy the hypocaust is found only in baths, but in cooler climates, such as Britain's, not only baths but also the living room and sometimes other rooms were heated. The form of ducting and mosaic floor of one Roman room are shown in Figure 1 (left); the *pilae* are illustrated in Figure 1 (right). The fuels used in hypocausts were charcoal, brushwood, and, occasionally, coal. Coal has been recorded on 20 sites in ancient Britain. At Ely remnants of unburnt fuel indicate that the coal came from the Forest of Dean, 130 miles away.

Such scientific development and refinement of life came to an end with the fall of the Roman Empire and the ruin of the cities that followed. The Dark Ages saw a return to a less civilized form of life; castles and homesteads employed the crude methods of heating used by primitive man. Drafty halls were warmed by a log fire in the centre of the stone floor. Enormously heavy fur-lined cloaks were worn to keep warm. It has taken 1,500 years for the comfort of the Roman system of floor heating to be rediscovered by modern civilization.

The advent of steam as a source of power in the Industrial Revolution of the 18th and early 19th centuries offered a new way of heating, first used in factories and mills. Steam conveyed in pipes was extensively used for heating not only for industrial needs but for schools, churches, courts of justice, assembly halls, and even homes and horticultural greenhouses.

Using steam for heat

The very hot surfaces of steam heating cause a parching effect on the air, often accompanied by a disagreeable odour of burnt dust. The advantages of hot water, with a lower surface temperature and milder general effect than that of steam, began to be recognized about 1830.

One of the first such systems was installed at the New Westminster Hospital, London. Hot water at low pressure has continued from that time to occupy a principal place in methods of heating; it is used in radiators, convectors, embedded floor and ceiling heating systems, and as a means of warming air for distribution by fans in a variety of ways.

In 1831 Jacob Perkins of England patented a revolutionary method of high-pressure hot-water heating in which a continuous circuit of very strong piping, receiving heat from a coil in the furnace, conveyed water in a closed system to coils disposed about the building. Circulation was by thermo syphon. The system achieved considerable popularity in spite of its high temperatures; its tubing was small and neat compared with the massive cast-iron pipes used with low-pressure apparatus. The high-pressure hot-water principle has been revived in a modern system developed first in continental Europe and later spread elsewhere, chiefly for industrial heating.

The need for some form of induced ventilation to enclosed spaces probably did not arise until the 19th cen-

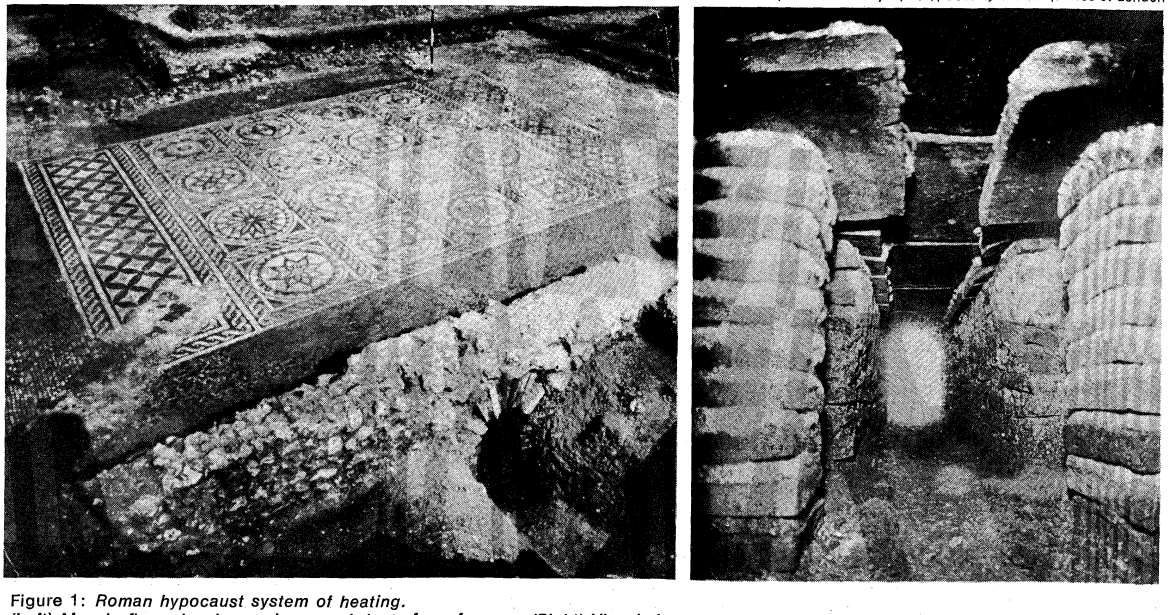

Figure 1: *Roman hypocaust system of heating.*

tury, by which time assembly halls, theatres, and churches were being built to hold hundreds and even thousands of people. In industry some amelioration of the atmosphere in the steamy, gas-lighted workrooms was forced on mill owners to offset an increasing sickness rate.

Mines had been ventilated from earliest times by furnaces kept burning at the base of vent shafts. Some of the early ventilating systems in buildings followed this method, for example, the New Houses of Parliament in London, rebuilt in 1837. There air was exhausted from the chambers by means of coke fires, kept burning day and night in the roof spaces beneath tall shafts, whose Gothic outlines remain a feature of the architecture, though the shafts are no longer used. The air was drawn in by the suction of these extraction shafts through gratings in the floor of the chambers, which were connected in turn to tunnels leading to the Thames River, from the banks of which the fresh air was drawn.

Another method of ventilating by heat was by the use of gas jets in large arenas and in assembly rooms and town halls. Fresh air was admitted by Tobin tubes connected to the outside, as shown in Figure 2. The ring of gas jets beneath an exhaust vent through the roof produced the necessary updraft.

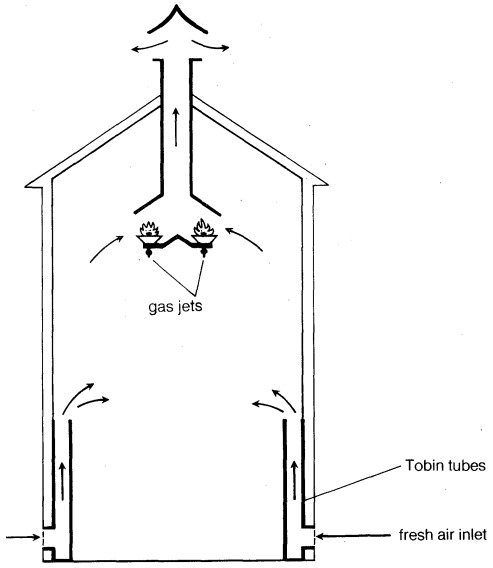

Figure 2: Early form of building ventilation. Gas jets produce updraft, drawing in fresh outside air through the Tobin tubes.

Although a rotary fan had been invented in the 16th century, a convenient power supply was not available until the days of ubiquitous electric current. From the 18th century steam drove fans in industrial installations.

The plenum system was an early method of combining heating with ventilation by using steam in tubes in an air duct to heat the air, the driving force being a fan, also steam driven. The heated air was delivered through ducts under pressure (or plenum), conveyed to all parts of the building. Schools, hospitals, and factories were often heated by this means.

India's wetted mat cooling system

Cooling by evaporation may have originated in India, where mats of wetted grass hung over openings on the windward side resulted in evaporative cooling by as much as 20 to 30° F (11 to 17° C). The mats were kept wet by hand or by a perforated trough above. Such a system employs one of the fundamental principles of air conditioning.

The term "air conditioning" is credited to Stuart W. Cramer, who in 1907 presented a paper on humidity control for textile mills before the American Cotton Manufacturers Association. Control of moisture content in textiles by addition of steam to the atmosphere had long been known as "conditioning." It was not, however, until 1911, when Willis Carrier published the results of many years of research, that the scientific basis of air conditioning was laid.

From air conditioning in industry, for the quality of the product, to air conditioning for comfort was but a step. Comfort air conditioning was developed in the 1920s for the increasingly large theatres, stores, and office blocks, in which the economic value was evident. The development of air conditioning as a major industry, however, awaited new refrigerating techniques.

Until the end of the 19th century, design of heating and ventilating systems was largely empirical. A change to scientific methods began to evolve in the 1890s. Research work was undertaken at the University of Berlin-Charlottenburg and in a few other places before World War I. After the war, research was begun in several countries, notably in the United Kingdom, the United States, Germany, Sweden, and France. Out of this international research effort modern air conditioning has grown.

This article is divided into the following sections:

I. Environmental factors

MAN AND HIS ENVIRONMENT

Body heat losses. The human body, like any other heat engine, consumes fuel (food) to generate heat. The heat leaves the body in the form of radiation and convection from the skin, evaporation of moisture from pores in the skin, and in the breath. Radiation and convection occur only if the air temperature or the surroundings are below blood heat. If approaching or above this condition, the sweat glands expand and heat is rejected solely by evaporation. High relative humidity coupled with high temperature renders life increasingly difficult.

At low temperatures, the blood vessels near the surface of the skin close up, leaving the epidermis dry and acting as an insulator. Shivering is a provision of nature to cause muscular activity and hence increase blood circulation.

Factors in human comfort

Human comfort. Four factors affect comfort: air temperature, radiation, relative humidity, and air movement. Most thermometers measure air temperature but are not influenced by infrared (long-wave) radiation, because their glass envelopes are opaque to such radiation. The human body, however, may receive heat from a radiant source; if so, air temperature must be reduced if body heat release is to remain normal. Conversely, if the body is losing heat by radiation to its surroundings, such as to the cold walls of a room, the air temperature must be raised for an equal degree of comfort.

The study of radiant effects is complex. The mean radiant temperature in an enclosed space is the mean of all the surfaces bounding the space in proportion to their areas and temperatures, the latter being calculable from the known conductivity of the materials and an assumed temperature difference between inside and outside. This calculation gives only an approximation; such factors as the effect of a large area of window, which may be cold in winter and hot in summer, produce variations in different parts of a room. Moreover, the body itself is sizeable, and its response varies according to differences of clothing. The matter is further complicated by the introduction of heated surfaces to warm the space and by the entrance of heat through windows via sunshine.

A close approximation to mean radiant temperature may be obtained by the use of the globe thermometer (Figure 3), consisting of an ordinary thermometer in a

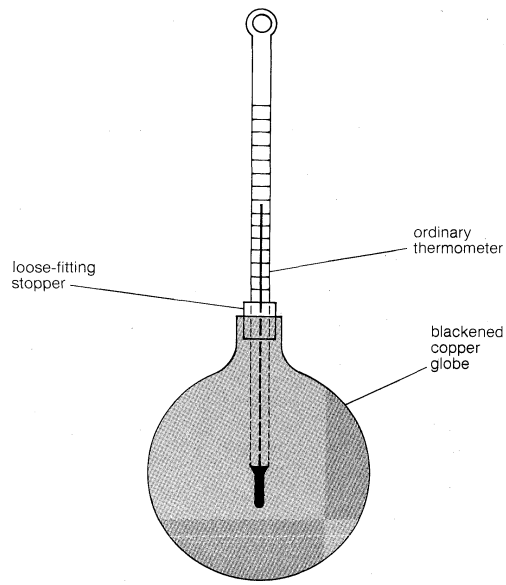

Figure 3: Globe thermometer for determining mean radiant temperature.

blackened, hollow metal sphere about six inches (15 centimetres) in diameter. If suspended in an enclosure in which all surfaces are at the same temperature as the air, the globe thermometer reads the same as an ordinary thermometer, regardless of air movement; but, if the surface and air temperatures differ, the globe becomes warmer or cooler in proportion to the positive or negative radiation falling on it. Given the globe temperature and air temperature, mean radiant temperature may be calculated.

Research in Great Britain on factory workers doing light sedentary work established that globe thermometer temperatures of 62°–68° F (17°–20° C) and air temperatures of 60°–68° F (16°–20° C) were regarded as comfortable. Persons seated at rest required temperatures a few degrees higher, as did those persons who were used to warmer climates.

The above criteria take no account of humidity. In colder climates, such as in northern Europe, variations in relative humidity within the range 40–70 percent have little effect on comfort. In warmer climates, in which sweating plays an important part in heat release, humidity must be taken into account. The effective temperature scale was developed in the United States in a long series of subjective tests in carefully conditioned rooms, from which lines of equal comfort or discomfort—effective temperature lines—were derived. Limits within which individuals feel comfortable may also be charted, establishing what is known as the "comfort zone," which differs for summer and winter.

How humidity affects heat release

The effective temperature scale takes no account of radiation. This can be included simply by using a globe thermometer instead of an ordinary thermometer. The scale so derived is the corrected effective temperature scale, which is no longer widely used. Another scale, resultant temperature, takes account of air temperature, radiation, and air speed. It is measured by a small blackened globe and is more sensitive to air temperature and movement and less to radiation than the globe thermometer. The wet resultant temperature takes account of humidity by using a wet-bulb thermometer—a useful device for determining relative humidity. It consists of a thermometer with the bulb wrapped in cloth kept moistened by a small reservoir of water. Evaporation causes cooling, the amount of cooling depending on the relative humidity.

Another scale is known as environmental temperature; it is weighted in that it is equivalent to two-thirds mean radiant temperature and one-third air temperature. It takes no account of air movement or humidity. Its application is in the study of the thermal properties of buildings.

Other influences affecting comfort. It is possible to enumerate here only a few of the other factors affecting comfort.

Quality of heat radiation. It has long been known that the human body derives greater comfort when the air temperature is lower than that of the surrounding wall and other surfaces. This probably accounts for the comfort of the panelled room common in the 18th and 19th centuries; even though the source of heat was no more than an open fire, the surfaces of the timber panelling were quickly warmed by radiation, while the air drawn in by the large flue ensured a low reading of the thermometer.

Radiant heating makes use of extended surfaces of wall or ceiling heated to some 100° F (38° C) or floor to 75° F (24° C). Air temperature may then be some 5° F (3° C) below that required with a convective system. Unfortunately, the effect of low-temperature radiation on the skin, coupled with the lack of air movement from convection currents, produces an enervating condition. Consequently, it has been suggested that a ventilation system accompany this form of heating to stimulate a freshening atmosphere.

Radiant heat sources employing higher temperatures, such as infrared panels or luminous reflector elements electrically heated, present the problem of directional effects; a certain intensity acceptable on the feet may be uncomfortable if directed at the head. At an air temperature of 50° F (10° C) or under, it is believed impossible to create a feeling of comfort, no matter how great the supply of radiant heat. These two considerations are bound up in one, namely, that as a means of distribution of warmth, very high-temperature radiant heat sources are inherently unsatisfactory.

The effect of radiant heat sources on the human body requires special attention. The great merit of the open coal fire was its wide range and constant variation of radiant wavelength, from the high incandescent parts of the fuel and flames to the dull, low-temperature radiation from the surrounding firebrick and cast-iron or tile decoration. Although the fireplace is decried as an inefficient item of heating equipment, it does have beneficial effects, on a limited scale, room by room. It is open to question, however, whether the effects of various wavelengths of radiation on the human skin and on the stimulation of the senses as a whole have been thoroughly explored.

The advantage of the open fire

The unrelieved monotony of a certain limited range of wavelengths, as from a gas fire or electric heater, can cause dryness and intense irritation of the skin. The human system seems to need stimulation from constantly varying conditions.

Temperature gradients. Because hot air rises, a system of heating relying on warming of air for heat distribution results in a higher temperature at the ceiling than near the floor. An exception is a floor-heating system, in which convection from the floor is balanced by radiation at the floor level.

In the case of a large open space, such as a factory, a system that minimizes temperature gradient is more effi-

cient than one in which the effect is disregarded. Thus, the once common use of overhead pipes produced inordinately high temperature gradients and high roof losses.

Radiant-heating systems in general minimize temperature gradients. Forced-convection systems are preferable to natural convection. Radiators employing extended surfaces below windows give lower air temperature rise than those concentrated on inner walls.

Uniformity of conditions. In an air-conditioned building, air temperatures differ little from those of surrounding surfaces. Thus, a state of thermometric uniformity may exist, except insofar as air movement is concerned. Comfort, as defined by a certain range of effective temperature, is likely to be achieved, but it is possible that the human body continuously so enveloped may suffer from not only physiological but also psychological enervation.

Air motion as a determinant of effective temperature

Air movement. The effective temperature depends on air velocity. The higher the air motion, the lower the effective temperature for a given temperature and relative humidity. An effective temperature of 70° F (21° C) with an air speed of 30 feet (nine metres) per minute, for instance, falls to 60° F (16° C) at an air speed of 600 feet (180 metres) per minute. The variation diminishes with increasing temperature until, at blood heat, air motion ceases to have any effect. It is for this reason that in hot, crowded atmospheres fanning seems to give little alleviation.

Air movement up to 50 feet (15 metres) per minute in an occupied space is usually considered acceptable and desirable, rising locally perhaps to 60 feet (18 metres) per minute and producing some degree of turbulence. There is a much stronger risk of complaints of drafts at higher air speeds.

The problem for the air-conditioning engineer is often to find ways of introducing large quantities of air into a space while keeping velocities in the occupied region within acceptable limits. Raising the relative humidity brings a higher effective temperature, which may allow a slightly higher air movement.

To summarize, it will be seen that the four factors involved in comfort, namely, air temperature, radiation, humidity, and air motion, are largely interdependent. There is no single instrument by which they may be measured collectively, yet the human body can quickly assess whether or not it is in a state of comfort. That state may be the result of any of the possible combinations of these factors.

ENVIRONMENTAL EFFECTS ON BUILDINGS

Heat losses in winter. *Desirable temperatures.* Given the fact that the human body loses heat to its surroundings, it is clear that the prime purpose of heating is to prevent that loss from becoming excessive. Thus, heating involves controlling air temperature or mean radiant temperature or both, within fairly narrow limits depending on activity. A temperature of 55° F (13° C) (lower limit) is appropriate for heavy manual work and 75° F (24° C) (upper limit) for sedentary workers and domestic living rooms. Acceptable temperatures also vary in different countries.

Apart from comfort, many industrial processes demand a strictly controlled temperature for the sake of the product. Printing machinery, for instance, requires a high temperature of 75 or even 77° F (24°–25° C) for the proper flow of ink.

Outside temperature. The maintenance of such temperatures internally when outside air temperature is low results in a flow of heat through the fabric of the building. This heat flow outwards is termed the transmittance loss.

Heat lost by transmittance

For design purposes, it is important to know the general pattern of outside temperature. It is not economical to design for the lowest temperature ever recorded. On the other hand, the average winter temperature is not suitable, because there may be frequent spells of several days or weeks when lower temperatures obtain.

Another factor that affects the choice of design temperature is the "fly-wheel" effect of the building. A massive structure may be expected to experience sudden cold spells of short duration with small effect internally, whereas a light construction rapidly transmits any drop of outside temperature.

Overload capacity of the system is also important under conditions of low external temperature; a system of heating with an inherent overload capacity may meet extremes of cold by drawing on this extra supply. Systems such as those relying on electrical resistances of fixed rating, however, have no such reserve.

Several countries have established basic design temperatures, generally following some law of probability but excluding extremes. In many countries in which prevailing conditions vary considerably from one latitude to another, regional zones of temperature have been established. A few basic design temperatures accepted in various parts of the world are given in Table 1.

Table 1: Design Temperatures for Heating Buildings in Cities of the World

	temperature	
	°F	°C
Auckland, N.Z.	45	7
Berlin	5	−15
Chicago	−10	−23
Cologne	10	−12
Hong Kong	45	7

Madrid	25	−4
New York City	0	−18
Oslo	−6	−21
Ottawa	−15	−26
Paris	21	−6
Rome	30	−1
Sydney	45	7
Tokyo	28	−2
Washington, D.C.	0	−18

Because of the influence of the Gulf Stream on the climate of the British Isles and western Europe, temperatures rarely drop below 20° F (−7° C), even though the latitude of London is the same as parts of northern Canada in which subzero temperatures regularly obtain. The influence of the great land masses is also significant, accounting for lower design temperature, for example in Berlin. The low temperatures of the Eastern seaboard of the United States are accounted for by the absence of the Gulf Stream and the effect of the land mass to the westward.

Effect of building materials on heat loss

Transmittance through building materials. The rate of heat loss through the structure per degree of temperature difference depends on the conductivity of the materials of roof, walls, windows, and floors. There is also a skin effect, by which the air immediately in contact with the surface constitutes an inert layer offering resistance to heat transfer. This is known as surface resistance and is greater for the still air of the interior than for the exterior, where the effect of wind comes into play. The outside surface resistance varies with different aspects and exposures.

The overall conductance of building material is the transmittance factor, U, and is expressed in British thermal units (BTU) per square foot per degree difference per hour or in watts per square metre per degree Celsius (W/m^2–° C). Researches carried out in various countries have established U factors for a great variety of common forms of construction, or they may be calculated from a formula. Some of the more common U factors, expressed in English and SI (revised metric) units, respectively, are given in Table 2.

Insulation. In the interests of economy it is now common practice to include some form of insulation in building construction. For walls, an inner layer of foamed slag or lightweight concrete block is often used, but such porous materials are generally unsuitable for load bearing, so that the structure must be framed or given load-bearing exterior walls. Curtain-wall construction used in

Table 2: Heat Loss of Building Materials as U Factor

	type	BTU* °F difference	W/m²–°C
Windows	single glazing	1.0	5.7
	double glazing	0.5	2.9
Wall	brick, 9 in. plastered, normal exposure	0.43	2.5
	brick, 11 in. cavity plastered, unventilated	0.30	1.7
	concrete, 6 in. plastered	0.58	3.3
Roof	flat, 6 in. concrete, lined insulation board	0.30	1.7
	pitched, tile-lined boards, plaster ceiling, attic boards	0.2	1.2
Floor	concrete on earth, hard finish	0.2	1.2
	boards on joists and cavity	0.32	1.8

* BTU per square foot per hour.

tall buildings for lightness often incorporates glass fibre slabs or similar material between the inner and outer skins. Similarly, roofs may be insulated in a variety of ways by linings or insulating materials. Ample data exist on the properties of insulating materials, such as avoidance of condensation. Condensation occurs when the temperature of the surface of window, wall, roof, or floor drops below the dew point of the air in the space. In hollow-wall, or cavity, construction, the temperature inside the wall may be such as to cause condensation within the construction. Certain porous materials produce the same effects. Condensation has become a serious problem in blocks of apartments of concrete construction, some of which are afflicted with mold growth on walls and on floors under carpets. The insertion of a vapour barrier is one way of preventing migration of moisture in cavity constructions.

It is usually possible to achieve a U factor of about 0.2 (1.2 in SI units) or less without prohibitive cost and with greatly reduced fuel consumption throughout the life of the building. In many countries insulation is mandatory for industrial and domestic premises, limits being set for the U factor.

Air change. In addition to the transmittance loss through the fabric of walls, roof, or elsewhere, there is an additional loss resulting from infiltration of air through cracks around windows and doors. If the roof is made of some form of sheeting, cracks allow the escape of warm air that collects near the ceiling. Air change also occurs through the opening of doors, particularly in a factory in which goods are constantly entering or leaving. In a tall building there is a natural inflow of cold air at ground floor and an outflow of warmed air on upper floors—the "chimney effect."

Air-change rate

The assessment of air change-rate cannot be scientifically accurate, because it depends on many factors. They include strength and direction of wind, size and type of windows, proportion of window opening area, temperature gradient within the space, and frequency of door opening. Air-change rates usually vary between one-half and three complete changes per hour.

Another approach uses research on windows of various types, with and without weather stripping, and at various wind speeds. The inflow rate particularly on tall buildings may by this means be related to what is the principal means of ingress.

By whatever means the air-change rate is assessed, the heat necessary to warm that air from outside temperature to inside temperature may then be calculated.

Total heat loss. The total heat loss for the room or space in question is then the sum of the transmittance losses and the air-change loss. Some designers add a height factor for lofty structures to allow for temperature gradient and an exposure factor for especially severe conditions.

Intermittent heating. The conventional approach to heat losses discussed above assumes steady state conditions. Heating is, however, frequently intermittent because of night shut-down or limited hours of occupancy, as in a school or church. Unsteady states may be simulated by computer analog techniques but these are of more academic than practical interest.

An allowance for intermittent heating may be made by a percentage addition to the capacity of the entire system, varying between 20 and 25 percent in systems that can only operate at fixed output. If overload capacity is available, however, as by raising temperature above normal in a water system, a lower addition is permissible.

In extremely cold weather, intermittent heating is impracticable and continuous running is essential if a specified temperature is to be maintained. This is because the pre-heat boost necessary to overcome the night loss of the building is beyond the capacity of an economically designed system.

Heat gains in summer. *Fabric gains.* Heat gains are the opposite of heat losses. In summer, external temperature is above internal temperature, and therefore heat flow is from outside to inside. The parts of the surface skin of the walls and roof that are exposed to sun are warmed above air temperature, thus adding to the rate of transmission.

Various methods have been devised to allow for this effect. One is the "sol-air" concept, by which the temperature increment because of solar heat may be estimated according to the nature and colour of the surface, the latitude, and the sun angle at different times of year.

While this factor applies throughout the day on a flat roof, walls of various aspect are subject to solar gain only for limited periods. Furthermore, mass has a delaying effect, so that solar gains undergo a shift in time depending on thickness and material of construction. In a building with many floors and many rooms per floor, it is necessary to treat each compartment separately to arrive at the heat load in each case, but the coincident total load will not be the sum of the individual room loads.

Heat gains through the fabric are calculated in the same manner as heat losses, using U factors and assumed temperature differences. Insulation is even more important for economy of cooling than of heating because the cost of cooling is usually much higher.

Air-change gains. In cooling as in heating, allowance must be made for air change, because warm air enters by infiltration and by door opening. The chimney effect is negative; that is, with the temperature cooler inside than it is outside, ingress is greatest at higher levels and the entrances at ground level act as outlets.

Glazing. Solar gains through glass in windows and roof lights demand separate consideration. They may constitute by far the heaviest cooling load because glass is transparent to the shorter wave lengths of solar radiation.

Shading of glazed areas

Such gains are so great that shading is generally essential for economy as well as to reduce glare. Such shading takes a variety of forms. One form is architectural, comprising louvred blades fitted externally and sometimes arranged to swivel according to time of day. Alternatively they may form a distinctive pattern resembling an egg crate. In certain latitudes in which the sun is mainly overhead, projections at each floor in the form of balconies may be adopted. Alternatively, external roller blinds may be used. Heat intercepted by any form of external protection is either re-radiated or lost by convection to the atmosphere.

Internal shades are less efficient as they become heated themselves and convert shortwave solar radiation into long-wave dull radiation, to which glass is opaque. In addition, convection currents carry heat into the room. Venetian blinds behind single glazing offer no reduction in solar gain; in fact they increase it slightly. A venetian blind in the interspace of double glazing is more effective.

Another method of reducing solar gain through windows is the use of heat-absorbing glass. This may take a variety of forms, some giving a greenish tint and some incorporating finely divided metallic particles, such as of copper or gold. This has the object of reflecting much of the incident radiation back into space but may be a source of complaint from neighbouring buildings because of the glare of high reflectivity.

Solar heat gains through glass vary throughout the day and for different seasons, as mentioned earlier in relation to walls. There is no time lag with glass as there is with walls.

Sun-path diagrams. The study of solar gains is assisted by use of a sun-path diagram drawn for the particular latitude. This diagram presents in graphic form the motion of the sun, its altitude and azimuth for various times of the year and hours of the day. When a plan of the building, correctly oriented, is superimposed, the angle of incidence on the various faces as well as the periods when they are subject to radiation can be noted.

Incidental heat gains. Throughout the year buildings have incidental sources of heat within their enclosed spaces. These derive from occupants, lighting, and machinery. In residential property, stoves, television sets, washing machines, and other appliances provide a source of heat gain.

In winter these gains are beneficial in reducing the amount of heating required from other sources, but in summer they raise temperatures internally and may require increased ventilation; in air-conditioned buildings they add to the cooling load.

Heat gains from machinery

In offices the greater use of accounting machines, card-punch systems, computers, and other electrical equipment, together with the present high standard of lighting, is responsible for rendering maintenance of satisfactory working conditions increasingly important.

Electrical equipment of all types generates heat. In effect all electrical energy supplied within a space is converted into heat except potential energy that is conveyed outside, as in pumping water or in a conveyor. Machine tools generate heat at the cutting head, and the product becomes warm and gives up heat to its surroundings. In all motors and machines, there is friction that generates heat.

All heat released within a space constitutes heat gain. Means of removing it are discussed below (see below *Air conditioning*).

II. Heating

Early methods of heating, as has been shown, consisted chiefly of burning fuel within the habitable space, the exception being the Roman hypocaust. In the home the fireplace was the central feature of the room. In other buildings braziers, and later enclosed stoves, were used. In cold regions, such as parts of Europe and North America, the stove continues in use to this day.

The early 19th century, with its increased population in the industrial countries, brought a demand for buildings of much greater size, such as assembly halls, factories, churches, schools, chapels, and hospitals, for which some method of heating other than local means was a necessity. Out of this need evolved what is now called central heating.

The essential components of a system of central heating are an appliance in which fuel may be burned for the generation of heat; a medium conveyed in pipes or ducts for transferring the heat to the space or spaces to be heated; and an emitting apparatus in the spaces for releasing the heat either by convection or radiation or both.

Steam heating has long predominated in the North American continent because of its very cold winters. It is here that the vacuum and vapour systems originated. For the home, ducted warm air has been by far the most common system. Hot water is, however, beginning to find a place.

In Great Britain and much of the European continent, hot water has become the favoured method of heating; steam heating is now rare except in industry. Ducted warm air, except for recent developments such as gas-warm air, has never been popular.

Most other countries have adopted the pattern of either the American or the European method, generally according to the cultural influence that has predominated.

While heating in winter is the sole need of many types of building, there is a tendency for air conditioning to supplant it, giving year-round control of temperature and humidity as well as ventilation.

GENERATION OF HEAT

The combustion of fuel is a molecular process in which the principal elements, carbon and hydrogen, react with oxygen from the atmosphere. The heat produced in this way arrives at the walls of a combustion chamber to be transferred to a medium such as air or water. The equipment is so arranged that the heated medium is constantly removed and replaced by a cooler supply—*i.e.*, by circulation.

If air is the medium, the equipment is called a furnace, and if water is the medium, a boiler or water heater. The term boiler more correctly refers to a vessel in which steam is produced, and water heater to one in which water is heated and circulated below its boiling point.

Coal or coke, oil, or manufactured or natural gas may be used as fuel. Solid fuel is stoked either by hand at intervals or mechanically by an automatic stoker. Ash and clinker resulting from the process are removed by hand or, in large plants, by mechanical means. The dust and dirt produced by solid fuel, and the labour it requires, have led to its decline.

Oil and gas require no labour except for occasional cleaning, and they are handled by completely automatic burners, which may be thermostatically controlled. There is no residual ash product for disposal. Gas requires no storage. Oil is pumped into storage tanks, which may be located at a distance from the heating equipment.

Advantages of oil and gas

Another source of heat for central heating is electricity. The relatively high cost can be reduced by off-peak use of current—that is, at night, when normal demand decreases. One method is by thermal storage: water in large insulated cylinders is raised to a high temperature at night, and the heat is dissipated throughout the following day in the heating apparatus in the building. The boiler takes the form of heating electrodes in a cylindrical vessel. Other methods of using electricity for heating are described below in the sections on direct heating and the heat pump.

Solar energy. The sun is the ultimate source of all energy on earth, whether as stored energy in fuels fossilized ages ago, as water power, or as nuclear energy. The sun's radiation, of which a minute portion is received on Earth, if converted at 100 percent efficiency into work at the Earth's surface, would yield about one horse power for each square yard or metre of ground. But in winter, solar energy is at minimum intensity in temperate climates because of the low angle of the sun. Furthermore, clouds interfere. Nevertheless, solar heating for warming and hot-water supply is used on a domestic scale in Israel, southern France, parts of the United States, and elsewhere.

In one form of solar heating the collector comprises a black metallic surface with piping attached, covered by double or triple glazing and backed by insulation. The collector is placed on the ground or on a roof, angled to be normal to the sun at midday or rotated to preserve normality. Water circulated through the piping of the collector is kept in a storage vessel with as little mixing as possible to preserve a high temperature. The stored water is then circulated in the heating system throughout the day and night as required.

Heat pump. The principle of the heat pump, or reverse heat cycle, was first enunciated by Lord Kelvin in 1851, but little note was taken of it until much later. The heat pump is in effect a refrigerator in reverse: a refrigerator produces cooling in an evaporator and rejects heat by means of a condenser, but in the heat pump low-temperature heat is supplied to the evaporator, and energy is added by the compressor, thus making the heat available at a higher temperature. Heat may be removed by air or water from the condenser for warming or water heating. The heat so derived is made up of the low-grade heat received by the evaporator plus the heat equivalent of the power input to the compressor. The ratio of heat input to heat output is termed the advantage and may be 3:1 or 4:1 depending on temperature difference. The closer the output temperature is to that of the low-grade source, the greater is the advantage. Thus the heat pump performs best when heating, say, a swimming pool.

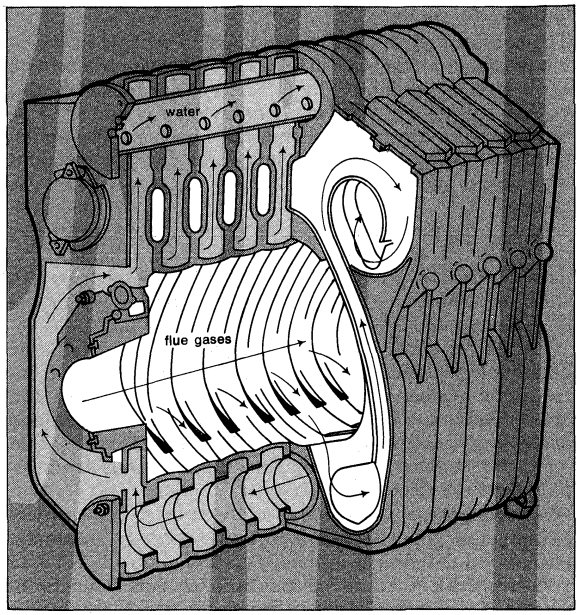

Figure 4: Modern oil-fired, cast-iron sectional boiler. Arrows show direction of flow of gases and water (see text).

Air conditioners that contain a compressor for cooling in summer may, by reversal valves, become suppliers of warm air in winter. Many commercial heat-pump units employ this method. In Switzerland heat-pump installations deriving electric power from hydroelectric sources were extensively adopted during World War II because of the shortage of fuel. In some U.S. cities heat pumps have been combined with cold-storage plants for heating buildings and city districts.

Other sources of low-grade heat that have been used with heat pumps are pipe coils buried in the earth, sewage, rivers, and cooling water from industrial processes. Unfortunately the high cost of the compressor plant and ancillary equipment usually renders the economics of the heat pump unattractive. Furthermore, the apparent advantage of using electrical power derived from a heat engine is largely cancelled out by heat rejected at the power station so that from a national or regional fuel-economy point of view little has been gained.

Boilers. Boilers solely for heating, as distinct from steam boilers for power, date from the early years of the 19th century. The earliest forms were simply made of wrought-iron plates rivetted together and set in brickwork. The tubular boiler for high pressure was followed by tubular heating surfaces for low pressures. All of these types of boiler were of low efficiency, probably not much over 50 percent, but coal was so cheap that this was of little account.

The cast-iron sectional boiler, first developed in the latter part of the 19th century in the United States, was cheaper and more efficient than the earlier forms. It could be added to or replaced in part, if required, and could be handled inside a confined space more easily than a one-piece boiler. Sectional boilers have survived to this day with little alteration; a modern form is shown in Figure 4. Larger duties may be met by using several in battery form.

The shell type of boiler

Because there is a limit in pressure and size for cast-iron boilers, the trend has been to the shell type boiler for high pressures and duties of greater magnitude. This type is formed of a cylindrical shell with furnace tube and fire tubes or a completely tubular form. While the principle of this design is old, modern applications achieve a high efficiency. Other types in common use include the firebox and smoke-tube form, similar to a locomotive boiler.

One of the hazards of boiler operation is fireside corrosion resulting from burning sulfur-bearing fuels such as coal and oil, which, with condensation, produce sulfuric acid. Precautions with regard to operating temperatures are necessary to prevent excessive corrosion and early failure.

Another hazard is internal furring, or deposition of scale-forming salts from the boiler water. This is more troublesome in steam-generating plants than in water heating on a closed circuit but may be met by suitable water treatment.

MEDIA FOR HEAT TRANSMISSION

Air. Air as a means of conveying heat over a distance suffers from the disadvantage of low density and low specific heat (a measure of the amount of heat that can be carried by a cubic foot of air), as compared with water, and is therefore confined to local distribution covering only short distances.

The so-called pipeless heater at one time common in the cold countries of Europe and Canada used air for heating houses and apartment buildings. It consisted of a coal-fired furnace in the basement; a cast-iron combustion chamber and flue surface contained in an enclosure or casing admitted return air from a grille in the floor or hall or staircase and delivered the heated air by natural buoyancy through a second grille, in such a way that it permeated the whole space. Its effect, so far as the rooms off the central space was concerned, depended on interior doors being left open.

In more recent developments, the air flow is forced by a fan, and the burner in the furnace is oil- or gas-fired. Air from the heater is conveyed through ducts to the various rooms (see Figure 5).

Another method using air for conveyance of heat is the plenum system already mentioned; once widely used for the heating of factories, it has been largely superseded by other methods. In this system air is, in effect, a secondary medium, the primary being steam or hot water. The system comprises a fan and a heater battery consisting of a series of pipe coils. The heated air is discharged by the fan through a system of ducts. The disadvantage of the system is its cumbersome ductwork and lack of flexibility.

Heated air has been used in more recent developments as a medium to provide radiant heating for industrial use. This consists of a closed system of overhead ducts with bare surfaces arranged for emission of radiant heat, while the transmitting ducts are insulated. A disadvantage is that there is a limit to the area that may be covered by such an arrangement because of the low volume-to-heat ratio.

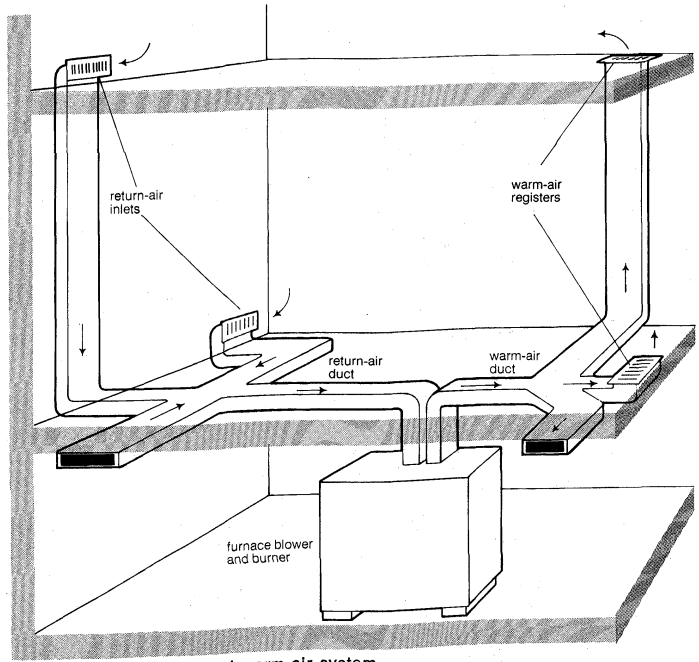

Figure 5: Perimeter forced warm-air system.

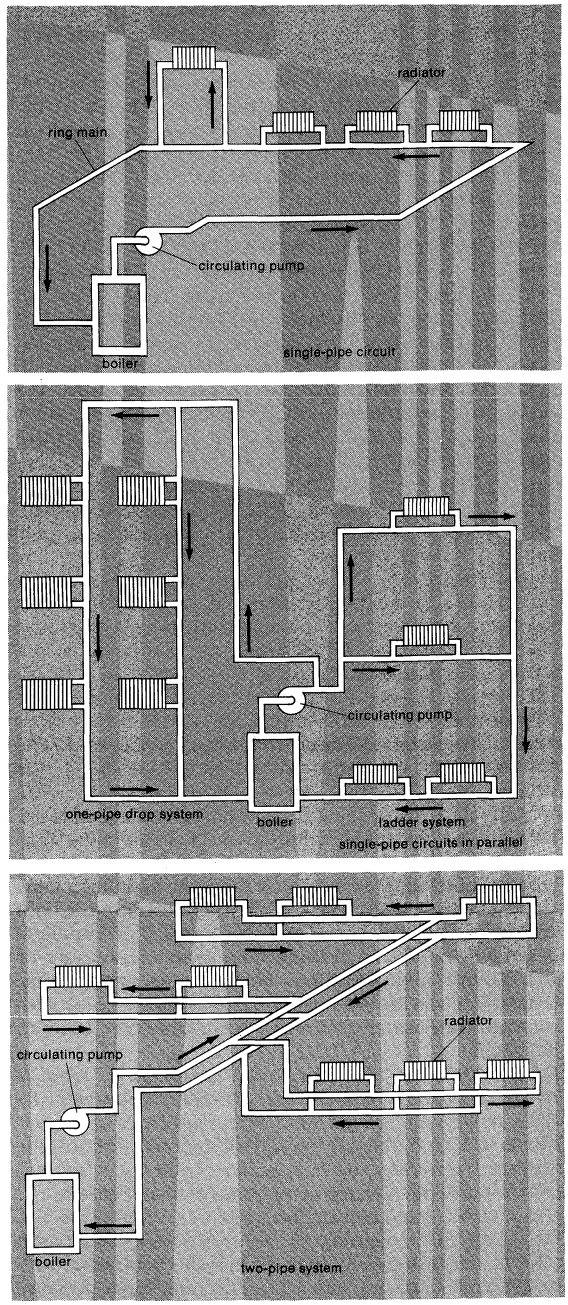

Figure 6: Hot-water systems with pump circulation (feed and vent pipes not shown).

The direct-fired air heater

Another recent development, chiefly for the heating of large factory spaces, is the direct-fired air heater. This comprises a combustion chamber fired by gas or oil, with a flue to the outside, and a casing with a fan to draw air from the working space. This air flows over the heated surface of the combustion chamber and then is discharged at considerable velocity back into the space. These units are made with large outputs and have the merit of flexibility to meet changes of plan.

Air is used as a heat-conveying medium in the new Anglican Cathedral, Liverpool, in which ducts below the floor convey warm air from a heater; after transferring heat to the floor the air is returned for reheating. In effect this is the Roman hypocaust system with air in place of the hot flue gases.

Hot water. Hot water is the most versatile of all the practicable media. It has the greatest specific heat at normal temperatures of all known liquids; it is stable after limitless cycles of heating and cooling; and it is cheap. Its one disadvantage is its low boiling point of 212° F (100° C) at atmospheric pressure; to achieve higher temperatures, the system must be sealed so that the water can be placed under pressure. In this condition temperatures up to 400° F (200° C) can be achieved.

For heating a building, the temperature of emitting surfaces must be adjusted to suit the weather. Hot water is most flexible in this respect, being easily controllable from minimum to maximum either by regulation of boiler temperature or by mixing return with flow water.

The hot water is circulated through pipes by thermosiphon (gravity) or by mechanical pump. The former was normal in earlier systems because an electrical supply was not often available; the pipes were necessarily large, and circulation was often sluggish. Various self-accelerating systems were devised to improve circulation. One, the Reck, made use of steam from a boiler injected into the rising column of hot water, which was thereby lifted, creating a considerable imbalance with the cooler return water columns. The differences in weight of the two columns was the force creating circulation.

Electricity has now virtually monopolized the pumping function. A small home pump with submerged rotor (rotating part of the motor) relies on a nonmagnetic shield such that the windings of the stator (stationary part of the motor) are in air, while the rotor is submerged in the water being circulated. The pump is silent and applicable to the smallest systems. On a larger scale circulating pumps take the normal form of standard centrifugal pumps. Figure 6 illustrates single and two-pipe, low-pressure, hot-water systems with pump circulation.

The low-pressure system

In a low-pressure system the water expands on heating and is allowed to rise through a pipe into a tank above the level of the highest part of the system. On cooling, the same water is returned.

An alternative method of accommodating expansion water takes the form of a closed vessel connected to the system near the boiler; this vessel contains a flexible diaphragm, above which is nitrogen under pressure. As the water in the system expands, the diaphragm rises, compressing the nitrogen still further and increasing the pressure (see Figure 7).

At low pressures, below the boiling point of water, the temperature drop from flow to return in a system is limited to some 30° or 40° F (17°–22° C); if the drop were larger, the average temperature of the radiator would be too low for economical heating. For more extensive systems, water under pressure may be used. High pressures (up to 10 atmospheres with temperatures to 366° F [186° C]) are used for industrial purposes.

If water at a temperature above atmospheric boiling point (212° F or 100° C) is used, pressure may be produced by steam, as in a steam boiler; the water, which is circulated by pump, is taken from and returned to the water supply below the steam cushion in the boiler. Normal water gauge fittings are used on the boiler, which is only partly filled with water, the level rising with expansion.

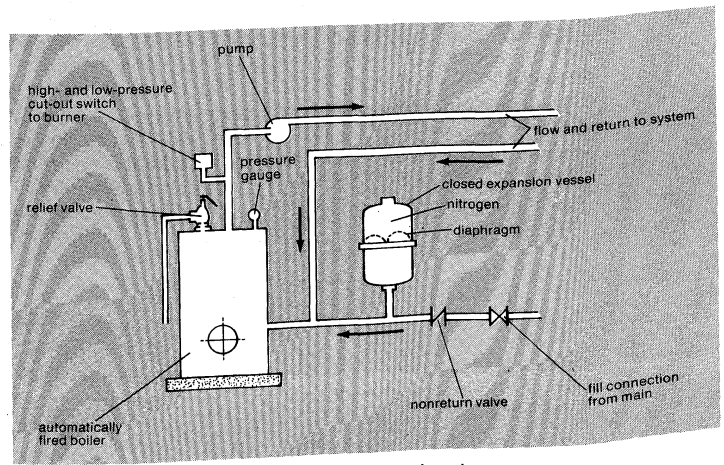

Figure 7: Low-pressure, hot-water system with closed expansion vessel.

Alternatively, in medium- and high-pressure systems, pressurization may be by a gas cushion using an external pressure vessel. Because higher pressures are usually associated with larger systems, the water of expansion is allowed to flow off into a separate tank, from which it is returned to the system on cooling by pump.

Heat-exchange liquids. Besides having a low boiling point unless under pressure, water is subject to expansion on freezing, with the danger of bursting pipes and boilers. Various heat-exchange liquids that avoid the problem have been developed for use in the chemical-engineering industry. These liquids have a boiling point in the region of 500° to 600° F (250°–300° C) at atmospheric pressure, but have the disadvantages of high cost, strong odour, and toxicity on leakage. So far, water has not been supplanted in spite of its disadvantages.

Steam. The latent heat of steam (the heat required to vaporize water to steam, or conversely, the heat given up by steam when it condenses to water) is used for heating by condensation within the heat-emitting surface. Latent heat of steam at atmospheric pressure is high, and steam may be conveyed in pipes at considerable velocity. Much less heat is stored in a steam system than in a hot water system, so a steam system heats up and cools down faster than a water system.

Inflexibility of steam

The disadvantage of steam lies in its inflexibility to meet variations of weather conditions. Hot water may easily be varied from about 100° F (38° C) upwards, whereas steam is constant at the temperature corresponding to pressure. Attempts to make steam more flexible have made use of sub-atmospheric or vapour systems, forming a vacuum within the system so that temperatures well below atmospheric boiling point may be achieved in the heat-emitting apparatus. Such systems, however, depend on a variety of devices calling for regular maintenance, and they are prone to be noisy.

When steam (or vapour) condenses in heat-emitting apparatus, it returns to the liquid state and must be removed quickly. For this purpose steam traps, allowing water but not steam to pass, are fitted on the outlets. The water, or condensate, is then returned by gravity to a collecting point, from which it is pumped back to the boiler. Some of the condensate re-evaporates when it is released from the traps at atmospheric pressure, forming flash-steam. This constitutes a loss, and means to employ flash-steam usefully are desirable. Steam thus has certain inherent losses, which may amount to as much as 10 percent.

Steam as a medium of heat transmission is now mostly confined to industry, where its use is required for other purposes than heating. Even so, high-pressure hot water in certain industrial processes is supplanting steam. Steam is also used in hospitals and similar institutions in which laundry, kitchen, and sterilizing require it. Heating in these cases is usually provided by the use of calorifiers, or heat exchangers, in which steam, the primary medium of distribution, heats water for distribution at lower temperature in the heating system. Similar arrangements supply hot water for baths, basins, sinks, and other facilities.

HEAT EMITTERS

Central, or indirect, heating. Heat emitters in central heating systems may be classified in two broad groups: primarily convective and primarily radiant. The first group may be sub-divided into those relying on natural convection and those relying on forced convection. Radiant systems may be divided according to temperature. Assuming hot water is the medium, the classification becomes: high temperature, 250°–350° F (120°–175° C); medium temperature, 140°–180° F (60°–80° C); low temperature, 100°–130° F (40°–55° C).

Primarily convective heating. The most familiar example in this group is the common radiator, which emits about 20 percent by radiation and 80 percent by natural convection. The term radiator is obviously a misnomer.

The earliest form of radiator was the box coil, consisting of a series of cast-iron pipes in a perforated casing. Later in the 19th century cast-iron sectional radiators came into use, often elaborately decorated. Radiators are now much lighter, with small water content; steel has largely replaced cast iron.

The natural convector comprises a heating element, with fins, firmly attached to a pipe through which the heating medium circulates. The element is placed at the bottom of a casing having an opening at the base and an outlet at the top. A flue effect is created by the rising column of warm air, drawing in air from along the floor of the room and discharging it heated at the top. The greater the height of the casing, the greater the flue effect, and hence the greater heat output for a given size of element. There is little radiation from the casing, which is warmed only by the air it contains.

Another form of heating surface in which convection predominates is the gilled (finned) pipe, often used in the past for heating in factories. No casing is used, and heat transfer is the result only of the convection currents set up in open air. Plain pipe surface also falls into this category. The large cast-iron pipes now used for greenhouse heating were at one time a common method of overhead factory heating. The convection-to-radiant component varies according to temperature and pipe size.

Forced convectors. The application of a fan to finned heating surfaces greatly increases the heat emission rate for a given surface area. This feature has been used in a great variety of ways, all of which are 100 percent convective with no radiant component.

Positioning of units

Unit heaters ranging in size from 100,000 BTU per hour (30 kilowatts) to 1,000,000 BTU per hour (300 kilowatts) or over, are commonly used for industrial heating. The units may be suspended overhead, discharging the warmed air towards the floor. In another form they are floor mounted, discharging horizontally above head level. Thermostatic control is achieved by switching the fans on and off.

Incorporating slow-speed silent fans, the same principle is used extensively for such purposes as heating school classrooms, entrance halls, and canteens. In such applications the element and fan are contained in a casing of cabinet type, giving a large output in a small space. Miniature forms are also available for domestic use with ratings on hot water as low as 6,000 BTU per hour (2 kilowatts).

Radiant heating. Emission of radiant heat from a surface is proportional to the difference between the fourth powers of the absolute temperature of the emitting surface and the mean radiant temperature of the enclosure. Emission by convection follows a simpler law; as emitting surface temperature is increased, the ratio of radiation to convection rises.

For economical heating of a large space, such as a factory, temperatures as high as may be consistent with reasonable cost of pressure parts are used. High-pressure hot water is particularly suitable in the range 300° to 350° F (150°–175° C), giving surface temperatures of 250° to 300° F (120°–150° C).

A radiant heating surface may consist of flat steel plates with a gridiron form of pipe coil welded to the back. The back may be insulated to give heat emission on one side only, or may be bare giving emission on both sides. In industrial installations, panels are slung well above head level, and sometimes inclined at an angle towards the floor. A bay width of 80 feet (24 metres) may easily be covered by such an arrangement. The advantage of radiant heating over unit heaters is that no moving parts are involved, and maintenance is easier.

Another form, strip heating, makes use of a continuous horizontal strip, with piping attached, which extends the length of the space to be heated, supported from the roof members. In some systems this strip is combined with lighting.

The surface colours of radiant heaters are unimportant except that they should not be metallic.

The medium temperature range is served by low-pressure hot water, usually between 140° and 180° F (60°–80° C). Because radiation is less intense, the system may be applied to buildings of many types.

Panel heating surfaces

Heating surfaces in the form of flat panels of steel or cast iron are used on walls and ceilings. They have the merit of cleanliness, though wall staining may result from the convection currents. There are numerous variants that increase convection, for example, finned surfaces at the back.

The panel system is commonly used to heat the ceiling, the radiant heat coming downward. Walls and floors have also been used. The system has the merit of being invisible and of avoiding convection current staining.

Water temperatures in the range 100° to 130° F (40°–55° C) are used. Coils of piping embedded in the structure warm the floor, wall, or ceiling (see Figure 8). In

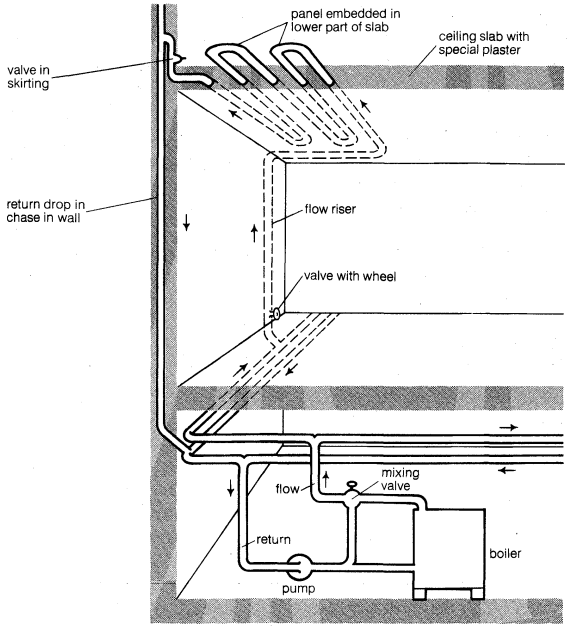

Figure 8: The panel system, consisting of hot-water pipes in ceiling.

the floor, a surface temperature of 75° F (24° C) is considered the maximum desirable for comfort, but in the ceiling, closer spacing of coils may be used giving surface temperatures of the order of 90°–100° F (30°–40° C).

For acoustical reasons, perforated tiles of metal or plaster, heated from above by coils fixed in the void space and covered by a thermal insulating blanket, have come into use. Higher temperature water is used than with the panel system. This system responds to control faster than one in which coils are embedded in the structure.

For an equal state of comfort, a system that is mainly or entirely convective must provide a higher air temperature in the heated space than one that relies mainly on radiation. This is because the cold surfaces of walls and windows are removing from the body heat that in the absence of radiation can only be replaced from the surrounding air.

Lower air temperatures, possible with radiant heating, mean lower air infiltration losses and lower temperature gradients from floor to ceiling. Thus radiant systems save fuel, unless heating is intermittent, as in a school. In that case the fully convective system is appropriate because of the rapidity with which air temperature may be raised in the morning and lowered at night.

Local, or direct, heating. The methods described above constitute central heating, which may otherwise be described as indirect. Local heating is direct—that is, heat is released within the space to be heated with no intermediary fluid for transmission. Such systems include electric heating, gas fires, gas convectors, gas-warm air, oil-warm air, oil stoves, and solid-fuel fires and stoves.

Electric heating. Electricity used at peak hours is generally expensive and confined to spot heating or to small buildings in which a central system is not practicable. In domestic applications the electric heater is a substitute for the now fast-disappearing coal fire.

Electric heating appliances in all cases, except one that will be discussed later, depend on resistance wire elements in one form or another, either bare or incorporated in a nonmetallic sheath that becomes heated. Elements are enclosed in tubes to give a lower surface temperature, or in cabinets to form convectors. Forced convectors include a fan to deliver air over the elements. Radiators containing oil are heated by elements in the base operating at temperatures similar to their hot water counterparts.

Radiant electric heating is either luminous or dull. The former includes the electric fire with various forms of reflector, and overhead units projecting a beam to floor level over a limited area. Dull emitters comprise panels of ceramic or other material, in which the elements are embedded, working at a surface temperature in the region of 160° F (70° C). In another form wire elements are embedded in wallpaper applied to walls or ceilings.

A recent development departs from wire resistances by using finely divided carbon molded into plastic sheet in such a way that, through electrical contact strips at the edges, the whole sheet becomes the heating element.

Because off-peak electricity is generally available at much lower rates, thermal storage has been developed for heating buildings during the day. In one method, use is made of the floor as the storage medium by embedding resistance elements in it. The surface temperature is limited for comfort to about 75° F (24° C), which in practice declines during the day; to be successful this method requires a midday boost.

The night-store heater

Another method of storage is the night-store heater. The storage material (ceramic or concrete) is raised by embedded elements to some 400° F (200° C). The outer casing, which is made of steel and insulated, gives a surface temperature of about 180° F (80° C) at the end of the charging period, declining to 100° F (40° C) at the end of the day. A variant of this includes a fan that delivers air through passages in the storage block, enabling output to be controlled. This latter principle has been developed further for use in apartments and residences by adding ducting, so that a number of rooms may be served from a single central unit.

Gas. The burning of gas within the space to be heated requires a flue, the provision of which restricts the system to buildings in which a rise through the roof or through an outer wall can be arranged. The presence of a flue, however, also assists in ventilation.

Old types of gas fire gave an efficiency of no more than 45 percent because of the loss via the flue. Modern types, arranging convection passages around the heated surfaces, increase efficiency to about 60 percent.

For the heating of factories and large spaces, overhead gas-burning radiant units, which use incandescent refractory plates, have been developed. Dull radiant heaters are also used; in this case the gas heats a refractory plate in front of which a metal surface forms the dull emitter.

Gas convectors are now usually of balanced draft type; that is, they receive combustion air from and discharge products of combustion through the same wall. Provided with a fan on a larger scale, they become forced-draft convectors to cover extensive areas.

Gas warm-air. This is a system developed for multistory apartments or single dwellings. Gas is consumed in a combustion chamber, from which a flue takes the products of combustion to the outside. A fan draws air from the space to be heated and delivers it over the outer surface of the combustion chamber, from which it is conveyed by short ducts to the various rooms of a dwelling. Fast heat-up and response to thermostatic controls render this system economical and acceptable, particularly for a household in which heating is required primarily in the morning and evening.

Oil stoves and oil warm-air. Portable oil stoves burning kerosene present a fire hazard, and represent only temporary means of heating. Oil-fired warm-air heaters have been developed on similar lines to gas, often fed

with oil via a meter from a central source. The burner is automatic as with gas, and also requires a flue.

Solid fuel heating. During the period since World War II, much research has been devoted to improving the open fire, still widely used in some countries. Efficiency has been raised, excess ventilation via the flue reduced, and all-night burning rendered possible. Anti-pollution legislation has restricted the open fire increasingly to smokeless fuel, such as the manufactured briquettes or low-temperature carbonization cokes. In rural districts wood is widely used and in some countries, such as Ireland and Scotland, peat.

The stove has already been mentioned as a customary means of domestic heating in cold countries on the continent of Europe and in North America. Versions using anthracite, burning for long periods without attention, were popular at one time, but declined with the rising cost of such fuel and the growing preference for other labour-saving methods.

District heating. District heating, a logical development of central heating, supplies heat for many buildings in a district or a complete town from mains laid in the street. The first such installation was at Lockport, New York, in 1877. Others followed in New York City, Detroit, and elsewhere, operated by steam. Recent technology favours greater use of hot water. There has been extensive development of district heating in Germany, the Soviet Union, France, and Denmark. In many systems heat has been derived as a by-product of electric power generation, thereby raising the overall thermal efficiency of a station from 25 or 30 percent to 50 or 60 percent. In some cases, notably in Hamburg and in the Pimlico Scheme, London, large, hot-water storage vessels have been included to level out the peaks and valleys of input. In Reykjavik, Iceland, hot water from thermal springs is piped to all buildings, and is run to a drain after use.

Various forms of conduit have been adopted for enclosing the mains of district heating systems, a recent one being the "pipe within a pipe." In this type, the pipe lengths are factory-insulated and enclosed within an outer protected steel or asbestos cement tube, the whole being buried in an excavation without structural duct of any kind.

Primary distribution from heat stations is usually in the form of high-pressure hot water circulated by pumps: it is reduced in temperature by heat exchangers at substations from which smaller areas are served. The apparatus in the buildings or dwellings is then conventional in form. Industrial areas may be served at higher temperatures.

Advantages of district heating include the avoidance of a multiplicity of small heating boilers, the reduction in pollution that results from the use of higher stacks, and the utilization of flue-gas cleaning facilities that would not be economical in small boilers, thus permitting the use of cheap fuel, including town refuse. There is also a saving of the traffic that would be involved in retail fuel deliveries.

The total energy system

A recent concept is the total energy system, which serves all of the heating, cooking, and electrical requirements of a group of buildings from a single source, such as natural gas. Electricity is generated in gas turbines, and the waste heat recovered to heat water. The hot water is used in winter for heating and in summer for cooling by an absorption refrigeration plant. The efficiency and economic advantages of such a system depend on a careful appraisal of relative year-round heat and power demands.

Control equipment. If a specified temperature is to be maintained, the input of heat to a space must be equivalent to the heat losses: thus, some means of control is necessary. Most systems of heating, whether direct or indirect, are governed by some form of thermostatic control, designed to maintain the air temperature set by a thermostat, which regulates the input of heat. In the central system, control is often by water temperature, the adjustment being made according to outside weather. Alternatively, control may be by room thermostat, coupled with a clock switch to change over to a lower setting at night. Electrical night storage systems are controlled by an anticipatory method, regulating the period of night charge according to the trend of external temperature.

Thermostatic control has the object of economizing heat as far as possible while avoiding underheating or overheating. Internal heat gains and solar gains may often contribute significantly to the total daily heat requirement of a building and, superimposed on the normal designed output of a heating system, can lead to uncomfortably high internal temperatures. A quickly responsive system is therefore desirable.

HOT-WATER SUPPLY (HWS)

The use of hot water from hot mineral springs for bathing dates from ancient civilizations. Water in shallow pools heated by the sun was also doubtless used. The Romans were the first to heat water artificially for bathing, using a furnace below a cistern; examples are found at Pompeii, Verulamium (Britain), and in the baths of Caracalla in Rome.

After the Romans no progress was made in heating water until the Industrial Revolution. In factories in which steam was available, it was injected "live" into water to be heated. In wealthy houses water was heated by a boiler forming part of the cooking range. In England in 1846, municipal bodies were first allowed by Act of Parliament to build public baths and washhouses.

Modern methods of providing hot water may, as with heating, be classed as either local or centralized. The local unit is fixed in the bathroom or kitchen adjacent to the draw-off points. The central system delivers hot water from a distance.

Hot water heaters

Local systems. These derive their heat from gas or electricity and are generally of small capacity. The gas heater may be instantaneous (*i.e.*, heating the incoming cold water as it flows through), or the heater may be packaged with a vessel to store a larger quantity of hot water for immediate use. The heater in this case is thermostatically controlled. The electric heater makes use of an immersion element, with thermostat, inserted in a storage cylinder or other vessel. No flue is needed.

Central systems. Installed in a residence, a boiler may form part of a cooking range fired with solid fuel (a back-boiler), or the boiler may be independent and fired with coke, oil, or gas. It is connected by circulating piping to a storage cylinder from which draw-off piping is taken to serve the various taps. The cylinder is supplied with cold water from a tank in the roof, served from the main through a ball valve. There is now a preference for the indirect cylinder in which water circulation from the boiler is on a closed circuit. In many countries, the cold feed is taken directly from the city main and the heating element is formed by a coil in the boiler.

In large installations, such as those for a hospital or hotel, the water is heated in calorifiers by steam or high-pressure hot water. The hot water is stored in cylinders from which secondary flow and return pipes distribute hot water throughout the building. Circulation is by pump. A water temperature of 140° F (60° C) is normal for most purposes but for kitchen use and sterilizing crockery and plates 180° F (80° C) is required. The extra temperature is usually added by a booster.

Solar water heating. Heating is usually necessary in a building only in winter; a hot water supply system usually requires heat in both summer and winter. As solar radiation is at a maximum in summer, it is more feasible for hot water supply than for direct heating. A number of examples exist in warmer climates. The water heated in the collector circulates to a storage vessel, devised to prevent undue mixing of the hot and cold water. Auxiliary means of supplying heat are needed for use on sunless days.

District water heating. If a supply of heat from district mains is available, hot water is heated from the same source. Local heat exchangers are provided, served from the mains.

III. Ventilation

The word "ventilation," from the Latin *ventus* or wind, means either the supply of fresh air or the circulation of air in a room. Life, of course, depends on oxygen. The supply of air to an enclosed space involves the removal of a corresponding volume of expired or vitiated air, possibly laden with smells, heat, noxious gases, or dust resulting from industrial processes. In such a case, air is a vehicle or scavenger of pollution. In a mine, air is a dilutant of inflammable gases. In a dye works, air is a conveyor of steam, removing fog that would otherwise render operations invisible.

Effects of human breathing

The normal adult at rest inhales about 18 cubic feet (500 litres) of air per hour, of which some five percent is absorbed as oxygen in the lungs. The exhaled breath gains from 3 to 4 percent of carbon dioxide (CO_2), equal to about 0.6 cubic feet (17 litres) per hour. If the same air is breathed over and over, a build-up of CO_2 takes place at the expense of oxygen. While CO_2 is non-toxic, such a concentration threatens asphyxiation as a result of insufficient oxygen.

As a criterion of ventilation, however, CO_2 content is inadequate. Of greater importance are temperature, humidity, and odour. The heat from the human body at rest at normal temperatures is sufficient to raise the temperature of 1,000 cubic feet (28,000 litres) of air per hour by 15° F (8° C), and it adds moisture by perspiration and exhalation from the lungs to the extent of about 0.8 grains per cubic foot (1.8 grams per cubic metre). Thus, for a given effective temperature to be maintained, a certain air flow rate can be postulated.

For crowded spaces the problems of smoking and body odour must be considered. Desirable fresh air quantities per person may vary from less than 1,000 to more than 2,000 cubic feet (36 to 60 cubic metres) per hour per occupant in spaces in which human occupancy alone is a factor.

Industrial ventilation rates are dependent on degrees of contamination, quantity of added heat or steam, and amount of solid matter added. Ventilation may be either natural or mechanical.

Natural ventilation results from thermal effects, such as those from a flue, or may be caused by wind, or both. The forces are small and often variable. Their effectiveness is aided by opening or closing windows. In large spaces, such as factories, natural roof ventilators often achieve a sufficient ventilation rate. Some form of inlet is provided at low level.

An interesting method of industrial ventilation, particularly suited to areas of high heat concentration, is the open roof, known as the Colt system. Controllable louvres are opened when conditions permit, giving a clear view of the sky; during rain they are partially closed under control of a rain-sensing device. The same opening acts as a smoke escape in the event of fire. The psychological effect of an open roof is considered highly favourable.

MECHANICAL VENTILATION: APPLICATIONS

Mechanical ventilation depends on the use of fans that either deliver fresh air into the space or exhaust it from the space; in the balanced system, both inlet and exhaust are by fans. Mechanical ventilation, being independent of thermal or wind effects, is positive and readily controllable; hence, if specified air-change rates are obligatory for health or other reasons, it is the only reliable method.

Mechanical inlet with natural exhaust tends to cause a slight pressure within the space, so that air leakage is outward. Thus, if it is installed in an internal office in a factory having a dust- or fume-laden atmosphere, the office will remain essentially contamination-free.

Mechanical exhaust with natural inlet causes a slight negative pressure in the space, so that air leakages are inward. In many cases this is desirable in order to avoid escape of fumes or smells into surrounding areas of the building. Examples occur in laboratories forming part of a college teaching block, in a hotel kitchen adjacent to restaurant areas, and in toilet accommodations generally. In industry, compartments and areas that entail grinding dust, paint spray, fumes, and smoke are similarly treated; these undesirable contaminants are then confined to the spaces in question, leaving surrounding areas free from pollution.

Air-flow patterns inside buildings

The balanced system is appropriate if the pattern of air distribution is important. In a theatre, cinema, hotel dining room, assembly hall, library, department store, or similar space occupied by large numbers of people, high air-flow rates are necessary, but drafts must be avoided. Air inlets must be situated to avoid direct impingement on the occupants, and vitiated air must be removed to maintain the required flow direction, particularly if smoking is permitted. According to building design, the flow pattern may be upward, downward, or mixed, *i.e.*, part up and part down. The downward system is more appropriate with air-conditioning in which the air is brought in cool and falls by gravity. For "straight" ventilation the upward system is most common: it comprises air inlets in side walls or in other locations above head level; air is removed by the exhaust system through apertures in the roof. In the mixed system some air is exhausted near floor level in order to remove smoke.

There are many variations of these methods to suit specific requirements. A few special cases follow.

Hospital operating theatres. A general downward air flow is favoured in order to remove bacteria carried in the air stream away from the body to the floor. Air is introduced at the ceiling at a rate equivalent to some 16 to 20 air changes per hour. Extraction of air is by means of apertures near the floor. Recent research, however, has shown that the downward action does not obtain in practice because of convection currents set up by body heat.

Exhibition halls. An interesting example of both downward and upward ventilation is afforded by the system installed at Earls Court Exhibition, London, which is among the largest covered exhibition areas in Europe. Figure 9 shows a section through half of the Main Hall.

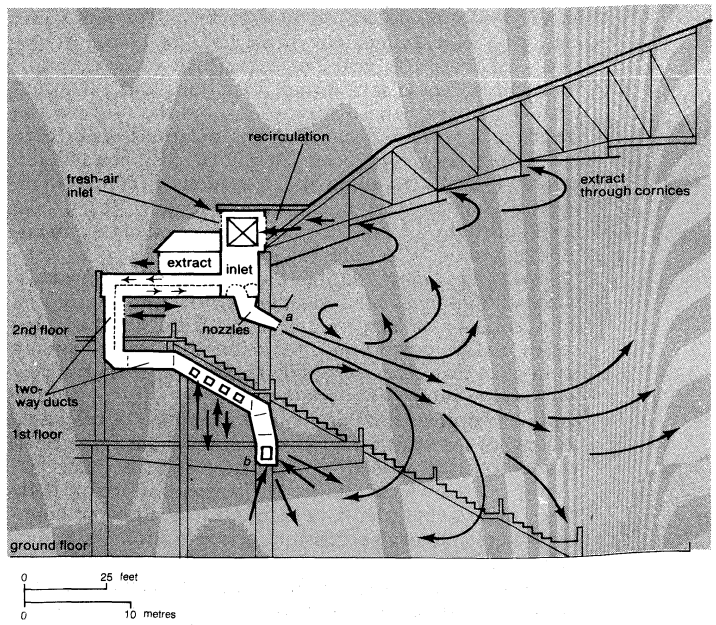

Figure 9: Section of Earls Court Exhibition Building Hall B, showing a two-way ventilating system, (A) for audiences and (B) for exhibitions. Air from *a* is extracted via side ducts under steps; from *b* via cornices in roof.

For exhibition purposes an upward system was required, so that in case of fire smoke could escape through the roof. For sporting events the stepped seating area extends from the balcony to the floor and a downward system was necessary.

The ventilating plants at roof level are arranged to deliver either through the nozzles (downward system) or through the dropping ducts to the spaces below and above the gallery (upward system). When functioning as

a downward system these ducts are reversed and act as extracts, some extraction also taking place through the roof. When functioning as an upward system, all extraction is via the roof.

Vehicular tunnels. Railway tunnels, though once the source of complaint because of the unpleasant smell of smoke and later from diesel fumes, constitute a nuisance rather than a danger because of the infrequency of trains. Natural ventilation caused by wind and the motion of the train has proved sufficient.

Long and busy highway tunnels, through which some 5,000 internal-combustion vehicles per hour may pass, constitute a serious potential hazard because of the exhaust gases, which must be diluted by mechanical ventilation. The principal hazard is carbon monoxide (CO), which may constitute from 3 to 6 percent of the exhaust fumes; unburned hydrocarbons, aldehydes, sulfur dioxide, and oxides of nitrogen may also be present. Ventilation rates of the order of 150 cubic feet of fresh air per minute per foot have been postulated as desirable for a two-lane tunnel and 300 cubic feet (eight cubic metres) for a four-lane tunnel, limiting the concentration of CO to one part per 10,000.

Carbon monoxide and other hazards

Methods of ventilation include the following: the longitudinal system, in which air is drawn in at the two ends of the tunnel and exhausted by a shaft with fans at the centre (*e.g.*, Saint-Cloud Tunnel, Paris); the upward system, in which blowing fans deliver air to a duct below road level, entering at curbside and exhausting through a duct overhead, which is connected to exhaust shafts with fans (*e.g.*, Lincoln and Holland tunnels, New York); the upward transverse system, in which the inlet is also at curbside but the exhaust is through the traffic space to exhaust shafts near the ends (*e.g.*, Mersey Tunnel, Liverpool, England); and the cross-flow system, in which blowing ducts and exhaust ducts occur on opposite sides of the tunnel (*e.g.*, Velsen, The Netherlands).

Underground railway tunnels. The ventilation of an electric railway tunnel is chiefly designed to remove heat. A single tunnel accommodates only one train, which acts as a loose-fitting piston for the distribution of ventilation air. The Victoria Line, part of the London Transport system, embodies 100 years of experience with tube railways. Fresh air is introduced at stations and exhausted by fans and shafts between stations, but the fans may be reversed in winter. Because drafts of almost gale force have been known to occur in public passageways and escalator shafts in some older sections of the system, pressure-relief shafts and cross-connecting ducts have been built into the new line, in order to reduce the maximum air speed to 15 miles (24 kilometres) per hour.

Industrial exhaust. Often, the main function of industrial ventilation is exhaust: that is, to remove airborne dust, solid particulate matter (*e.g.*, from grinding processes and woodworking), toxic fumes, steam, vapours from chemical processes, and smoke (*e.g.*, from foundry work and welding). The primary purpose of such ventilation is to protect the worker and to reduce atmospheric content of harmful products to an innocuous level. Such ventilation is governed by legislation in most industrial countries. Threshold limits of concentration of toxic gases and vapours have been published; in some countries these include permissible concentrations of radioactive materials.

Filtering airborne, solid particles

Airborne solids are usually collected as near to the point of production as possible and are then exhausted by fans through ductwork. The fan discharge to atmosphere is through a cyclone or filter to avoid external pollution.

Smokes, fumes, vapours, and dust are collected in hoods over the area of production and are exhausted to the atmosphere. Wet scrubbers, or chemical absorbent towers, are usually arranged to arrest the discharge of harmful gases. If greasy fumes emanate from the operation, as in a kitchen or food-processing department, filtration may be necessary at the source to avoid the hazard of fire in the ducts.

Extraction of air is often on a considerable scale and means for replacement are necessary. These may be through inlets around the building perimeter near the floor. To prevent drafts, mechanical inlet fans followed by an air heater and filter are used; sometimes fresh air is drawn through the roof by means of units strung overhead.

MECHANICAL VENTILATION: EQUIPMENT

Fans. All systems of mechanical ventilation include a fan, driven by an electric motor. Fans are available in various types according to application. The simple propeller or disc type, with three, four, six, or more blades arranged on a shaft, is suitable for free-air ventilation. It is noisy and inefficient, however, if working against the resistance of heaters, filters, and ducts.

The axial-flow fan, with airfoil blades, is more efficient, but its higher speeds cause noise. This noise can be absorbed in suitably designed silencers.

The centrifugal fan consists of a drum on which is mounted a series of curved blades, coaxial with the spindle or shaft. On rotation, air is drawn along the centre line of the shaft, and thrown out by centrifugal force from the blades in a spiral flow.

The centrifugal fan, which is capable of delivering air against appreciable resistance without undue speed and noise, finds wide use in applications that require quiet running. Another type, the mixed-flow, is a cross between the propeller and the centrifugal. The tangential fan consists of an extended drum that creates a flow in which the air is drawn in on one side of the drum and expelled from the other side. Its use has been confined to small convectors and electric heaters.

Heaters. Most ventilating applications demand some means of air warming during winter. The source of heat is commonly hot water or steam, but electricity is used on a limited and local scale, as is indirect-fired gas. Heaters take a variety of forms, with thermostatic control of heat input regulating outgoing temperature.

Filters. Air cleanliness is of paramount importance in many applications, such as hospitals, office blocks, computer rooms, photographic chemical production, food industries, and so on. Particulate matter in the air of urban localities may contain soots from chimneys, dust of various kinds, pollens, industrial waste, carbon from wear of tires on roads, and oily deposits from diesel fume exhausts. Particles range in size from 0.01 micron to 100 microns (1000 microns = 1 millimetre). Tobacco smoke particles are of the order of 0.1 micron, and atmospheric dusts range from 0.5 to 10 microns. The smallest dust particle visible to the naked eye is about 12 microns, and a human hair is about 100 microns in diameter.

Air filters are classified either on a weight test or on a blackness test. On a weight test, heavier particles account for the greatest mass and a coarse filter may show a high efficiency, but on a blackness test the stain resulting from minute particles may predominate and show such a filter to be very inefficient. For test purposes, therefore, sample dusts of various orders of fineness are used to permit reliable performance data for filters of various types. Filters are available in several types.

Types of air filters

The impact type is usually composed of metal plates, metal coils, or turnings, coated with a viscous fluid to which particles adhere. Impact filters are efficient on a weight test but inefficient on a blackness test.

Fabric types consist of some form of textile material or woven fibre that arrests particles in the interstices until they are clogged. Paper types and others using glass fibre or similar material also work in this way. Of low efficiency when used with fine particles, they improve sharply in blackness tests of particles larger than about 1 micron.

In electrostatic filters, dust-laden air is passed over electrically charged wires, giving a charge to all particulate matter present. The air and particles then enter a series of parallel plates, which are alternately charged and grounded. The charged dust particles are repelled onto the oil-coated grounded plates, to which they adhere. In this way airborne solids of all sizes are arrested for subsequent removal by washing. Efficiency is high throughout the range of particle size.

An absolute filter uses a special form of paper capable of removing the last traces of staining.

Activated charcoal has a high degree of porosity and is very useful in absorbing odours and undesirable gases. Such removal may be desirable if air is recirculated for economy of heating or cooling, or if stray gases, such as sulfur dioxide, are present.

The air washer consists of a series of water sprays causing a mist through which the air from the plant flows. Most of the particulate matter in the air stream in urban localities is, however, not readily wettable, and the air washer as an air cleaner is of low efficiency. It is more useful as a means of humidity control and in air conditioning as a means of cooling.

Cleaning. The cost of cleaning and maintenance of filters rises according to their efficiency. Impact types may be cleaned and re-coated manually or automatically. Fabric types may be thrown away when dirty and replaced, or the filter material may be moved from a clean roll to a dirty roll, as in a camera film. Electrostatic filters are cleaned by periodic washing down with hot water. Other systems rely on sparking between the plates to cause agglomerated material to be discharged and subsequently arrested on a coarse after-filter. Absolute filters are used only as secondary filters; when used, they are simply discarded.

There is a relationship between cost of filtration equipment and its maintenance that determines the degree of filtration efficiency. In a machine shop a coarse degree of filtration may be adequate, while in a hospital or in a factory producing transistors, the highest efficiency obtainable may be required.

Noise control. Air moved by any means is liable to set up sound waves because air itself is the medium by which sounds reach the ear. The impulse given to air on impact with successive blades of a fan is an obvious source of noise that may be conveyed through ducts to areas at a distance.

Degrees of noise toleration vary according to environment. In an environment in which machinery is at work the ear becomes accustomed to a high level of sound, and noise from ventilation systems is lost in the overall din. In a board room with double windows and heavy carpeting, on the other hand, a small noise from ventilating plant would be intolerable.

The punkah fan

Circulation of air. The punkah ceiling fan, once common in restaurants, stores, and offices all over the world, originated in the tropics before the days of air conditioning. Perspiration from the skin was the chief means of body-heat release, and the mere movement of air over the surface gave relief by evaporation, until temperature approached blood temperature and air movement ceased to be effective. For this reason, circulating fans fail to provide real relief in warm climates.

IV. Air conditioning

The term "air conditioning," first used in connection with the ventilation of textile mills, has come to mean a system in an enclosed space in which temperature and humidity are controlled within close limits, regardless of external and internal influences. It also involves control of air cleanliness and avoidance of drafts and noise.

Temperature may be controlled only by adding or by removing heat; *i.e.*, by heating or cooling. Humidity may be controlled only by adding or by removing moisture. An air-conditioning plant is designed to perform both these functions.

The need for air conditioning in temperate climates arises from many causes. Modern building construction, using large areas of glass in light curtain walling, creates conditions in which solar gain is often so great as to make such buildings untenable without means for cooling. Internal heat gains have also increased considerably because of greater intensity of lighting and the presence of electrical machinery. In offices it has been shown that efficiency is higher, and absenteeism through illness lower, in air-conditioned space. In shops and stores, air conditioning improves the atmosphere and attracts customers. Air conditioning for comfort is especially necessary in crowded assembly spaces such as theatres, cinemas, exhibition halls, night clubs, and lecture halls.

Importance of air conditioning in hospitals

In hospitals, air conditioning is now common for operating theatres, special treatment areas, pediatric units, X-ray departments, and spaces using radioactive isotopes and electron microscopes. The completely air-conditioned hospital is becoming more common, particularly in areas of high urban development. Here, considerations of air cleanliness and the need for sealed windows to exclude noise and dirt are determining factors. These considerations also apply to hotels.

Other spaces in which air conditioning has become accepted as a basic amenity include passenger aircraft, passenger ships, railroad passenger cars, motor coaches, and, in many regions, automobiles. Television and radio studios, with their high heat inputs from lighting, would become unbearably hot without air conditioning. The need in subtropical and tropical climates for relief from enervating and oppressive conditions is, of course, especially pronounced.

Reference has been made earlier to the effective temperature scale and the zone of comfort. All air conditioning applications in which human comfort is the design aim must create conditions lying within this zone, though there may be need for variation upwards in very warm climates to avoid undue thermal shock on entering from outside into an air-conditioned space. Representative examples of external dry-bulb and wet-bulb temperatures as a basis of design are given in Table 3.

Table 3: Dry- and Wet-Bulb Temperatures as Basis of Design

	dry bulb		wet bulb	
	°F	°C	°F	°C
Allahabad, India	115	46	—	—
Auckland	79	26	67	19
Berlin	89	32	69	21
Cape Town	93	34	72	22
Chicago	96	36	75	24
Cologne	87	31	69	21
Hong Kong	91	33	82	28
Madrid	96	36	72	22
New York City	94	34	75	24
Paris	90	32	70	21
Rome	96	36	74	23
Seville	107	42	82	28
Sydney	95	35	72	22
Tokyo	92	33	79	26
United Kingdom	85	29	68	20
Washington, D.C.	97	36	77	25

The inside temperature suggested for an arid climate is 76° F (24° C), being reduced to 71° F (22° C) effective temperature as the outside temperature falls below maximum.

In industry, another consideration applies, namely the quality of the product. An atmosphere in which temperature and humidity are controlled is essential in a wide range of manufacture, including food processing, colour printing, and textile printing, and the manufacture of textiles, photographic materials, electrical precision instruments, and gauges. The manufacture of synthetic materials and other modern manufacturing techniques often required stable atmospheric conditions in order to meet traditional product standards, such as those of the leather industry, with its long tradition of the treatment and tanning of hides, for which natural conditions of the environment had sufficed.

The windowless factory, a recent innovation, can only function with air conditioning, which can be justified on economic grounds, partly through saving on window heat losses and gains.

The properties of mixtures of air and water vapour are best understood from a study of the psychrometric chart of which Figure 10 is a simplified version. The horizontal scale is dry-bulb temperature, the vertical scale is absolute moisture content. Oblique lines represent wet-bulb temperatures. The limiting curve or 100 percent saturation line also represents dew-point, at which dry-bulb

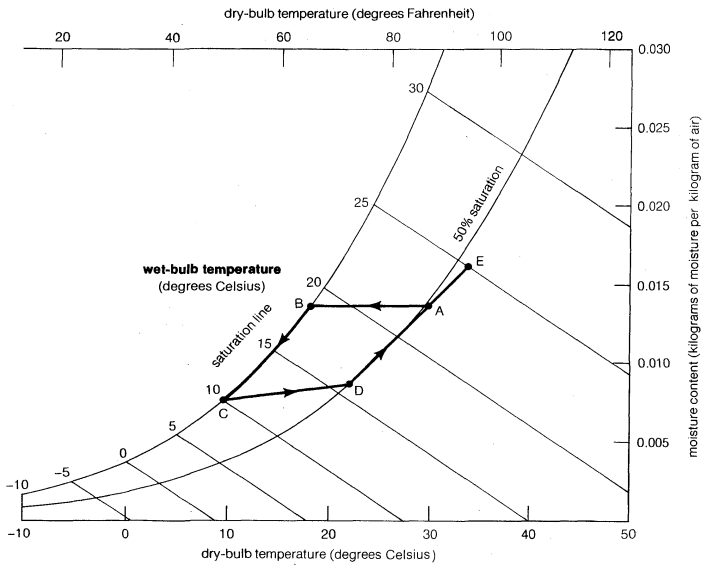

Figure 10: Portion of a simplified psychrometric chart showing the dehumidifying effect of cooling.

and wet-bulb temperatures are the same. Intermediate curves between 100 percent and 0 percent saturation are inserted on the full chart to give percentage saturation, such as the 50 percent drawn. Other data, not shown here, give total heats or enthalpies, vapour pressures, and volume lines.

The saturation curve

If an air–water-vapour mixture from a room is cooled progressively from a point A, it will arrive at point B on the saturation curve. Further cooling is then only accompanied by reduction in moisture content; *i.e.*, by condensation. Having then arrived at a point C, the air may be said to be dehumidified with respect to its initial condition at A. If then delivered to the room, heat gains within the room or through the enclosure cause a rise of temperature and a moisture gain from occupants or from other sources of water vapour, so that the air will arrive at condition D, which may be taken as the design condition for the room.

Fresh air for ventilation may be introduced at condition E; the balance of air in circulation is made up of recirculated air from the room. The mixture is then at the starting point state A, determined by the relative proportions of the two sources of air. From this point the cycle repeats. Some heat might in practice be added at point C to reduce the temperature differential of air entering the room.

The above example illustrates the process of cooling and dehumidification during summer. Another cycle obtains in winter when warming of incoming air is necessary, as well as addition of moisture; *i.e.*, humidification.

Cooling and dehumidification involve reduction of sensible heat (lowering the temperature) of air and vapour, and removal of latent heat of water vapour. The sum of these two heats or enthalpies constitutes the cooling load, generally accomplished by a refrigerating plant. Similarly, warming and humidification involve the addition of sensible heat (raising the temperature) and of latent heat of evaporation, the total being the heating load supplied by a boiler or other source of energy.

TEMPERATURE AND HUMIDITY CONTROL

Cooling. *Evaporation.* One of the earlier methods of cooling was by evaporation of water. In tropical climates of low humidity such as India, a wetted brattis or shutter, fanned by hand, provided some measure of cooling.

The modern equivalent is the air washer in which water is sprayed into the air stream by a pump; evaporation results, causing a reduction of temperature, though at the expense of an increase of humidity. In terms of effective temperature, it adds little to comfort.

Refrigeration. By the application of refrigeration to air conditioning, true control of atmospheric conditions may be achieved. On reduction of temperature, the desired condition of moisture is obtained, subject to prescribed control. Dehumidification in a crowded atmosphere is at least as important as lowering of temperature. The lowered air temperature that is issuing from the dehumidifying plant may, however, be too low for delivery into the occupied space without causing drafts. To overcome this problem of drafts, some reheating may be applied.

Four principal means of cooling by refrigeration

Cooling by refrigeration is applied in four principal ways.

1. By direct expansion of refrigerant gas in cooling coils, usually tubular, with fins over which the air passes. The fins run vertically to allow condensation to fall to the base and then to a drain. The coils constitute the evaporator of the refrigeration plant. Direct expansion is used with refrigerants such as one of the Freon group. This method is used in most small air-conditioning units.
2. By chilling water in a tubular evaporator, with the water circulated by pump through cooling coils as in 1. The system may be extended to serve a number of such cooling coils in various parts of a building, confining the refrigerant gas to the central plant.
3. Chilled water may alternatively be sprayed into the air to be cooled in an air washer and dehumidifier. As explained earlier, the washing function has low efficiency, hence the prime purpose of the sprays is for cooling. This method is often used in large plants to avoid the use of massive cooling coil surfaces. In an alternative form of washer, water is sprayed over cells of fibre-glass through which the air passes.
4. In the sprayed-coil system, chilled water coils are used as in 2 but they are contained in a washer casing as in 3. Water, sprayed over the coils by pump, is constantly recirculating. As condensation occurs the spray water grows in volume and overflows from the base tank to a drain. One merit of this system is compactness.

The refrigeration plant used for air conditioning follows the principles of normal commercial equipment (see REFRIGERATION EQUIPMENT).

Another class of refrigerator is the absorption machine using lithium bromide as the cooling medium, and requiring only heat from gas, hot water, or steam. The relative merits of absorption versus mechanical compression are beyond the scope of the present article.

A combination of centrifugal compressor with turbine drive and an absorption plant is used in a number of installations in the United States. The exhaust steam from the turbine supplies the heat for the absorption machine, effecting a high thermal efficiency.

The condenser, forming part of any refrigerating plant, is, for small direct-expansion plants, usually air cooled. For larger sizes, water circulation is employed in a conventional manner, making use of evaporative coolers in any of the various forms.

Adsorbents. Another method of dehumidification is by the use of an adsorbent such as silica gel, a form of silica in a finely divided state. Water vapour in air passed through a bed of such material is adsorbed, generating heat that is removed by cooling water. Regeneration by heating to a higher temperature drives off the moisture, the bed being cooled by air for re-use. Two plants are needed for continuous use, one dehydrating and one regenerating, with change-over arrangements. Very low humidities are obtainable with this system, rendering it particularly suitable for industries in which very dry air is required. This method is not primarily used for air conditioning.

Liquid adsorbents such as aqueous solutions of lithium chloride and calcium chloride have also been used industrially as a means of dehydration.

Peltier effect. J.-C.-A. Peltier, a French physicist, in 1834 noted that heat was produced at the junction of two dissimilar metals when a current was passed through, and that if the current were reversed, the junction would be cooled. If current were passed between two properly constructed junctions connected in series, one junction would be heated and one cooled; in effect, heat was transferred from one junction to the other.

In the application of the Peltier effect to air conditioning, materials having low thermal conductivity and high

Thermoelectric cooling and heating

electrical conductivity are used. Such materials include semiconductors formed of alloys of bismuth telluride (Bi_2Te_3) and bismuth selenide (Bi_2Se_3). In practical applications, an assembly is made up in the form of fins alternately in the hot air stream and in the cool air stream. Separate fans deliver air over the two sets of fins, that from the hot junction to the atmosphere and that from the cooled air fins to the space to be cooled. By changing over the air streams the same system may be used for heating the space. The hot junction to the atmosphere may alternatively be water cooled. (See also THERMOELECTRIC DEVICES).

Warming and humidifying. For year-round use in countries in which heating is required in winter, the air-conditioning system includes means for warming the air. In small self-contained units this may be accomplished with a heat pump. By changing over the direction of circulation of refrigerant, the evaporator becomes the condenser so that warm air is delivered to the room; meanwhile the condenser becomes the evaporator, accepting outside air and returning it to outside at a lower temperature.

In larger plants the air warming is achieved by heating coils supplied with hot water or steam or, in special cases, heated by gas or electricity.

Humidification is necessary under many winter conditions in which low outside temperatures are accompanied by low moisture content. Vapour may be added to the air stream by direct injection of steam, or water spray from the main, or by evaporation from pans heated electrically. If an air washer is used, the same unit serves the double purpose of dehumidifying in summer, when supplied with chilled water, and humidifying in winter when the spray water is warmed.

Equipment. *Central plant.* An air-conditioning plant serving a single space such as a banquet room is shown diagrammatically in Figure 11. The functions of the various parts are noted in the caption. In this example, direct-expansion cooling coils are used, in addition to an air heater, and water or steam is injected for humidification. The arrangements for air circulation within the space may take many forms. As shown, a small amount of air is exhausted to the atmosphere from the ceiling to remove smoke; the low level extract is recirculated, or, when favourable weather prevails, may be rejected, in which case the plant handles entirely fresh air through the fresh-air intake. This method saves power for operating the refrigerating compressor. Air filtration takes one of the forms referred to above.

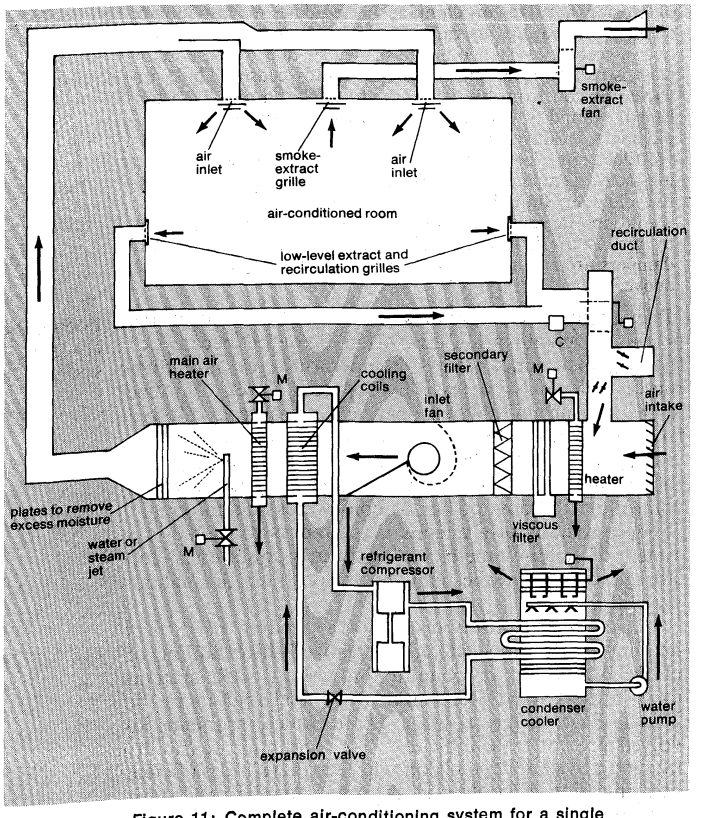

Figure 11: Complete air-conditioning system for a single room, involving heating, cooling, and humidifying as needed. M denotes motorized valves; C denotes temperature and humidity controls.

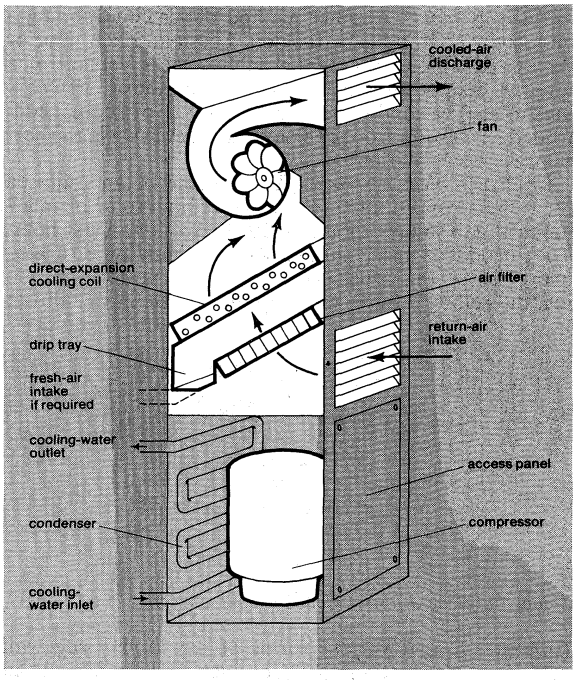

Figure 12: Simplified version of a self-contained air-conditioning unit.

Self-contained units. One form of this type is shown in Figure 12. The condenser here is water cooled, but it may alternatively be air cooled. Provision for warming is not included, but may be added. Some relatively crude forms of air conditioning merely consist of a series of such self-contained units.

Fan-coil units. If a large number of rooms are to be served, one method is to provide each with a unit supplied with conditioned air from a central plant. Another method takes in fresh air from outside. In both cases, a fan also recirculates air from the room. The temperature is regulated by a thermostat controlling water flow to the coil, which receives chilled or warm water according to the time of year.

Induction system. This system has been extensively developed for multistory office blocks and hotels. Conditioned air from a central plant is conveyed at high velocity through small ducts to each unit. This "primary" air is discharged through a series of small jets, so that a flow of "secondary" room air is induced that passes over the coil surface within the unit. Chilled or warm water is supplied to the coil on a change-over system according to outside temperature. Alternatively three-pipe and four-pipe systems have been developed so that some units on the warm side of the building that are subject to solar gain may select chilled water, while those on the cool side may select warm water.

Dual-duct system. This system dispenses entirely with water circulation and makes use of two ducts, one supplying warm air and one cool air. A blender unit serves to control admission of air from the ducts according to the dictates of a controlling thermostat in the room. Greater air quantities are handled by the central plant than in the induction system, but the change-over problem is avoided and the system is more versatile in dealing with internal areas as well as perimeter rooms.

Variable volume system. This mainly applies to internal areas of a building. It achieves control of temperature by variation of the quantity of air admitted from the central plant.

Zoned system. Another method of air conditioning a multistory building is by the zoned system. Each floor or section of a floor is provided with a large version of a fan-coil unit, from which ducts run out above false ceilings to supply conditioned air to a group of rooms, controlled as a group from one point. Air returns via the corridor for recirculation.

Air distribution systems. The volume of air required for full air conditioning of a space of high solar or internal heat gains may amount to 20 changes of air per hour. To introduce this volume without noticeable drafts, many devices have been developed: the perforated ceiling, the ceiling diffuser (see Figure 13), the linear diffuser

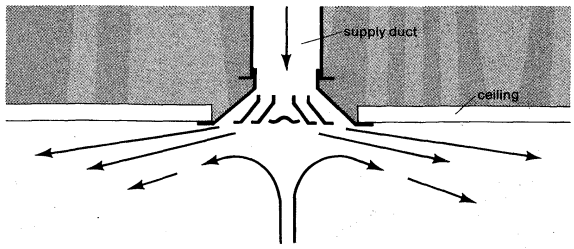

Figure 13: Air flow from a typical ceiling diffuser.

(Figure 14), and various forms of directional side wall grilles. The induction and dual-duct systems rely on an under-window position for perimeter distribution. Diffusion from there is accomplished without noticeable draft.

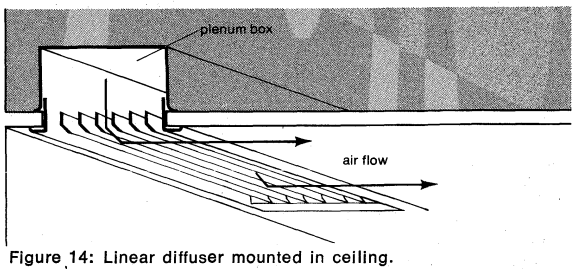

Figure 14: Linear diffuser mounted in ceiling.

Ceiling panels. A fundamentally different approach to cooling is that in which surfaces of the ceiling are cooled by panels maintained at a temperature lower than that of the room. The sole purpose of air distribution is then ventilation. An essential feature of such a system is that the ventilation air is conditioned so that its dew-point remains below the surface temperature of the cooling surface in the room, avoiding condensation.

The same concept has been applied in removing heat from ceiling light fixtures. If the heat from intensive systems of lighting is removed by cool water circulating around the fitting, heat gain to the space is stopped at the source. This avoids large air flows after the heat is radiated to the wall and floor surfaces of the room. Another approach to the same problem is to arrange for extraction of air via the lighting fittings, though this may increase cleaning maintenance.

The heat pump in air conditioning. Self-contained heat pump units may be used for cooling in summer and heating in winter by reversing valves in the refrigerant piping, so that the condenser and evaporator change function.

Another air-conditioning application of the heat pump is in the multistory block of offices in which areas in the core have a perpetual cooling problem because of lighting and occupancy heat gains, while the perimeter spaces are subject to heat losses. The heat removed from the centre core of such a building by means of air extraction is up-graded in the condenser to supply the heating needs of the exterior while the core receives the cool air from the evaporator.

In another system, the heat-recovery system, individual room-conditioning units are connected to a water circulation system to receive water from a constant-temperature circuit and return it either warmed (if cooling) or cooled (if heating) to the common return. The latter is then either heated, through a heat exchanger and boiler, or cooled, by means of a cooling tower on the roof. Recovery of heat from exhaust air may be included in the system.

The heat recovery system

Controls. Perfect functioning of any air-conditioning system relies entirely on the correct operation of the control equipment. The principles of control apparatus are simple enough, requiring only a means of detecting temperature and humidity and a source of power to operate valves or dampers in response to the demands of the controller.

Various systems have been evolved, some of them electrical, some pneumatic, all consisting basically of one element to sense conditions and one to convert signals into practical realities of heat or water vapour. In a large system a series of controls is necessary. In a multistory building, for example, there is the control of the central plant, the refrigerators and the boilers; then the control is required for the circulating water or air sent out, either heated or cooled. Some aspects of the building are subject to solar gain, others not. Some areas may be sparsely occupied, some may contain conference rooms holding several hundred persons. In industry the quality of product may depend on temperature and humidity being controlled within narrow limits.

To deal with the variety of conditions encountered, each control system must be individually designed. The permissible tolerance in variation of conditions must be decided. A plus or minus of 2° F (1° C) may be acceptable in an exhibition hall but would not suit a gauge room of a machine shop.

Electrical control systems are of three main types.

1. On-off thermostatic switching. This suffices for the small unit room-conditioner in which cooling is the main object and humidity control incidental.
2. Potentiometric. In this type the temperature-sensing device may use a volatile liquid and Bourdon tube or bimetallic helix to move a wiper arm (mechanically) over a resistance forming one arm of a bridge circuit. The out-of-balance current in the bridge then actuates a contactor to cause a motor to rotate in the appropriate direction, either opening or closing a valve, or damper, to regulate the amount of cooling or heating. In turn, this motor runs a wiper arm over a second resistance in the bridge so that, when equilibrium is restored, the motion of the motor ceases. Thus, any valve position from fully open to fully closed may be established. Humidity control may likewise be achieved by employing a sensitive material.
3. Electronic. This system dispenses with mechanical moving parts. Temperature is measured by a temperature-sensitive element, humidity by a hygrometric-sensitive element. Variations in resistance are converted into sizeable current by means of thermionic valves or transistors. Valves and dampers are actuated by the current through motors as in 2, above.

Pneumatic control systems may equally perform the necessary functions and are often favoured because of their greater simplicity. A temperature- or humidity-sensitive element progressively opens or closes an orifice in the sensing unit. When open, air pressure is relieved from above a diaphragm in a pneumatic actuator; when closed, pressure builds up. The actuator is connected to the spindle of a valve or to the lever of a damper, for controlling the flow of hot or cold water, steam, or air. Compressed air for a pneumatic system is conveyed in a system of small-diameter piping from a compressor and storage cylinder in the plant room to points throughout the building.

Pneumatic control systems

District air conditioning. Corresponding to district heating is the concept of centralized distribution of chilled water for air conditioning. Many such systems exist in the United States and in tropical regions in the Middle East, such as Kuwait. The technical problems involved present little difficulty. The economic feasibility of such a system depends on whether there is a sufficient concentration of cooling load to warrant the capital expenditure on plant and mains distribution. This situation occurs in high-density urban areas that typically include department stores, hospitals, office blocks, blocks of

apartments, theatres, and exhibition halls. Each building requiring air conditioning is connected to chilled water mains, which are fed to air-cooling batteries of the central plants; alternatively, fan-coil cooler units are served from the system, obviating the need for local refrigerating machinery and simplifying maintenance problems.

Centralization of cooling load brings a bonus in terms of total capacity. Diversity of demand as between one building and another results in a considerable reduction in overall load as compared with the sum of all the loads taken separately. As much as 60 percent reduction in total demand may apply to an extensive system.

Noise and vibration control. Early air-conditioning equipment was likely to be noisy, particularly the self-contained units. Such units have since achieved a much better standard of quietness. In all air conditioning the first problem in respect to noise is the fan. Given the sound power level at each frequency range it is possible to determine in advance the attenuation of fan noise resulting from ducts, changes of direction, and grilles. If too great a sound level remains, a slower speed fan may be selected, or means may be incorporated for sound absorption, such as lining ducts with acoustic absorbing material or inserting a silencer. The latter usually takes the form of an enlarged section of duct in which the air stream is split up by vanes of honeycomb covered with absorbent material. Use is also made of perforated plate backed by such material. The length of a silencer is determined by the need for a certain sound-level reduction at various frequency ranges. High frequencies are more easily absorbed by this means than low, but the ear has a greater tolerance to low-pitch sounds.

Silencing a fan

Ductwork systems were at one time designed on the assumption that low velocities of air movement resulted in quietness. The general use of high velocities coincided with the induction and dual-duct systems. Systems with velocities in the range of 3,000 to 4,000 feet (900 to 1,200 metres) per minute are as quiet as any conventional system using large ducts. This quietness is achieved by careful acoustic design throughout, with special attention to final terminal units.

In addition to airborne noise conveyed through ducts, there is the problem of mechanical vibration entering the structure. A refrigerating compressor mounted in a plant room on the roof may set up vibrations that are conveyed through the columns to a lower floor. Such a plant may not in itself be noisy, but it may set up resonance in the structure. Pumps, fans, motors, and compressors all contribute to the problem, which can be minimized by careful selection of speeds, types of equipment, and mounting arrangements.

ASSOCIATED COMFORT FACTORS

Ionization of air. Gases contain molecules or groups of molecules that become charged positively or negatively by natural ionizing forces near the Earth's surface; these charged molecules, or ions, include radioactive elements in the soil, cosmic rays, frictional electricity generated by rain drops, and lightning. Artificial ionization may be brought about by electrical discharges and short-wave ultraviolet radiation.

Research has shown that occupation of a room reduces the ionic content. Ventilation with fresh air at a rate of 160 cubic feet (five cubic metres) per minute per person is required to maintain the normal content.

It has also been shown that mechanical ventilation may reduce the ion content by 30 percent as a result of absorbence on metal duct walls, negative ions being removed at a faster rate than positive. Heating in a central fan system increases ion count, while cooling reduces it. Washing by sprays removes the small ions but produces many large negative ions.

Observations reported by research workers are summarized briefly in Table 4.

It has been postulated that the effect of ions occurs at the cellular level, but whether the electric charge causes a change of conductivity of the cell is not known.

Tests conducted in 1959 on tissues of rabbits and mice showed that positive ions irritate by causing a decrease in mucous flow, a drying of the surface and other effects. Negative ions have the reverse effect.

Table 4: Effects of Ions on Humans

	positive ions	negative ions
Mucous membranes	irritation	relief
Respiration	accelerated	decelerated
Hay fever	discomfort	relief
High blood pressure and rapid pulse	rise in pressure and pulse	relaxation

All this evidence seems to show that ion content has some physiological impact, but a study by the American Society of Heating, Refrigeration and Air Conditioning Engineers in 1962 produced no statistical evidence that the ionic state had any effect on sensations. A British authority concluded from this and other evidence

The question of ion content

> that the differences which normally occur in the ion content of the air of occupied rooms do not exert any significant influence on subjective sensations . . . . if there is any effect it is too small to be of engineering significance.

Ozone. Ozone is a gas with the chemical symbol O_3 (that is, each molecule has three oxygen atoms as compared with two in normal oxygen, O_2) and is present in the air in small quantities. Ozone is unstable and readily breaks down into normal oxygen plus a detached oxygen atom, O. The detached atom appears to combine rapidly with most available substances, producing a virulent oxidizing effect. This property gives ozone various applications, such as eliminating odours and clarifying water and other substances. It is no longer applied in ventilation and air conditioning owing to the smell caused by oxides of nitrogen that always accompany ozone.

Ultraviolet irradiation. Micro-organisms, especially those in moist droplets, are vulnerable to ultraviolet radiation. Serious, though temporary, inflammation of the eyes is caused by exposure to such rays, so use must be indirect in applications involving human exposure.

Sterile chambers, such as laboratories, may be irradiated with ultraviolet light to produce complete sterility before being opened for work. Indirect radiation of the upper part of rooms is another method, reliance being placed on mixing of air from the lower area by natural or mechanical means. Another method used in some hospitals has been to direct irradiation onto a curtain at the entrance to infants' cubicles.

For use in ventilation ducts, ultraviolet lamps are arranged so that air passing through the duct is sterilized, but the intensities and air flows required in ducts of various sizes are uncertain. The use of ultraviolet irradiation has an application in the biochemical field, though it has been stated that no method of sterilization, whether by irradiation or chemical means, within the limits of what is tolerable, deals with more than 50 to 70 percent of bacteria. With the present state of knowledge it therefore appears that for air conditioning in general, irradiation by ultraviolet light cannot be regarded as a practical means of reducing the spread of infection and disease.

Mixing of air. Brief reference has been made earlier to the problem of air distribution in the large quantities necessary for air conditioning without draft. Air speeds much more than 30 feet (9 metres) per minute at head level are generally regarded as a draft.

The temperature of the incoming air is important. In order to minimize air quantity and hence cost on a cooling cycle, the greater the differential between cool inlet air and room air the better. On the other hand, cold air entering a warm room at low velocity drops rapidly, thus being liable to cause local cold spots. No more than 10° or 12° F (6°–7° C) differential can be allowed.

Air issuing from a jet entrains "secondary" air from the surrounding space in the ratio of three to one or even six to one depending on configuration and velocity. Techniques have been developed to make use of this feature to enable a smaller quantity of primary cooled air to mix with a larger volume of room air at point of entry, reducing an initial temperature differential of 30° F (17° C) to no more than 10° F (6° C) at a distance from the outlet

Use of air entrainment

at which the stream breaks up into nondirectional eddies.

The technique must take into consideration relationship to wall surfaces and proximity of one discharge point to another. Streams of air in opposite directions meeting at ceiling level have a propensity to fall toward the floor or, if striking a side wall, to continue to descend, as in a waterfall.

Another technique, already referred to, is to split the air flow up into a large number of very small streams, each in effect constituting its own jet pattern. Equipment of this type breaks down the entraining air of high-temperature differential by mixing with room air and so allows the conditioned space to benefit from cooling without noticeable local drafts.

Possibly less acute is the problem of the location of extract or return-air grilles. Discomfort caused by these can usually be alleviated by spacing. In many cases extraction may occur at ceiling level, even though inlet air also enters at ceiling.

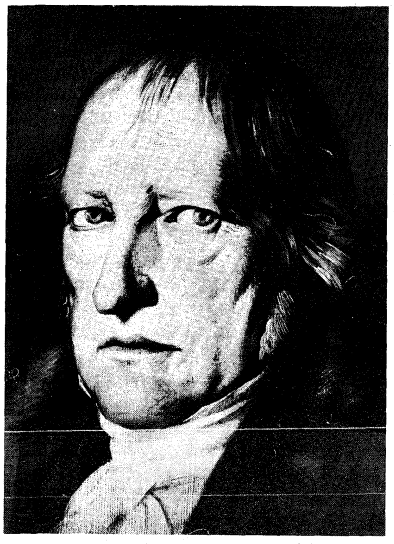
Hegel, Georg Wilhelm Friedrich

G.W.F. Hegel was the last of the great philosophical-system builders of modern times. His work, following upon that of Kant, Fichte, and Schelling, thus marks the pinnacle of classical German philosophy. As an absolute Idealist inspired by Christian insights and grounded in his mastery of a fantastic fund of concrete knowledge, Hegel found a place for everything—logical, natural, human, and divine—in a dialectical scheme that repeatedly swung from thesis to antithesis and back again to a higher and richer synthesis. His influence has been as fertile in the reactions that he precipitated—in Kierkegaard, the Danish Existentialist; in the Marxists, who turned to social action; in the Vienna Positivists; and in G.E. Moore, a pioneering figure in British Analytic philosophy—as in his positive impact.

Deutsche Fotothek, Dresden



Hegel, oil painting by Jakob von Schlesinger, *c.* 1825. In the Staatliche Museen zu Berlin.

Early life. Hegel was born at Stuttgart on August 27, 1770, the son of a revenue officer. He had already learned the elements of Latin from his mother when he entered the Stuttgart grammar school, where he remained until he was 18. As a schoolboy he made a collection of extracts, alphabetically arranged, comprising annotations on classical authors, passages from newspapers, and treatises on morals and mathematics from the standard works of the period.

University and private studies

In 1788 Hegel went as a student to Tübingen with a view to taking orders, as his parents wished. Here he studied philosophy and classics for two years and graduated in 1790. Though he then took the theological course, he was impatient with the orthodoxy of his teachers; and the certificate given to him when he left in 1793 states that, whereas he had devoted himself vigorously to philosophy, his industry in theology was intermittent. He was also said to be poor in oral exposition, a deficiency that was to dog him throughout his life. Though his fellow students called him "the old man," he liked cheerful company and a "sacrifice to Bacchus" and enjoyed the ladies as well. His chief friends were a pantheistic poet, J.C.F. Hölderlin, his contemporary, and the nature philosopher F.W.J. Schelling, five years his junior. Together they read the Greek tragedians and celebrated the glories of the French Revolution.

On leaving college, Hegel did not enter the ministry; instead, wishing to have leisure for the study of philosophy and Greek literature, he became a private tutor. For the next three years he lived in Berne, with time on his hands and the run of a good library, where he read Edward Gibbon on the fall of Rome and *De l'esprit des loix*, by

Charles Louis, baron de Montesquieu, as well as the Greek and Roman classics. He also studied the critical philosopher Immanuel Kant and was stimulated by his essay on religion to write certain papers that became noteworthy only when, more than a century later, they were published as a part of *Hegels theologische Jugendschriften* (1907). Kant had maintained that, whereas orthodoxy requires a faith in historical facts and in doctrines that reason alone cannot justify and imposes on the faithful a moral system of arbitrary commands alleged to be revealed, Jesus, on the contrary, had originally taught a rational morality, reconcilable with the teaching of Kant's ethical works, and a religion that, unlike Judaism, was adapted to the reason of all men. Hegel accepted this teaching; but, being more of a historian than Kant, he put it to the test of history by writing two essays: first, a life of Jesus in which he attempted to reinterpret the gospel on Kantian lines and, second, an answer to the question of how Christianity had ever become the authoritarian religion that it was, if in fact the teaching of Jesus was not authoritarian but rationalistic.

Move to Frankfurt am Main

Hegel was lonely in Berne and was glad to move, at the end of 1796, to Frankfurt am Main, where Hölderlin had gotten him a tutorship. His hopes of more companionship, however, were unfulfilled: Hölderlin was engrossed in an illicit love affair and shortly lost his reason. Hegel began to suffer from melancholia and, to cure himself, worked harder than ever, especially at Greek philosophy and modern history and politics. He read and made clippings from English newspapers, wrote about the internal affairs of his native Wurtemberg, and studied economics. Hegel was now able to free himself from the domination of Kant's influence and to look with a fresh eye on the problem of Christian origins.

Emancipation from Kantianism. It is impossible to exaggerate the importance that this problem had for Hegel. It is true that his early theological writings contain hard sayings about Christianity and the churches; but the object of his attack was orthodoxy, not theology itself. All that he wrote at this period throbs with a religious conviction of a kind that is totally absent from Kant and Hegel's other 18th-century teachers. Above all, he was inspired by a doctrine of the Holy Spirit. The spirit of man, his reason, is the candle of the Lord, he held, and therefore cannot be subject to the limitations that Kant had imposed upon it. This faith in reason, with its religious basis, henceforth animated the whole of Hegel's work.

His outlook had also become that of a historian—which again distinguishes him from Kant, who was much more influenced by the concepts of physical science. Every one of Hegel's major works was a history; and, indeed, it was among historians and classical scholars rather than among philosophers that his work mainly fructified in the 19th century.

"The Spirit of Christianity"

When in 1798 Hegel turned back to look over the essays that he had written in Berne two or three years earlier, he saw with a historian's eye that, under Kant's influence, he had misrepresented the life and teachings of Jesus and the history of the Christian Church. His new-won insight then found expression in his essay "Der Geist des Christentums und sein Schicksal" ("The Spirit of Christianity and Its Fate"), likewise unpublished until 1907. This is one of Hegel's most remarkable works. Its style is often difficult and the connection of thought not always plain, but it is written with passion, insight, and conviction.

He begins by sketching the essence of Judaism, which he paints in the darkest colours. The Jews were slaves to the Mosaic Law, leading a life unlovely in comparison with that of the ancient Greeks and content with the material satisfaction of a land flowing with milk and honey. Jesus taught something entirely different. Men are not to be the slaves of objective commands: the law is made for man. They are even to rise above the tension in moral experience between inclination and reason's law of duty, for the law is to be "fulfilled" in the love of God, wherein all tension ceases and the believer does God's will wholeheartedly and single-mindedly. A community of such believers is the Kingdom of God.

This is the kingdom that Jesus came to teach. It is founded on a belief in the unity of the divine and the human. The life that flows in them both is one; and it is only because man is spirit that he can grasp and comprehend the Spirit of God. Hegel works out this conception in an exegesis of passages in the Gospel According to John. The kingdom, however, can never be realized in this world: man is not spirit alone but flesh also. "Church and state, worship and life, piety and virtue, spiritual and worldly action can never dissolve into one."

In this essay the leading ideas of Hegel's system of philosophy are rooted. Kant had argued that man can have knowledge only of a finite world of appearances and that, whenever his reason attempts to go beyond this sphere and grapple with the infinite or with ultimate reality, it becomes entangled in insoluble contradictions. Hegel, however, found in love, conceived as a union of opposites, a prefigurement of spirit as the unity in which contradictions, such as infinite and finite, are embraced and synthesized. His choice of the word *Geist* to express this his leading conception was deliberate: the word means "spirit" as well as "mind" and thus has religious overtones. Contradictions in thinking at the scientific level of Kant's "understanding" are indeed inevitable, but thinking as an activity of spirit or "reason" can rise above them to a synthesis in which the contradictions are resolved. All of this, expressed in religious phraseology, is contained in the manuscripts written toward the end of Hegel's stay in Frankfurt. "In religion," he wrote, "finite life rises to infinite life." Kant's philosophy had to stop short of religion. But there is room for another philosophy, based on the concept of spirit, that will distill into conceptual form the insights of religion. This was the philosophy that Hegel now felt himself ready to expound.

Career as lecturer at Jena. Fortunately, his circumstances changed at this moment, and he was at last able to embark on the academic career that had long been his ambition. His father's death in 1799 had left him an inheritance, slender, indeed, but sufficient to enable him to surrender a regular income and take the risk of becoming a *Privatdozent.* In January of 1801 he arrived in Jena, where Schelling had been a professor since 1798. Jena, which had harboured the fantastic mysticism of the Schlegel brothers and their colleagues and the Kantianism and ethical Idealism of J.G. Fichte, had already seen its golden age, for these great scholars had all left. The precocious Schelling, who was but 26 on Hegel's arrival, already had several books to his credit. Apt to "philosophize in public," Schelling had been fighting a lone battle in the university against the rather dull followers of Kant. It was suggested that Hegel had been summoned as a new champion to aid his friend. This impression received some confirmation from the dissertation by which Hegel qualified as a university teacher, which betrays the influence of Schelling's philosophy of nature, as well as from Hegel's first publication, an essay entitled "Differenz des Fichte'schen und Schelling'schen Systems der Philosophie" (1801), in which he gave preference to the latter. Nevertheless, even in this essay and still more in its successors, Hegel's difference from Schelling was clearly marked; they had a common interest in the Greeks, they both wished to carry forward Kant's work, they were both iconoclasts; but Schelling had too many romantic enthusiasms for Hegel's liking; and all that Hegel took from him—and then only for a very short period—was a terminology.

Relationship with Schelling

Hegel's lectures, delivered in the winter of 1801–02, on logic and metaphysics, were attended by about 11 students. Later, in 1804, with a class of about 30, he lectured on his whole system, gradually working it out as he taught. Notice after notice of his lectures promised a textbook of philosophy—which, however, failed to appear. After the departure of Schelling from Jena (1803), Hegel was left to work out his own views untrammelled. Besides philosophical and political studies, he made extracts from books, attended lectures on physiology, and dabbled in other sciences. As a result of representations made by himself at Weimar, he was in February 1805 appointed extraordinary professor at Jena: and in July

1806, on Goethe's intervention, he drew his first stipend —100 thalers. Though some of his hearers became attached to him, Hegel was not yet a popular lecturer.

Hegel, like Goethe, felt no patriotic shudder when Napoleon won his victory at Jena (1806): in Prussia he saw only a corrupt and conceited bureaucracy. Writing to a friend on the day before the battle, he spoke with admiration of the "world soul" and the Emperor and with satisfaction at the probable overthrow of the Prussians.

The Phenomenology of Mind

At this time Hegel published his first great work, the *Phänomenologie des Geistes* (1807; Eng. trans., *The Phenomenology of Mind*, 2nd ed., 1931). This, perhaps the most brilliant and difficult of Hegel's books, describes how the human mind has risen from mere consciousness, through self-consciousness, reason, spirit, and religion, to absolute knowledge. Though man's native attitude toward existence is reliance on the senses, a little reflection is sufficient to show that the reality attributed to the external world is due as much to intellectual conceptions as to the senses and that these conceptions elude a man when he tries to fix them. If consciousness cannot detect a permanent object outside itself, so self-consciousness cannot find a permanent subject in itself. Through aloofness, skepticism, or imperfection, self-consciousness has isolated itself from the world; it has closed its gates against the stream of life. The perception of this is reason. Reason thus abandons its efforts to mold the world and is content to let the aims of individuals work out their results independently.

The stage of *Geist*, however, reveals the consciousness no longer as isolated, critical, and antagonistic but as the indwelling spirit of a community. This is the lowest stage of concrete consciousness, the age of unconscious morality. But, through increasing culture, the mind gradually emancipates itself from conventions, which prepares the way for the rule of conscience. From the moral world the next step is religion. But the idea of Godhead, too, has to pass through nature worship and art before it reaches a full utterance in Christianity. Religion thus approaches the stage of absolute knowledge, of "the spirit knowing itself as spirit." Here, according to Hegel, is the field of philosophy.

Period as Gymnasium rector at Nürnberg. In spite of the *Phänomenologie*, however, Hegel's fortunes were now at their lowest ebb. He was, therefore, glad to become editor of the *Bamberger Zeitung* (1807–08). This, however, was not a suitable vocation, and he gladly accepted the rectorship of the Aegidiengymnasium in Nürnberg, a post he held from December 1808 to August 1816 and one that offered him a small but assured income. There Hegel inspired confidence in his pupils and maintained discipline without pedantic interference in their associations and sports.

In 1811 Hegel married Marie von Tucher (22 years his junior), of Nürnberg. The marriage was entirely happy. His wife bore him two sons: Karl, who became eminent as a historian; and Immanuel, whose interests were theological. The family circle was joined by Ludwig, a natural son of Hegel's from Jena.

At Nürnberg in 1812 appeared *Die objektive Logik*, being the first part of his *Wissenschaft der Logik* ("Science of Logic"), which in 1816 was completed by the second part, *Die subjektive Logik*.

Period as university professor. This work, in which his system was first presented in what was essentially its ultimate shape, earned him the offer of professorships at Erlangen, at Berlin, and at Heidelberg.

Hegel's philosophical system

At Heidelberg. He accepted the chair at Heidelberg. For use at his lectures there, he published his *Encyklopädie der philosophischen Wissenschaften im Grundrisse* (1817; "Encyclopaedia of the Philosophical Sciences in Outline"), an exposition of his system as a whole. Hegel's philosophy is an attempt to comprehend the entire universe as a systematic whole. The system is grounded in faith. In the Christian religion God has been revealed as truth and as spirit. As spirit, man can receive this revelation. In religion the truth is veiled in imagery; but in philosophy the veil is torn aside, so that man can know the infinite and see all things in God. Hegel's system is thus a spiritual monism but a monism in which differentiation is essential. Only through an experience of difference can the identity of thought and the object of thought be achieved—an identity in which thinking attains the through-and-through intelligibility that is its goal. Thus, truth is known only because error has been experienced and truth has triumphed; and God is infinite only because he has assumed the limitations of finitude and triumphed over them. Similarly, man's Fall was necessary if he was to attain moral goodness. Spirit, including the Infinite Spirit, knows itself as spirit only by contrast with nature. Hegel's system is monistic in having a single theme: what makes the universe intelligible is to see it as the eternal cyclical process whereby Absolute Spirit comes to knowledge of itself as spirit (1) through its own thinking; (2) through nature; and (3) through finite spirits and their self-expression in history and their self-discovery, in art, in religion, and in philosophy, as one with Absolute Spirit itself.

"Encyclopaedia of the Philosophical Sciences"

The compendium of Hegel's system, the "Encyclopaedia of the Philosophical Sciences," is in three parts: "Logic," "Nature," and "Mind." Hegel's method of exposition is dialectical. It often happens that in a discussion two people who at first present diametrically opposed points of view ultimately agree to reject their own partial views and to accept a new and broader view that does justice to the substance of each. Hegel believed that thinking always proceeds according to this pattern: it begins by laying down a positive thesis that is at once negated by its antithesis; then further thought produces the synthesis. But this in turn generates an antithesis, and the same process continues once more. The process, however, is circular: ultimately, thinking reaches a synthesis that is identical with its starting point, except that all that was implicit there has now been made explicit. Thus, thinking itself, as a process, has negativity as one of its constituent moments, and the finite is, as God's self-manifestation, part and parcel of the infinite itself.

This is the sort of dialectical process of which Hegel's system provides an account in three phases.

"*Logic.*" The system begins with an account of God's thinking "before the creation of nature and finite spirit"; *i.e.*, with the categories or pure forms of thought, which are the structure of all physical and intellectual life. Throughout, Hegel is dealing with pure essentialities, with spirit thinking its own essence; and these are linked together in a dialectical process that advances from abstract to concrete. If a man tries to think the notion of pure Being (the most abstract category of all), he finds that it is simply emptiness; *i.e.*, Nothing. Yet Nothing *is*. The notion of pure Being and the notion of Nothing are opposites; and yet each, as one tries to think it, passes over into the other. But the way out of the contradiction is at once to reject both notions separately and to affirm them both together; *i.e.*, to assert the notion of becoming, since what becomes both is and is not at once. The dialectical process advances through categories of increasing complexity and culminates with the absolute idea, or with the spirit as objective to itself.

"*Nature.*" Nature is the opposite of spirit. The categories studied in "Logic" were all internally related to one another; they grew out of one another. Nature, on the other hand, is a sphere of external relations. Parts of space and moments of time exclude one another; and everything in nature is in space and time and is thus finite. But nature is created by spirit and bears the mark of its creator. Categories appear in it as its essential structure, and it is the task of the philosophy of nature to detect that structure and its dialectic; but nature, as the realm of externality, cannot be rational through and through, though the rationality prefigured in it becomes gradually explicit when man appears. In man nature rises to self-consciousness.

"*Mind.*" Here Hegel follows the development of the human mind through the subconscious, consciousness, and the rational will; then through human institutions and human history as the embodiment or objectification of that will; and finally to art, religion, and philosophy, in which finally man knows himself as spirit, as one with

God and possessed of absolute truth. Thus, it is now open to him to think his own essence; *i.e.*, the thoughts expounded in "Logic." He has finally returned to the starting point of the system, but en route he has made explicit all that was implicit in it and has discovered that "nothing but spirit is, and spirit is pure activity."

Hegel's system depends throughout on the results of scientific, historical, theological, and philosophical inquiry. No reader can fail to be impressed by the penetration and breadth of his mind nor by the immense range of knowledge that, in his view, had to precede the work of philosophizing. A civilization must be mature and, indeed, in its death throes before, in the philosophic thinking that has implicitly been its substance, it becomes conscious of itself and of its own significance. Thus, when philosophy comes on the scene, some form of the world has grown old.

At Berlin. In 1818 Hegel accepted the renewed offer of the chair of philosophy at Berlin, which had been vacant since Fichte's death. There his influence over his pupils was immense, and there he published his *Naturrecht und Staatswissenschaft im Grundrisse*, alternatively entitled *Grundlinien der Philosophie des Rechts* (1821; Eng. trans., *The Philosophy of Right*, 1942). In Hegel's works on politics and history, the human mind objectifies itself in its endeavour to find an object identical with itself. *The Philosophy of Right* (or *of Law*) falls into three main divisions. The first is concerned with law and rights as such: persons (*i.e.*, men as men, quite independently of their individual characters) are the subject of rights, and what is required of them is mere obedience, no matter what the motives of obedience may be. Right is thus an abstract universal and therefore does justice only to the universal element in the human will. The individual, however, cannot be satisfied unless the act that he does accords not merely with law but also with his own conscientious convictions. Thus, the problem in the modern world is to construct a social and political order that satisfies the claims of both. And thus no political order can satisfy the demands of reason unless it is organized so as to avoid, on the one hand, a centralization that would make men slaves or ignore conscience and, on the other hand, an antinomianism that would allow freedom of conviction to any individual and so produce a licentiousness that would make social and political order impossible. The state that achieves this synthesis rests on the family and on the guild. It is unlike any state existing in Hegel's day; it is a form of limited monarchy, with parliamentary government, trial by jury, and toleration for Jews and dissenters.

The Philosophy of Right

After his publication of *The Philosophy of Right*, Hegel seems to have devoted himself almost entirely to his lectures. Between 1823 and 1827 his activity reached its maximum. His notes were subjected to perpetual revisions and additions. It is possible to form an idea of them from the shape in which they appear in his published writings. Those on *Aesthetics*, on the *Philosophy of Religion*, on the *Philosophy of History*, and on the *History of Philosophy* have been published by his editors, mainly from the notes of his students, whereas those on logic, psychology, and the philosophy of nature have been appended in the form of illustrative and explanatory notes to the corresponding sections of his *Encyklopädie*. During these years hundreds of hearers from all parts of Germany and beyond came under his influence; and his fame was carried abroad by eager or intelligent disciples.

Three courses of lectures are especially the product of his Berlin period: those on aesthetics, on the philosophy of religion, and on the philosophy of history. In the years preceding the revolution of 1830, public interest, excluded from political life, turned to theatres, concert rooms, and picture galleries. At these Hegel became a frequent and appreciative visitor, and he made extracts from the art notes in the newspapers. During his holiday excursions, his interest in the fine arts more than once took him out of his way to see some old painting. This familiarity with the facts of art, though neither deep nor historical, gave a freshness to his lectures on aesthetics, which, as put together from the notes taken in different years from 1820 to 1829, are among his most successful efforts.

Philosophies of aesthetics; of religion; of history

The lectures on the philosophy of religion are another application of his method, and shortly before his death he had prepared for the press a course of lectures on the proofs for the existence of God. On the one hand, he turned his weapons against the Rationalistic school, which reduced religion to the modicum compatible with an ordinary worldly mind. On the other hand, he criticized the school of Schleiermacher, who elevated feeling to a place in religion above systematic theology. In his middle way, Hegel attempted to show that the dogmatic creed is the rational development of what was implicit in religious feeling. To do so, of course, philosophy must be made the interpreter and the superior discipline.

In his philosophy of history, Hegel presupposed that the whole of human history is a process through which mankind has been making spiritual and moral progress and advancing to self-knowledge. History has a plot, and the philosopher's task is to discern it. Some historians have found its key in the operation of natural laws of various kinds. Hegel's attitude, however, rested on the faith that history is the enactment of God's purpose and that man had now advanced far enough to descry what that purpose is: it is the gradual realization of human freedom.

The first step was to make the transition from a natural life of savagery to a state of order and law. States had to be founded by force and violence; there is no other way to make men law-abiding before they have advanced far enough mentally to accept the rationality of an ordered life. There will be a stage at which some men have accepted the law and become free, while others remain slaves. In the modern world man has come to appreciate that all men, as minds, are free in essence, and his task is thus to frame institutions under which they will be free in fact.

Hegel did not believe, despite the charge of some critics, that history had ended in his lifetime. In particular, he maintained against Kant that to eliminate war is impossible. Each nation-state is an individual; and, as Hobbes had said of relations between individuals in the state of nature, pacts without the sword are but words. Clearly, Hegel's reverence for fact prevented him from accepting Kant's Idealism.

The lectures on the history of philosophy are especially remarkable for their treatment of Greek philosophy. Working without modern indexes and annotated editions, Hegel's grasp of Plato and Aristotle is astounding, and it is only just to recognize that it was from Hegel that the scholarship lavished on Greek philosophy in the century after his death received its original impetus.

Recognition and honours

At this time a Hegelian school began to gather. The flock included intelligent pupils, empty-headed imitators, and romantics who turned philosophy into lyric measures. Opposition and criticism only served to define more precisely the adherents of the new doctrine. Though he had soon resigned all direct official connection with the schools of Brandenburg, Hegel's real influence in Prussia was considerable. In 1830 he was rector of the university. In 1831 he received a decoration from Frederick William III. One of his last literary undertakings was the establishment of the Berlin *Jahrbücher für wissenschaftliche Kritik* ("Yearbook for Philosophical Criticism").

The revolution of 1830 was a great blow to Hegel, and the prospect of mob rule almost made him ill. His last literary work, the first part of which appeared in the *Preussische Staatszeitung* while the rest was censored, was an essay on the English Reform Bill of 1832, considering its probable effects on the character of the new members of Parliament and the measures that they might introduce. In the latter connection he enlarged on several points in which England had done less than many continental states for the abolition of monopolies and abuses.

In 1831 cholera entered Germany. Hegel and his family retired for the summer to the suburbs, and there he finished the revision of the first part of his *Science of Logic*. Home again for the winter session, on November 14, after one day's illness, he died of cholera and was buried, as

he had wished, between Fichte and Karl Solger, author of an ironic dialectic.

Personage and influence. In his classroom Hegel was more impressive than fascinating. His students saw a plain, old-fashioned face, without life or lustre—a figure that had never looked young and was now prematurely aged. Sitting with his snuffbox before him and his head bent down, he looked ill at ease and kept turning the folios of his notes. His utterance was interrupted by frequent coughing; every sentence came out with a struggle. The style was no less irregular: sometimes in plain narrative the lecturer would be specially awkward, while in abstruse passages he seemed especially at home, rose into a natural eloquence, and carried away the hearer by the grandeur of his diction.

The early theological writings and the *Phenomenology of Mind* are packed with brilliant metaphors. In his later works, produced as textbooks for his lectures, the "Encyclopaedia of the Philosophical Sciences" and the *Philosophy of Right*, he compresses his material into relatively short, numbered paragraphs. It is only necessary to translate them to appreciate their conciseness and precision. The common idea that Hegel's is a philosophy of exceptional difficulty is quite mistaken. Once his terminology is understood and his main principles grasped, he presents far less difficulty than Kant, for example. One reason for this is a certain air of dogmatism: Kant's statements are often hedged around with qualifications; but Hegel had, as it were, seen a vision of absolute truth, and he expounds it with confidence.

Emergence of Hegelianism

Hegel's system is avowedly an attempt to unify opposites—spirit and nature, universal and particular, ideal and real—and to be a synthesis in which all the partial and contradictory philosophies of his predecessors are alike contained and transcended. It is thus both Idealism and Realism at once; hence, it is not surprising that his successors, emphasizing now one and now another strain in his thought, have interpreted him variously. Conservatives and revolutionaries, believers and atheists alike have professed to draw inspiration from him. In one form or another his teaching dominated German universities for some years after his death and spread to France and to Italy. The vicissitudes of Hegelian thought to the present day are detailed in the article HEGELIANISM. In the mid-20th century, interest in the early theological writings and in the *Phänomenologie* was increased by the spread of Existentialism. At the same time, the growing importance of Communism encouraged political thinkers to study Hegel's political works, as well as his "Logic," because of their influence on Karl Marx. And, by the time of his bicentennial in 1970, a Hegelian renascence seemed to be in the making, at least in the United States and in Germany.

BIBLIOGRAPHY. A collected edition of Hegel's published works, together with a great deal of material culled from his lectures, was published by his pupils within a few years of his death in 1831. This edition, with some rearrangement, was reissued by HERMANN GLOCKNER in 26 volumes, including a comprehensive index (1927–40). In 1905 the Philosophische Bibliothek (Leipzig, later Hamburg) began publication of a new edition with a carefully revised text edited by GEORG LASSON and later by JOHANNES HOFFMEISTER; volumes appeared for over 50 years, but it was never completed. It has now been enhanced by a comprehensive edition sponsored by the Deutsche Forschungsgemeinschaft; it is to contain about 50 volumes. The first volume appeared in 1968.

English translations of most of Hegel's works were published in the later 19th and early 20th century, but, apart from those by W. WALLACE (*Logic* and *Mind—i.e.*, the first and third parts of the *Encyclopaedia*), they are not always very satisfactory and they have no notes. With a view to remedying this deficiency, new English translations have appeared of the *Philosophy of Right* (1942, often reprinted), the *Science of Logic* (1969), and the *Philosophy of Art* (1973), as well as translations of writings not translated previously, namely, the *Early Theological Writings* (1948; rev. ed., 1971), some *Political Writings* (1969), and, twice, the *Philosophy of Nature*—the second part of the *Encyclopaedia* (1970), the latter in three volumes. With the exception of the *Science of Logic* and the Oxford translation of the *Philosophy of Nature*, all these translations are annotated.

The best short account of Hegel's philosophy in English is still EDWARD CAIRD, *Hegel* (1883, reprinted 1968), but it has been brought up to date in certain respects by G.R.G. MURE, *The Philosophy of Hegel* (1965); and in more detail by W.A. KAUFMANN, *Hegel* (1965). An attempt to interest modern philosophers in Hegel is contained in J.N. FINDLAY, *Hegel* (1958), but this important and lively work is for consideration only by those already acquainted with Hegel. As an introduction to Hegel, G.R.G. MURE, *An Introduction to Hegel* (1940), is more reliable but it is not an exposition. The standard long exposition of Hegel's mature system is still KUNO FISCHER, *Hegels Leben, Werke und Lehre*, esp. as edited by H. FALKENHEIM (1911); while in English there is W.T. STACE, *The Philosophy of Hegel* (1924). This concentration on Hegel's mature system alone, as if it were self-explanatory, has long been outdated. In 1900 Wilhelm Dilthey maintained that Hegel could only be understood if there were a study of his early manuscripts and, on the basis of these, a history of his development written. He wrote such a history in *Die Jugendgeschichte Hegels* (1906). This seminal work, hardly noticed at all by writers in English before 1965, gave rise to an immense literature in Germany, France, and Italy. The most important and most brilliant study of the young Hegel may be that of GEORG LUKACS, *Der junge Hegel* (1948), although he writes from a Marxist point of view. But the most exhaustive is that of THEODOR HAERING, *Hegel: Sein Wollen und sein Werk*, 2 vol. (1929–38). Reliable and more readable than this are the two volumes of HERMANN GLOCKNER issued (1929 and 1940) as an appendix to his edition of the collected works. Even these, however, have been outdated by the flood of new material collected by the Hegel-Archiv at Bochum in West Germany and published in a series of volumes of *Hegel-Studien* (1961 and subsequent years). This material has not yet been condensed into monographs. The same is true of the four volumes of Hegel's letters, edited by JOHANNES HOFFMEISTER (1952–60). These could be used for the preparation of a new biography of Hegel to supersede the admirable, but now obsolete, one by K. ROSENKRANZ (1824).

The following are the most recent commentaries on individual works, or short guides to them: (*Phenomenology of Spirit*): JEAN HYPPOLITE, *Genèse et structure de la Phénoménologie de l'Espirit de Hegel* (1946). (*Logic*): G.R.G. MURE, *A Study of Hegel's Logic* (1950). (*Nature*): There are few, even short, studies in any language, but the apparatus in the English translation by M.J. PETRY, 3 vol. (1970), provides a full and learned commentary. (*Law, Morality, and the State*): WILHELM SEEBERGER, *Hegel; oder, die Entwicklung des Geistes zur Freiheit* (1961), which, incidentally, is a good introduction to Hegel's thought as a whole; but HUGH A. REYBURN, *The Ethical Theory of Hegel* (1921, reprinted 1967); and FRANZ ROSENZWEIG, *Hegel und der Staat*, 2 vol. (1920), have not been superseded. Both are excellent summaries, but the latter is a commentary as well. (*Art*): JACK KAMINSKY, *Hegel on Art* (1962), is a fair summary of Hegel's lectures. (*Religion*): T.M. KNOX, *A Layman's Quest* (1969), deals in chapters 5 and 6 not only with Hegel's lectures on the philosophy of religion but with all his other writings elsewhere on religion.

(T.M.K.)

Hegelianism

Hegelianism is the name given to a diversified philosophical movement that developed out of a monumental system of thought constructed during the first third of the 19th century by the German Idealist G.W.F. Hegel, generally considered to have been one of the most broadly and profoundly learned philosophers of modern times. The term is here so construed as to exclude Hegel himself and to include, therefore, only the ensuing Hegelian movements. As such, its thought is focussed upon history and logic, a history in which it sees, in various perspectives, that "the rational is the real" and a logic in which it sees that "the truth is the Whole."

GENERAL CONSIDERATIONS

Problems of the Hegelian heritage. The Hegelian system, in which German Idealism reached its fulfillment, claimed to provide a unitary solution to all of the problems of philosophy. It held that the speculative point of view, which transcends all particular and separate perspectives, must grasp the *one* truth, bringing back to its proper centre all of the problems of logic, of metaphysics (or the nature of Being), and of the philosophies of nature, law, history, and culture (artistic, religious, and philosophical). According to Hegel, this attitude is more than a formal method that remains extraneous to its own content; rather, it represents the actual development of

the Absolute—of the all-embracing totality of reality—considered "as Subject and not merely as Substance" (*i.e.*, as a conscious agent or Spirit and not merely as a real being). This Absolute, Hegel held, first puts forth (or posits) itself in the immediacy of its own inner consciousness and then negates this positing—expressing itself now in the particularity and determinateness of the factual elements of life and culture—and finally regains itself, through the negation of the former negation that had constituted the finite world.

Dialectical development of the Absolute

Such a dialectical scheme (immediateness–alienation–negation of the negation) accomplished the self-resolution of the aforementioned problem areas—of logic, of metaphysics, and so on. This panoramic system thus had the merit of engaging philosophy in the consideration of all of the problems of history and culture, none of which could any longer be deemed foreign to its competence. At the same time, however, the system deprived all of the implicated elements and problems of their autonomy and particular authenticity, reducing them to symbolic manifestations of the one process, that of the Absolute Spirit's quest for and conquest of its own self. Moreover, such a speculative mediation between opposites, when directed to the more impending problems of the time, such as those of religion and politics, led ultimately to the evasion of the most urgent and imperious ideological demands and was hardly able to escape the charge of ambiguity and opportunism.

Stages in the history of the interpretation of Hegel. The explanation of the success of Hegelianism—marked by the formation of a school that, for more than 30 years, brought together the best energies of German philosophy—lies in the fact that no other system could compete with it in the richness of its content or the rigour of its formulation or challenge its claim to express the total spirit of the culture of its time. Moreover, as Hegelianism diffused outward, it was destined to provoke increasingly lively and gripping reactions and to take on various articulations as, in its historical development, it intermingled with contrasting positions.

Four stages can be distinguished within the development of Hegelianism. The first of these was that of the immediate crisis of the Hegelian school in Germany during the period from 1827 through 1850. Always involved in polemics against its adversaries, the school soon divided into three currents: (1) The right, in which the direct disciples of Hegel participated, defended his philosophy from the accusation that it was liberal and pantheistic (defining God as the All). These "old Hegelians" sought to uphold the compatibility of Hegelianism with evangelical orthodoxy and with the conservative political policies of the Restoration (the new order in Europe that followed the defeat of Napoleon). (2) The left—formed of the "young Hegelians," for the most part indirect disciples of Hegel—considered the dialectic as a "principle of movement" and viewed Hegel's identification of the rational with the real as a command to modify the cultural and political reality that reactionism was merely justifying and to make it rational. Thus the young Hegelians interpreted Hegelianism in a revolutionary sense—*i.e.*, as pantheistic and then, consecutively, as atheistic in religion and as liberal democratic in politics. (3) The centre, which preferred to fall back upon interpretations of the Hegelian system in its genesis and significance, with special interest in logical problems.

Hegelian right, centre, and left

In the second phase (1850–1904), in which Hegelianism diffused into other countries, the works of the centre played a preponderant role; thus in this phase of the history of the interpretation of Hegel, usually called Neo-Hegelian, the primary interest was in logic and a reform of the dialectic.

In the first decade of the 20th century, on the other hand, there arose still in Germany a different movement, after Wilhelm Dilthey, originator of a critical approach to history and humanistic studies, discovered unpublished papers from the period of Hegel's youth. This third phase, that of the Hegel renaissance, was characterized by an interest in philology, by the publication of texts, and by historical studies; and it stressed the reconstruction of the genesis of Hegel's thought, considering especially its cultural matrices—both Enlightenment and Romanticist—and the extent to which it might present irrationalistic and so-called pre-Existentialist attitudes.

In the fourth stage, after World War II, the revival of Marxist studies in Europe finally thrust into the foreground the interest in Hegel–Marx relationships and in the value of the Hegelian heritage for Marxism, with particular regard to political and social problems. This fourth phase of the history of Hegelianism thus appropriated many of the polemical themes of the earlier years of the school.

CRISES IN THE EARLIER HEGELIAN SCHOOL

The earlier development of Hegelianism can be divided, according to predominant concerns, into three periods: (1) polemics during the life of Hegel (1816–31), (2) controversies in the religious field (1831–39), and (3) political debates (1840–44), though discussions on all of the problems continued through all three periods.

Polemics during the life of Hegel: 1816–31. While Hegel was still living, discussion was dominated by the master. It was not a matter of polemics within the school but only one of objections against the system from various quarters: from speculative theists; from Johann Herbart, a prominent student of the philosophy of mind, and his followers; and from disciples of Friedrich Schelling, an objective and aesthetic Idealist, and of Friedrich Schleiermacher, a seminal thinker of modern theology.

The substantive history of the school stems from Hegel's later teaching at Berlin and from the publication of his *Naturrecht und Staatswissenschaft im Grundrisse* (1821; Eng. trans., *The Philosophy of Right*, 1942). This book was reviewed by Herbart, who reprimanded Hegel for mixing the monism of the Rationalist Spinoza with the transcendentalism of Kant, which had explored the conditions of the possibility of knowledge in general. There were also certain critics who directed the liberal press against Hegel for attacking Jakob Fries, a psychologizing Neo-Kantian, in the introduction of *The Philosophy of Right*. Some of the polemical writings of Hegel made a notable impact—*e.g.*, a preface that he wrote for a book by one of his earliest disciples, Hermann Hinrichs, on the relation of faith to reason (1822). In this preface, Hegel saw the two things as the same in content but different in form—which for faith is the representation and for reason is the concept.

Particularly significant were eight articles in the *Jahrbücher für wissenschaftliche Kritik* (founded 1827; "Yearbooks for Scientific Critique"), a journal of the Hegelian Right. Important among these were a review by Hegel that was unexpectedly eulogistic about the thesis that philosophy and evangelical orthodoxy are compatible and another review in which Hegel responded indirectly to arguments of Herbart. Among Hegel's critics can be distinguished speculative theists such as Christian Weisse of Leipzig and Immanuel Fichte, the son of the more famous Johann Fichte, who reproached him for his panlogism and proposed to unify thought and experience in the concept of a free God, the Creator. Among the most loyal disciples of Hegel were Hermann Hinrichs, his collaborator and Karl Rosenkranz, who defended the Hegelian solution of the faith–reason problem (which had asserted the identity of content and difference of form), thus aptly defending the free rationality of religion.

Articles in *Jahrbücher*

Period of controversies chiefly in religion: 1831–39. The tone of these early polemics became animated and embittered after the death of Hegel. But, inasmuch as conditions in Germany, during the Restoration, inhibited the liberalization of political discussions, the milieu of controversy shifted to the religious realm and became related to problems of immortality, Christology, and general theology.

Shortly before Hegel's death, the youthful Ludwig Feuerbach, who later became a pioneer of naturalistic humanism, had published his *Gedanken über Tod und Unsterblichkeit* (1830; "Thoughts on Death and Immortality"), in which he contended that, from the Hegelian point of view, death must be necessary in order for man

Feuerbach and Strauss

to be transformed from the finite to the infinite and it is thus a privilege for man preferable to empirical personal survival. This work was held to confirm the charge of pantheism that orthodox adversaries had directed at Hegel's system. On this point, at the appearance of two volumes by Johann Friedrich Richter, a pantheist and critic of religion, Hegel's disciples intervened, in an argument employing not a few dialectical artifices, to conciliate Hegelian statements with the traditional doctrine of immortality.

The polarization of historical positions that the debate on immortality could not adequately express soon came into the open with *Das Leben Jesu kritisch bearbeitet* (1835–36; Eng. trans., *The Life of Jesus Critically Examined*, 1846), of David Friedrich Strauss, a biographer and radical theologian. This work brought the problem of the nature of Christ up to date from the point of view that had been reached by biblical criticism; *i.e.*, Christology was no longer an issue of denominational dogma but, rather, a problem of the interpretation and evaluation of the Gospel sources and of their meaning in the historical development of civilization. In this approach, the narrowly philological outlook was overcome by a reconstruction in terms of a philosophy of history strangely suggestive of the young Hegel. The thesis of the book was that the Gospel account is interwoven with myths that are not the works of individuals but of the collective poetic activity of the first Christian community, myths that resulted in part from messianic expectations, in part from the memory of the historical figure of Jesus, and in part from a transfiguration of the real elements. The aim of the myths was to demonstrate that philosophy and religion are the same in content and to offer, in an imaginative guise (as in parables), the meaning of the one truth that Substance is unification of the divine nature and of the human, which Christ symbolized and which is realized in the spirit of all humanity.

Strauss's work provoked a lively reaction, to which he replied in his *Streitschriften* (1837–38; "Controversial Writings"), proposing the image of a Hegelian school split, like the French Parliament, into a right (Göschel, and several others), a centre (Rosenkranz), and a left (Strauss himself). There were responses from the right and centre and from Bruno Bauer, a philosopher, historian, and biblical critic. From the anti-Hegelian side there was, above all, *Die evangelische Geschichte* (1838; "The History of the Gospels"), by Weisse, who, conceding to Strauss the necessity to rationalize the Gospel story, propounded a speculative interpretation of the Christ figure as an incarnation of the Logos (Word), in contrast to the mystic and pantheistic views.

Weisse, Ruge, Schelling

Meanwhile, Bauer shifted toward the left in a polemic against the orthodox Ernst Hengstenberg, a vehement accuser of the Hegelians, and in his *Kritik der Geschichte der Offenbarung* (1838; "Critique of the History of Revelation"). In 1838 was founded the earliest journal of the left, the *Hallische Jahrbücher für deutsche Wissenschaft und Kunst* ("Halle Yearbooks for German Science and Art"), coedited by the activist philosopher Arnold Ruge and T. Echtermeyer. At first, the journal maintained a moderate tone, and Hegelians of the centre and right also contributed articles. In June, however, it veered to the democratic-liberal side as Ruge struck out against an accuser of the young Hegelians and as Feuerbach attacked earlier Hegelians. Hegelianism, which marks the culmination of speculative philosophy, Feuerbach charged, does not demonstrate its own truth, because its contrast between sensory reality and intellectual concept comprises an irresoluble contradiction. Thus, its dialectic turns out to be a "monologue with itself," bereft of authentic mediation with the world. Hegelian philosophy, he held, is a "rational mystique," and what is needed is a return to nature, which, as objective reason, ought to become a principle of philosophy and of art. Thus an extensive examination of contemporary culture was conducted by the journal's editors in an article that depicted Romanticism as a movement degraded to a reactionary stance and extolled the spirit of reform and of liberal (yet royalist) Prussianism.

As for issues in the fields of logic and metaphysics, after several polemical exchanges the interest of philosophers was attracted to the publicist reawakening that came to Schelling, who reactivated certain anti-Hegelian criticisms. These criticisms dealt with the impossibility of building a valid philosophy upon the pure concept assumed as a point of departure and endowed with autonomous movement. Such a philosophy would be vitiated by presuppositions of what ought to be demonstrated and by hypostatizations (*i.e.*, the making of an idea into an entity). Schelling proposed, on the other hand, that the real itself be taken as the subject of development, to be grasped with a "lively intuition"; and that, while accepting a "negative philosophy" (such as that of Rationalism and Hegel) pointing to the conditions *without which* one cannot think, one must also add a "positive philosophy" delineating the conditions *by means of which* thought and reality can exist, premised on the existence of a free creative God.

Period of atheistic and political radicalism: 1840–44. The ensuing years marked one of the most intense periods in the cultural life of modern Europe.

Anti-Hegelian criticism. Advancing from Aristotelian presuppositions, an important critique against the Hegelian logic was presented by the classical philosopher and philologist Friedrich Adolf Trendelenburg in his *Logische Untersuchungen* (1840; "Logical Investigations"). In Hegel's view, the passage from Being to Nothing and to Becoming can be posited as a pure beginning "without presuppositions" of logic. In Trendelenburg's view, however, this passage is vitiated by its spurious dependence upon the surreptitious presupposition of the Empirical movement, without which support neither the passage from Being to Nothing (and vice versa) nor the recognition of Becoming as the "truth" of this primal opposition of concepts can be justified. Secondly, he charged that Hegel confused (1) the logical opposition or contradiction of *A* against non-*A* with (2) the real contradiction or contrariety of *A* against *B*. Contradiction (1) consists in the mere repetition of the first term with a negative sign; and from it no concrete movement can proceed. In contrariety (2), however, the opposition of the second term to the first is concrete—thus the second term cannot be deduced from the first and, instead, should be derived on its own account from empirical experience. Thus Hegel constructed his entire system, Trendelenburg charged, on an arbitrary dialectic of elements intrinsically real (contraries), which he mistakenly treated as though they were abstract opposites (contradictories) and were such by logical necessity.

Meanwhile, Schelling continued to teach his "positive philosophy"—of mythology and of revelation (of a personal God). Hence the philosophy of the later Schelling became the target of all of the criticisms from the left and likewise exerted a notable influence on the speculative theists. Meanwhile, the centre, on account of the critique of Trendelenburg, oriented itself toward the future reforms of Hegelianism.

Kierkegaard and Fischer

Among those who attended Schelling's lectures was Søren Kierkegaard, the man who was destined to become one of the founding fathers of Existentialism and whose religious individualism represents the earliest major result of the diffusion of Hegelianism outside of Germany. In all of his works—but above all in his *Philosophiske Smuler* (1844; Eng. trans., *Philosophical Fragments*, 1936) and his *Afsluttende uvidenskabelig Efterskrift* (1846; Eng. trans., *Concluding Unscientific Postscript*, 1941)—Kierkegaard waged a continuous polemic against the philosophy of Hegel. He regarded Hegel as motivated by the spirit of the harmonious dialectical conciliation of every opposition and as committed to imposing universal and panlogistic resolutions upon the authentic antinomies of life. Kierkegaard saw these antinomies as emerging from the condition of the individual, as a single person, who, finding himself always stretching to attain ascendance over his existential limitations in his absorption in God and at the same time always thrust back upon himself by the incommensurability of this relationship, cannot find his salvation except through the paradoxical in-

version of the rational values of speculative philosophy and through the "leap of faith" in the crucified Christ. Kierkegaard's claim that the nexus of problems characterizing man's condition as an existing being is irreducible to any other terms lay at the very roots of Existentialism. It was destined to condition the critical relationship of this current of thought to Hegelianism throughout its subsequent history. Moreover, Kierkegaard's thought—still more than that of Strauss—seemed reminiscent of those problem areas explored in the young Hegel's religious thought—issues that were destined to appear only later when Hegel research would gain precise knowledge of the writings of Hegel's youth.

At this time the attitude of the centre was oriented toward reforms of the Hegelian system in the field of logic and historiography, as reflected especially in the emergence of Kuno Fischer, one of the foremost historians of philosophy. In the fundamental triad of the dialectic, as Fischer saw it, Being and Nothing are not equally static and neutralizing. The real movement does not interpose itself into their relationship because Being is here to be understood as the Being of thought, which, to the degree that it is a thinking of Nothing, possesses that dynamic surplus that becomes manifest in the moment of Becoming. It was in making responses to this view that the forthcoming Neo-Hegelian movement in Europe found some of its motivations.

Theological radicalism. In 1840 political conditions in Germany changed with the succession of the young Frederick William IV, whose minister began to repress the liberal press and summoned to Berlin in an anti-Hegelian capacity both Schelling and the conservative jurist F.J. Stahl, a stubborn critic of Hegel. Far from weakening the movement, however, these actions radicalized its revolutionary manifestations. Strauss, in *Die christliche Glaubenslehre* (1840–41; "The Christian Doctrine of Faith"), reaffirmed the opposition of philosophical pantheism to religious theism as a means of reunifying the finite and the infinite; and Feuerbach established a philosophical anthropology in his major work *Das Wesen des Christentums* (1841; Eng. trans., *The Essence of Christianity*, new ed. 1957), in which man reappropriates his essence, which he had alienated from himself by hypostatizing it in the idea of God. The essence of man is reason, will, and love; and these three faculties comprise the consciousness of the human species as a knowledge of the infinity that man must regain. Man must thus reverse the theological propositions that express the spurious objectification of his universality in God; for this objectification had been effected through the individual consciousness in its effort to surmount its limitations. Thus Feuerbach interpreted the Christian mysteries as symbols of the alienation of human properties absolutized as divine attributes, and he criticized the contradictions of theology that are found in such concepts as God, the Trinity, the sacraments, and faith. Man's reappropriation of his essence from such religious alienation is consummated in the "new religion" of humanity, of which the supreme principle is that "Man is God to man."

Feuerbach and Bauer

To this period belong also the major critiques of Bruno Bauer on the Johannine (1840) and Synoptic (1841–42) Gospels. Differentiating his position from the pantheistic and mysticizing Substance of Strauss, Bauer held that the Gospels were not the unconscious product of the original community but a product of the self-consciousness of the Spirit in a given stage of its development. There followed two works specifically concerning Hegel, in which, feigning an orthodoxy from which he charged Hegel with atheism and radicalism, Bauer maintained, in the form of a parody, the revolutionary interpretation of Hegel that became customary in the current of the Hegelian left.

Sociopolitical radicalism. In the years 1841–43, the repressive measures of the government reached ever more decisive extremes: Bauer was debarred from teaching; Feuerbach did not even attempt to teach; and Ruge was enjoined to publish the *Hallische* in Prussia instead of Leipzig. (Actually, he transferred it to Dresden and changed its name to the *Deutsche Jahrbücher.*) Here also appeared one of Ruge's major writings, "Die Hegelsche Rechtsphilosophie und die Politik unserer Zeit" (1842; "The Hegelian Philosophy of Right and the Politics of our Time"), in which Ruge denounced Hegel's political conservatism, charging that his contemplative reason was reduced to the acceptance of existing conditions, to the exclusion of every effort to modify reality, and to the absolutizing of the Prussian state as the model of an ideal state. Ruge's journal was suppressed early in 1843, but in March he published in Switzerland his *Anekdota zur neuesten deutschen Philosophie und Publicistik* ("Anecdotes for the Latest German Philosophy and Political Journalism"), containing articles by Bauer, Ruge, Marx, Feuerbach, and others.

Feuerbach's article developed the claim that the method of speculative philosophy, which is the ultimate form of theology, is to invert the subject and predicate—*i.e.*, to substantialize the abstract and to treat concrete determinations as attributes or "logical accidents" of hypostatized abstractions. The inversion of speculative propositions, he held, leads to the philosophical reappropriation of man's essence; the philosophy of the future will achieve mastery through the negation of the Hegelian philosophy —and this is exactly what he entitled his forthcoming book: *Grundsätze der Philosophie der Zukunft* (1843; "Basic Principles of the Philosophy of the Future"). In place of the immediate Absolute of Hegel, he argued, there must be substituted the immediate individual existent—corporeal, sensible, and rational. Man's reappropriation of himself will be possible whenever his need to transcend his own limitations finds fulfillment in another person and in the totality of the human species: "thus man is the measure of reason."

Meanwhile, a schism had been ripening in the left wing: (1) On the one hand, there were the "Free Berliners" (initially the young Friedrich Engels, later to become Marx's theoretician, the radical anarchist Max Stirner, and the Bauer brothers), who, deeming themselves faithful to Hegel, developed a philosophy of self-consciousness (understood in a subjective and superindividualistic sense) directed toward treating social and historical problems with aristocratic intellectual detachment. (2) On the other hand, there was the group that included Ruge, the publicist Moses Hess, the scholarly poet Heinrich Heine, and Karl Marx. Influenced in their theories by Feuerbach, this group directed radicalism toward an experience deepened by the classical Enlightenment and embraced the rising Socialism. They thus involved Hegel in their critique of the political, cultural, and philosophical conditions of the time. The most widely known result of the first trend was Stirner's book *Der Einzige und sein Eigentum* (1845; "The Individual and His Property"), in which the fundamental thesis of individualistic anarchism can be discerned. The unique entity, in Stirner's view, is the individual, who must rebel against the attempt made by every authority and social organization to impose upon him a cause not his own and must be regarded as a focus of absolutely free initiative—a goal to be reached by emancipating himself from every idea-value imposed by tradition.

The work of Marx

The years between 1840 and 1844, however, saw the emergence of a figure incomparably more representative of the crisis of German Hegelianism than any already cited, that of Karl Marx, who was destined to guide the experience of this crisis toward a revolution of world-historical scope. Marx's study of Hegel dates from his university years in Berlin, the earliest result of which was his doctoral dissertation with the exceedingly important preparatory notes, in which he ventured an original application of Hegelian method to the problem of the great crises in the history of philosophy. At first a friend of Bauer, Marx clung closely, however, to the democratic wing of the left. In 1843 he completed an important critical study of Hegel's *Philosophy of Right*, in which he reproached Hegel for having absolutized into an ideal state the Prussian state of the time. Such absolutizing, he charged, lent itself to generalizations of broad critical scope with respect to the idealistic procedure of hypostatizing the Idea and brought about (as allegorical deriv-

atives from it) certain concrete political and social determinations, such as family, classes, and the state powers. Not yet a Communist, Marx nonetheless completed, in his *Kritik der hegelschen Staatsrechts* (written in the summer of 1843, published 1929; "Critique of Hegel's Constitutional Law"), a criticism of the erroneous relationship initiated in Hegel between society and the state, which was destined to lead Marx from the criticism of the modern state to that of modern society and its alienation.

It will be recalled that Hegel had likewise proposed the concept of alienation, describing the dialectic as a movement of the Absolute that was determined by its alienating and then regaining itself (thus overcoming the self-negation). Already in the *Economic and Philosophic Manuscripts of 1844* (German ed., 1932; Eng. trans., 1959), Marx had enunciated a general critique of the Hegelian dialectic that revealed its a priori nature, which, in Marx's view, was mystifying and alienated inasmuch as Hegel did nothing but sanction, by a method inverted with respect to real relationships, the alienation of all the concrete historical and human determinations.

Marx then directed himself against his former colleagues on the left—against Bauer in his *Die heilige Familie* (1845; Eng. trans., *The Holy Family*, 1956) and against Stirner in his *Die deutsche Ideologie* (1845–46; Eng. trans., *The German Ideology*, 1938), criticizing their "ideologism" (*i.e.*, the illusion that Idealism can be carried into the revolutionary camp since it is ideas that make history). The historical Materialism that Marx counterposed against Idealism expressed the conviction that the basis comprising the relations of production, both economic and social, conditions the superstructure of political, juridical, and cultural institutions and that the interchange among these spheres of production within the totality of an historical epoch must be designed to overcome their contradictions. This Materialism, though not belonging any more to Hegelianism, was destined nonetheless to remain linked to it by continuing polemical relationships and overlapping problem areas throughout the subsequent history of the movement.

Along with Marx must, of course, be mentioned his colleague Friedrich Engels, who was more tied, however, to the Hegelian conception of the dialectic—particularly regarding the dialectic of nature—than Marx was.

HEGELIANISM THROUGH THE MID-20TH CENTURY

Development and diffusion of Hegelianism in the later 19th century. In Germany, the second half of the 19th century witnessed a decline in the fortunes of Hegelianism, beginning with the *Hegel und seine Zeit* (1857; "Hegel and His Age"), by Rudolph Haym, a historian of the modern German spirit. The decline was urged on by Neo-Kantianism and Positivism as well as by the political realism of Bismarck. Hegelian influences still appeared in the first representatives of historicism (which urged that all things be viewed in the perspective of historical change). The surviving Hegelians, however, such as Kuno Fischer and Johann Erdmann, devoted themselves to the history of philosophy. Strauss and the Bauer brothers were won over to conservatism, and even Ruge, returning from exile in England, became a conservative.

Decline in Germany

Political and cultural problems: East Europe and the U.S. The diffusion of Hegelianism outside of Germany was oriented in two directions. With respect to its political and cultural problems, the Hegelian experience developed in east European philosophers and critics such as the Polish count Augustus Cieszkowski, a religious thinker whose philosophy of action was initially influenced by the left; and the theistic metaphysician Bronisław Trentowski. Among the Russians can be cited the literary critic Vissarion Belinsky, the democratic revolutionary writers Aleksandr Herzen and Nikolay Chernyshevsky, and certain anarchists such as the Russian exile and revolutionist Mikhail Bakunin. And among the French there were Hegelian Socialists such as Pierre-Joseph Proudhon.

In the United States, the interest in Hegelianism was stimulated by its political aspects and its philosophy of history. Its two centres, the St. Louis and Cincinnati schools, seemed to duplicate the German schism between a conservative and a revolutionary tendency. The former was represented by the Hegelians of the St. Louis school: the German Henry Brokmeyer and the New Englander William Harris, a pedagogue and politician, and the circle that they founded called the St. Louis Philosophical Society, which published an influential organ, *The Journal of Speculative Philosophy*. Their legitimism, or support for legitimate sovereignty, was expressed in the quest for a foundation, dialectical as well as speculative, for American democracy and in a dialectical interpretation of the history of the United States. The Cincinnati group, on the other hand, gathered around August Willich, a former Prussian officer, and John Bernard Stallo, an organizer of the Republican Party. Willich had participated in the Revolution of 1848 as a democratic partisan in south Germany, and, as an exile, had been in lively intercourse with Marx. He founded the *Cincinnati Republikaner,* in which he reviewed Marx's *Zur Kritik der politischen Ökonomie* (1859) and endeavoured to base the principles of social democracy upon the humanistic foundations of Feuerbach. Stallo, on the other hand, tried to interpret the political philosophy of Hegel in republican terms. The democratic community became, for him, the realization of the dialectic rationality of the Spirit with a rigorous separation of church and state.

St. Louis and Cincinnati schools

Logic and Metaphysics: Italy, England. The second trend in non-German Hegelianism was directed, in Italy and in England, to problems of logic and metaphysics. A vigorously speculative rethinking of the foundations of Hegel's *Wissenschaft der Logik* was engaged in by the major liberal Italian philosopher Bertrando Spaventa and his associates. Spaventa's *Studi sull' etica di Hegel* (1869) consisted of a direct liberal translation of Hegel's *Philosophy of Right*. Seeking to rediscover the connection between the thinking of the Italians of the 16th century and that of the German Idealists, Spaventa encountered the system of problems involved in the relationship between Kant and Hegel. He adopted from Kuno Fischer the solutions by which Fichte, Schelling, and Hegel had rendered Kant's transcendental ego consummatively veritable. He thus proposed an epistemological (idealistic theory of knowledge) interpretation of the Hegelian logic, according to which one premise of the logic is the dialectic of consciousness described in Hegel's *Phenomenology of Mind*, and the problems of the genesis of logic are resolved in the sense that Being is, from first to last, Becoming; *i.e.*, it is thought in action, which negates the objective residue of thought-out Being and, for that reason, is confirmed as a creative process. From Spaventa, whose intention was to vindicate the freedom and autonomy of thought against denominational dogmatism, was derived the foundation for the subjectivistic formalization of Hegelianism soon undertaken by Giovanni Gentile, an early-20th-century Idealist.

As in Italy, so also in England, interest in Hegel arose from the philosopher's need to round out his experience of classical German thought by tracing its vicissitudes since the time of Kant; and this interest was directed toward the fields of epistemology and logic and in this instance was applied to problems of religion and not of politics. The pioneer in English Hegelianism was James Hutchison Stirling, through his work *The Secret of Hegel* (1865). Stirling reaffirmed the lineage of thought that Fischer had traced "from Kant to Hegel," endeavouring to penetrate the dialectic–speculative relationship of unity in multiplicity as the central point of the dialectic. Toward Hegelianism as a unifying experience the ethics scholar Thomas Hill Green, the foremost representative of Hegelianism at Oxford, applied himself, though with more original attitudes; and the brothers John and Edward Caird dedicated themselves to right-wing interpretations of religious subjects—Edward in a well-known monograph entitled *Hegel* (1883).

Hegelianism in the first half of the 20th century. At this point, the development of Hegelianism branched out in two directions: one of which, in England and Italy,

pursued the tendencies of the Neo-Hegelians of the preceding decades, while the other, in Germany and France, accomplished the philological interpretative renewal known as the Hegel renaissance.

Neo-Hegelianism in England and Italy. With respect to the first tendency, there appeared in England at the turn of the century various outstanding works on Hegel's logic by authors who were partly Hegelian in spirit. These scholars, toiling through the system of problems that they shared—which focussed on establishing a criterion for the unification of the multiplicity of experience—ended up in diverse positions: those of Bernard Bosanquet and John Ellis MacTaggart, for example, who were translators and commentators of Hegelian works; but above all that of the foremost spiritualistic philosopher then in England, F.H. Bradley, author of the renowned *Appearance and Reality* (1893), whose development led him to positions more and more at odds with the absolute panlogism of Hegel. His affirmation of the dualism of appearance and reality was the result of a critique of the category of relations, which, by introducing contradictions between the qualities of the thing, utterly shattered the unity of experience in which it might seem that true reality could be reached—a reality that in Bradley's view it is not given to thought to attain.

Bradley, Royce, Croce

The echoes of this Idealistic system were not long in being felt in the United States by one of its most profound philosophers, an absolute Idealist, Josiah Royce, who, in *The World and the Individual* (1900–01), discussed the skeptical Idealism of Bradley in order to overthrow its consequences in favour of a conception of the infinite as a self-representative system and of the world (or the All) as an individualized realization of the intentional aims of the Idea copresent in a superior eternal consciousness. In Anglo-Saxon Neo-Hegelianism, the Hegelian experience has always been merely an episode—which fact serves to refine, by contrast, the methods of experimentalism that are more congenial to the Empirical tradition in England.

In Italy, on the other hand, the Neo-Hegelianism of the 20th century took the form of a spiritualistic reaction to the spread of Positivism that had followed upon the unification of Italy. This reaction developed in two directions: that of the historicism of Benedetto Croce and that of the actualism of Giovanni Gentile, two scholars who divided the realm of philosophy between themselves and occupied it—rather heavy-handedly—for four decades. The Crocean reform of Hegelianism dates from his volume *Ciò che è vivo e ciò che è morto della filosofia di Hegel* (1907; "What Is Living and What Is Dead in the Philosophy of Hegel") and from the systematic works of his so-called "philosophy of the spirit." Croce accepted the dialectic from Hegel as a requirement for the unification of opposites; but he rejected its system, in which Hegel would put in opposition and treat dialectically certain intellectual forms that are not really opposite but only distinct—such as the beautiful, the true, the useful, and the good, each of which has its dialectical opposite over against itself that it has to overcome within the purview of each grade. Consequently, renouncing the possibility of a philosophy of nature or of history, Croce formulated a development of so-called "distinct grades" according to the spiritual forms of art, of philosophy, of economics, and of ethics and contended that the comprehensive meaning of the development of the Spirit is given by history "as thought and as action" and a realization of freedom.

Gentile, on the other hand, accentuated the opposition of subject and object by considering every objective factuality as surpassed by the living dialectical development of the act—*i.e.*, the becoming of the Spirit in its own self-making, proceeding from an originating self-establishment, or *autoktisis*, of the Spirit itself. From this position he derived an absolute subjectivism that exploited all the possibilities for dialectically transforming every fixed position into its opposite, a downright sophistry of disengagement. Gentile's pro-Fascist stance, however, condemned his actualism to collapse.

Hegelian renaissance in Germany and France. Already from the beginnings of the century, however, there had been in Germany a change in Hegelian interpretation instigated by Wilhelm Dilthey's re-examination, in 1905, of the youthful manuscripts of Hegel and by the publication by one of Dilthey's principal disciples, Herman Nohl, of *Hegels theologische Jugendschriften* (1907; "The Theological Writings of Hegel's Youth"). Inasmuch as there had been heretofore only fragmentary notices on these unpublished literary remains, the effect of this rereading of the texts was to place them in contrast with the works of his maturity; they thus emerged as dealing, for the most part, with various problem areas in ethics, religion, and history; as lacking systematic preoccupations; and as rich discourse, tending to the mystic, which invited their comparison with the severe technical uniformity of his major works. Hermeneutical interest, however, centred especially on the problem of the beginnings of the philosophy and dialectic of Hegel, of which the first formulations were investigated in order to collate their meanings with those of the major works and of the *Phenomenology*, which was a key work of the Hegelian evolution inasmuch as it participated both in the romanticized colouring of the youthful writings and in the systematic demands of the *Encyklopädie der philosophischen Wissenschaften im Grundrisse*.

Publication of the *Jungendschriften*

Scholars were soon led to investigate the historical matrices of Hegel's intellectual culture—the late Enlightenment and dawning Romanticism—a direction of inquiry that yielded imposing contributions rich in discussions that continue to this day. These studies began with Dilthey's monograph, which pointed out the irrationalistic and vitalistic aspects of Hegel's youthful writings. In addition, a basic work by Franz Rosenzweig, *Hegel und der Staat* (1920), genetically reconstructed the political thought of the young Hegel in relation to its historical sources and concluded that the influence of Rousseau prevented Hegel from becoming the genuine "national philosopher of Germany." Jean Wahl, a French metaphysician and historian of philosophy, wrote on the "wretched conscience," interpreting Hegel existentially. Further, the German philosopher Richard Kroner studied the development from Kant to Hegel integrating it with the contributions of early Romanticism. And Hermann Glockner, a Bavarian aesthetic intuitionist, saw following one another in the development of Hegel a so-called "pantragistic" phase up to the *Phenomenology* and, subsequently, an opposing "panlogistic" phase that betrayed the most lively and concrete instances of the preceding phase—a work that approached the efforts at interpreting Hegel that were made by the Nazis.

HEGELIAN STUDIES TODAY

Today one has to speak not of the presence of Hegelianism as an operating philosophical current but only of studies on Hegel and of an experience of the Hegelian philosophy, to which, however, almost none of the present-day orientations in philosophy is foreign. The repeated encounter of Western culture with Marxist thought after World War II has brought to the fore the political, ethical, and religious implications of Hegelianism; and a marshalling into opposing camps analogous to that of the earlier crisis of the school is taking shape. Today there are no orthodox Hegelians, but there are denominational critics of Hegelianism, especially Catholic, whose cognizance of Hegel's painful development invokes, despite their differences, a certain fellow feeling with him.

In the centre are found scholars of a liberal and radical frame of mind but with varying orientations with respect to historical interpretations. Karl Löwith, a German philosopher of history and culture, sees Hegel as the initiator of the "historicist" crisis in modern thought, culminating in Marx and in Kierkegaard; and to this he contrasts the metahistorical perspective reflected in the Nietzschean motif of the "eternal return," based on the ideal of a Goethean serenity. In France, Alexandra Kojève, noteworthy for his effort to harmonize Hegel with Martin Heidegger, proposes a reinterpretation of the *Phänomenologie* as a manifesto of the emancipation of "man the servant" from all alienations. Jean Hyppolite, author

of an outstanding commentary on the *Phänomenologie*, usually presents a restrained humanistic interpretation of the Hegel of Jena. This renaissance of the study of Hegel has conditioned the thought of some of the major thinkers of France. Particularly notable, however, is the Hegelian conditioning of German philosopher-sociologists such as Theodor Wiesengrund Adorno and Herbert Marcuse. The former is sometimes regarded as the most Hegelian thinker of the mid-20th century because he sought to bring again to the fore Hegel's dialectic, understood in a new anti-intellectualistic sense, as a method for the solution of present-day social problems. Marcuse, a partisan of a Diltheian interpretation, approaches the position of the first Hegelian left, ending up in what critics see as a neoromantic anarchism. The major merit of both of these thinkers lies in their incisive analyses of aspects of modern consumer societies, especially American—though their proposed remedies remain uncertain.

Three currents of Marxist interpretation

The major interest, however, in the contemporary interpretation of Hegel is displayed by the Marxist camp. Marxist interpretation of Hegel had permeated the entire history of Hegelianism (notwithstanding the fact that the critical activity of young Marx against Hegel had been vehemently conducted and had led to various effects). This interpretation had settled upon the distinction made by Engels between the method and the system of Hegel's philosophy—*i.e.*, between the dialectic considered as a revolutionary "principle of movement" that achieves fulfillment in human culture and regarded, on the other hand, as reactionary because idealistic and conservative. With varying emphases on critical issues, this interpretation was continued in subsequent Marxist thinkers—from the Russians Georgy Plekhanov and Lenin to Mao Tse-tung and Stalin—the latter of whom affirmed the complementariness of historical and dialectical Materialism.

Today many Marxist scholars, especially in the countries of eastern Europe, remain favourable to the traditional line of Engels; and above all György Lukács, a Hungarian philosopher and literary critic and author of a volume on the young Hegel, does so. With the intention of revealing the romantic and irrationalistic presuppositions of Naziism, Lukács re-evaluates, in German culture, the tendency of the Enlightenment and of democracy, which he recognizes in the young Goethe, in Schiller, in Hölderlin, and in the young Hegel—in whom he sees, however, a reactionary involution.

A secondary tendency, which is drawing attention in France, with the work of Louis Althusser, draws Marx close to Structuralism, a recent school that seeks, through a "human science," to probe the systematic structures evinced in cultural life. In this school Marx's humanism is viewed as a temporary, Feuerbachian phase, surpassed by commitment to the scientific observation of the structure of bourgeois society. Such Structuralistic interpretation of Marxism thus runs the risk of departing from a due emphasis on the *historical* substance of Marxian Materialism.

The latter motive is, on the other hand, the essential aim of a third Marxist current, in Italy, initiated by Galvano della Volpe, a critical aesthetician who discusses the relationship between bourgeois and Socialist democracy and champions, in aesthetics, a critical and antiromantic Aristotelianism. This current has been continued by Mario Rossi, who asks one to read again in full the texts of Hegel and Marx, to reconstruct the related movements, and to compare the Materialistic conception of history with more recent philosophical currents such as Structuralism, present-day sociology, and the logic of the sciences.

A conclusion of a theoretical–systematic nature concerning Hegelianism has today become not only impossible but also inopportune, because its possible interest has been effectively replaced by that of the sheer history of the movement. The latter has shown how the substantial ambiguity of the philosophy and dialectic of Hegel can be resolved only when its claim to be able to solve all problems on a theoretical level and to achieve a "circular" decisiveness in its arguments—which violates the conditioning specificity of historical facts—is refuted. It is then the scholar's task to explore the limits of Hegel's thought as well as its conditioned inadequacies—but also its merits, which are above all those of having expressed and documented the major part of the cultural problems of modern civilization.

BIBLIOGRAPHY

Critical works: Works presenting a critical consideration of Hegelianism viewed as a whole are very few. See, however: STEPHAN D. CRITES, "Hegelianism," in the *Encyclopedia of Philosophy*, vol. 3, pp. 451–459 (1967); MARIO ROSSI, *Introduzione alla storia delle interpretazioni di Hegel* (1953), and *Da Hegel a Marx*, 2 vol. (1970); and RENE SERREAU, *Hegel et l'hégélianisme*, 3rd ed. (1968).

Historical works: J.E. ERDMANN, *Darstellung der Deutschen Philosophie seit Hegels Tode* (1963); WILLY MOOG, *Hegel und die Hegelsche Schule* (1930); KARL LOWITH, *Von Hegel zu Nietzsche*, 3rd ed. (1953; Eng. trans., *From Hegel to Nietzsche: The Revolution in Nineteenth-Century Thought*, 1964); the two anthologies edited by KARL LOWITH, *Die Hegelsche Linke* (1962), and HERMANN LUBBE, *Die Hegelsche Rechte* (1962), on the Left and Right, respectively.

In various countries: (*Germany*): HEINRICH LEVY, *Die Hegel-Renaissance in der deutschen Philosophie* (1927). (*Italy*): MARIO ROSSI (ed.), *Sviluppi dello Hegelismo in Italia* (1957); BENEDETTO CROCE, *Saggio sullo Hegel*, 5th ed. (1967). (*Slavic countries*): Contributions of authors from Russia, Poland, the Balkans, and Czechoslovakia are presented in *Hegel bei den Slaven*, 2nd ed., ed. by DMITRIJ TSCHIZEWSKIJ (1961); see also BORIS JAKOWENKO, *Ein Beitrag zur Geschichte des Hegelianismus in Russland* (1934). (*England*): HIRA-LAL HALDAR, *Neo-Hegelianism* (1927). (*United States*): LOYD D. EASTON, "Hegelianism in Nineteenth-Century Ohio," *Journal of the History of Ideas*, 23:355–378 (1962), for the Cincinnati school; HENRY A. POCHMANN, *German Culture in America: Philosophical and Literary Influences 1600–1900*, pp. 257–294 (1957), for the St. Louis school.

Other works: A. CORNU, *Karl Marx et Friedrich Engels*, 2 vol. (1955–58), is very rich in materials and citations from the *Hallische* and *Deutsche Jahrbücher*. See also HERBERT MARCUSE, *Reason and Revolution: Hegel and the Rise of Social Theory*, 2nd ed. (1954); SIDNEY HOOK, *From Hegel to Marx* (1950); and *The Monist*, vol. 48, no. 1 (1964), of which the entire issue is on the topic "Hegel Today."

(M.R.)

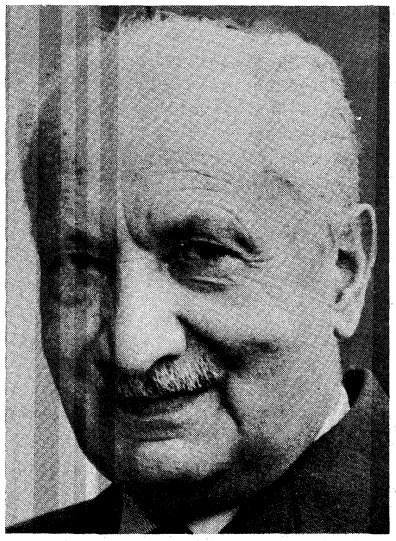
Heidegger, Martin

Martin Heidegger has been called the most original thinker in the field of contemporary German philosophy. As a leading exponent of Existentialism in the broad sense of that term, he exerted a profound influence on a younger generation of continental European cultural personalities. A critic of technological society and of the role of science, Heidegger has no place for God, whose absence nevertheless plays an important role in his thinking. He does not exalt human goals but sees human existence as a cult of Being—a notion not very unlike certain notions of God. Heidegger invented a strange and difficult vocabulary in order to obviate the trivializing effect of traditional philosophic jargon; but he believed, on the other hand, that some of the most common words, like "to dwell" and "to see," can reveal basic truths about man's existence. Heidegger has made the study of human existence subservient to more profound purposes—to the quest for the meaning of Being conceived as the fundamental principle of reality. This concern is also revealed in the central issue explored in his *Einführung in die Metaphysik* (1953; Eng. trans., *An Introduction to Metaphysics*, 1959); namely, the question "Why is there anything at all and not rather nothing?" Heidegger is thus the most influential ontologist, or student of "Being" as Being, among contemporary philosophers.

Background and youth. Heidegger was born September 26, 1889, in the small town of Messkirch, in Baden, southwest Germany. The son of a Catholic sexton, Heidegger showed an early interest in religion and, upon finishing high school, joined the Jesuits as a novice.

His education

At the University of Freiburg, he studied Catholic theology and medieval Christian philosophy. In fact, his interest in philosophy had already begun when, at secondary school, he started an intensive study of the late 19th-



Heidegger.
Camera Press—Pix

century Catholic philosopher Franz Brentano, author of a "descriptive" psychology, as presented in Brentano's *Von der mannigfachen Bedeutung des Seienden nach Aristoteles* (1862; "On the Manifold Meaning of Being According to Aristotle").

For the rest of his life Heidegger was to contemplate the possibility that there is a basic sense of the verb "to be" that lies behind its variety of usages. From his early study of Brentano also stems his enthusiasm for the Greeks, especially the pre-Socratics, whose thought marks the dawning of the penetrating reflection that transpired before the cleavage of thinking into poetry, philosophy, and science occurred.

The philosophy of Heidegger is obviously dependent upon the philosophers prior to Socrates, upon Plato and Aristotle, and upon the Gnostics, who claimed secret knowledge. He was particularly influenced, however—positively or negatively—by several 19th- and early 20th-century philosophers: by the Danish theological thinker Søren Kierkegaard and the Dionysian vitalist Friedrich Nietzsche, founders of Existentialism; by the historical vitalist Wilhelm Dilthey, noted for directing the attention of philosophers to the human and historical sciences; and by the founder of Phenomenology, Edmund Husserl.

When still in his 20s, Heidegger studied at Freiburg with Heinrich Rickert, later of the southwest school of axiological Kantianism, and with Husserl, who was then already famous; and for five years he was schooled in the Phenomenological method, in which the philosopher closely examines immediate experience and its objects in their essential aspects. Husserl's Phenomenology, and especially his struggle against the intrusion of psychology into essential studies of man—which he felt should, instead, be conducted on the philosophical level—determined the background of the young Heidegger's doctoral dissertation, completed in 1914. Consequently, what Heidegger later said and wrote about anxiety, thinking, forgetfulness, curiosity, distress, care, or awe was not meant as psychology; and what he said about man, publicness, and other-directedness was not intended to be sociology, anthropology, or political science. His utterances were meant, instead, to disclose ways of Being.

His magnum opus: "Being and Time." Heidegger started teaching at the University of Freiburg during the winter semester of 1915 and earned his habilitation through a study of the 13th-century British Franciscan philosopher Duns Scotus. In this position, now as a colleague of Husserl, Heidegger was expected to carry the Phenomenological movement further along within the spirit of his former master. As a religiously inclined young man, however, he went his own way instead and in 1927 astonished the German philosophical world with an almost unreadable work, *Sein und Zeit* (Eng. trans., *Being and Time*, 1962)—a work that, however, was immediately felt to be of prime importance, whatever its relation to Husserl might be. In spite of, or perhaps partly because of, its intriguingly difficult style, this book, which was Heidegger's magnum opus, was acclaimed as a deep and important work not only in German-speaking countries but also in Latin countries, where Phenomenology was already well known. It strongly influenced Sartre in France and other Existentialists; and despite Heidegger's protestations, he was classed, on the strength of this book, as the leading atheistic Existentialist. Its reception in the English-speaking world, however, was rather chilly, and its influence negligible until the 1960s. Since then, more and more universities have offered courses on Heidegger, and careful translations and commentaries have begun to appear. The influence of this book up to 1970 was still profound, but hardly stirring.

Heidegger's notion of the meaning of Being

In *Being and Time*, Heidegger's declared purpose is to bring to light what it means for a man to be, or, more accurately, *how* it is to be. This leads to a more fundamental question: what it means to ask "What is the meaning of Being?" These questions lie behind the obviousness of everyday life and, therefore, also behind the empirical questions of natural science. They are usually overlooked because they are too near to be grasped in everyday life. One might say that the whole prophetic mission of Heidegger amounts to making each man ask that question with maximum involvement. Whether he will ever arrive at any definite answer or not is, in the present crisis of mankind, of secondary importance.

This crisis, according to Heidegger, stems from a deep fall (*Verfall*) that Western thought has undergone, owing to a one-sided technical development, a development that results in alienation (*Entfremdung*), or, as expressed in terms more central to Heidegger's thought, in a "highly inauthentic way of being." Fallenness, or inauthenticity, belongs to the inescapable way of human existence; *i.e.*, it is an existential, an essential, potentiality (*Möglichkeit*), but epochs and individuals may be coloured by it in different degrees. This somewhat stern outlook has been mitigated, however, in Heidegger's later writings, in which he suggests that there are possibilities of redemption by "thinking of Being" and, thus, again coming closer to Being—a process in which, he believes, continental European rather than Eastern or Western countries are to lead the way.

The wealth of ideas contained in *Being and Time* is best discussed, however, in conjunction with those developed in another, short work, *Was ist Metaphysik?* (1929; Eng. trans., *What is Metaphysics?*, 1949). At the time of publishing *Being and Time*, Heidegger had been a professor ordinarius at Marburg for several years (since 1923). He resigned that post and, in 1928, returned to Freiburg, this time as Husserl's successor. *What Is Metaphysics?* was Heidegger's inaugural lecture; it elaborates one of his favourite themes, *das Nichts* ("nothing"); *i.e.*, the no-thing (see below).

Phenomenological and etymological methods

As Heidegger learned from Husserl, it is the phenomenological and not the scientific method that unveils man's ways of Being. Thus, in pursuing this method, Heidegger comes into conflict with the dichotomy of the subject–object relation, which has traditionally implied that man, as knower, is something (some-thing) within an environment that stands over against him. This relation, however, must be transcended. The deepest knowing, on the contrary, is a matter of *phainesthai* (Greek: "to show itself" or "to be in the light"), the word from which phenomenology, as a method, is derived. Something is just "there" in the light. Thus, the distinction between subject and object is not immediate but comes only later through conceptualization, as in the sciences.

As an aid in the effort to get back to "Thinking of Being" and its redemptive effects, Heidegger employs linguistic or hermeneutical techniques. He develops his own German, his own Greek, and his own kind of etymologies. He coins, for example, about 100 new complex words ending with "-being." In reading his works one must, thus, translate many of its key terms back into Greek words and then consider his free, often very spe-

cial (but never uninteresting), interpretations and etymologies.

Man stands out (*ex-sists*, not merely *ex-ists*) from things, says Heidegger in *Being and Time*, never being completely absorbed by them, but nevertheless being nothing (no-thing) apart from them. Man dwells in a world that he has been and continues to be thrown into until death. Being thrown into things, being-there (*Da-sein*), he falls away (*Verfall*) and is on the point of being submerged into things. He is continually a pro-ject (*Ent-wurf*); but periodically, or even normally, he may be submerged in things to such a degree that he is temporarily absorbed (*Aufgehen in*). He is then nobody in particular; and a structure that Heidegger calls *das Man* ("the they") is revealed, which recalls certain Anglo-American sociological criticisms of modern industrial society that stress man's "other-directedness," his tendency to measure himself in terms of his peers. But Heidegger's phenomenological metaphors avoid social science terms as much as possible in favour of ontological terms. Characteristic of *das Man* are idle talk (*Gerede*) and curiosity (*Neugier*). In *Gerede*, talker and listener do not stand in any genuine personal relation or in any intimate relation to what is talked about; hence, it leads to shallowness. Curiosity is a form of distraction, a need for the "new," a need for something "different," without real interest or capability of wonder.

Anxiety and freedom

But there is a mood, anxiety or dread (*Angst*), that functions to disclose (dis-close) authentic being, freedom (*Frei-sein*), as a potentiality. It manifests the freedom of man to choose himself and take hold of himself. The relevance of time, of the finiteness of human existence, is then experienced as a freedom to meet his own death (*das Freisein für den Tod*), a preparedness for and continuous relatedness to his own death (*Sein zum Tode*). In anxiety, all entities (*Seiendes*) sink away into a "nothing and nowhere," man hovers in himself as ex-sisting, being nowhere at home (*Un-heimlichkeit, Un-zu-hause*). He faces no-thing-ness (*das Nichts*); and all average, obvious everydayness disappears—and this is good, since he now faces the potentiality of authentic being.

Thus, the "sober" (*nüchtern*) anxiety and the implied confrontation with death are for Heidegger primarily of methodological importance: fundamentals are revealed. Among the structures revealed are potentialities for being joyfully active (". . . knowing joy [*die wissende Heiterkeit*] is a door to the eternal"). Anxiety opens man up to Being. But this does not imply that Being partakes in the dark aspect of dread; Being is associated with "light" and with "the joyful" (*das Heitere*). Being "calls the tune"; "to think Being" is to arrive at one's (true) home. Though Heideggerian students are often baffled by just what Being and thinking stand for, it is clear that Heidegger opposes a mere cult of mankind and wishes to call attention to something greater.

Later life. In the early 1930s, there occurred an event in the thought of Heidegger that scholars call his *Kehre* ("turning around"), which is said by some specialists to involve a turning away from the problem of *Being and Time*. This was denied by Heidegger himself, who insisted that he had been asking the same basic question since his youth. But in his later years he clearly became more reluctant to offer any answer. He did not even indicate a way in which to reach an answer to the basic problem of *Being and Time*.

At about the time of the *Kehre*, there also occurred Heidegger's short but eloquent pro-Nazi participation in the cultural politics of the Third Reich, which became a matter of considerable controversy. Even before Hitler assumed power in November 1933, German universities were exposed to heavy pressures. They were supposed to support the "national revolution" and eliminate Jewish scholars and doctrines (such as relativity). The anti-Nazi scientist who had been the rector at Freiburg resigned in protest, and the teaching staff unanimously elected Heidegger as his successor.

Heidegger's inauguration speech ("The German University's Self-Affirmation") was widely declared to be an affirmation of Nazism. To be sure, he divided student tasks into work service, military service, and scientific service; but this fell within the area of the authoritarian educational policy of Plato; and the speech ended not with a "*Heil*, Hitler!" but with a quotation from Plato's *Republic:* "All great things stand in peril." The speech turned against scientific specialization; it urged the asking of the question "What is it to be?"; and it warned against losing oneself in "things" (*Seiendes;* opposite *das Sein*). On other occasions, however, Heidegger gave solidly pro-Hitler speeches. "The Führer himself," he said, "and he alone is the German reality, present and future, and its law." In short, Heidegger succumbed to Hitlerism, but not to Nazi cultural policy or philosophy.

Under some pressure, Heidegger joined the Nazi Party and did not try to leave it. His relations to the party, however, and to the whole Nazi environment rapidly deteriorated. He resigned as rector as early as the beginning of 1934. After World War II, Heidegger characterized Hitlerism as the historical explosion of a structural sickness in mankind as a whole and expressed concern that it would take time to get rid of the poison.

In November 1944 Heidegger terminated his university lectures, and in 1945 the occupying powers forbade him to take up official lecturing again. He was "investigated"; but his support of Hitler in 1933–34 was not found to be of the serious, "active" kind, and he did not lose his professional rights. His status remained a matter of controversy, however, until he reached the age of retirement in 1959. Nevertheless, he gave influential regular lectures in the years 1951–58, and his attitude in 1933–34 did not affect his strong position within the international Phenomenological movement.

Evaluation

Perhaps the specific pretension of Heidegger's phenomenological method rests on a grandiose illusion, and perhaps the search for thinking Being is merely a disguised quest for a kind of belief in God; perhaps his abstruse terminology is only a mask covering and mystifying a more traditional approach. Such irreverent evaluations would scarcely be unsympathetic to Heidegger, if joined with the intent to verify or falsify it by genuinely following his own path through his writings. After all, he asks, or rather, provokes, us *to question*, not to listen to any answers. It is, therefore, misleading to present Heidegger's philosophy as a set of clearly understandable results. His metaphors must remain, rather than be translated into a usual philosophical terminology that he rejected.

Heidegger preferred to live in his retreat in the Black Forest and in his last years had few followers in his effort to think Being. He died in the town where he was born on May 26, 1976.

MAJOR WORKS

"Das Realitätsproblem in der modernen Philosophie," *Philosophisches Jahrbuch der Görresgesellschaft*, 25 (1912); *Die Lehre vom Urteil im Psychologismus: Ein kritisch-positiver Beitrag zur Logik* (1914); *Die Kategorien- und Bedeutungslehre des Duns Scotus* (1916); "Der Zeitbegriff in der Geschichtswissenschaft," *Zeitschrift für Philosophie und philosophische Kritik*, 161 (1916); *Sein und Zeit: Erste Hälfte*, first as a contribution to the *Jahrbuch für Philosophie und phänomenologische Forschung*, 8 (1927), then as a separate book (1927; 11th ed., 1967; *Being and Time*, 1962); *Kant und das Problem der Metaphysik* (1929; Eng. trans. by James Churchill, *Kant and the Problem of Metaphysics*, 1962); *Vom Wesen des Grundes* (1929; *The Essence of Reasons*, 1969); *Was ist Metaphysik?* (1929; 10th ed., 1969; "What Is Metaphysics?" in the selective volume *Existence and Being*, ed. by W. Brock, 1949); *Die Selbstbehauptung der deutschen Universität* (1933); *Hölderlin und das Wesen der Dichtung* (lecture of 1936, printed 1937; Eng. trans. in *Existence and Being*); *Platons Lehre von der Wahrheit*, first as a contribution to *Geistige Überlieferung* (1942), then in book form (1947), Eng. trans. in William Barrett and H.D. Aiken (eds.), *Philosophy in the Twentieth Century*, vol. 2 (1962); *Vom Wesen der Wahrheit* (1943, from lectures given 1930–32; 4th ed., 1961; Eng. trans. in *Existence and Being*); *Erläuterungen zu Hölderlins Dichtung* (1944; 3rd ed., 1963); *Brief über den "Humanismus,"* first with *Platons Lehre . . .* (1947), then separately (1949), Eng. trans. in *Philosophy in the Twentieth Century; Holzwege* (1950; 4th ed., 1963); *Einführung in die Metaphysik* (1953; 3rd ed., 1967; *An Introduction to Metaphysics*, 1959); *Der Feldweg* (1953; 4th ed.,

1969); *Vorräge und Aufsätze* (1954; 3rd ed., 1967); *Was heisst Denken?* (1954; *What is Called Thinking?*, 1968); *Aus der Erfahrung des Denkens* (1954); *Was ist das—die Philosophie?* (1956; *What Is Philosophy?*, 1958); *Zur Seinsfrage* (1956; *The Question of Being*, 1958); *Der Satz vom Grund* (1957); *Identität und Differenz* (1957; *Essays in Metaphysics: Identity and Difference*; 1960); *Unterwegs zur Sprache* (1959; *On the Way to Language*, 1971); *Der Ursprung des Kunstwerkes*, (1960; Eng. trans. in A. Hofstadter and R. Kuhns [eds.], *Philosophies of Art and Beauty*, 1964); *Nietzsche*, 2 vol. (1961); *Die Frage nach dem Ding: Zu Kants Lehre von den transzendentalen Grundsätzen* (1962; *What Is a Thing?*, 1967); *Kants These über das Sein* (1962).

BIBLIOGRAPHY. H. ALBERT, *Traktat über kritische Vernunft* (1968), a very competent critique of Heidegger's conception of cognition as revelation and of the general tradition to which it belongs; A. DE WAELHENS, *La Philosophie de Martin Heidegger*, 5th ed. (1967); H. FEICK, *Index zu Heideggers Sein und Zeit* (1961), a useful collection of definitions and a survey of occurrences of key terms, not severely restricted to *Sein und Zeit;* M. GRENE, "Heidegger, Martin," in P. EDWARDS (ed.), *Encyclopedia of Philosophy*, vol. 3 (1967), a courageous attempt to furnish an understandable translation and a concentrated survey of Heideggerian conceptions (perhaps too far removed, however, from the German tradition); H. LUBBE, "Bibliographie der Heidegger-Litteratur 1917–1955," *Zeitschrift für Philosophische Forschung*, vol. 11 (1957), excellent; G. LUKACS, "Heidegger redivivus," in *Sinn und Form*, 1:37–62 (1949), an influential philosophical and Marxist evaluation of the work and influence of Heidegger by a brilliant theoretician; J. MACQUARRIE, *An Existentialist Theology: A Comparison of Heidegger and Bultmann* (1955), an interpretation of Heidegger's system as a partial rediscovery of fallenness, care, death, and guilt—of the biblical understanding of man; A. NAESS, "Heidegger," in *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre* (1968), an introduction along the lines of the present article; O. POGGELER, *Der Denkweg Martin Heideggers* (1963), perhaps the most Heideggerian initiation to Heidegger's thinking; W.J. RICHARDSON, *Heidegger: Through Phenomenology to Thought*, with preface by Heidegger (1963), a useful reference, indispensable for advanced study, though not more difficult than others within the phenomenological tradition; G.J. SEIDEL, *Martin Heidegger and the Pre-Socratics: An Introduction to His Thought* (1964), a clear account of an obscure theme with penetrating critical conclusions and bibliography.

(A.D.N.)

Heilungkiang

Heilungkiang (Hei-long-jiang in Pin-yin romanization), the northernmost province of China's Northeast Region (formerly known as Manchuria), is bounded on the north and east by the Union of Soviet Socialist Republics along the Hei-lung Chiang (Hei-lung River)—known in the Soviet Union as the Amur River—and Ussuri River (Wu-su-li Chiang), on the west by the Inner Mongolian Autonomous Region of China, and on the south by the Chinese province of Kirin. The name of the province is derived from Hei-lung Chiang (Black Dragon River). The province has an area of about 272,300 square miles (705,300 square kilometres), including the administrative area of Hu-lun-pei-erh-meng (Hulunbuir League), which was transferred to it from the Inner Mongolian Autonomous Region in 1969. Late in the 1950s the population was over 14,000,000; in 1970 it was estimated at 25,000,000. The capital is Harbin.

Heilungkiang occupies about three-fifths of the area of the three Northeast provinces and has about one-third of this region's population. All but about 8 percent of its population are Chinese; the rest are Manchus, Mongolians, Koreans, Hui (Chinese Muslims), and other small groups. The long international border with the Soviet Union has been the scene of Sino-Russian clashes from the 17th century into the 1960s.

HISTORY

Early peoples of the province

The prehistoric population of the region appears to have consisted of people who bred pigs and horses; known as Tungids, they occupied much of northeastern Asia. Stone Age fishermen, the Sibirids and Ainoids, lived along the rivers and coast. Northern Manchuria remained until the 19th century an undeveloped steppe and forest region occupied by a few primitive nomadic tribes. In 1650 the Russians built a fort on the Amur River, which the Chinese regarded as their territory. Consequently, they destroyed the fort in 1685. In 1689 the Treaty of Nerchinsk was signed between Russia and China, recognizing Chinese dominion over both banks of the Amur, extending to its mouth and Sakhalin Island. Russian expansion was thus checked for almost two centuries.

In 1858 Russia annexed the region north of the Amur River to its mouth and two years later the region east of the Ussuri River to the Sea of Japan, including the important seaport of Vladivostok (Hai-sheng-wei) and the Ussuri–Amur river port of Khabarovsk (Pai-li). The Russians occupied Heilungkiang from 1900 to 1905 and maintained their domination—despite their defeat by Japan in the Far East in 1904–05—because of Russian control of the strategic Chinese Eastern Railway, running through the region from west to east. After the 1917 Russian Revolution, the Bolsheviks renounced special privileges in northern Manchuria as a friendly gesture toward China. The province remained under Chinese control until Japan invaded Manchuria on September 18, 1931. Heilungkiang became a part of the Japanese puppet state of Manchoukuo from 1932 to 1945. On August 15, 1945, just before Japan's unconditional surrender, Soviet troops entered Manchuria, but they evacuated it later to make way for the Chinese People's Liberation Army. After the Sino-Soviet rift in 1960, border clashes occurred repeatedly along the international border. (For a detailed description of the provincial capital, see HARBIN.)

THE NATURAL ENVIRONMENT

Physical features. The province of Heilungkiang occupies more than half of the huge Manchurian Plain, surrounded on three sides by old mountain ranges of medium elevation. Its central part is the Sungari–Nen river plain, delimited by the Greater Khingan Range (Ta-hsing-an-ling Shan-mo) on the west, the Lesser Khingan Range (Hsian-hsing-an-ling Shan-mo) on the north, and the Chang-kuang-ts'ai Ling (Chang-Kuang-t'sai Mountains) and the Lao-yeh Ling (Lao-yeh Mountains) on the east. The general elevation of the southern part of the Greater Khingan Range is around 3,000 feet above sea level; the elevation gradually drops toward the northeast to about 1,600 feet at its junction with the Lesser Khingan Range.

Mountain ranges

The Greater Khingan Range is composed mainly of igneous rocks resistant to erosion and weathering. Glaciers toward the end of the Tertiary Period (10,000,000 to 2,500,000 years ago) dug U-shaped valleys through which the tributaries of the Amur run. The structure of the Lesser Khingan Range is more complex. Its northern part is composed of granite, volcanic basalt, and other metamorphic rocks. The average elevation is about 2,300 feet; the granite peaks near I-ch'un rise to about 3,770 feet. The western slope facing the Nen Chiang (Nen River) is gentle, while the eastern slope is steep. The southern end of the Lesser Khingan is composed of archlike, folded, stratified rock. The highest peaks may reach 3,280 feet or more, but the hills are generally lower. The valleys of the foreland are often broad and smooth, dotted with swamps. The rolling Sungari–Nen Chiang plain, at an elevation of 490 to 600 feet, has many bogs and swamps. In contrast, sand dunes occur in the drier western part of the plain.

The Hei-lung Chiang (Amur) is the longest stream in the province. Its upper and middle sections serve as the international boundary for a distance of 1,180 miles. Its average frozen period is 178 days at Hei-ho and 183 days at Mo-ho. Its chief tributary, the 1,159-mile-long Sungari River, is the main waterway of the province, however. It has two sources: the second Sungari River, originating in Kirin Province, and the Nen Chiang, originating on the border of Inner Mongolia. The two streams join at San-ch'a Ho (Three-Prong River). The Sungari drainage system covers an area of 202,154 square miles, most of which lies within the province.

The Ussuri River forms the Sino-Soviet boundary on

the east. It flows along a longitudinal valley between mountains. It is a broad, slow-moving river and has a tributary linking it with Lake Khanka (Hsing-k'ai Hu), the largest freshwater lake in East Asia (1,691 square miles). Only a quarter of the lake, which is on the Sino-Soviet border, belongs to China.

Climate and soils. The province has severe winters, lasting five to eight months. Summer is short but coincides with the rainy season, making it possible to raise temperate crops in most areas. There are considerable regional differences in climate. The northwest has a cold, wet, temperate climate with very cold winters; summer thaw is only superficial. Hu-ma, at the confluence of the Amur River and its tributary, the Hu-ma-erh Ho, has a mean temperature of −17.7° F (−27.6° C) in January. The July mean temperature is 74.5° F (23.6° C). There are only four months with mean temperatures over 50° F (10° C).

A temperate, wet climate prevails in the eastern section, in the drainage basin of the Ussuri River and the lower Sungari River. In the central core of the province the climate is temperate, with a deficiency of water and very severe winters. Nen Chiang, in the northern Tung-pei plain, 728 feet above sea level, has a mean temperature of −15.9° F (−26.6° C) in January, and 70° F (21.1° C) in July. The mean annual precipitation is 20 inches, most of which falls during the active growing season from June to September. Spring wheat and soybeans are grown in the plain, with its fertile black soil, put under cultivation after 1950 as a part of the opening up of the "great northern wilderness" (*pei-ta-huan*).

The southern part of the province is also very cold in winter but enjoys a warmer summer and a longer growing period. Harbin has mean temperatures of −2° F (−19° C) in January and 72° F (22° C) in July. Its mean annual precipitation is 21.6 inches. The natural vegetation is steppe grass.

Soil patterns

The soils in the province are complex. In both the Greater and Lesser Khingan mountains soils differ with altitude. Black earths are prevalent in the foothills and mountain gray forest soils higher up. Still higher, the cold, wet soils are podsilized; *i.e.*, the soluble salts (carbonates and iron and aluminum oxides) along with soluble organic matter are leached out of the topsoil and deposited in an underlying subsoil. Such soils are of low fertility, and their cultivation causes erosion. The famous chernozem, or black soil, that covers one-fourth of the province is found in the Sungari–Nen river plain (the northern section of the Great Manchurian Plain). Its eastern part has the best soils, two feet deep or more, with good texture and high humus content, yielding crops for years without fertilization. The chernozem lands form the main agricultural region of the province, growing wheat, soybeans, kaoliang, and millet. The soil is suitable for sugar beets and flax.

Vegetable and animal life. The original vegetation of the province was forest–prairie, but it has been largely destroyed by cultivation; the remaining trees are predominantly poplars. There are many species of herbaceous plants, pasture grasses, and sorghums. The central part of the plain was originally prairie–steppe; the western part of the plain is a drier steppe.

The province has two distinct fauna districts. The first is the Manchurian Plain, which constitutes the larger part of the province. It has a predominance of temperate mixed forest fauna, with a significant admixture of elements of the Eurasian taiga. Among the district's representative animals are the Manchurian hare, the eastern field vole, the rat hamster, the Far Eastern finches, the Buteo hawk, the needle-footed owl, and some species of flycatchers. Insects include the duckling beetle, the ground beetle, and the bumblebee. The region's fauna yield valuable fur and pelts, including the sable, panther, fox, chipmunk, Manchurian hare, and light-coloured polecat.

The second district, the Greater Khingan taiga, has a fauna more akin to that of the boreal forests of Europe and Siberia. The more common wildlife includes the brown bear, squirrels, chipmunks, some forest voles, the Kolinsky, or Asiatic, mink, the wood hen, the crossbill, and the Siberian frog. Among the insects may be mentioned long-horned beetles, the ground beetle, and the Siberian silkworm. During the long, cold winter the birds migrate to warmer regions as far south as the Malay Peninsula.

THE PEOPLE AND THE ECONOMY

Population. The national census of June 30, 1953, recorded 11,897,309 inhabitants in the province. The registered population at the end of 1957 was 14,860,000. The government did not release detailed demographic data in the 1950s and 1960s. After 1957 even the annual population registration statistics of the provinces were not published. The government's published estimate of 1967–68 was 21,000,000, and a broadcast by Radio Harbin in 1970 cited a figure of 25,000,000, which included the population of Hu-lun-pei-erh-meng (Hulunbuir League). If the latter figures are approximately correct, the population more than doubled in 17 years' time. The rapid increase may reflect the success of the national program of resettling peasants from North China. It also reflects the high rate of natural increase throughout China after World War II, resulting largely from improvements in sanitation, medical care, and nutrition.

Industrial development has drawn a great number of peasants from the countryside to the cities, especially to do unskilled construction work. In 1957 the total number of workers in the province was 1,200,000, an increase of 149 percent since 1952. The increase of rural population during the same period was only 12 percent.

The density of population was 83 per square mile in 1957; by 1970 it had risen to 92 per square mile. Population density varies considerably within the province, which is larger than Sweden. Rural districts in the vicinity of Harbin have densities ranging from 750 to over 1,000, while the forested Greater Khingan mountains in the northernmost part of the province have one or two persons per square mile. In a great part of the Sungari Plain, population densities range from 250 to more than 1,000 per square mile. In the Nen Chiang plain, a region of recent settlement, as well as in the Lower Sungari Plain, the rural population around the large cities has reached 250–500 per square mile, while farther away it is less than 130. The other major areas of the province are sparsely populated.

Ethnic groups

Although the population is predominantly Chinese, the remaining 8 percent contains some significant ethnic groups: Manchus, Koreans, Muslims, Mongolians, Ta-hu-erh, O-lun-chun (Oronchon), O-wen-k'o, Ho-che, and Chi-erh-chi-szu. Minor groups include Tibetans, Russians, and Yakuts. After the establishment of the Communist government, a number of autonomous *hsien* (territorial divisions) and autonomous villages were created in areas inhabited by ethnic minorities. The Manchus form the largest minority group, numbering about 630,000, distributed in the southern part of the province. They have been culturally assimilated by the Chinese majority. Most of them farm; their way of life is similar to the Chinese, and intermarriage is common, especially among the former nobility and the educated.

Korean immigration started during the reign of Hsien-feng (1851–62). After the Japanese annexation of their country (1910–45), a large number of Koreans emigrated to Heilungkiang and Kirin provinces, where they have converted large areas of swampy wasteland into rice paddies. They number about 232,000, living mostly in southeastern Heilungkiang, where many autonomous Korean villages have been established. Next numerically are the Muslims (42,000), who live and work mostly in the bigger cities as merchants, handicraftsmen, and proprietors of beef and mutton restaurants. Those in An-ta and Chao-tung raise goats and dairy cattle. There are about 38,000 Mongolians living in the drier western part of the province, where they engage in farming and animal husbandry. A third of them live in Tu-erh-po-t'e Mongol Autonomous Hsien.

The Ta-hu-erh number about 23,000 (out of 40,000 in China), living mostly in the upper Nen Valley, on the

eastern foreland of the Greater Khingan Range. They are believed to have come from the north side of the Amur River during the 15th and 16th centuries. Hunters originally, they became the earliest farmers of Heilungkiang. Probably the O-lun-ch'un, now numbering only about 1,300, also came from north of the Amur River, later to settle down in he Khingan ranges as farmers and hunters. They had domesticated the deer and were once known as the "deer riders." The O-lun-ch'un were among the earliest inhabitants of the Upper and Middle Amur. The O-wen-k'o tribesmen moved into the province in the 1st century AD. They are believed to be descendants of the Su-shen tribes (Tungusic) of the Chou dynasty. They now live in the Amur River Valley, near Ai-hui and Hei-ho, numbering about 400. Originally hunters, they have learned to farm since 1949.

Russians entered the province at the end of the 19th century and during the early 20th. A great number of emigrés arrived after the Bolshevik Revolution. Those who became Chinese citizens have remained, many of them women who married Chinese and live mostly in Harbin and in the towns along the Amur River.

Urbanization and industrialization. In 1957, city dwellers formed 36 percent of the total population; the urban population in the province had more than doubled since 1949. New industrial centres were established, and older ones were greatly expanded.

The growth of the city of Chia-mu-ssu

The city of Chia-mu-ssu, on the right bank of the Sungari River, was a town of less than 10,000 inhabitants in 1925. During the Japanese occupation (1933–45) it was built up as a military and air base. Four strategic railways were completed linking the city with T'u-men, on the North Korean border; Sui-hua, to the west; Ho-kang, to the north; and Shuang-ya-shan, to the east. By 1941 Chia-mu-ssu had 113,411 people.

Rapid industrial development began under the Chinese Communists. The city began to produce threshing machines, pressing machines, grain sowers, combines, mining machinery, and electrical and telecommunication equipment. The Chia-mu-ssu paper mill is one of the largest in China, producing both for domestic needs and for export. There is also a food-processing industry: sugar refining, meat processing, edible oils and tallow, brewing, and confectioneries. By 1962 Chia-mu-ssu had over 300,000 inhabitants.

Another burgeoning industrial city is Shuang-ya-shan (Twin-Ducks Hill), about 43 miles east of Chia-mu-ssu. Its development began after World War II and was based on the Shuang-ya-shan coalfield, which extends over 117 square miles, with 45 seams of good coking coal. The city also has a number of large plants engaged in metal processing, food processing, and the production of lumber and construction materials. It grew from 26,000 inhabitants in 1949 to almost 110,000 by 1958.

Ch'i-ch'i-ha-erh (Tsitsihar), the second-largest city and former capital of the province, also grew phenomenally in the 1950s. Over a dozen large machinery-manufacturing plants were built, making it a key centre of the industrialization program. It also has a large food-products industry. The population was 704,000 in 1958.

Harbin

Harbin, the largest city and capital of the province, with a population of 2,000,000 (1970 estimate), only grew up in 1898 as a construction base for the Chinese Eastern Railway across northern Manchuria. It soon became the major transportation hub and communications centre of northern Manchuria, with direct rail links to the Russian railroad network and to the Sea of Japan; through the South Manchurian Railway, it is linked with the Chinese and Korean rail networks and the Pacific. In 1932 the city had a population of 380,000. There were numerous handicraft industries and small oil-pressing and flour mills. By the 1950s the Harbin area had become one of China's primary industrial-development centres, with an emphasis on heavy industry. It produced a variety of industrial machines, machine tools, and agricultural machinery. Chemical and fertilizer industries were added. The city is also a food-processing centre, as well as a producer of textiles, lumber, and construction materials.

Harbin is also an important educational centre, especially in engineering and applied science. The Harbin Polytechnical University was founded in 1920 to train technical personnel for the Chinese Eastern Railway. By 1960 it offered 40 specialized programs in ten departments of engineering and technology, as well as a graduate school.

Transportation and administration. Heilungkiang had about 2,500 miles of railroads in 1957, or 12.5 percent of the national total. Little was added in the 1960s. The five trunk lines are the Harbin–Dairen (Lü-ta), Harbin–Manchou-li, Harbin–Chia-mu-ssu, Harbin–Sui-fen-ho, and Ch'i-ch'i-ha-erh–Ssu-p'ing lines. There are also ten secondary lines.

Inland waterways are not important, handling less than 2 percent of the freight volume in 1957. About 47 percent of the freight was carried by railroads, 48 percent by animal- and man-drawn carts, and less than 3 percent by motor trucks.

Administrative units of the province

Heilungkiang Province is one of 29 primary administrative divisions of the People's Republic of China. The province is divided into 6 special districts (*chuan-ch'ü*) and 8 municipalities under the direct control of the province (*shih*). The latter category includes Harbin, Ch'i-ch'i-ha-erh, Chia-mu-ssu, Ho-kang, Shuang-ya-shan, Mu-tan-chiang, Chi-hsi, and I-ch'un. The subprovince-level units are further subdivided into 64 counties (*hsien*), one autonomous county (*tzu-chih-hsien*), and one county level municipality (*shih*). The *hsien* has been the basic territorial division of China since ancient times.

Under the *hsien* is the *hsiang* (rural district, or civil township). In the late 1950s the *hsiang* was supplanted by the people's communes. During the Great Proletarian Cultural Revolution of the late 1960s many local administrative organizations were replaced with revolutionary committees. The Heilungkiang Communist Party organization was in disarray until it was reconstituted on August 26, 1971.

BIBLIOGRAPHY. The most comprehensive contemporary regional monographs of the province are the two volumes edited by SUN CHING-CHIH: *The Economic Geography of the Amur and Ussuri Regions of Heilungkiang Province* (Eng. trans. 1957); and *Economic Geography of Northeast China* (Eng. trans. 1962). In the 1960s the Chinese People's Republic stopped publishing basic economic statistics, but data up to 1958 and more recent estimates may be found in THEODORE SHABAD, *China's Changing Map*, 2nd ed. (1972). The best atlas is the CIA publication: *Communist China: Administrative Atlas* (1969).

(F.Hu.)

Heine, Heinrich

Heinrich Heine's international fame rests to a large extent on his *Buch der Lieder* (1827; *The Book of Songs*), the poems of which have been carried, in Heine's own phrase, "on wings of song" throughout the world by the more than 2,000 lieder settings of Robert Schumann, Franz Schubert, and many other composers. But he was more than the most famous love poet of the 19th century and, perhaps, of all European literature since Petrarch. He wrote many kinds of poetry and prose; he was a satirist and wit of exceptional skill; and his efforts as a writer of political and social commitment and of opposition to the oppression of his time today form the base for a new evaluation of his significance.

Early life. Heine was born of Jewish parents in Düsseldorf on December 13, 1797. His father was a handsome and kindly but somewhat ineffectual merchant; his mother was fairly well educated for her time and sharply ambitious for her son. Much of Heine's early life, however, was influenced by the financial power of his uncle Salomon Heine, a millionaire Hamburg banker who endeavoured to trade generosity for obedience and with whom Heine remained on an awkward and shifting footing for many years. After he had been educated in the Düsseldorf Lyceum, an unsuccessful attempt was undertaken to make a businessman of him, first in banking, then in retailing. Eventually, his uncle was prevailed upon to finance a university education, and Heine attended the universities of Bonn, Göttingen, Berlin, and Göttingen

again, where he finally took a degree in law with absolutely minimal achievement in 1825. In that same year, in order to open up the possibility of a civil service career, closed to Jews at that time, he converted to Protestantism with little enthusiasm and some resentment. He never practiced law, however, nor held a position in government service; and his student years had been primarily devoted not to the studies for which his uncle had been paying but to poetry, literature, and history.

Heine's pre-university years are rather obscure, but during this period he apparently conceived an infatuation for one, and possibly both, of his uncle's daughters, neither of whom had the slightest notion of mortgaging her future to a dreamy and incompetent cousin. Out of the emotional desolation of this experience arose, over a period of years, the poems eventually collected in *The Book of Songs*. The sound of Romantic poetry was firmly lodged in Heine's ear; but the Romantic faith, the hope for a poeticization of life and the world to overcome the revolution, alienation, and anxiety of modern times, was not in his heart. Thus, he became the major representative of the post-Romantic crisis in Germany, a time overshadowed by the stunning achievements of Goethe, Schiller, and the Romantics but increasingly aware of the inadequacy of this tradition to the new stresses and upheavals of the modern age. The most consistent characteristic of Heine's thought and writing throughout his career is a taut and ambiguous tension between "poesy," as he called the artistic sensibility, and reality. His love poems, though they employ Romantic materials, are at the same time suspicious of them and of the feelings they purportedly represent. They are bittersweet and self-ironic, displaying at the same time poetic virtuosity and a skepticism about poetic truth; their music is now liquid, now discordant, and the collection as a whole moves in the direction of desentimentalization and a new integration of the poet's self-regard in the awareness of his artistic genius.

Early poetry

The steady growth of Heine's fame in the 1820s was accelerated by a series of experiments in prose. In the fall of 1824, in order to relax from his hated studies in Göttingen, he took a walking tour through the Harz Mountains and wrote a little book about it, fictionalizing his modest adventure and weaving into it elements both of his poetic imagination and of sharp-eyed social comment. *Die Harzreise* ("*The Harz Journey*") became the first piece of what were to be four volumes of *Reisebilder* (1826–31; *Pictures of Travel*); the whimsical amalgam of its fact and fiction, autobiography, social criticism, and literary polemic was widely imitated by other writers in subsequent years. Some of the pieces were drawn from a journey to England Heine made in 1827 and a trip to Italy in 1828, but the finest of them, "Ideen. Das Buch Le Grand" (1827; "Ideas. The Book Le Grand"), is a journey into the self, a wittily woven fabric of childhood memory, enthusiasm for Napoleon, ironic sorrow at unhappy love, and political allusion.

Later life and works. When the July Revolution of 1830 occurred in France, Heine did not, like many of his liberal and radical contemporaries, race to Paris at once but continued his more or less serious efforts to find some sort of paying position in Germany. In the spring of 1831 he finally went to Paris, where he was to live for the rest of his life. He had originally been attracted by the new Saint-Simonian religion (a socialistic ideology according to which the state should own all property and the worker should be entitled to share according to the quality and amount of his work); it inspired in him hopes for a modern doctrine that would overcome the repressive ideologies of the past and put what he variously called spiritualism and sensualism, or Nazarenism (adherence to Judeo-Christian ideals) and Hellenism (adherence to ancient Greek ideals), into a new balance for a happier human society. His critical concern with political and social matters deepened as he watched the development of limited democracy and a capitalist order in the France of the citizen-king, Louis-Philippe. He wrote a series of penetrating newspaper articles about the new order in France, which he collected in book form as *Französische Zustände* (*French Affairs*, 1906) and followed with two studies of German culture, *Die Romantische Schule* (1833–35; *The Romantic School*) and "Zur Geschichte der Religion und Philosophie in Deutschland" (1834–35; "On the History of Religion and Philosophy in Germany"), in which he mounted a criticism of Germany's present and recent past and argued the long-range revolutionary potential of the German heritage of the Reformation, the Enlightenment, and modern critical philosophy. The books were conceived with a French audience in mind and were originally published in French. In 1840–43 he wrote another series of newspaper articles about French life, culture, and politics, which he re-edited and published as *Lutezia*, the ancient Roman name for Paris, in 1854.

Move to Paris

During these years, then, Heine's attention turned from "poesy" to writing of contemporary relevance. His second volume of poems, *Neue Gedichte* (1844; *New Poems*), illustrates the change. The first group, "Neuer Frühling" ("New Spring," written mostly in 1830/31), is a more mannered reprise of the love poems of *Buch der Lieder*, and the volume also contains some ballad poetry, a genre in which Heine worked all his life. But the second group, "Verschiedene" ("Varia"), is made up of short cycles of sour poems about inconstant relationships with the blithe girls of Paris; the disillusioning tone of the poems was widely misunderstood and held against him. Another section is called "Zeitgedichte" ("Contemporary Poems"), a group of harsh verses of political satire. Several of these were written for Karl Marx's newspaper *Vorwärts* ("Forward"). Heine had become acquainted with the young Marx at the end of 1843, and it was at this time that he produced, after a visit to his family in Germany, a long verse satire, *Deutschland. Ein Wintermärchen* (1844; *Germany, a Winter's Tale*), a stinging attack on reactionary conditions in Germany. Though Heine remained on good, if not intimate, terms with Marx in later years, he never was much taken with Communism, which did not fit his ideal of a revolution of joy and sensuality. About the time that he met Marx, he also wrote another long poem, *Atta Troll. Ein Sommernachtstraum* (*Atta Troll, a Midsummer Night's Dream*, 1843–45), a comic spoof of radical pomposity and the clumsiness of contemporary political verse.

Heine's early years in Paris were the happiest of his life. From an outcast in the society of his own rich uncle, he was transformed into a leading literary personality, and he became acquainted with many of the famous and prominent people of his time. In 1834 he found in an uneducated shopgirl, Crescence Eugénie Mirat, whom for some reason he called "Mathilde," a loyal if obstreperous mistress. He married her in 1841. But troubles were soon hard upon him. His critical and satirical writings brought him into grave difficulties with the German censorship,

and, at the end of 1835, the Federal German Diet tried to enforce a nationwide ban on all his works. He was surrounded by police spies, and his voluntary exile became an imposed one. In 1840 Heine wrote a witty but ill-advised book on the late Ludwig Börne (1786–1837), the leader of the German radicals in Paris, in which Heine attempted to defend his own more subtle stand against what he thought of as the shallowness of political activism; but the arrogance and ruthlessness of the book alienated the public in all camps.

Though never destitute, Heine was always out of money; and when his uncle died in 1844, all but disinheriting him, he began, under the eyes of all Europe, a violent struggle for the inheritance, which was settled with the grant of a right of censorship over his writings to his uncle's family; in this way, apparently, the bulk of Heine's memoirs was lost to posterity. The information, revealed after the French Revolution of 1848, that he had been receiving a secret pension from the French government, further embarrassed him.

The worst of his sufferings, however, were caused by his deteriorating health. An apparently venereal disease began to attack one part of his nervous system after another, and from the spring of 1848 he was confined to his "mattress-grave," paralyzed, tortured with spinal cramps, and partially blind. Heine returned again to "poesy." With sardonic evasiveness he abjured his faith in the divinity of man and acknowledged a personal God in order to squabble with him about the unjust governance on the world. His third volume of poems, *Romanzero* (1851), is full of heartrending laments and bleak glosses on the human condition; many of these poems are now regarded as among his finest. A final collection, *Gedichte 1853 und 1854 (Poems 1853 and 1854)*, is of the same order. After nearly eight years of torment, Heine died on February 17, 1856, and was buried in the Montmartre Cemetery.

Last poetry

Heine's power to annoy was as great as his power to charm and move, and rarely has a great poet been so controversial in his own country. His aggressive satires, radical postures, and insouciance about his methods made him appear to many as an unpatriotic and subversive scoundrel, and the growth of anti-Semitism contributed to the case against him. Efforts in the late 19th and early 20th centuries to erect monuments to him in various German cities touched off riots and shook governments. In view of the popularity of many of his songs, the Nazis were obliged to include them in anthologies but marked them "author unknown." For many decades his literary reputation was stronger abroad, especially in France, England, and America, where his wit and ambivalence were better appreciated, than at home. Today the evaluation of Heine's political role and its relationship to Marxism supplies a bone of contention between East and West. Deplorable as much of this history of his reputation has been, it is testimony to the enduring impact of a genuinely European poet and writer.

MAJOR WORKS

Gedichte (1821), first collection of poems; *Tragödien nebst einem lyrischen Intermezzo* (1823), the tragedies were *Almansor* and *William Ratcliff; Reisebilder*, vol. 1: "Die Heimkehr," "Die Harzreise," "Nordsee I," first of the "North Sea" cycles (1826); vol. 2: "Nordsee II," "Nordsee III," "Ideen. Das Buch Le Grand," "Briefe aus Berlin" (1827); vol. 3 included "Reise von München nach Genoa" and "Die Bäder von Lucca" (1829); vol. 4 included "Die Stadt Lucca" and "Englische Fragmente" (1831); *Buch der Lieder* (1827); *Französische Zustände* (1832), a collection of political essays; *Zur Geschichte der neueren schönen Literatur in Deutschland* (1833), on contemporary German literature; reprinted and expanded in *Die Romantische Schule* (1835); *Der Salon*, 4 vol. (1834–40), vol. 1 included a description of French painting, the "Salon" of 1831, a collection of poems, and "Aus den Memoiren des Herren von Schnabelewopski"; vol. 2 (1835) consisted largely of a synopsis of the history of religion and philosophy in Germany, "Zur Geschichte der Religion und Philosophie in Deutschland"; vol. 3 (1837) contained two prose works, "Elementargeister" and "Florentinische Nächte"; vol. 4 (1840) included "Vertraute Briefe über die französische Bühne" and the opening chapters of the novel *Der Rabbi von Bacherach; Ludwig Börne, eine Denkschrift* (1840); *Deutschland. Ein Wintermärchen* (1844), satirical verse; *Neue Gedichte* (1844), second collection of shorter poems; *Atta Troll. Ein Sommernachtstraum* (1847), mock-epic poem; *Der Doktor Faust. Ein Tanzpoem* (1851); *Romanzero* (1851), included the "Historien," "Lamentationen," and "Hebräische Melodien"; *Gedichte 1853 und 1854* (1854); *Lutezia* (1854), political essays written 1840–43; *Vermischte Schriften* (1854), included "Geständnisse" and "Götter im Exil."

TRANSLATIONS: *Heinrich Heine: The Poems*, trans. by Louis Untermeyer (1937), is the most comprehensive English translation of Heine's poetry; various of Heine's works have been translated into English many times and into some 50 other languages. Other notable English translations are: *The Prose Writings of Heinrich Heine*, ed. by Havelock Ellis (1887); *The Works of Heinrich Heine*, trans. by C.G. Leland *et al.*, 12 vol. (1892–1905); *The Poems of Heine*, trans. by E.A. Bowring (1859); and *Heinrich Heine: The North Sea*, trans. by Vernon Watkins (1951).

BIBLIOGRAPHY. GOTTFRIED WILHELM and EBERHARD GALLEY, *Heine-Bibliographie (1817–1953)*, 2 vol. (1960); SIEGFRIED SEIFERT, *Heine-Bibliographie 1954–1964* (1968).

Manuscripts, papers, and memorabilia: The major collections of materials are in the Heine Archive of the Landes- und Stadtbibliothek, Düsseldorf; in the Bibliothèque Nationale in Paris; and in the Nationale Forschungs- und Gedenkstätten der klassischen deutschen Literatur in Weimar. Manuscript materials are also at Harvard and Yale. Since 1962 the Düsseldorf archive has published a *Heine-Jahrbuch* with a running annual bibliography.

Editions: ERNST ELSTER (ed.), *Sämtliche Werke*, 7 vol. (1887–90); OSKAR WALZEL *et al.* (eds.), *Sämtliche Werke*, 10 vol. (1910–15; index volume, 1920); HANS KAUFMANN (ed.), *Werke und Briefe*, 10 vol. (1961–64); FRIEDRICH HIRTH (ed.), *Briefe*, 6 vol. (1950–51), letters. New critical editions are being prepared in Düsseldorf and Weimar.

Biographies: ADOLF STRODTMANN, *Heinrich Heines Leben und Werke*, 2nd ed., 2 vol. (1873–74), the first and, in some ways, still the best comprehensive biography; LUDWIG MARCUSE, *Heinrich Heine: Ein Leben zwischen Gestern und Morgen* (1932; Eng. trans., *Heine: A Life Between Love and Hate*, 1933); LOUIS UNTERMEYER, *Heinrich Heine: Paradox and Poet*, vol. 1, *The Life* (1937), a companion volume to the translation of poems; E.M. BUTLER, *Heinrich Heine: A Biography* (1956); H.H. HOUBEN, *Gespräche mit Heine* (1926), a compendium of contemporaries' recollections and a valuable biographical sourcebook; FRITZ MENDE, *Heinrich Heine, Chronik seines Lebens und Werkes* (1970), a day-by-day account of all known events and activities in Heine's life.

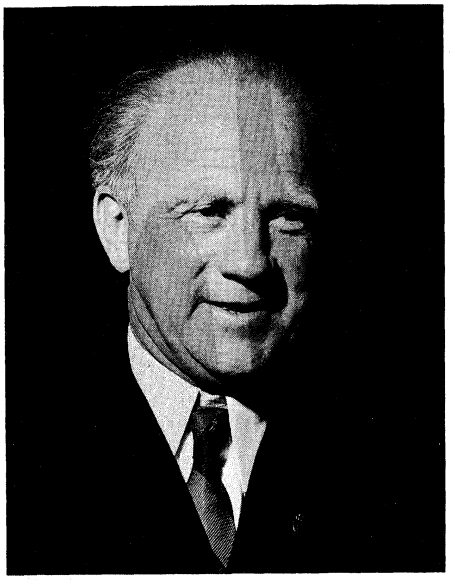
Critical studies: BARKER FAIRLEY, *Heinrich Heine: An Interpretation* (1954); WILLIAM ROSE, *Heinrich Heine: Two Studies of His Thought and Feeling* (1956); S.S. PRAWER, *Heine: The Tragic Satirist* (1961); LAURA HOFRICHTER, *Heinrich Heine* (1963); JEFFREY L. SAMMONS, *Heinrich Heine: The Elusive Poet* (1969).

(J.L.Sa.)

Heisenberg, Werner Karl

Werner Heisenberg, physicist, philosopher, and public figure, helped to establish the modern science of quantum mechanics, out of which came the famous "indeterminacy principle." He contributed significant refinements to a conceptual understanding of the atomic nucleus, ferromagnetism, cosmic rays, and elementary particles. In his philosophical writings, he insisted that the scientist is as much an "actor" as a "spectator" in scientific inquiry. He conceived of a Platonic central order, consisting of a set of universal symmetries that are exhibited in all natural phenomena. In his view, these symmetries constitute the rationale for a mathematical equation that may be applied to all systems of particulate matter. As a public figure, he actively promoted the peaceful use of atomic power after World War II and, in 1957, led other German scientists in opposing a move to equip the West German Army with nuclear weapons.

Born December 5, 1901, in Würzburg, Germany, Heisenberg studied physics at the University of Munich, where he wrote his doctoral dissertation in 1923 on turbulence in fluid streams. Interested in Niels Bohr's account of the planetary atom, Heisenberg went to the University of Göttingen to study under Max Born and then, in the fall of 1924, to the Universitets Institut for Teoretisk Fysik in Copenhagen to study under Bohr. In June 1925, while recuperating from an attack of hay fever on



Heisenberg.
Edo Keonig—Black Star

Helgoland, an island in the North Sea, he solved a major physical problem—how to account for the stationary (discrete) energy states of an anharmonic oscillator—and in so doing laid the program for the development of quantum mechanics (the science that accounts for discrete energy states and other forms of quantized energy, as in the light of atomic spectra and in the phenomenon of stability exhibited by macroscopic pieces of matter). A few months later, he published the article "Über quantentheoretische Umdeutung kinematischer und mechanischer Beziehungen" ("About the Quantum-Theoretical Reinterpretation of Kinetic and Mechanical Relationships"), in which he proposed a reinterpretation of the basic concepts of mechanics. Physical variables were to be represented by matrices, or arrays, of numbers and would deal only with "observable," or measurable, quantities. Heisenberg and other eminent physicists then used the new quantum mechanics to interpret many atomic and molecular spectra, ferromagnetic phenomena, and electromagnetic behaviour. Alternative forms of the new quantum theory were proposed in 1926 by Erwin Schrödinger and P.A.M. Dirac.

Indeterminacy principle

In 1927 Heisenberg published his indeterminacy principle, which stated the theoretical limitations imposed by quantum mechanics upon certain pairs of variables that constantly affect each other, such as position and momentum. He held that in their new designations as conjugate observables (an interrelated pair of measurable quantities), indeterminacy ruled that no quantum mechanical system could simultaneously possess an exact position and exact momentum. Indeterminacy affects all phenomena, great and small, but its significance is usually confined to the microphysical domain.

Bohr and Heisenberg elaborated a philosophy of complementarity to take into account the new physical variables, each of which would be relative to an appropriate measurement process on which it depends. The new conception of the measurement process in physics emphasizes the active role of the scientist, who, in the act of making measurements, interacts with the observed object and thus causes it to be revealed not as it is in itself but as a function of measurement. Many physicists, including Albert Einstein, Schrödinger, and Louis de Broglie, refused to accept the philosophy of complementarity.

From 1927 to 1941, Heisenberg was professor at the University of Leipzig. For the following four years, he was director of the Kaiser Wilhelm Institute for Physics in Berlin. During World War II, he worked with Otto Hahn, one of the discoverers of nuclear fission, on the development of a nuclear reactor. Although he did not publicly oppose the Nazi regime, he was hostile to its policies and acted so as to prevent Germany from developing effective nuclear weapons. After the war, he organized and became director of the Max Planck Institute for Physics and Astrophysics at Göttingen, later moving with the institute, in 1958, to Munich.

Universal nonlinear spinor equation

In the postwar period, Heisenberg began working on a universal nonlinear spinor equation (a nonlinear differential equation for complex vector-like entities representing all possible states of matter) for particulate systems that would exhibit the basic set of universal symmetries (relative to possible observer viewpoints) in nature and yet be capable of explaining the variety of elementary particles generated in high-energy collisions.

In his writings on the philosophical implications of quantum mechanics, Heisenberg vigorously opposed the Logical Positivism developed by philosophers in Vienna. In the theory of knowledge of quantum physics, he stressed the active role of the observer and replaced the absolute objects of classical science with relativized observational situations. Quantum mechanics implies that on the subatomic level the traditional idea of scientific causality needs broadening, since the behaviour of particles can be predicted only on the basis of probability; and that Newton's laws concerning the motion of bodies in space and time do not fit the basic processes within the atom. But classical physics remains valid in his view for a wide domain of macroscopic phenomena. The indeterminacy principle is of significance therefore primarily for subatomic particles.

Heisenberg married Elizabeth Schumacher (1937); they had seven children. Although known primarily as a physicist, he continued in the classical tradition of philosophy, seeking a new solution to the ancient problem of the One and the Many. Widely acknowledged as one of the seminal thinkers of the 20th century, Heisenberg was awarded the Nobel Prize for Physics in 1932 and honoured with the Max Planck Medal, the Matteucci Medal, and the Barnard College Medal of Columbia University. He died at Munich on February 1, 1976.

BIBLIOGRAPHY. P.A. HEELAN, *Quantum Mechanics and Objectivity* (1965), is the only critical study of Heisenberg's philosophy of science in English. M. JAMMER, *The Conceptual Development of Quantum Mechanics* (1966), is the most complete historical study of Heisenberg's contribution to quantum mechanics. Books by Heisenberg include *Die physikalischen Prinzipien der Quantentheorie* (1930; Eng. trans., *The Physical Principles of the Quantum Theory*, 1930), his most important, containing themes of his early papers amplified as a treatise; *Wandlungen in den Grundlagen der Naturwissenschaft* (1948; Eng. trans., *Philosophic Problems of Nuclear Science*, 1952), a collection of his early essays; *Physics and Philosophy: The Revolution in Modern Science* (1958), his Gifford lectures; and *Der Teil und das Ganze* (1969; Eng. trans., *Physics and Beyond*, 1971), an autobiographical memoir of his early life.

(P.A.H.)

Hellenistic Law

Hellenistic law is that body of law, of essentially Greek origin, that applied to Greek and Hellenized inhabitants of Egypt, Palestine, Syria, Asia Minor, and other countries of the ancient Near East during the period beginning with the death of Alexander the Great in 323 BC and the founding of the Hellenistic monarchies by his Macedonian successors, and ending with the absorption of these monarchies into the Roman Empire. One generally considers the year 30 BC to be the end of this period, when Egypt came under Roman rule; but as early as the mid-2nd century BC, Rome had conquered certain areas of Asia Minor, while Doura-Europus (on the Euphrates) remained independent until about AD 164. With the advent of Rome the influx of Roman law began. But it came slowly, and as a result, Hellenistic law continued to develop for some time. In fact, the development of Hellenistic law continued, be it with Roman influences, at least until AD 212, when Roman citizenship was conferred upon all the inhabitants of the Roman Empire.

Since classical authors give practically no information about Hellenistic law, modern knowledge is derived from such other sources as papyruses, parchments, and inscriptions on which are found some contracts, petitions,

and records of lawsuits. Any investigation into Hellenistic law is further hampered by two factors: first, no legal code nor contemporary legal treatises exist, making it necessary to reconstruct the law from single cases; second, the documents that do survive come mainly from Egypt (though there are records, for instance, from Delphi in Greece that offer some information about slavery, property law, and the status of women), and as a result, knowledge of Hellenistic law is restricted primarily to Egypt.

The character of Hellenistic law. *The origins of Hellenistic law.* In classical Greece every autonomous city-state had its own body of law. Because these legal systems had some general principles in common, some scholars have considered Greek law to be a unified body of law. Yet, because there appear to be many differences in the actual regulations of the various city-states, it can be contended that Greek law was instead a plurality of laws. The legal capacity of women, for example, was very restricted in Athens, much more than it was in Sparta or Gortyn on Crete; further, in Thessaly, women were equal to men in legal matters. There must have been considerable differences in the laws concerning other matters, because by the 4th century BC it was necessary to institute a special tribunal in Athens to deal with cases involving traders from other city-states. The existence of this tribunal implies that some "international" law must have regulated the affairs of those who travelled from one city-state to another (see also GREEK LAW).

As Alexander the Great swept through the Near East, citizens of the Greek city-states began to settle in the conquered areas. The oldest Greek legal document from Hellenistic Egypt shows something of a heterogeneous population living in Elephantine in 311 BC. The document records a marriage, and since the bride came from one city-state and the groom from another, the question arises as to the law of which city-state applied. It appears that neither one did, but rather that a "common law" was used among all Greeks who lived in Hellenistic countries. This Hellenistic law evolved from various Greek laws of the preceding period in much the same way as the common Greek language, *koinē*, evolved from the various Greek dialects spoken by the people. Although the exact origin of this common language and common law is unknown, there is speculation that it lies in the preceding period, when Greeks from various parts of the empire began to come in contact with each other.

The unity of Hellenistic law. Although there were some influences from local law, private Hellenistic law does appear, in many respects, to be universal—in the same way as, in the linguistic field, the *koinē* was largely uninfluenced by other local languages and remained the uniform Greek language of the whole Hellenistic world. Originally, scholars had thought that, at least in Egypt, a special variety of Hellenistic law had existed, but recent finds outside Egypt show clearly that institutions thought to be specific to Egypt also occurred elsewhere in the Hellenistic world: joint wills have been found to have existed in Asia Minor, not only in Egypt; marriages between siblings appear to have occurred in many parts of the Hellenistic world; and finally, the sale of land has been found to have been, in many respects, the same in Doura-Europus, near the border of Mesopotamia, as it was in Egypt.

In the area of public law there were more local variances. This was due to the fact that the first Hellenistic monarchs adopted, to a large extent, the administrative and fiscal regimes of the previous governments—Syrian, Egyptian, and so forth. Other local occurrences, such as the regular flooding of the Nile valley, served to influence legal practice as they did daily life.

Certain unique attributes of Hellenistic law. One of the most striking features of Hellenistic law is the absence of fixed legal terminology such as that found in Roman law. Although, for example, the *kyrios* usually means the guardian of a woman and *epitropos* the guardian of a minor or a ward, scholars acknowledge that either word might be substituted for the other.

Another striking feature is the flexibility of the legal system and the absence of fixed and clearly defined rules of contract. Sometimes, for example, it is difficult to distinguish a loan from a sale on credit or a sale with deferred delivery. Land lease might be combined with loan of seed corn. Manumission of slaves might be combined with the obligation to stay with someone for a certain period of time. Land lease might involve payment of a debt. Yet, at the same time, in penal law and torts (involving civil wrongs and injuries) different kinds of offenses were distinguished and subject to specific actions.

Importance given to written documents

A final striking feature is the importance given to written documents. A written document was the favourite method of proving a right or the extinction of an obligation. This feature is common to all the legal systems of the Hellenistic world, but it was apparently unknown in ancient Greece.

The relation to local law. The first Hellenistic monarchs respected the local law that applied to the indigenous inhabitants. Local law remained in force during the entire Hellenistic Age, so that when the Roman period began Hebraic law was still in Palestine, Babylonian law in Mesopotamia, and Egyptian law in Egypt. Special tribunals had made possible this survival: in Hellenistic Egypt Greek tribunals administered justice according to Greek law, Egyptian tribunals according to Egyptian law, and Jewish tribunals according to Hebraic law. Further, the king received petitions on matters of Jewish law or Egyptian law, and decisions apparently were made according to their respective laws.

In the beginning of the Hellenistic Age everyone was bound by his own law in conformity with the principle of personality; later on, this principle was abandoned so that everyone became free to choose the system of law he wished to be governed by. From that point on, the language used by the parties to a contract determined which system of law applied. The important thing here is that freedom of choice allowed the parties to avail themselves of procedures not found in their own law; for example, Jews entered into Greek loans with interest (forbidden by Jewish law) and divorced by mere consent (unknown to Jewish law).

Freedom of choice

Such freedom of choice does not mean that the law of the Jews or Egyptians or other peoples disappeared. On the contrary, the recent discoveries near the Dead Sea and the evidence from Egypt show that Jews used their own as well as Hellenistic law in the same way as they also used both the Hebrew and Greek languages. The Egyptians also appear to have preserved their language and, in some respects, their law, although both were submerged for several centuries until the Coptic period.

The principal subjects of Hellenistic law. *Law of persons.* Slaves were not very numerous in Hellenistic Egypt, perhaps because the economic condition of many a free person was such that his actual position was not very different from that of a slave. A slave was capable of owning property and of engaging in legal transactions and thus had more rights than a slave in ancient Greece.

Among free persons, women held a special place. Though their capacity was much less restricted than it had been under the law of Athens, the assistance of a guardian was still often required, even if only as a formality. In local Egyptian law there were no restrictions on the legal capacity of women.

Family law

The *oikos* or closed family, characteristic of ancient Greece, disappeared with the broadening of horizons in the Hellenistic Age, and the process of transferring the bride from her father's to her husband's *oikos* disappeared with it. Marriage was constituted simply by actual cohabitation with a view toward a common life as spouses; and divorce was effectuated by ending this cohabitation; in neither case was a legal act involved. Both spouses were free to divorce. No written document was required for constituting a valid marriage or divorce; the main purpose of such documents was to arrange property settlements. Polygamy and marriages between brothers and sisters or other close relatives occurred, though not very often.

Unlike the Roman paterfamilias (head of family), who had absolute power over his children, a Hellenistic fa-

ther had no more than a simple paternal authority. A mother also had a maternal authority over her children, especially when they were fatherless. Adoption existed, and the persons adopted were usually free persons and not foundlings, who were considered as slaves.

Law of property. In line with the character of Hellenistic law, there is no clear terminology that distinguishes such legal notions as "ownership" and "possession," "movables" and "immovables," although in practice these categories of goods existed, as did different qualities of ownership. It is true that because the king was said to own all the land, the question arises as to whether private ownership could exist. Yet private persons did freely buy and sell land, leased it and paid taxes on it, so that it appears that the king's sovereign rights to the land were meant merely to assert his right to levy taxes.

There were several categories of land, although their exact nature often is not known. "Royal land" in Egypt and Seleucia seems to have been the private property of the king, and "holy" or "temple land" that of the temples. On the other hand, so-called temple domains existed; private persons could own land situated there, but they were obliged to pay a tax to the temple in question. Another kind of land was called *klēros*, originally a fee temporarily held either by individual soldiers (in Egypt) or by entire military colonies (in Seleucia and pre-Hellenistic Egypt), granted to them in return for military and other services. Gradually such lands became private property and lost their military aspect, so that by the 1st century BC they even could be owned by women.

Inheritance. The Egyptian law of inheritance was fundamentally different from the Greek, although the differences tended to disappear in Hellenistic law. In Egyptian law, when someone died, a member of his family assumed his position within the family; the heir took over the entire property, including the debts, for which he became responsible. He could not decline the inheritance and was responsible to his prospective heirs to preserve the estate. In contrast, in Greek law, the heir inherited the assets only; he was not responsible for the debts and could decline the inheritance. According to Hellenistic law, the property tended to be divided among the heirs—the primary heirs being the natural or adopted children (male and female) of the deceased. The inability of Athenian women to make a will survived in Alexandria but disappeared in the rest of the Hellenistic world.

Obligations. One of the major problems in the history of law is the question of whether or not debtors could be held responsible for their debts or how, in the proceedings, they became liable. With regard to Hellenistic law, scholars have questioned the existence of contracts based merely on consent and, though the sources appear to show that such contracts did exist, many scholars have denied it and concluded that, for example, a debtor became liable, not by promising something but by submitting himself to punishment when he could not perform what he had promised to do; or that he became liable by adding a surety to his contract rather than simply his consent.

Liability of a debtor

Sale. The evidence on sale is limited almost exclusively to immovables and valuable goods, since the sale of movables usually occurred without a written document. Sale was usually a cash transaction, with the goods sold being delivered at the same time that payment was made. It might happen, however, that the price was paid in advance or that the goods were delivered on credit, in which case there might be a question as to when transfer of ownership took place. It appears that this caused no difficulty in Hellenistic law, although the time of actual transfer of ownership is not known.

Loan and deposit. Credit was common and was found in a variety of forms; interest could be paid in money, in kind, in the performance of services, and so forth. A maximum rate of interest on loans of money was introduced in Egypt around 250 BC, at about 24 percent per year; this was reduced in Roman times to about 12 percent per year. Loans in kind, however, required the borrower to pay 50 percent, regardless of the duration of the loan.

Sometimes the amount named in the contract was the amount to be repaid, either because interest was not required or because it had already been calculated in the amount. This type of contract, very common in Roman Egypt, is generally thought to have influenced the development of a similar Roman loan, because the regular Roman loan did not allow for interest.

Torts and criminal law. There was no distinction in Hellenistic law between public and private law, and therefore between offenses against the state and against individuals. Consequently, the actions and procedures dealing with such offenses are quite mixed. Distinctions were made, however, between premeditated offenses and unpremeditated offenses. Offenses committed at night, in a temple, by armed men, or by a band were considered as aggravated offenses and, therefore, more serious.

The Athenian democratic principle that every citizen was entitled to bring an action when a public offense had taken place disappeared in Egypt except in the case of fiscal offenses against the state. In this instance, the motivating concern was not one of democratic principle but the interest of the state.

There were many different actions for offenses. They were directed usually toward compensation for damages and at civil monetary penalties (many of these cases could be settled by agreement in order to avoid an action), but public penalties such as confiscation of the offender's property and the death penalty occurred, especially in cases of fiscal offenses against the state. In general, corporal punishment seems to have been inflicted only on slaves.

Procedure. It is a striking feature that in Egypt jurisdiction was exercised not only by courts made up of a group of judges or by single magistrates but also, to a certain degree, by influential private persons.

Several Greek, Jewish, and Egyptian courts administered justice in Egypt. It is not known how the Jewish courts were organized, but a royal official was attached to the Greek and Egyptian courts in order to prepare the cases and to carry out the sentences. The king could, in the person of this official, supervise the courts, especially the Egyptian ones.

Execution was accomplished by an executive officer, against the property as well as the person of the debtor. A debtor could be placed in detention, but it is not known if he could be sold as a slave. Hellenistic monarchs tried to abolish punishment against an individual's person for other than fiscal debts, but they did not succeed.

BIBLIOGRAPHY. R. TAUBENSCHLAG, *The Law of Greco-Roman Egypt in the Light of the Papyri, 332 B.C.–640 A.D.*, 2nd ed. (1955); and E. SEIDL, *Ptolemäische Rechtsgeschichte*, 2nd ed. (1962), are the best recent handbooks but are mainly concerned with Hellenistic law in Egypt. No general account of Hellenistic law as such exists. Many important articles are collected in the selected works of R. TAUBENSCHLAG, *Opera Minora*, 2 vol. (1959). Of a more general interest are: J.G. WINTER, *Life and Letters in the Papyri* (1933); E.G. TURNER, *Greek Papyri: An Introduction* (1968); and A. DEISSMANN, *Licht vom Osten: Das Neue Testament und die neuentdeckten Texte der hellenistisch-römischen Welt*, 4th ed. (1923; Eng. trans., *Light from the Ancient East: The New Testament Illustrated by Recently Discovered Texts of the Graeco-Roman World*, new ed. 1927, reprinted 1965).

An extensive bibliography of Hellenistic law may be found in J. MODRZEJEWSKI, "Monde Hellénistique," vol. A/8 of *Introduction bibliographique à l'histoire du droit et à l'ethnologie juridique*, ed. by J. GILISSEN (1965); more recent bibliographies are regularly published in the *Revue Historique de Droit Français et Étranger*, and in *Studia et Documenta Historiae et Iuris*.

Some important collections of Greek papyruses from Egypt are: L. MITTEIS and U. WILCKEN, *Grundzüge und Chrestomathie der Papyruskunde*, 4 vol. (1912), with a thorough commentary; A.S. HUNT and C.C. EDGAR, *Select Papyri*, vol. 1, *Private Documents*, 3rd ed. (1959), vol. 2, *Public Documents*, 2nd ed. (1956), with English translations of the documents; and M. DAVID and B.A. VAN GRONINGEN, *Papyrological Primer*, 4th ed. (1965), with explanatory and bibliographical annotations.

Hellenistic Religions

The Hellenistic Age (*c.* 300 BC–AD 300), when taken as a whole, constitutes one of the most creative periods in the history of religions. It was a time of spiritual revolution in the Greek and Roman empires, when old cults died or were fundamentally transformed and when new religious movements came into being.

Nature and significance. The Hellenistic Age may be broadly defined as the period from the Greco-Macedonian conqueror Alexander the Great (356–323 BC) to Constantine, the first Christian Roman emperor (d. AD 337), and its religions may be confined to those that were active within the Mediterranean world. The empire of Alexander and his successors created a great world community which, whether in Macedonian, Greco-Roman, or its later Christian form, established a cultural unity that was destined to be broken only 1,000 years later with the advent of Muslim imperialism (beginning in 7th century AD). This empire was so vast as truly to stagger the imagination. Extending from the Strait of Gibraltar to the Indus River, from the forests of Germany and the steppes of Russia to the Sahara Desert and the Indian Ocean, it took in an area of 1,500,000 square miles (most of Europe, the Mediterranean, the Near and Middle East, Africa, Persia, and the borderlands of India) and had a total population of over 54,000,000.

The study of Hellenistic religions is a study of the dynamics of religious persistence and change in this vast and culturally varied area. Almost every religion in this period occurred in both its homeland and in diasporic centres—the foreign cities in which its adherents lived as minority groups. For example, Isis (Egypt), Baal (Syria), the Great Mother (Phrygia), Yahweh (Palestine), and Mithra (Kurdistan) were worshipped in their native lands as well as in Rome and other cosmopolitan centres. With few exceptions, each of these religions, originally tied to a specific geographical area and people, had traditions extending back centuries before the Hellenistic period. In their homeland they were inextricably tied to local loyalties and ambitions. Each persisted in its native land with little perceptible change save for its becoming linked to nationalistic or messianic movements (centring on a deliverer figure) seeking to overthrow Greco-Roman political and cultural domination. Indeed, many of these native religions underwent a conscious archaism during this period, attempting to recover earlier forms and practices. Old texts in native languages (especially those related to relevant themes such as kingship) were recopied, national temples were restored, and old, mythic traditions were revived. From Palestine to Persia one may trace the rise of Wisdom literature (the teachings of a sage concerning the hidden purposes of the deity) and Apocalyptic traditions (referring to a belief in the dramatic intervention of a god in human and natural events) that represent these central concerns—*i.e.*, national destiny, the importance of traditional lore, the saving power of kingship, and the revival of mythic images. Each of these native traditions likewise underwent hellenization (modifications based on Greek cultural ideas), but in a manner frequently different from their diasporic counterparts.

The dispersion of local and area cults and the resultant changes

Each of these native religions also had diasporic centres that exhibited marked change during the Hellenistic period. There was a noticeable lessening of concern on the part of the members of the dispersed religious group for the density and fortunes of the native land and also a relative severing of the traditional ties between religion and the land. Certain cult centres remained sites of pilgrimage or objects of sentimental attachment; but the old beliefs in national deities and the inextricable relationship of the deity to certain sacred places was weakened. Rather than a god who dwelt in his temple, the diasporic traditions evolved complicated techniques for achieving visions, epiphanies (manifestations of a god), or heavenly journeys to a transcendent god. This led to a change from concern for a religion of national prosperity to one for individual salvation, from focus on a particular ethnic group to concern for every man. The prophet or saviour replaced the priest and king as the chief religious figure. In the diasporic centres, as is generally characteristic of immigrant groups, there were two circles. The first (or inner circle) was composed of devout, full-time adherents of the cult for whom the deity retained a separate and decisive identity (*e.g.*, Yahweh alone, there is one Zeus Sarapis, Isis is queen over all). Its membership was drawn from the ethnic group for whom the deity was indigenous, and the group tended to continue to speak the native language. The second (or outer circle) was composed of either second and third generation immigrants or converts from groups for whom the religion was not native. These individuals tended to speak Greek, and this began the lengthy process of reinterpretation of the archaic religion. Ancient sacred books were translated or paraphrased into Greek—*e.g.*, the 4th–3rd-century-BC Babylonian priest Berosus' version of Babylonian materials, the 4th–3rd-century-BC Egyptian priest Manetho's Egyptian accounts, the Jewish Septuagint (Greek version of the Old Testament), or the 1st-century-AD Jewish historian Josephus' *Antiquities of the Jews*, and the ethnic histories of the 1st-century-BC Greek writer Alexander Polyhistor. In each case the material was reinterpreted both in light of common Hellenistic ideals and in accord with the special traditions and needs of the diasporic community. Both the inner and outer circles fostered esotericism (secrets to be known only by initiates)—the former by its use of native language and its oral recollection of traditions from the homeland; the latter by its use of allegory and other similar methods to radically reinterpret the sacred texts. The difference between these groups was responsible for many shifts in the character of the religion. Most notable was the shift from elements characteristic of native religion in its definition of religion (*e.g.*, local tradition and custom, informal knowledge orally transmitted, and birth) to formulated dogma, creeds, law codes, and rules for conversion and admission that were characteristic of diasporic religion. It was a shift from "birthright" to "convinced" religion.

The history of Hellenistic religions is rarely the history of genuinely new religions. Rather it is best understood as the study of archaic Mediterranean religions in their Hellenistic phase within both their native and diasporic settings. It is usually by concentrating on the diaspora that the Hellenistic character of a cult has been described.

History. *Religion from the death of Alexander to the reformation of Augustus: 323–27 BC.* The conquests of Alexander opened the way for religious interchange between East and West; the political structures left behind by Alexander and continued by his successors provided strong incentives for the hellenization of native religions. Characteristic of this first period of Hellenistic religious history were the following developments: (1) the introduction of Oriental cults into the West, especially those associated with female deities who were either worshipped in frenzied rites of self mutilation (*e.g.*, the Phrygian Cybele, brought to Rome in 204 BC; the Syrian Atargatis; or the Cappadocian Ma-Bellona) or in adoring contemplation of their beneficence and gentle rites of divine rebirth (*e.g.*, the Egyptian Isis, whose cult was widespread in the Greco-Roman world by the middle of the 2nd century BC); (2) the hellenization of native cults (most famously that of the archaic Egyptian god Sarapis whose Greek form was promulgated by Ptolemy I, the founder of the Egyptian Ptolemaic dynasty in 305 BC); (3) the development of the ideology of divine kingship based on Oriental kingship traditions; and (4) the rise of nationalistic and messianic movements directed against internal and external hellenization; *e.g.*, the Maccabean rebellion led by Judas Maccabeus against Jewish hellenizing parties and the Syrian overlords in 167–165 BC, and the numerous Egyptian rebellions, especially that led by the Egyptian independence leader Harmakhis in Thebais in 207/6 BC.

Religious interchange between East and West

Religion from the Augustan reformation to the death of Marcus Aurelius: 27 BC–180 AD. Oriental cults underwent their most significant expansion westward during this period. Particularly noticeable was the success of a variety of prophets, magicians, and healers—*e.g.*, John

the Baptist, Jesus, Simon Magus, Apollonius of Tyana, Alexander of Abonouteichos, and the cult of the healer Asclepius—whose preaching corresponded to the activities of various Greek and Roman philosophic missionaries. A developing tension between these "new" Eastern religions and the archaic Greco-Roman traditions was expressed internally in the attempt by the emperor Augustus to revive traditional Roman religious practices. Attempts were made to expel foreigners or to suppress foreign worship—*e.g.*, the suppression of the Bacchic mysteries (salvation cults devoted to the god Dionysus, or Bacchus) in Rome in 186 BC, or the numerous attempts to prohibit the worship of the Egyptian goddess Isis in Rome, beginning in 59 BC. The Augustan reformation also restored Roman sacred books and Greek temples. Externally, the developing tension was expressed in wars, riots, and persecutions, such as the Jewish-pagan riots in Alexandria in AD 38 and 115–116, the Jewish-Roman wars of AD 66–70 and 132–135, or the beginning of the persecution of Christians under the Roman emperor Nero in AD 64. Another cause of tension was the elaboration of a full-blown cult of "Emperor worship," beginning with the deification of Augustus (September 17, 14 AD).

Developing tensions between the Greco-Roman and the Eastern religions

Religion from Commodus to Theodosius I: AD 180–395. After the death of the "philosopher-king" Marcus Aurelius (121–180), his son Commodus (161–192) became emperor, and a period of political instability began. The dominant feature of the concluding period of the Hellenistic Age—and shortly thereafter—was the rapid growth of Christianity throughout the Roman Empire, culminating in the conversion to Christianity of the emperor Constantine (313) and the religious legislation of the emperor Theodosius (347–395) affirming in 380 the dogmas of the Christian Council of Nicaea, which was convened in 325 under the auspices of Constantine, and prohibiting paganism in a decree of 392. In this period the various Hellenistic cults were victims of active hostilities, which were expressed through prohibition, acts of violence, and theological polemics between pagans and Christians (*e.g.*, the pagan philosophers Maximus of Tyre and Celsus, and the Christian philosophical theologians Irenaeus, Tertullian, and St. Clement of Alexandria, all of the 2nd century); but there were also brief periods of pagan vitality. The Neoplatonic school (based on a complicated system of levels of reality) of Plotinus (203/4–269) and Porphyry (*c.* 234–*c.* 305) represented the culmination of Hellenistic religious philosophy. The Syrian solar cults of Sol Invictus (the unconquerable Sun) and Jupiter Dolichenus played an important role under the emperors Antoninus (86–161), the Severans—Septimius (146–211) and Alexander (208–235)—and Elagabalus (reigned 218–222) and were hailed as the supreme deities of Rome under Aurelian (d. 275), whose Sun temple was dedicated in 274. From Parthia, the dualistic and spiritual teachings of the Iranian prophet Mani (*c.* 215–274) were widely disseminated throughout the Empire. The Persian cult of the ancient Iranian god of light, Mithra, spread rapidly throughout the western and northern Empire during the 3rd through 5th centuries. Although these various traditions enjoyed brief imperial patronage under Julian (reigned 361–363), they eventually were subsumed under the political and religious hegemony of Christianity (see below).

Mythology and theology. The archaic religions of the Mediterranean world were primarily religions of etiquette. At the centre of these religions were complex systems governing the interrelationships between gods and men, individuals and the state, living men and their ancestors. The entire cosmos was conceived as a vast network of relationships, each component of which, whether divine or human, must know its place and fulfill its appointed role. The model for this all-encompassing system was the divine society of the gods, and the map of this system was the order of the planets and stars. Through astrology, divination, and oracles, man discerned the unalterable patterns of destiny and sought to bring his world (the microcosm) into harmony with the divine cosmos (the macrocosm; see also ASTROLOGY).

The centrality of the relationship between the gods and men

This archaic pattern of affirming and celebrating the order of the cosmos was expressed in the typical creation myth of the Near Eastern and Mediterranean world, a creation by combat between the forces of order and chaos. Order was understood to be something won in the beginning by the gods, and it was this primordial act of salvation that was renewed and re-experienced in the cult.

In the Hellenistic period a new religious world was experienced that required new religious expressions. The old religions of conformity and place no longer spoke to this new religious situation and its questions. What if the law and order of the cosmos was no longer seen as the creative expression of limits and the delineation of roles, but rather as an evil, perverse, confining structure from which man and the cosmos must escape? Rather than the archaic structures of celebration and conformity to place, the new religious mood spoke of escape and liberation from place and of salvation from an evil, imprisoned world. The characteristic religion of the Hellenistic period was dualistic. Man sought to escape from the despotism of this world and its rulers (exemplified by the seven planetary spheres) and to ascend to another world of freedom. Hellenistic man saw himself as an exile from his true home, the Beyond, and he sought for ways to return. He strove to regain his place in the world beyond this world where he truly belonged, to encounter the god beyond the god of this world who was the true god, and to awaken that part of himself (his soul or spirit) that had descended from the heavenly realm by stripping off his body, which belonged to this world. The questions that the religions of the Hellenistic period sought to answer may be seen in a fragment from the 2nd-century Anatolian Gnostic teacher Theodotus: "What liberates is the knowledge of who we were [before our earthly existence] and what we have become [on earth]; where we were [the Beyond] and the place to which we have been thrown [the world]; where we are going and from what are we redeemed; what is birth and what is rebirth" (preserved in Clement of Alexandria, *Excerpta ex Theodoto*, 78.2).

Salvation as liberation through knowledge of one's origin, identity, and destiny

The gods. In the Greco-Roman world during the Hellenistic period, archaic deities were transformed in part because of the new spirit of the age and in part by foreign influences. A number of the old chthonic (underworld) and agricultural (fertility) gods and the old agricultural mysteries (corporate renewal religions related to fertility concepts) fundamentally altered their character. Rather than an expression of the alternation of life and death, of fertility and sterility, and a celebration of the promise of renewal for the land and the people, the seasonal drama was homologized to a soteriology (salvation concept) concerning the destiny, fortune, and salvation of the *individual* after death. The collective agricultural rite became a mystery, a salvific experience reserved for the elect (such as the Greek mystery religion of Eleusis). Other traditions even more radically re-interpreted the ancient figures. The cosmic or seasonal drama was interiorized to refer to the divine soul within man that must be liberated. Such cults were dualistic mysteries distinguishing sharply between the body and soul. They taught that it is the soul alone that was initiated by passing through death or the Underworld, or by being dismembered so that it might be freed from the body and regain its rightful mode of spiritual existence (such as the Orphic—mystical—reinterpretation of the role of the agricultural god Dionysus). In the gnostic mysteries (the esoteric dualistic cults that viewed matter as evil and the spirit good), this process was carried further through the identification of the experiences of the soul that was to be saved with the vicissitudes of a divine but fallen Soul, which had to be redeemed by cultic activity and divine intervention. This view is illustrated in the concept of the paradoxical figure of the saved saviour, *salvator salvandus*.

Other deities, who had previously been associated with national destiny (*e.g.*, Zeus, Yahweh, Isis), were raised to the status of transcendent, supreme deities whose power and ontological status (relating to being or existence) far surpassed the other gods, who were understood as their servants or antagonists. The religious man sought to make contact with, or to stand before, this one, true god

Individual piety

of the Beyond. The piety of the individual was directed either toward preparing himself to ascend up through the planetary spheres to the realm of the transcendent god or toward calling the transcendent god down that he might appear to him in an epiphany or vision. These techniques for achieving ascent or a divine epiphany make up the bulk of the material that has usually been termed magical, theurgic (referring to the art of persuading a god to reveal himself and grant salvation, healing, and other requests), or astrological and that represents the characteristic expression of Hellenistic religiosity.

Mythology. The cosmogonies (dealing with the origins of the world) and cosmologies (dealing with the ordering of the world) of the Hellenistic period centred around the problem of accounting for the distance between this world and the Beyond, or on accounting for the evil nature of this world and its gods. Many mythic schema were employed regarding the origin and ordering of this world. It was viewed as being: the result of the conscious or unconscious emanation from the transcendent realm; the result of the fall of a deity from the Beyond; the creation of a hostile, ignorant, or evil deity; or a joke or mistake. The purpose of this speculation was both pragmatic and soteriological: if one could determine how this creation came into being, one could reverse it or overcome it and be saved.

Institutions. The temples and cult institutions of the various Hellenistic religions were repositories of the knowledge and techniques necessary for salvation and were the agents of the public worship of a particular deity. In addition, they served an important sociological role. In the new, cosmopolitan ideology that followed Alexander's conquests, the old nationalistic and ethnic boundaries had broken down and the problem of religious and social identity had become acute. The Hellenistic Age was characterized by the rapid growth of private religious societies (*thiasoi*). Though some were organized according to national origin or trade, the majority were dedicated to the worship of a particular deity. In many instances these groups began as immigrant associations (*e.g.*, an Egyptian association of devotees of Amon was chartered in Athens at the beginning of the 3rd century BC); but they often transcended these origins and became a new form of religious organization in which citizens of various countries, freemen and slaves, could be united by their common devotion and share in a common religious heritage. Admission to such groups was voluntary (in contradistinction to the archaic national or familial religious organizations) and demanded the payment of dues, submission to collective authority, and the acceptance of strict codes of morality. Most of these groups had regular meetings for a communal meal that served the dual role of sacramental participation (referring to the use of material elements believed to convey spiritual benefits among the members and with their deity) and the social function of brotherhood; *i.e.*, the security of membership in a group and a shared sense of identity.

Hellenistic religions as voluntary associations

The influence of Hellenistic religions. The archaic gods worshipped during the Hellenistic period possessed a remarkable longevity. The Eleusinian Mysteries, founded in the 15th century BC, ceased in the 4th century AD; Dionysus, whose name first appears on tablets dated to *c.* 1400 BC, was last celebrated in the beginning of the 6th century AD; the last temple of Isis, whose cult extended back to the 2nd millennium in Egypt, was closed in 560 AD. Yet even after these ceased as objects of devotion in the post-Constantinian period, they continued to exercise their influence. Hellenistic philosophy (Stoicism, Cynicism, Neo-Aristotelianism, Neo-Pythagoreanism, and Neoplatonism) provided the key formulations for Jewish, Christian, and Muslim philosophy, theology, and mysticism through the 18th century. Hellenistic magic, theurgy, astrology, and alchemy remained influential until modern times in both East and West. Theosophy and other forms of the occult, especially since the Renaissance, drew their inspiration from the Hellenistic mystery cults, Hermeticism (Greco-Egyptian astrological, magical, and occultic movement), and Gnosticism. Various Jewish, Christian, and Muslim sectarian groups continued the theologies of many of the Hellenistic religions (especially dualistic modes of thought). Hellenistic sacred art and architecture has remained the basis of Christian and Jewish iconography and architecture to the present day. Figures such as Alexander the Great generated a vast body of religious literature, especially in the Middle Ages. Many of the symbols and legends associated with Hellenistic deities persisted in folk literature and hagiography (stories of saints and "holy" persons). The basic forms of worship of both the Jewish and Christian communities were heavily influenced in their formative period by Hellenistic practices, and this remains fundamentally unchanged to the present time. Finally, the central religious literature of both traditions—the Jewish Talmud (an authoritative compendium of law, lore, and interpretation), the New Testament, and the later patristic literature of the Early Church Fathers—are characteristic Hellenistic documents both in form and content.

BIBLIOGRAPHY. The most useful cultural and political history containing valuable discussions of controversial issues with full bibliography is R. COHEN, *La Grèce et l'hellenisation du monde antique*, 2nd ed. (1948). W.W. TARN and G.T. GRIFFITH, *Hellenistic Civilisation*, 3rd ed. (1952); and M.I. ROSTOVTZEFF, *The Social and Economic History of the Hellenistic World*, 3 vol. (1941), remain the standard English works. M.P. NILSSON, *Geschichte der griechischen Religion*, 2nd ed., vol. 2 (1961); and K. PRUMM, *Religionsgeschichtliches Handbuch für den Raum der altchristlichen Umwelt* (1954), are indispensible as general handbooks and for the rich bibliographies they contain. The magnificent encyclopaedia now in progress, *Reallexikon für Antike und Christentum* (1950–), will be, when completed, the best single resource for the study of Hellenistic and early Christian religion.

A varied selection of texts in good English translation may be found in E.R. BEVAN, *Later Greek Religion* (1927); F.C. GRANT (ed.), *Hellenistic Religions: The Age of Syncretism* (1953); E. BARKER (ed.), *From Alexander to Constantine* (1956); and R.M. GRANT (ed.), *Gnosticism: A Sourcebook of Heretical Writings from the Early Christian Period* (1961).

Important general interpretations include: F. CUMONT, *Oriental Religions in Roman Paganism* (Eng. trans. from 2nd French ed., 1911), the 4th ed. *Les religions orientales dans le paganisme romain* (1929), is considerably expanded; P. WENDLAND, *Die hellenistisch-römische Kultur in ihren Beziehungen zu Judentum und Christentum* (1912); H.R. WILLOUGHBY, *Pagan Regeneration* (1929); A.J. FESTUGIERE, *L'Ideal religieux des Grècs et l'Evangile* (1932), *Personal Religion among the Greeks* (1960); A.D. NOCK, *Conversion* (1933); M.P. NILSSON, *Greek Piety* (Eng. trans. 1948); E.R. GOODENOUGH, *Jewish Symbols in the Greco-Roman Period*, 13 vol. (1953–70); S.K. EDDY, *The King is Dead: Studies in the Near Eastern Resistance to Hellenism 334–31 B.C.* (1961); E.B. DODDS, *Pagan and Christian in an Age of Anxiety* (1965); A.J. TOYNBEE (ed.), *The Crucible of Christianity* (1969); and J. FERGUSON, *The Religions of the Roman Empire* (1970). In addition to these works (all of which contain full bibliographies), see the individual volumes in the important series in progress, ed. by M.J. VERMASEREN, *Études préliminaires aux religions orientales dans l'Empire romain.*

(J.Z.S.)

Helmholtz, Hermann von

One of the greatest scientists of the 19th century, Hermann Ludwig Ferdinand von Helmholtz made fundamental contributions to physiology, optics, electrodynamics, mathematics, and meteorology, but is best known for his statement of the law of the conservation of energy. In addition, he brought to his laboratory research the ability to analyze the philosophical assumptions on which much of 19th-century science was based, and he did so with clarity and precision.

Born at Potsdam near Berlin, on August 31, 1821, Helmholtz' delicate health confined him to home for his first seven years. His father was a teacher of philosophy and literature at the Potsdam Gymnasium, and his mother was descended from William Penn, the founder of Pennsylvania. The young Helmholtz thrived in this intellectual, though impecunious, home atmosphere, where his father taught him Latin, Greek, Hebrew, French, English, Italian, and Arabic. His father also introduced him to the prevailing Hegelian "Nature philosophy," which deduced conclusions from philosophical constructs instead of empirical data. Pretending to contain the key

Helmholtz.
By courtesy of the Ruprecht-Karl-Universitat, Heidelberg, Germany

to the secrets of nature, this transcendental view became an important influence on his career.

After graduating from the Gymnasium, Helmholtz in 1838 entered the Friedrich Wilhelm Medical Institute in Berlin, where he received a free medical education on the condition that he serve eight years as an army doctor. At the institute he did his first research under the distinguished physiologist, Johannes Müller. He attended physics lectures, worked his way through the standard textbooks of higher mathematics, and learned to play the piano with a skill that later helped him in his work on the sensation of tone.

On graduation from medical school in 1843, Helmholtz was assigned to a regiment at Potsdam. Since his army duties were few, he did experiments in a makeshift laboratory he set up in the barracks; at that time he also married Olga von Velten, daughter of a military surgeon.

Early success

Before long, Helmholtz' obvious scientific talents led to his release from military duties. In 1848 he was appointed assistant at the Anatomical Museum and extraordinary professor at the Academy of Fine Arts in Berlin, moving the next year to Königsberg in East Prussia (now Kaliningrad), to become assistant professor and director of the Physiological Institute. But Königsberg's harsh climate was injurious to his wife's health, and, in 1855, he became professor of anatomy and physiology at the University of Bonn, moving in 1858 to Heidelberg. During these years, his scientific interests progressed from physiology to physics. His growing scientific stature was further recognized in 1871 by the offer of the Chair of Physics at the University of Berlin; in 1882, by his elevation to the nobility; and, in 1888, by his appointment as first Director of the Physico-Technical Institute at Berlin, the post he held for the rest of his life.

The variety of positions he held reflects his interests and competence but does not reflect the way in which his mind worked. He did not start out in medicine, move to physiology, then drift into mathematics and physics. Rather, he was able to coordinate the insights he had acquired from his experience in these disciplines and to apply them to every problem he examined. His great work, *Handbook of Physiological Optics* (1867), was characterized—like all of his scientific works—by a keen philosophical insight, molded by exact physiological investigations, and illustrated with mathematical precision and sound physical principles.

Attack on "Nature philosophy"

The general theme that runs through most, if not all, of Helmholtz' work may be traced to his rejection of "Nature philosophy," and the violence of his rejection of this seductive view of the world may well indicate the early attraction it had for him. "Nature philosophy" derived from the German philosopher Immanuel Kant, who in the 1780s had suggested that the concepts of time, space, and causation were not products of sense experience but mental attributes by which it is possible to perceive the world. Therefore, the mind did not merely record order in nature, as the Empiricists insisted; rather, the mind organized the world of perceptions, so that, reflecting the divine reason, it could deduce the system of the world from a few basic principles. Helmholtz opposed this view by insisting that all knowledge came through the senses. Furthermore, all science could and should be reduced to the laws of classical mechanics, which, in his view, encompassed matter, force, and, later, energy, as the whole of reality.

Helmholtz disagreed with his mentor in physiology, Müller, who, influenced by the biological component of "Nature philosophy," assumed that the organism as a whole was greater than the sum of its physiological parts. Above all, Müller believed, organs were endowed with a nonmaterial vital force that coordinated physiological action to produce the harmonious organic behaviour that characterized the living creature; and since this vital force was not subject to experimental investigation, physiological experiment was impossible. This attitude was anathema to Helmholtz and he set out to destroy it. His doctor's thesis in 1842 on the connection between nerve fibres and nerve cells of invertebrates introduced him to physiological processes and stimulated him to investigate the problem of the nature and origin of animal heat. His measurement of the velocity of the nerve impulse in 1850 followed immediately upon Müller's remark that because this impulse was an example of "vitalism," it would never be measured. There was no "vital force," he was convinced, because organisms employed the same forces as those in inorganic nature, forces that he now considered in terms of classical mechanics. His resulting paper, "On the Conservation of Force," gave him claim to be one of the discoverers of the principle of the conservation of energy. His later physiological investigations continued his attack on both vitalism—nonmaterial cause of many living processes—and "Nature philosophy."

Discovery of the conservation of energy

The eye, furthermore, considered by vitalists to be an exquisite example of the divine mind at work, was shown by Helmholtz to be a rather imperfect piece of workmanship. While conducting these researches, he invented the ophthalmoscope and the ophthalmometer, the latter instrument permitting the measurement of accommodation of the eye to changing optical circumstances.

In 1863 Helmholtz published his masterly work *On the Sensation of Tone as a Physiological Basis for the Theory of Music*. Here, fundamental physiological and anatomical researches were combined with the mathematical and physical analysis of wave motion to produce a firm foundation for the aesthetic analysis of music. Helmholtz now used the physics and physiology of sound to attack Kant's theory of perception. Similarly, Helmholtz' views on non-Euclidean geometry appear to have been stimulated by Kant's statements that Euclidean geometry reflected the basic structure of the human mind.

Helmholtz' work in electricity and magnetism reveals his conviction that classical mechanics was probably the best mode of scientific reasoning. He was one of the first German scientists to appreciate the work in electrodynamics of the British scientists Michael Faraday and James Clerk Maxwell. Faraday had appeared to strike at the foundation of Newtonian physics by his unorthodox rejection of action at a distance; that is, action between two bodies in space without alteration of the medium between them. Maxwell, however, by interpreting the mathematics of Faraday's laws, was able to show that there was no contradiction between Newtonian physics and classical mechanics. Helmholtz further developed the mathematics of electrodynamics. He spent his last years in an unsuccessful attempt to reduce the entire field of electrodynamics to a minimum set of mathematical principles, an attempt in which he had to rely increasingly on the mechanical properties of the "ether," a weightless substance then thought to pervade all space. Though he was unsuccessful in his original purpose, he was almost able to deduce all electromagnetic effects from the ether's supposed properties. The discovery of radio waves by his pupil, Heinrich Hertz, in 1888, was viewed as the experimental confirmation of the theories of Faraday, Maxwell, and Helmholtz. The special and general theories of relativity, proposed by Albert Einstein, destroyed Helmholtz's theories by eliminating the ether.

Helmholtz' early work on sound and music had led him

to the study of wave motion. His work on the conservation of energy familiarized him with the problems of energy transfer. These two areas coalesced in his later years in his studies of meterology, but the phenomena were so complex that he could do little more than point the way to future areas of research.

Helmholtz was the end product of the development of classical mechanics. He pushed it as far as it could go. When he died in Berlin on September 8, 1894, the world of physics was poised on the brink of revolution. The discovery of X-rays, radioactivity, and relativity led to a new kind of physics in which Helmholtz' achievements, although impressive, had little to offer the new generation.

BIBLIOGRAPHY. There are two biographies of Helmholtz available to the reader of English. LEO KOENIGSBERGER, *Hermann von Helmholtz*, 3 vol. (1902–03; abr. Eng. trans., 1906, reprinted 1965), is often technical and sometimes difficult to understand. J.G. MCKENDRICK, *Hermann Ludwig Ferdinand von Helmholtz* (1899), deals only with Helmholtz' medical career. RICHARD M. and ROSLYN P. WARREN have published a collection of Helmholtz' writings on perception, entitled *Helmholtz on Perception: Its Physiology and Development* (1968), with critical comments. Helmholtz' *Popular Lectures on Scientific Subjects*, 2 vol. (1873; 2nd series, 1881), are excellent introductions to his thought.

(L.P.W.)

Helsinki

The capital of Finland since 1812, and that nation's leading seaport, Helsinki, despite a turbulent history stretching back for more than four centuries, is one of the most modern of European cities in terms of character and appearance. Founded in 1550, it was ravaged by a plague in 1710 and burned to the ground in 1713. Large parts of the city were destroyed by another great fire in 1808, and there is little physical evidence of its early history. Its development has also mirrored the strife-torn history of Finland: centuries of competitive Swedish and Russian domination, linked with national aspirations of marked individuality. Its destiny was controlled by a succession of visiting kings and tsars before it emerged, in 1917, as the administrative centre of the new Republic of Finland, and, as such, developed into the Helsinki of today. By the 1970s, it had become a vital economic and cultural centre, whose regional and international importance was well indicated by the popular titles given the city—"the daughter of the Baltic" and "the city between east and west." At intervals—for example, as host city to the 1952 Olympic Games—Helsinki has been known as an international sports centre, but from the 1960s onward, its name has equally often been connected with attempts to lessen international tension, as in the case of the American–Soviet talks on the limitation of strategic arms, begun in 1969. A further apellation—"the white city of the north"—draws attention to the physical appearance of the city, built largely of local light-coloured granite, and to the fact that, after Reykjavík, in Iceland, it is the world's most northerly capital. It has a spacious and well-planned atmosphere, and a stark but beautiful setting.

Historical development. For many centuries Finland, a part of the Swedish realm, was the scene of repeated wars between that nation and the growing Russian state. It was against this background that King Gustav Vasa of Sweden founded Helsinki, on June 12, 1550. The young settlement—whose Swedish name is Helsingfors—was intended to compete, in the economic field, with the city of Reval (now Tallinn, in the Estonian S.S.R.) situated on the opposite side of the Gulf of Finland. Helsinki was originally located on the Vantaa estuary but moved down to its present location, a promontory with a fine, island-sheltered harbour, in 1640. The trading centre numbered fewer than 2,000 when the plague of 1710 killed most of the inhabitants. Three years later it was burned by Swedish forces retreating from an attack by the fleet of the Russian tsar Peter the Great, and development was hindered by further Russian attacks later in the 18th century. Another fire, in 1808, added to the city's difficulties.

Early misfortunes

In 1809, Finland was ceded to Russia. The national capital during the period of Swedish hegemony had been Turku (Åbo) in the southwest of the country, facing Sweden, and thus both political and military motives played a part in the decision of the Russian tsar Alexander I to move the capital of the new grand Duchy from Turku to Helsinki, in 1812. In 1748 the settlement became much more secure when a fortress—once called the Gibraltar of the north—was constructed on a group of small islands outside the harbour of Helsinki, although the fortress (called Sveaborg by the Swedes and later Suomenlinna by the Finns) was bombarded by a French–British fleet in 1855 during the Crimean War.

Meanwhile, the centre of Helsinki had been completely reconstructed in an impressive imperial and monumental style, under the influence of a German-born architect, C.L. Engel, active in the then Russian capital, St. Petersburg. The completed city centre was comprised of a number of distinctive buildings still to be seen in the 1970s. These include government buildings, the main building of Helsinki University, and the cathedral, known as the Great Church, completed in 1852. All of them surround the broad expanse of Senate Square, which is often considered to be one of the most beautiful in the whole of Europe. Not far from the square rise the cupolas of the Uspenski Orthodox Cathedral, one of the few recognizable reminders of the period of Russian rule. Tsar Nicholas I visited Helsinki in person in 1833, and the health spa that subsequently opened attracted members of the Russian upper class from Moscow and St. Petersburg over a period of decades.

Reconstruction and growth

In the 1860s and 1870s industrialization brought great changes to the social and economic fabric of the city and started a development that made Helsinki Finland's largest industrial city. Population—a mere 4,000 in 1810—increased rapidly and was over 22,000 by 1860, 60,000 by 1890, and 111,000 by 1904. Although the policy of Tsar Alexander II toward Finland and its capital was liberal, by the end of the 19th century the Russians saw social changes within the grand duchy, including a national Finnish movement, as a threat to their position. Nicholas II and his governor general, Nikolay Bobrikov, initiated a russification program. Bobrikov, who had assumed dictatorial powers, was shot by a young Finn in 1904, and Helsinki became the centre of a group of activists working for the liberation of Finland. A national declaration of independence was proclaimed by the parliament in Helsinki in December 1917, and the capital was occupied by Finnish red guards and Russian units during the ensuing short but bloody civil war between "white" and "red" zones. Conditions soon became more stabilized, with the Helsinki parliament electing Finland's first president in 1919. The following half century saw the full development of Helsinki into an important centre of trade, industry, and culture, a process interrupted only by the war years of the 1940s.

A distinctive architectural style, modern in concept and graceful in execution, achieved prominence during this period, complementing the buildings of a century earlier. The railway station (designed by Eliel Saarinen, 1914) and the National Pensions Institute (by Alvar Aalto, 1956) were notable examples of the work of Finnish architects with international reputation. At the turn of the century the population had numbered less than 100,000; by the early 1970s greater Helsinki—including a number of modern suburbs acquired during the 1940s—had more than 815,000 inhabitants. The spacious and well-planned atmosphere of the city was nevertheless successfully maintained.

Modern architecture

The site. Helsinki is surrounded by the sea on three sides, and only 68 square miles (177 square kilometres) of its total administrative area of 173 square miles (448 square kilometres) consist of land. The city can expand only to the north, northwest and northeast, and it is in these areas that the 17 new suburbs of the mid-20th century are located. Helsinki is located at 60° N latitude (comparable to the location of Greenland's Kap Farvel, Nunivak Island of Alaska, and the upper Kamchatka Peninsula of the Soviet Union), but the Baltic Sea influ-

ence contributes to a rather mild climate. The average summer temperature is 61° F (+16° C) and the average winter temperature 21° F (−6° C). Icebreaker activity keeps at least part of the extensive harbour facilities open during the winter months. Helsinki is mainly built on rock, but there are only a few high points, while parts of the present centre of the city are actually built on filled-in seabed.

The people. Helsinki proper had 525,628 inhabitants in 1969, of whom a majority—291,000—were women. Greater Helsinki numbered about 815,000 persons in 1971, nearly 18 percent of Finland's total population. There was a continued movement of people into and out of the central city, with an average annual net gain of some 5,000 citizens by the late 1960s and early 1970s. Those leaving Helsinki proper went mostly to the suburbs of greater Helsinki. In the early 1970s the majority of the city's inhabitants—some 60 percent—had been born elsewhere. Reflecting its heritage, Helsinki is a bilingual city, with 85 percent of the population claiming Finnish, and 14 percent Swedish, as their mother tongues. As in the case of other northern European cities, the religious composition of Helsinki is overwhelmingly Protestant, with 85 percent adhering to the Lutheran faith. A small minority—about 2 percent—is Orthodox. Of the economically active population, 24 percent work in industry, 30 percent in the service professions, and 25 percent in commercial activities. About 22 percent of the population of Helsinki is in the 0–14 age group, with a tenth in the over-65 group.

Bilingualism

Economic life. Helsinki's economic life and development is based on its excellent harbours and on good railway and road connections to the extensive interior of the nation. More than half of Finland's total imports consequently pass through Helsinki, and are handled by the large wholesale enterprises in the city. Only 10 percent of the national exports, on the other hand, pass through Helsinki, as the largest export ports are elsewhere along the Finnish coast. In her capacity as Finland's largest industrial city, Helsinki is responsible for 17 percent of the nation's gross industrial production, with food and metal processing, printing, textiles, and clothing among the main industries. Many of those products exhibit the functional contemporary design for which the nation is famous. In connection with expansion programs, some of the larger industries had moved to the outer Helsinki region in the 1970s. The Wärtsilä shipyard (producing icebreakers, liners, and cable-laying ships) and the wares of the Arabia porcelain factory, one of the largest of its kind in Europe, are, in their distinctive ways, internationally famous.

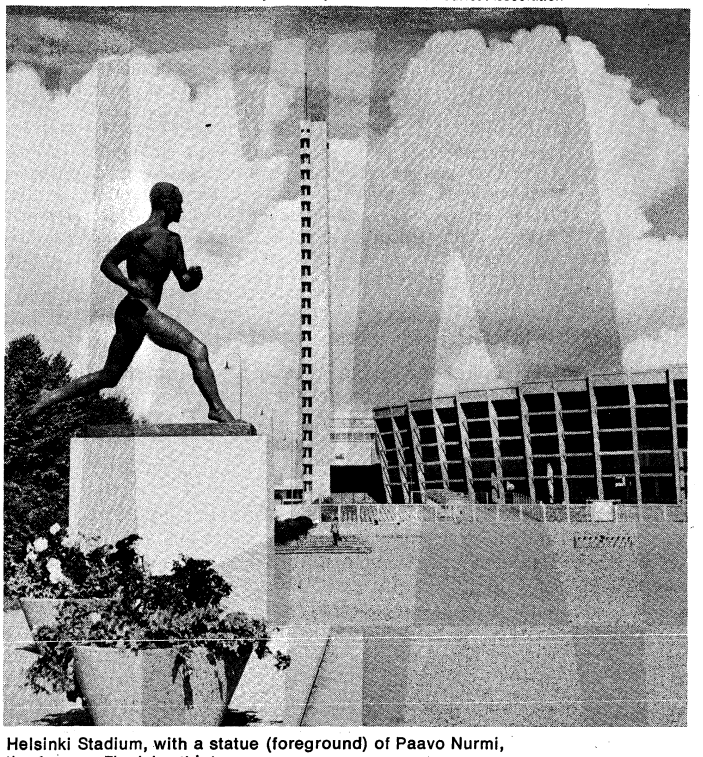
Political and governmental institutions. The parliament and the government of Finland meet and function in Helsinki. A city council has headed the municipal government since 1875. Elected every fourth year, it is the highest policy-making body of the capital. The city board and various committees prepare and execute the decisions of the council. The city board includes the mayor and six assistant city managers, together with 11 members who are elected each year by the City Council, on the basis of the relative strength of the political parties represented on that body. The city managers are responsible for matters concerning real estate, hospitals, public utilities, education and culture, construction and public works, and personal and social welfare, while the mayor is responsible for central administration and finance. The city board is assisted by some 50 administrative boards and commissions.

City managers

The presidential palace is located in Helsinki, which, as a capital, also houses the highest courts of the country, and the Bank of Finland.

Services. Many of the services provided for by the city of Helsinki—notably education in elementary and trade schools and in medical care—are free, or almost free. Of the total municipal expenditure, some 27 percent is used for medical care and social welfare functions, 10 percent for education, 9 percent for public works, and some 20 percent for such public utilities as electricity, water, gas, and transportation. Large sums are also invested in long-term transportation projects. In 1968 the City Council voted to construct Helsinki's first subway, which will total 7.2 miles, and of which 2.4 miles will be tunnel. The first Finnish-constructed "test train" for the subway was ready in 1972. Some 400,000 passengers are carried daily by municipally run buses and streetcars. The number of motor vehicles in the city is close to 100,000, of which more than 80,000 are private cars. The physical geography of Helsinki, constricting routes through the neck of a promontory, makes transportation and traffic planning a constant problem, even in this well laid out city.

By courtesy of the Finnish Tourist Association



Helsinki Stadium, with a statue (foreground) of Paavo Nurmi, the famous Finnish athlete.

Cultural life and recreation. Thirteen theatres, an opera and ballet company, and three symphony orchestras contributed to the year-round cultural activity of the Finnish capital in the early 1970s. An annual Helsinki festival features world famous orchestras and artists and a program of rich variety. In addition to museums and art galleries, the cultural interests of Helsinki citizens are furthered by a fine, modern city theatre, by Timo Penttilä, with an audience capacity of more than 1,000, and a new concert building, of a striking design, by Alvar Aalto. Helsinki University, with 23,000 students, is the largest university in Scandinavia.

Helsinki is a city for recreation. The sea, open or frozen, gives opportunity for sports ranging from yachting to a somewhat perilous car racing, and there are close to 300 separate sports grounds for both winter and summer events. The city provides close to 200 miles of ski routes, and there are numerous spacious parks, where young and old alike can enjoy the Helsinki air, which—thanks to the influence of sea breezes—is surprisingly clean for an industrial city. The many beaches and rocky islands are covered with sunbathers in the summer, while in winter the frozen bays are dotted with people fishing through the ice.

BIBLIOGRAPHY

Geography and topography: HEIKKI BROTHERUS, *Helsinki and Her People* (1966), is the fullest description of the city, with many illustrations. See also MATTI KURJENSAAR and PEKKA LOUNELA, *Helsinki in Color* (1966); FRED RUNEBERG, *Helsinki* (1964), mainly pictures and annotations; and G. MARTENSON (ed.), *Helsinki, Capital of Finland* (1950), also a well-illustrated account. LAURI AHO (ed.), *Helsinki: The Face of the Capital* (1959); and CLAIR AHO, *Helsinki,*

Daughter of the Baltic (1951), are almost entirely illustrations; KEYO PETAJA (ed.), *Helsinki* (1970), covers the city's architecture. OLIVER WARNER, *A Journey to the Northern Capitals* (1968), is a personal account with a section on Helsinki.

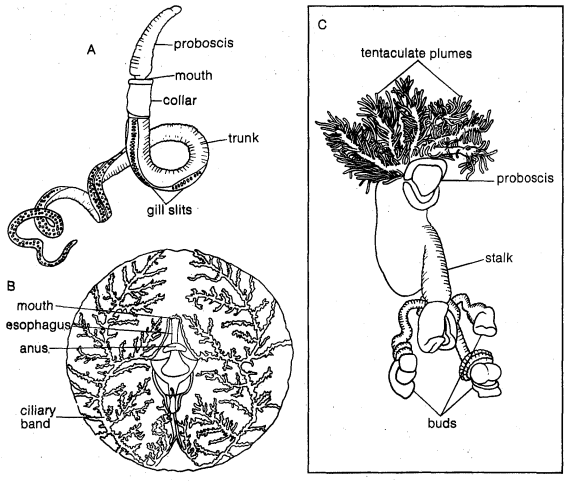
Scientific aspects and economics: The HELSINKI HARBOR BOARD, *Port of Helsinki* (1967), describes that particular aspect of the city; while W. SMITH and P. POLVINEN (eds.), *Helsinki Metropolitan Transportation Study*, bk. 1, *Helsinki* (1969), is an exhaustive survey. S.T.H. JAATINEN, *The Birthplace Field of Helsinki According to the Census of 1950* (1962), illustrates past population patterns.

(C.F.S.)

Hemichordata

The Hemichordata are a group of wormlike marine invertebrates closely related to the chordates. The term Hemichordata—from the Greek *hemi*, meaning "half," and *chorde*, meaning "string," thus, "half-chordate"—was first proposed because the buccal diverticulum, a tubular outgrowth from the mouth cavity forward into the proboscis, or "snout," resembled a rudimentary notochord—the dorsal, or back side, supporting axis of the more primitive vertebrates. This theory has since been rejected, however, because it has been determined that the diverticulum bears little resemblance in origin and function to the vertebrate notochord. The hemichordates are sometimes given phylum rank and are so treated in this article; some authorities place the group at various other taxonomic levels with the other so-called protochordates. The Hemichordata consist of three classes:

From (A) Borradaile *et al.*, *The Invertebrata* (1963); Cambridg University Press, (B) P. Meglitsch, *Invertebrate Zoology* (1967); Oxford University Press, (C) C. Burdon-Jones



Body plans of representative Hemichordata.
(A) Acorn worm, *Dolichoglossus kowalewskii*, (B) *Planctosphaera*, (C) *Cephalodiscus*.

Enteropneusta, Pterobranchia, and Planctosphaeroidea. Enteropneusta, or acorn worms, are solitary, wormlike, bilaterally symmetrical animals, often brilliantly coloured. They are known as acorn worms because of the appearance of the proboscis and collar. Pterobranchia are minute, colonial, tube-building forms. Planctosphaeroidea are known only from a few floating larvae. Enteropneusts are common in the intertidal zones from the White Sea and Greenland south to New Zealand and the Cape of Good Hope; they are found offshore to depths of 400 metres (about 1,300 feet) or more. They vary in size from a few centimetres long (*Saccoglossus pygmaeus* of the North Sea) to two metres (about seven feet) or more (*Balanoglossus gigas* of Brazilian coastal waters). Most species of the pterobranch genus *Cephalodiscus* inhabit offshore waters at depths of about 165 to 2,000 feet in the Antarctic and south temperate seas. *Rhabdopleura*, also a pterobranch, is cosmopolitan on various sea bottoms at depths of about 16 to 1,650 feet from the sub-Arctic to the sub-Antarctic.

Size range and distribution

Natural history. *Reproduction and life cycle.* Among some Enteropneusta, the fertilized egg develops into a free-swimming larva—called a tornaria larva—similar to the starfish larva. The tornaria is barely visible as it spirals continuously through the water, propelled by the powerful beat of the telotroch, a belt of cilia, or tiny hairlike structures. These larvae may drift for weeks, feeding on plankton (microscopic plants and animals). Such larvae are called planktotrophic to distinguish them from lecithotropic larvae (*e.g.*, the larvae of *Saccoglossus* and other members of the family Harrimanidae), which are nourished by their own yolk reserves.

The tornaria gut is L-shaped. A short gullet leads from the mouth to a globular stomach; a straight intestine passes from the stomach to the anus. A thin-walled triangular vesicle, or sac, in front of the mouth leads to the outside through a pore on the dorsal surface; the vesicle develops into the proboscis coelom, or cavity, and the pore becomes the proboscis pore of the adult. As the enteropneust larva grows older, two pairs of vesicles, which develop on either side of the stomach, become the collar cavity and the trunk cavity. The free-swimming larva of the enteropneustan *Saccoglossus* does not develop a mouth or begin to feed until after it has settled to the sea bottom. It then develops a tail, which it uses to attach itself, and builds a burrow. Initially, the larva feeds at the surface by straining particles from the water drawn in through the mouth. This method is superseded by one that first entails selecting a surface to which to attach itself and then burrowing or foraging on that surface with its proboscis. The enteropneust tail is a relic of the stalk of more primitive relatives, the pterobranchs.

Mouthless larva of *Saccoglossus*

Among enteropneusts, the sexes are separate and fertilization is external. Asexual reproduction is known in one species of *Balanoglossus;* small pieces separated from the posterior end regenerate into mature adults.

The lecithotropic larvae of the pterobranchs, *Cephalodiscus* and *Rhabdopleura*, develop within the parent coenoecium (*i.e.*, a nonliving coat that is secreted by glands in the proboscis) and disperse during their short free-swimming stage. They rapidly develop the tripartite arrangement of the adult (*i.e.*, proboscis, collar, and trunk). The anus, at first near the posterior end, moves forward near the mouth as the intestine becomes U-shaped (an adaptation to tube dwelling). After settling, the larva of *Rhabdopleura* forms a coenoecium. It develops into a colony by a progressive process of budding and segregation from a creeping stolon (a rootlike extension) that remains attached to the bottom.

Behaviour and ecology. In general, Enteropneusta live in U-shaped, coiled, or sinuous burrows excavated beneath stones or live among the attachments of sea plants. *Balanoglossus gigas* burrows 75 centimetres (about 30 inches) or more. Adult enteropneusts use the proboscis and collar for burrowing. The proboscis penetrates the sand or mud and by rhythmic contraction and distention draws the collar into the burrow. Alternate elongation and dilation of the collar provide an anchoring effect for drawing the trunk forward. Movement within the burrow is accomplished by rhythmical contractions of muscle and by the action of cilia. Mucus secreted by certain cells provides lubrication. Mucus may have a cleansing and protective function, for large amounts are produced when the animals are disturbed by handling. Despite the mucus, bottom-feeding fishes eat the worms when they stretch from their burrows to forage.

Sand, mud, and organic debris collected by enteropneusts during burrowing and foraging pass into the gut. Water drawn into the mouth provides oxygen and delivers fine food particles that are strained from the current as it passes out through the gill slits.

In the Harrimanidae (*e.g.*, *Saccoglossus*), development from egg to adult is direct; there is no tornaria larva. Eggs and sperm, released within the burrows, are subsequently expelled into the water, where fertilization takes place. The reproductive process is initiated by tidal and climatic factors, particularly a rise in water temperature at the onset of spring tides. The females spawn first, followed shortly by the males. The eggs and young drift freely for three to four days.

Spawning

The minute animals, or zooids, comprising a *Rhabdopleura* colony are restricted in movement because they

are attached to each other by a stolon. The zooids of *Cephalodiscus* are not so attached and thus can move in and out of their tubes to feed at or on the surface. They feed on particles of organic matter trapped by the cilia and mucus secretions on their tentacles. *Atubaria* has no coenoecium and lives free with its stalk entwined around other organisms on the sea floor.

Form and function. The adult hemichordate is distinguished by the division of its body and body cavities, or coeloms, into three basic parts: the proboscis, collar, and trunk. A central nervous system is absent, but there is a concentration of nerve tissue in the collar, which is linked with a nervous system in the epidermis, or outer covering. The circulatory system usually includes a contractile heartlike vesicle, blood vessels, and sinuses. The pharynx may be perforated by numerous paired gill slits, or they may be absent.

The second region of the body, the collar, may bear two or more tentacle-like plumes, which may have a double row of ciliated tentacles well supplied with secretory cells. The tentacles are special adaptations for feeding on particles suspended in the water. The network of nerve cells and fibres lying within the epidermis is linked with two main nerve tracts that lie dorsally median (*i.e.*, toward the body midline on the upper side) and ventrally median (on the lower side). The dorsal side of the collar has a neurochord formed by an inpocketing of the epidermis; it may have a central lumen, or cavity, that opens to the exterior anteriorly and posteriorly, or it may have a series of lacunae, or spaces. The neurochord contains large nerve cells, extensions of which reach almost to the tip of the proboscis and into the ventral nerve cord. These cells probably facilitate rapid responses such as abrupt contractions of the anterior trunk when the proboscis is touched. The general body surface is innervated by a primitive receptor system, which consists of scattered sensory cells. There is no well-defined centre of stimuli and responses.

Role of the glomerulus in excretion

Excretion may be effected by means of the glomerulus. This organ forms a thick mass of cells and blood-filled cavities on either side of the heart vesicle. In some enteropneusts the cells of the glomerulus contain yellow or brown granules, thus suggesting the possible excretory function for the glomerulus. The blood is driven from the heart vesicle into the glomerulus, where it is presumably cleansed of wastes before passing into the blood vessels and sinuses.

The enteropneusts have five coelomic cavities: one in the proboscis, which opens to the exterior by a small pore on the proboscis stalk; two in the collar, which lie side by side and are indirectly connected to the exterior through small ciliated pores that open on either side into the first pair of gill chambers; and two in the trunk, which also lie side by side but have no internal or external connections.

The pharynx of *Cephalodiscus* and *Atubaria* is perforated by a pair of gill passages connecting the gut with the exterior. In *Rhabdopleura* these are represented by a pair of grooves, a simplification that may be a consequence of the animal's minute size and its adaptation to a tube-dwelling habit.

The sexes are separate. The reproductive organs consist of a large number of saclike ovaries or testes arranged in a row along each side of the anterior part of the trunk, below the gill pores. In some species they are lodged in prominent genital ridges, or wings. Each sac opens to the surface by a simple pore, through which the eggs or sperm are liberated.

Knowledge of the third class of hemichordates, the Planctosphaeroidea, is based solely on the descriptions of a few larvae, transparent spheres about one centimetre (0.4 inch) in diameter in which the viscera can be seen clearly. Ciliary bands that wind over the surface are highly branched and bilaterally symmetrical, as in the free-swimming tornaria, which in every respect this larva resembles. The planctosphaera larva differs only in having a pair of blind, boot-shaped inpocketings on either side of the intestine and stomach. Since the tornaria bears no resemblance to the adult, it is assumed that the planctosphaera larva is equally different from its adult form.

Paleontology and classification. *Evolution.* The hemichordates have remained a general primitive group, at a low level of evolution, closely linked with the echinoderms (*e.g.*, starfish, sea urchins) and sharing with them and the other protochordate groups a sessile (*i.e.*, fixed to a surface) or semi-sessile ancestor, which was bilaterally symmetrical and had a tripartite body and coelom. The comparatively simple larval development of the Hemichordata suggests that they have deviated less from the ancestral stock than have echinoderms or protochordates.

Annotated classification. The members of the phylum differ to such a great extent that early workers had considerable difficulty in interrelating them.

PHYLUM HEMICHORDATA

Solitary or colonial, more or less wormlike body with 3 divisions; proboscis, collar, and trunk; epidermal nervous system; open circulatory system with a contractile heart vesicle, blood vessels and sinuses; glomerulus, with or without gill slits; with or without tentacles on collar; fewer than 100 species.

Class Enteropneusta (acorn worms)

So called because of the resemblance of the proboscis and collar to an acorn; solitary, wormlike, frequently brilliantly coloured: yellow, orange, red, violet, or green; live in burrows in sand or mud; numerous gill slits, a straight alimentary canal; collar without tentaculate plumes; a few centimetres to about 2 m (about 6.5 ft) long; worldwide distribution not common, but often abundant locally.

Family Harrimanidae

Proboscis long, cylindrical, and flexible, often many times longer than the collar; gill slits numerous dorsally or dorsolaterally placed, opening directly to exterior; proboscis skeleton with 2 short or medium-length side arms; development direct by way of a lecithotrophic larva where known; a few cm to 0.5 m (about 20 in.) in length; found in northern and southern seas; *Saccoglossus*.

Family Spengelidae

Proboscis generally short, a few times longer than collar; proboscis skeleton with long side arms; gill silts may extend over most of the pharynx; length, a few to 30 cm (about 1 ft), in genus *Willeyia* some may reach 2 m; found in northern and southern seas.

Family Ptychoderidae

Proboscis short, often ovoid, only a few times longer than collar; proboscis skeleton with very short side arms, gill silts confined to dorsal and dorso-lateral region of pharynx; pharynx strongly constricted into dorsal respiratory and ventral digestive parts; a few cm to more than 2 m long; widespread throughout Indo-Pacific and Atlantic waters; *Balanoglossus*.

Class Pterobranchia

Small hemichordates, with or without gill silts, 2 or more tentaculate arms or plumes on collar; live in aggregations or colonies housed in externally secreted encasement attached to or embedded in some sediment; aggregations develop by budding from 1 sexually produced zooid; genus *Cephalodiscus* mostly Sub-Antarctic or Antarctic, south temperate regions around Australia, New Zealand, and South Africa, tropical seas around Indonesia, Sri Lanka (formerly Ceylon), India, and Indochina: genus *Rhabdopleura* common throughout coastal waters of northern Europe, on coral reefs in Sri Lanka, and southward to latitude 66° S.

Class Planctosphaeroidea

Knowledge based upon descriptions of a few specimens of 1 species: *Planctosphaera pelagica;* transparent, spherical, bilaterally symmetrical, with sinuous branched ciliary bands radiating over surface; believed to be the larva of an unknown hemichordate.

Hemingway, Ernest

Ernest Hemingway, American novelist and short-story writer, who became notable for the intense masculinity of his writing as well as for his adventurous and widely publicized life, achieved a fame surpassed by few, if any, American authors of the 20th century. The virile nature of his writing, which attempted to re-create the exact physical sensations he experienced in big-game hunting, bullfighting, and warfare, in fact masked an aesthetic sensibility of great delicacy. A celebrity long before he reached middle age, his popularity has been validated by serious critical opinion.

Hemingway, 1959.

The first son of Clarence Edmonds Hemingway, a doctor of medicine devoted to hunting and fishing, and Grace Hall Hemingway, whose interests were artistic, Ernest Miller Hemingway was born on July 21, 1899, in Oak Park, Illinois, a suburb of Chicago. His life and career were to combine the divergent predilections of his parents, but the same life and career can be seen in large part as a never ended rebellion against the prudery and conventionalism of both father and mother and the place of his birth. He was educated in the public schools there and began to write in high school, where he was active and outstanding. But in his work he rejected Oak Park and what it stood for; as many of his short stories were later to indicate, the parts of his boyhood that mattered most were summers spent with his family on Walloon Lake in upper Michigan. On graduation from high school in 1917, impatient for a less sheltered environment, he did not enter college but went to Kansas City, where he was employed as a reporter for the *Star*, a leading newspaper of the time, which gave him valuable vocational training. Repeatedly rejected for military service because of a defective eye, he managed to enter World War I as an ambulance driver for the American Red Cross. On July 8, 1918, not yet 19 years old, he was injured on the Austro-Italian front at Fossalta di Piave. Decorated for heroism and hospitalized in Milan, he fell in love with a Red Cross nurse, Agnes von Kurowsky, who declined to marry him. These were experiences he was never to forget.

After recuperating at his home and in Michigan, Hemingway renewed his efforts at writing, for a while worked at odd jobs in Chicago, married Hadley Richardson, and sailed for France as a foreign correspondent for the *Toronto Star*. Advised and encouraged by other American writers in Paris—Scott Fitzgerald, Gertrude Stein, Ezra Pound—he began to see his nonjournalistic work appear in print there, and in 1925 his first important book, a collection of stories called *In Our Time*, was published in New York. The following year he published *The Sun Also Rises*, a novel with which he scored his first solid success. A pessimistic but sparkling book, it deals with a group of aimless expatriates in France and Spain—members of the postwar "lost generation," a phrase that Hemingway scorned while making it famous. This work also introduced him to the limelight, which he both craved and resented for the rest of his life.

First novels

The writing of books occupied him for most of the postwar years. Meanwhile, however, his first marriage, which produced a son, John, had failed, and he had married Pauline Pfeiffer, who was to bear his other two children, Patrick and Gregory. Based in Paris, he had also travelled widely for the skiing, bullfighting, fishing, or hunting that by then had become part of his life and formed the background for much of his writing. His position as a master of short fiction had been advanced by *Men Without Women* in 1927 and thoroughly established with *Winner Take Nothing* in 1933. At least in the public view, however, the novel *A Farewell to Arms* (1929) overshadowed both. Reaching back to his experience as a young soldier in Italy, he developed a grim but lyrical novel of great power, fusing love story with war story.

Many critics argue that by this stage Hemingway had done all of his best writing. The judgment is too harsh, but it is true that his success from this time on was mixed with unaccustomed failure and that his books were to appear less frequently. He once confessed that if he had spent less time hunting and fishing he might have written more. To these diversions might be added both his attraction to war, which was to absorb whole years of his life, and an energetic pursuit of personal enjoyment, for which he had an enormous capacity. Although he eventually drew on many of his adventures for books, he was at least as avid for the experience as for the literary use to which he might put it. His love of Spain and his passion for bullfighting resulted in *Death in the Afternoon* (1932), a learned study of a spectacle he saw more as tragic ceremony than as sport. Similarly, an African safari resulted in *Green Hills of Africa* (1935), an account of big-game hunting. Mostly for the fishing, he bought a house in Key West. Lured by the idea of catching the great marlin in the Gulf Stream of Cuba, he also bought his own fishing boat, "Pilar." A minor novel of 1937 called *To Have and Have Not* is set in and near Key West during the economic depression. Hemingway had now become concerned with social problems.

Activities during the Spanish Civil War

By now Spain was in the midst of civil war. Still deeply attached to that country, Hemingway made four trips there, once more a correspondent. He raised money for the Loyalists, who supported the government of the republic against the uprising of General Franco, and wrote a play called *The Fifth Column* (1938), set in besieged Madrid. As in many of his books, the protagonist of the play is based on the author, and his mistress on the writer and journalist Martha Gellhorn, whom Hemingway married when his divorce became final. Following his last visit to the Spanish war he purchased Finca Vigía (Lookout Farm), an unpretentious estate outside Havana, Cuba, and went with his bride to cover another war—the Japanese invasion of China.

The harvest of his considerable experience of Spain in war and peace was the novel *For Whom the Bell Tolls* (1940), the most successful of all his books as measured in sales. A substantial and often impressive work, it deals with a volunteer American guerrilla in the Spanish war who blows up a strategic bridge near Segovia in an attack that he knows is doomed to fail and in which he is left to die. All of his life Hemingway was fascinated by war—in *A Farewell to Arms* he focussed on its pointlessness, in *For Whom the Bell Tolls* on the comradeship it creates—and he was soon to become involved in World War II. For a long time he had bitterly predicted that the Spanish Civil War was a prelude to it. After he returned to Cuba he established what he called the Crook Factory, an informal but officially approved counterintelligence organization designed to deal with the influx of German spies in Cuba and with submarines off its coast. Also approved was a second plan, under which he outfitted his boat, "Pilar," in such a way as to attract U-boats, which he and his

crew might then destroy. He managed both operations efficiently, but before long he was disappointed at scoring no significant victories; and to get closer to the actual fighting he made his way to London, once again a journalist. He flew several missions with the Royal Air Force and crossed the English Channel with American troops on D-Day (June 6, 1944). Attaching himself to the 22nd Regiment of the 4th Infantry Division, he saw a good deal of action in Normandy and in the Battle of the Bulge. He also participated in the liberation of Paris and, although ostensibly a newsman, he impressed professional soldiers not only as a man of courage in battle but also as a real expert in military matters, guerrilla activities, and intelligence collection in particular.

Following the war in Europe, Hemingway returned to his home in Cuba and, his third marriage having gone the way of the others, he married his fourth wife—Mary Welsh, herself a correspondent whom he had met in London and with whom he was to spend the rest of his life. Established in Cuba at the Finca, where he began to work seriously again, they travelled widely, including one trip to Africa where they made a safari and were injured in two plane crashes. Soon after (in 1953), he received the Pulitzer Prize in fiction for a short, heroic novel—about an old Cuban fisherman who hooks and boats a giant marlin only to lose it to sharks—called *The Old Man and the Sea* (1952). This book, which played a role in gaining for him the Nobel Prize for Literature in 1954, was as enthusiastically praised as his previous novel, *Across the River and Into the Trees* (1950), the story of a professional army officer who dies while on leave in Venice, had been damned.

Pulitzer and Nobel prizes

By 1960 Fidel Castro's revolution in Cuba had driven Hemingway from his Finca. He had purchased another house in Ketchum, Idaho, and tried to lead his life and do his work as before. For a while he succeeded, but, anxiety-ridden and depressed, he was twice hospitalized at the Mayo Clinic in Rochester, Minnesota, where he received electroshock treatments. On July 2, 1961, two days after his return to the house in Ketchum, he took his life with a shotgun.

He left behind, however, a substantial amount of manuscript, some which has been published. *A Moveable Feast*, the memoir of his apprentice days in Paris, was issued in 1964. *Islands in the Stream*, three closely related novellas growing directly out of his peacetime memories of the Caribbean island of Bimini, of wartime Havana, and of searching for U-boats off Cuba, appeared in 1970.

A consummately contradictory man, Hemingway was witty, cheerful, irascible, by turns generous and selfish, expansive and egocentric. Hedonistic and dedicated, in love with life and yet by his own admission obsessed with death, an inveterate sportsman and omniverous reader, hard-drinking and early-rising, uninhibited, intricate, powerful, and damaged, he was himself a personification of the courage—which in a famous phrase he defined as "grace under pressure"—that mercilessly deserted him in the end.

MAJOR WORKS

NOVELS: *The Torrents of Spring* (1926); *The Sun Also Rises* (1926; English title, *Fiesta*, 1927); *A Farewell to Arms* (1929); *To Have and Have Not* (1937); *For Whom the Bell Tolls* (1940); *Across the River and Into the Trees* (1950); *The Old Man and the Sea* (1952); *Islands in the Stream* (1970).

SHORT STORIES: *In Our Time* (1925); *Men Without Women* (1927); *Winner Take Nothing* (1933).

OTHER WORKS: *Death in the Afternoon* (1932), on bullfighting; *The Green Hills of Africa* (1935), on big-game hunting; *The Fifth Column and the First Forty-Nine Stories* (1938), a play published with collected short stories; *A Moveable Feast* (1964), sketches of his early life in Paris.

Henry II the Saint, Emperor

The last of the Saxon rulers of Germany, Henry II was canonized by Pope Eugenius III, more than 100 years after his death, in response to church-inspired legends. He was, in fact, far from saintly, but there is some truth in the legends concerning his religious character. Together with Henry III, he was the great architect of cooperation between church and state, following a policy inaugurated by Charlemagne and promoted by Otto the Great (German king 936–973). His canonization is sometimes justified on the grounds that he was a great representative of the medieval German priestly kings.

Born in Bavaria on May 6, 973, Henry II became king of Germany in 1002 and Roman Emperor in 1014. His father Henry, duke of Bavaria, having been in rebellion against two preceeding German kings, was forced to spend long years in exile from Bavaria. The younger Henry found refuge with Bishop Abraham of Freising and was later educated at the Cathedral School of Hildesheim. Exposed thus to strong church influence in his youth, religion influenced him strongly. Contemporaries observed an ironic trait in his character and were also impressed by his ability to intersperse his speeches with biblical quotations. Though devoted to church ritual and personal prayer, he was a tenacious and realistic politician, not adverse to alliances with heathen powers. Usually in poor health, he yet performed for 22 years the office of the itinerant king, riding on horseback through his dominions to judge and compose feuds, pursue rebels, and extend the power of the crown.

After the death of King Otto III in January 1002, Henry, aware of strong opposition to his succession, captured the royal insignia which were in the keeping of the dead king's companions. At Otto's funeral the majority of the princes declared against Henry, and only in June, with the assistance of Archbishop Willigis of Mainz, did Henry secure both election and coronation. It took another year before his recognition was final.

Succession to the throne

Henry turned his first attention to the east and made war against Polish king Bolesław I the Brave. After a successful campaign, he marched into northern Italy to subdue Arduin of Ivrea, who had styled himself king of Italy. His sudden interference led to bitter fighting and atrocities, and although Henry was crowned king in Pavia on May 15, 1004, he returned home without defeating Arduin, to pursue his campaigns against Bolesław. In 1003 Henry had made a pact with the Liutitian tribe against the Christian Bolesław, and allowed them to resist German missionaries east of the Elbe. Henry was more interested in political power than in spreading Christianity. Supported by his tribal allies he waged several campaigns against Poland, until in 1018, at Bautzen, he made a lasting compromise peace.

Sensitive to tradition and anxious to be crowned emperor, Henry decided in late 1013 on another expedition to Italy. He marched straight to Rome, where he was crowned by Pope Benedict VIII, on February 14, 1014. By May he was back in Germany, seeking to fulfill his duties to Italy by charging German officials with the administration of the country. He even convened an Italian imperial court at Strassburg in 1019. In 1020 Pope Benedict visited him in Germany and begged him to put in another appearance in Italy to fight the Greeks in the south and protect the papacy against the Lombard princes. Henry reluctantly responded the following year, fighting both Greeks and Lombards successfully; but he withdrew at the first opportunity.

Henry's main interest and success were concentrated on the consolidation of a peaceful royal regime in Germany. He spent much time and energy in elaborating the so-called Ottonian system of government. Inaugurated by Otto I, this system was based upon the principle that the lands and the authority of the bishops ought to be at the disposal of the king. Henry made generous grants to the bishops and, by adding to their territorial holdings, helped to establish them as secular rulers as well as ecclesiastical princes. He freely availed himself of the royal right to appoint faithful followers to these bishoprics. He insisted on episcopal celibacy—to make sure that on the death of a bishop the see would not fall into the hands of the bishop's children. In this way, he managed to create a stable body of supporters who made him more and more independent of rebellious nobles and ambitious members of his own family.

Foundation of the Bamberg bishopric

His greatest achievement was the foundation of the new bishopric of Bamberg. The upper region of the Main River was poorly populated, and Henry set aside large tracts of personal property to establish the new bishopric, much against the wishes of the bishop of Würzburg in the middle Main region. He obtained the consent of other bishops at a synod in Frankfurt in late 1007. The new bishop was consecrated on Henry's birthday in 1012. In 1020 Bamberg was visited by the pope, and it quickly developed into a splendid cathedral town where contemporary scholastic culture and art, as well as piety, found the support of Henry and his queen, Cunegunda.

During the last years of his reign Henry planned, in concert with Pope Benedict VIII, an ecclesiastical reform council at Pavia to seal the system of ecclesiastico-political order he had perfected in Germany. But he died suddenly in July 1024, before this could be done.

HOLTZMANN, *Geschichte der sächsischen Kaiserzeit, 900–1024*, 3rd ed., pp. 383–487 (1955), present Henry II according to accepted modern scholarly opinion. W.v.d. STEINEN, *Kaiser Heinrich der Zweite der Heilige* (1924), is romantic but unusually sensitive to later medieval opinion. T. SCHIEFFER, "Heinrich II und Konrad II," *Deutsches Archiv*, 8:384–437 (1951), supplies the necessary critical revision of modern research. For pictures, see P.E. SCHRAMM, *Die deutschen Kaiser und Könige in Bildern ihrer Zeit*, pp. 196 ff. (1928). Informative and summary treatments of Henry II may be found by A. DOVE in *Allgemeine deutsche Biographie*, vol. 11, pp. 376–384 (1880); by M.L. BULST-THIELE in B. GEBHARDT, *Handbuch der deutschen Geschichte*, 9th ed., vol. 1, pp. 284–298 (1970); and by H. APPELT in *Neue deutsche Biographie*, vol. 8, pp. 310–313 (1968).

(P.Mu.)

Henry III, Emperor

The German king and Holy Roman emperor Henry III was a powerful advocate of the Cluniac reform movement that sought to purify the Western Church in the 11th century. The last emperor who was able to dominate the papacy, he was troubled in the latter part of his reign by opposition to his rule both in Germany and Italy.

Youth and marriage

Henry was born on October 28, 1017, the son of the emperor Conrad II and Gisela of Swabia. He was more thoroughly trained for his office than almost any other crown prince before or after. With the Emperor's approval, Gisela had taken charge of his upbringing, and she saw to it that he was educated by a number of tutors and acquired an interest in literature.

Henry III between two abbots, miniature from his gospel, *c.* 1040. In the Universitätsbibliothek, Bremen, West Germany (Ms. b. 21).
By courtesy of the Universitatsbibliothek, Bremen, West Germany

In 1036 Henry married Gunhilda (Kunigunde), the young daughter of King Canute of England, Denmark, and Sweden. Because her father had died shortly before, the union with this frail and ailing girl brought with it no political advantages. She died in 1038, and the emperor Conrad died the following year.

His 22-year-old successor as German king resembled him in appearance. From his mother Henry inherited much, especially her strong inclination to piety and church services. His accession to the throne, unlike that of his two predecessors, did not lead to civic unrest, but his reign was burdensome from the beginning. Probably over questions of principle, the self-willed Emperor quarrelled with the aging Gisela during her last years.

He devoted his energies above all to the contemporary movement to bring an end to war among Christian princes, although his own policies were not always pacific. In possession of the duchies of Franconia, Bavaria, Swabia, and Carinthia, he had attempted to carry on his father's policy of supremacy in the east and, in fact, attained sovereignty over Bohemia and Moravia.

It may have been at this time that Henry, prematurely believing he had reached the zenith of his power, displayed openly, as if it were a matter of governmental policy, his leanings toward the clerical-reform party. Intending to re-create a theocratic age like that of Charlemagne, he failed to realize that this could be done only as long as the papacy was powerless.

Still a childless widower, he married Agnes, the daughter of William V of Aquitaine and Poitou, in 1043. The match must have been intended primarily to cement peace in the west and to assure imperial sovereignty over Burgundy and Italy, and Agnes' total devotion to the church reform advocated by the Cluniac monasteries probably confirmed Henry in his decision to take her for his wife. In November 1050 she bore him a son, who later became the emperor Henry IV. There followed another boy, Conrad, and three daughters. What Henry still lacked was the highest honour—his coronation as emperor at the hands of the pope.

When Henry reached Rome in 1046, three rivals were claiming the papacy. Henry wanted a pacified Italy, in which German supremacy was uncontested, and he wanted to receive the imperial crown from unsullied hands. He convoked a synod at Sutri, which, at his bidding, elected as the new pope a German, Suidger, bishop of Bamberg, who was inaugurated as Clement II. On the same day he crowned the imperial couple.

Control of the papacy

Rome became an imperial city, and the control over the church—*i.e.*, the decisive vote in future conclaves—passed into the hands of the German king. In succeeding

years Henry made use of this right to appoint a pope three more times. When the Normans were beginning their conquest of Calabria, Henry did not intervene to any extent in southern Italy; instead he left this problem to Pope Leo IX, who was defeated by the Normans.

Believing that the basis of his power was secure, the Emperor expected to be as successful with his internal projects as he had been in foreign affairs; but this was not to be the case. He could not carry out his ecclesiastical reforms in Germany or its neighbouring territories because he was virtually without friends among the clergy. He was increasingly opposed by the Scandinavian Church and by that of the Saxons. Also, he had to contend during most of his reign with Godfrey II, duke of Upper Lorraine, whom he repeatedly pardoned instead of disciplining.

There was unrest everywhere. In 1054–55, dukes Conrad of Bavaria and Welf III of Carinthia attempted to overthrow Henry's rule through a widely spread conspiracy, and only their demise saved him from great trouble. Conrad, who had fled to Hungary, managed to subvert that country to such an extent that German influence remained permanently weakened. Although resistance against him stiffened with time, Henry continued to rule with moderation. Perhaps because he was aware of a lessening of his powers, his actions became haphazard. Instead of holding on to duchies that he had inherited, he entrusted them to others; but he chose badly and seldom acted decisively against his disloyal feudatories. He no longer inspired fear in his opponents—the Saxon and south German lay nobility, the alliance between Lorraine and Tuscany, the increasingly independent papacy, and the adventure-seeking Normans.

Opponents of the Emperor's policy thought it was excessively indulgent toward the church and hostile toward the lay princes. Some of this criticism was voiced among the ranks of the ecclesiastical reformers. Matters had come to such an impasse that Henry no longer pleased anyone. His demands on the people to support his military strength were heavy from the beginning, and his revenues from inheritances and confiscations were also considerable. If the empire's basic wealth did not increase in his reign, it was because he used it to fulfill the demands of his clerical friends, even as he bestowed duchies on lay nobles in order to appease them. It is not surprising that, under these circumstances, he was compelled to find other sources of revenue by seeking credits, foreclosing mortgages, and looking after the interests of his treasury when conferring high imperial offices or church benefices. The abolition of simony (the sale of church offices) was difficult even for as high-principled a ruler as Henry, and, as a result, his enemies accused him of greed. According to some sources, Henry III was rumoured to have become "untrue to himself" and inaccessible to the common people in old age; he was reported to have refused to grant a judicial hearing to "the poor." In contrast, in the early years of his reign, he could not be praised enough for his zeal in the administration of justice.

Disintegration of the empire

His change of personality may have resulted from the blunders and failures of his rule. After 1046 this man, shaped partly by religious ideals and partly by the harsh realities of political life, saw all his gains being swept away: northeast Germany, Hungary, southern Italy, and Lorraine. Even the part of his work that he considered his very own, church reform, began to turn against him. A high priest among men, who did penance even while ruthlessly persecuting and even hanging heretics, Henry learned at the end of his days that clemency, goodness, and earthly justice do not necessarily benefit a prince.

On the other hand, it may have been a physical disease that changed Henry. In 1045 he was so tortured with illness that negotiations concerning the succession were begun. The bad tidings from all corners of the empire must have complicated his condition. In September 1056 he fell sick in his favourite residence, the imperial palace at Bodfeld near Goslar, and, having assured the succession of his son Henry, he died on October 5.

BIBLIOGRAPHY. There is no contemporary biography, English-language work, or detailed treatise on Henry III. ERNST STEINDORFF, *Jahrbücher des deutschen Reichs unter Heinrich III*, 2 vol. (1874–81), is still the only comprehensive treatment. RYLEY, *Cambridge Medieval History*, vol. 3, pp. 272–308 (1922).

(H.L.M.)

Henry IV, Emperor

German king and Holy Roman emperor, Henry IV, in one of the most famous episodes in medieval history, engaged in a monumental contest of strength with the great reforming pope, Gregory VII. Gregory, who stood for the supremacy of the spiritual over the temporal order, sought to deprive the German kings of the right of investiture of ecclesiastical offices (*i.e.*, the right to confer on prelates the symbols of their spiritual authority). The power of the German crown, however, largely depended on this right, since it linked the high ecclesiastics to the crown as a counterweight against the territorial nobles, and Henry IV thus regarded retention of the right of investiture and the curtailment of the power of the nobles as his chief task.

Early years. The only surviving son of Emperor Henry III and Agnes of Poitou, he was born in Goslar (now in West Germany) on Nov. 11, 1050. Henry III, who had retained a firm hold on the church, had resolved a schism in Rome (1046), opening new activities for the reformers. At Easter 1051, the boy was baptized after the German princes had taken an oath of fidelity and obedience at Christmas 1050. On July 17, 1053, he was elected king at Tribur (modern Trebur, in West Germany) on condition that he would be a just king. In 1054 he was crowned king in Aix-la-Chapelle (modern Aachen, in West Germany), and the following year he became engaged to Bertha, daughter of the margrave of Turin. When the Emperor died in October 1056, at the age of 39, succession to the throne and survival of the dynasty were assured. The princes of the realm raised no objection when nominal government was handed over to the six-year-old boy, for whom his pious and un-

Henry IV, illumination from the manuscript *Ekkehardi historia*, c. 1113. In possession of Corpus Christi College, Cambridge.

worldly mother became regent. Yet the early death of Henry III was the beginning of a fateful change that marked all of his son's reign. In his will, the late Emperor had appointed Pope Victor II as counsellor to the Empress, and the Pope solved some of the conflicts between the princes and the imperial court that had endangered peace in the empire.

Regency

After Victor's early death (1057), however, the politically inept Empress committed a number of decisive mistakes. On her own, and without the benefit of the advice of a permanent group of counsellors, she readily yielded to various influences. She turned over the duchy of Bavaria, which Henry III had given to his son in 1055, to the Saxon count Otto of Nordheim, thus depriving the king of an important foundation of his power. She gave the duchy of Swabia to Count Rudolf of Rheinfelden—who married her daughter—and the duchy of Carinthia to Count Berthold of Zähringen; both of them eventually became opponents of Henry IV. The death of the Emperor also marked the disruption of German influence in Italy and of the close relationship between the king and the reform popes. Their independence soon became apparent in the elections of Stephen IX and Nicholas II, which were not influenced (as under Henry III) by the German court; in the new procedure for the election of the popes (1059); and in the defensive alliance with the Normans in southern Italy. This alliance was necessary for the popes as an effective protection against the Romans and was not directed against the German king. Yet the Normans were considered usurpers and enemies of the Holy Roman Empire, and thus the pact resulted in strained relations between the Pope and the German court, and these strains were aggravated by papal claims and disciplinary action taken by Nicholas II against German bishops. While the German king had so far been known as a supporter of the reformers, the Empress now imprudently entered into an alliance with Italian opponents of church reform and brought about the election of Cadalus, bishop of Parma, as antipope (Honorius II) against the reigning pope, Alexander II, who had been elected by the reformers. But since she did not give effective support to Honorius, Alexander was able to prevail. Her unwise church policy was matched by an obscurely motivated submissive policy at home, which, by unwarranted cession of holdings of the crown, weakened the material foundations of the king's power and, in addition, encouraged the rapacity of the nobles. Increasing discontent reached a climax in a conspiracy of the princes led by Anno, archbishop of Cologne, in April 1062. During a court assembly in Kaiserswerth he kidnapped the young king and had him brought to Cologne by ship. Henry's attempt to escape by jumping into the Rhine failed. Agnes resigned as regent and the government was taken over by Anno, who settled the conflict with the church by recognizing Alexander II (1064). Anno was, however, too dominating and inflexible a man to win Henry's confidence, so that Adalbert, archbishop of Bremen, granting more freedom to the lascivious young king, gained increasing and finally sole influence. But he used it for such unscrupulous personal enrichment that Henry, who was declared of age in 1065, had to ban him from court early in 1066. This incident marks the beginning of the King's own rule, for which he was badly prepared. Repeated changes in the government of the empire had an unsettling effect on the boy king and had, moreover, prevented him from being given a regular education. The selfishness of his tutors, the dissolute character of his companions, and the traumatic experience of his kidnapping had produced a lack of moral stability during his years of puberty. In addition, his love of power, typical of all the rulers of his dynasty, contributed to conduct often characterized by recklessness and indiscretion.

Henry's abduction by Anno

In 1069, after three years of marriage, he suddenly announced his intention of divorcing his wife, Bertha. Following protests by high church dignitaries, he dropped his plan but his mercurial behaviour incurred the displeasure of the reformers. At the same time he was faced with domestic difficulties that were to harass him throughout his reign. After his mother had freely dispensed of lands during her regency, he began to increase the royal possessions in the Harz Mountains and to protect them by castles, which he handed over to Swabian ministerials (higher civil servants directly responsible to the crown). Peasants and nobles in Saxony were stirred up by the ruthless repossession of former royal rights that had long ago been appropriated by nobility or had become obsolete and by the highhanded and severe measures of the foreign ministerials. Henry tried to stop the unrest by imprisoning Duke Magnus of Saxony and by depriving the widely respected Otto of Bavaria of his duchy, after having unjustly accused him of plotting the murder of the King (1070). Then a rebellion broke out among the Saxons, which in 1073 spread so rapidly that Henry had to escape to Worms. After negotiations with Welf IV, the new duke (as Welf I) of Bavaria, and with Rudolf, the duke of Swabia, Henry was forced to grant immunity to the rebels in 1073 and had to agree to the razing of the royal Harz Castle in the final peace treaty in February 1074. When the peasants, destroying the castle, also desecrated the church and the tomb of one of the King's sons, Henry declared the peace broken. This incident assured him of support from all over the empire, and in June 1075 he won an overwhelming victory that resulted in the surrender of the Saxons. It also forced the princes at Christmas to confirm on oath the succession of his one-year-old son Conrad.

Saxon wars

Role in investiture conflict. This rebellion affected relations between Henry and the Pope. In Milan a popular party, the Patarines, dedicated to reforming the city's corrupt higher clergy, elected its own archbishop, who was recognized by the Pope. When Henry countered by having his own nominee consecrated by the Lombard bishops, Alexander II excommunicated the bishops. Henry did not yield, and it was not until the Saxon rebellion that he was ready to negotiate. In 1073 he humbly asked the new pope, Gregory VII, to settle the Milan problem. The King having thus renounced his right of investiture, a Roman synod, called to strengthen the Patarine movement, forbade any lay investiture in Milan; henceforward Gregory regarded Henry as his ally in questions of church reform. When planning a crusade, he even put the defense of the Roman Church into the King's hands. But after defeating the Saxons, Henry considered himself strong enough to cancel his agreements with the Pope and to nominate his court chaplain as archbishop of Milan. The violation of the agreement on investiture called into question the King's trustworthiness, and the Pope sent him a letter warning him of the melancholy fate of King Saul (after breaking with his church in the person of the prophet Samuel) but offering negotiations on the investiture problem. Instead of accepting the offer, which arrived at his court on January 1, 1076, Henry, on the same day, deposed the Pope and persuaded an assembly of 26 bishops, hastily called to Worms, to refuse obedience to the Pope. By this impulsive reaction he turned the problem of investiture in Milan, which could have been solved by negotiations, into a fundamental dispute on the relations between church and state. Gregory replied by excommunicating Henry and absolving the King's subjects from their oaths of allegiance. Such action equalled dethronement. Many bishops who had taken part in the Worms assembly and had subsequently been excommunicated now surrendered to the Pope, and immediately the King was also faced with the newly aroused opposition of the nobility. In October 1076 the princes discussed the election of a new king in Tribur. It was only by promising to seek absolution from the ban within a year that Henry could reach a postponement of the election. The final decision was to be taken at an assembly to be called at Augsburg to which the Pope was also invited. But Henry secretly travelled to northern Italy and in Canossa did penance before Gregory VII, whereupon he was readmitted to the church. For the moment it was a political success for the King because the opposition had been deprived of all canonical arguments. Yet, Canossa meant a change. By doing penance Henry had admitted the legality of the

Penance at Canossa

Pope's measures and had given up the king's traditional position of authority equal or even superior to that of the church. The relations between church and state were changed forever.

The princes, however, considered Canossa a breach of the original agreement providing for an assembly at Augsburg and declared Henry dethroned. In his stead, they elected Rudolf, duke of Swabia, in March 1077, whereupon Henry confiscated the duchies of Bavaria and Swabia on behalf of the crown. He received support from the peasants and citizens of these duchies, whereas Rudolf relied mainly on the Saxons. Gregory watched the indecisive struggle between Henry and Rudolf for almost three years until he resolved to bring about a decision for the sake of continued church reform in Germany. At a synod in March 1080, he prohibited investiture, excommunicated and dethroned Henry again, and recognized Rudolf. The reasons for this act of excommunication were not as valid as those advanced in 1077, and many nobles who had so far favoured the Pope turned against him because they thought the prohibition of investiture infringed upon their rights as patrons of churches and monasteries. Henry now succeeded in deposing Gregory and in nominating Guibert, archbishop of Ravenna, as pope at a synod in Brixen (Bressanone). When the opposition of the princes was crippled by the death of Rudolf in October 1080, Henry, freed of the threat of enemies to the rear, went to Italy to seek a military decision in his struggle with the church. After attacking Rome in vain in 1081 and 1082, he conquered the city in March 1084. Guibert was enthroned as Clement III and crowned Henry emperor on March 31, 1084. Gregory, the legitimate pope, fled to Salerno, where he died on May 25, 1085. A number of cardinals joined Clement, and, feeling that he had won a complete victory, the Emperor returned to Germany. In May 1087 he had his son Conrad crowned king. The Saxons now made peace with him. Further, Henry replaced bishops who did not join Clement with others loyal to the king.

Crowned emperor

Later crises in Italy and Germany. The escape and death of Gregory VII and the presence of Clement III in Rome caused a crisis in the reform movement of the church, from which, however, it quickly recovered under the pontificate of Urban II (1088–1099). The marriage, arranged by Urban in 1089, of the 17-year-old Welf V of Bavaria with the 43-year-old countess Matilda of Tuscany, a zealous adherent of the cause of reform in the church, allied Henry's opponents in southern Germany and Italy. Henry was forced to invade Italy once more in 1090, but after initial success, his defeat in 1092 resulted in the uprisings in Lombardy; and the rebellion of his son Conrad, who was crowned king of Italy by the Lombards, led to general rebellion. The Emperor found himself cut off from Germany and besieged in a corner of northeastern Italy. In addition, his second wife Praxedis of Kiev, whom he had married in 1089 after the death of Bertha in 1087, left him, bringing serious charges against him. It was not until Welf V separated from Matilda, in 1095, and his father, the deposed Welf IV, was once more granted Bavaria as a fief, in 1096, that Henry was able to return to Germany (1097).

In Germany, sympathy for reform and the papacy no longer excluded loyalty to the Emperor. Gradually Henry was able to consolidate his authority so that in May 1098 the princes elected his second son, Henry V, king in place of the disloyal Conrad. But peace with the Pope, which was necessary for a complete consolidation of authority, was a goal that remained unattainable. At first a settlement was impossible because of Henry's support for Clement III, who had died in 1100. Paschal II (1099–1118), a follower of the reformist policies of Gregory VII, was unwilling to conclude an agreement with Henry. Finally, the Emperor declared that he would go on a crusade if his excommunication were removed. To prepare for the crusade, he forbade all feuds among the great nobles of the empire for four years (1103). But unrest started again when reconciliation with the church did not materialize and the nobles thought the Emperor was restricting their rights in favour of his son. Henry V feared a controversy with the princes. In alliance with Bavarian nobles he revolted against the Emperor in 1104 to secure his throne by sacrificing his father. The Emperor escaped to Cologne, but when he went to Mainz his son imprisoned him and on December 31, 1105, extorted his apparently voluntary abdication. Yet Henry IV was not yet prepared to give up. He fled to Liège and with the Lotharingians defeated Henry V's army near Visé on March 22, 1106. Henry IV suddenly died in Liège on August 7, 1106. His body was transferred to Speyer but remained there in an unconsecrated chapel before being buried in the family vault in 1111.

Judgment of Henry by his contemporaries differed according to the parties to which they belonged. His opponents considered the tall, handsome king a tyrant—the crafty head of heresy—whose death they cheered because it seemed to usher in a new age. His friends praised him as a pious, gentle, and intelligent ruler, a patron of the arts and sciences, who surrounded himself with religious scholars and who, in his sense of law and justice, was the embodiment of the ideal king. In his attempt to preserve the traditional rights of the crown, Henry IV was only partially successful, for while he strengthened the king's position against the nobles by gaining the support of the peasants, the citizens, and the ministerials, his continuing battles with the reforming church over investiture ultimately weakened royal influence over the papacy.

(F.-J.Se.)

Henry V, Emperor

German king and Holy Roman emperor, last of the Salian dynasty, Henry V settled the controversy between the German kings and the papacy over the right to invest bishops with their offices begun by his father, Henry IV.

He was born in Utrecht on November 8, 1086, the second son of Henry IV and his first wife, Bertha of Turin. After his father became emperor, Henry's elder brother, Conrad, was elected German king; Henry succeeded him

The struggle with the church

after Conrad had rebelled unsuccessfully against his father, being crowned on January 6, 1099. In 1104, in the conflict between the papacy and his father, he sided with the Bavarians and Saxons against his father. As a promoter of church reform willing to compromise with the papacy, he had the support of the church. He took his father prisoner and forced him to abdicate (December 31, 1105) but was not certain of his throne until his father's death on August 7, 1106. He had already sent messengers to Pope Paschal II inviting him to come to Germany; he was prepared to reach a settlement provided the Pope granted him full rights of investiture of bishops. The Pope rejected this condition. Henry was still able to consolidate his rule in Germany. Campaigns against Hungary (1108) and Poland (1109) failed, but Henry reasserted German lordship over Bohemia in 1110. In 1110 he became betrothed to Matilda, daughter of Henry I of England, marrying her in 1114.

An understanding with the Pope in the controversy over investiture was essential to Henry. The church possessed not only spiritual rights but secular rights as well. Henry journeyed to Rome in 1110 and again demanded the right of investiture. The Pope was willing to command the German churches to give back all lands and rights received from the crown if Henry would renounce the right to investiture, a bargain that was acceptable to Henry but not to the German bishops and princes. Henry then imprisoned the Pope, forcing him to grant the right of investiture. On April 13, 1111, the Pope crowned him emperor in St. Peter's. In the satisfaction that he had achieved what Henry IV had not, he arranged a memorial ceremony for his father in Speyer on August 7, 1111.

In Germany, Henry V followed his father's policy of favouring the class of civil servants known as *ministeriales* and also the towns, thus provoking the antagonism of the princes. Rebellion soon broke out; Archbishop Adalbert of Mainz fomented unrest in the upper Rhineland, and the revolt of Lothair of Supplinburg (later to become king as Lothair III and emperor as Lothair II) in Saxony ended in 1115 in a severe defeat for Henry.

There was also strong opposition to Henry within the church. While the Pope kept to his agreement with Henry, a council in Rome declared the privilege granted to Henry invalid. Papal legates in Germany pronounced Henry's excommunication, and consequently he lost the support of the German bishops. Despite this, he went to Italy in 1116 to take possession of the inheritance of Matilda of Tuscany, who had died in 1115. Further negotiations with the Curia over the investiture question were without success. When, in 1118, Pope Gelasius II was elected successor to Paschal II, Henry set up an antipope, Gregory VIII; but the move failed. Henry was called back from Italy in 1118 by an ultimatum from the German princes, who threatened to dethrone him. He was forced to make political concessions. When Gelasius II's successor, Calixtus II, offered to negotiate with him, Henry was prepared to drop his demand for full rights of investiture, but these negotiations failed. As his domestic difficulties increased, the princes finally took the initiative and negotiated the Concordat of Worms (1122). The King had to renounce the right to invest the bishops with ring and crozier and to accede to their canonical election, while the Pope granted the King the right to be present at the election, the right to a deciding voice if the election was indecisive, and the right to enfeoff the elected bishop with the temporalities of his see. This arrangement, however, applied only to Germany, whereas in Italy and in Burgundy the enfeoffment was to follow consecration and would therefore be a pure formality.

The deciding voice of the princes

Henry's subsequent struggle with the princes and, especially, with Lothair was without success. At the same time he became involved in the conflict between the English and the French. The death of the successor to the English throne had made Matilda, Henry's wife, the heiress and created the prospect of a German–English empire. Henry therefore supported his father-in-law in his conflict with France but could achieve nothing militarily. He died of cancer at Utrecht, in the Netherlands, on May 23, 1125, and was buried in Speyer Cathedral. Henry was childless. His successor was his former enemy Lothair III, duke of Saxony, who was elected king largely through the efforts of the church.

As a ruler, Henry V showed political skill, but his reach exceeded his grasp. He had dethroned his father by allying himself with the princes and presenting himself as a champion of the church's rights. Once in power, he took up his father's cause but was unable to force the church to grant him his demands. The settlement of 1122, which secured the King's influence over the German church, was brought about mainly by the German princes. By intervening in the conflict between the King and the church, they won a victory for themselves against the King, a fact that dominated the subsequent history of Germany.

BIBLIOGRAPHY. There is no really critical biography of Henry V. A summary of recent research and a full bibliography may be found in B. GEBHARDT and H. GRUNDMANN, *Handbuch der deutschen Geschichte*, vol. 1 (1970). See also *The Cambridge Medieval History*, vol. 5 (1964).

Henry I of England

The youngest and ablest of William the Conqueror's sons, and king of England from 1100 until his death in 1135, Henry I greatly strengthened the crown's executive powers and reunited the duchy of Normandy with the English kingdom.

By courtesy of the trustees of the British Museum

Henry I, miniature from a 14th-century manuscript. In the British Museum (Cottonian Claud D11 45 B).

Henry was born in England in 1069. He was crowned at Westminster, on August 5, 1100, three days after his brother, King William II, William the Conqueror's second son, had been killed in a hunting accident. Duke Robert Curthose, the eldest of the three brothers, who by feudal custom had succeeded to his father's inheritance, Normandy, was returning from the First Crusade and could not assert his own claim to the English throne until the following year. The succession was precarious, however, because a number of wealthy Anglo-Norman barons supported Duke Robert, and Henry moved quickly to gain all the backing he could. He issued an ingenious Charter of Liberties which purported to end capricious taxes, confiscations of church revenues, and other abuses of his predecessor. By his marriage with Matilda, a Scottish princess of the old Anglo-Saxon royal line, he established the foundations for peaceable relations with the Scots and support from the English. And he recalled St. Anselm, the scholarly archbishop of Canterbury whom his brother, William II, had banished.

When Robert Curthose finally invaded England in 1101 several of the greatest barons defected to him. But Henry, supported by a number of his barons, most of the Anglo-Saxons, and St. Anselm, worked out an amicable settlement with the invaders. Robert relinquished his claim to England, receiving in return Henry's own territories in Normandy and a large annuity.

Although a crusading hero, Robert was a self-indulgent, vacillating ruler who allowed Normandy to slip into chaos. Norman churchmen who fled to England urged Henry to conquer and pacify the duchy and thus pro-

vided moral grounds for Henry's ambition to reunify his father's realm at his brother's expense. Paving his way with bribes to Norman barons and agreements with neighbouring princes, in 1106 Henry routed Robert's army at Tinchebrai in southwestern Normandy. Robert was captured and remained Henry's prisoner for the rest of his life.

Church–state relations

Between 1104 and 1106 Henry had been in the uncomfortable position of posing, in Normandy, as a champion of the church while fighting with his own archbishop of Canterbury. St. Anselm had returned from exile in 1100 dedicated to reforms of Pope Paschal II, which were designed to make the church independent of secular sovereigns. Following papal bans against lay lords investing churchmen with their lands and against churchmen rendering homage to laymen, Anselm refused to consecrate bishops whom Henry had invested and declined to do homage to Henry himself. Henry regarded bishoprics and abbeys not only as spiritual offices but as great sources of wealth. Since in many cases they owed the crown military services, he was anxious to maintain the feudal bond between the bishops and the crown.

Ultimately, the issues of ecclesiastical homage and lay investiture forced Anselm into a second exile. After numerous letters and threats between king, pope, and archbishop, a compromise was concluded shortly before the battle of Tinchebrai and was ratified in London in 1107. Henry relinquished his right to invest churchmen while Anselm submitted on the question of homage. With the London settlement and the English victory at Tinchebrai, the Anglo-Norman state was reunified and at peace.

In the years following, Henry married his daughter Matilda (also called Maud) to Emperor Henry V of Germany and groomed his only legitimate son, William, as his successor. Henry's right to Normandy was challenged by William Clito, son of the captive Robert Curthose, and Henry was obliged to repel two major assaults against eastern Normandy by William Clito's supporters: Louis VI of France, Count Fulk of Anjou, and the restless Norman barons who detested Henry's ubiquitous officials and high taxes. By 1120, however, the barons had submitted, Henry's son had married into the Angevin house, and Louis VI—defeated in battle—had concluded a definitive peace.

The settlement was shattered in November 1120, when Henry's son perished in a shipwreck of the "White Ship," destroying Henry's succession plans. After Queen Matilda's death in 1118, he married Adelaide of Louvain in 1121, but this union proved childless. On Emperor Henry V's death in 1125, Henry summoned the empress Matilda back to England and made his barons do homage to her as his heir. In 1128 Matilda married Geoffrey Plantagenet, heir to the county of Anjou, and in 1133 she bore him her first son, the future King Henry II. On December 1, 1135, Henry I died at Lyons-la-Forêt in eastern Normandy, whereupon his favorite nephew, Stephen of Blois, disregarding Matilda's right of succession, seized the English throne. Matilda's subsequent invasion of England unleashed a bitter civil war that ended with King Stephen's death and Henry II's unopposed accession in 1154.

Assessment

Henry I was a skillful, intelligent monarch who achieved peace in England, relative stability in Normandy, and notable administrative advances on both sides of the Channel. Under Henry, the Anglo-Norman state his father had created was reunited. Royal justices began making systematic tours of the English shires, but although his administrative policies were highly efficient, they were not infrequently regarded as oppressive. His reign marked a significant advance from the informal, personal monarchy of former times toward the bureaucratized state that lay in the future. It also marked a shift from the wide-ranging imperialism of earlier Norman leaders to consolidation and internal development. In the generations before Henry's accession, Norman dukes, magnates, and adventurers had conquered Southern Italy, Sicily, Antioch, and England. Henry won his major battles but preferred diplomacy or bribery to the risks of the battlefield. Subduing Normandy in 1106, he contented himself with keeping domestic peace, defending his Anglo-Norman state against rebellion and invasion, and making alliances with neighbouring princes.

BIBLIOGRAPHY. There exists no biography of Henry I. A.L. POOLE, *From Domesday Book to Magna Carta, 1087–1216*, 2nd ed. (1955), contains a good sketch and bibliography of the reign. R.W. SOUTHERN, *Medieval Humanism*, ch. 11 (1970), deals perceptively with Henry's patronage system. On Henry's early years, see C.W. DAVID, *Robert Curthose, Duke of Normandy* (1920); on Henry's administration, H.G. RICHARDSON and G.O. SAYLES, *The Governance of Mediaeval England from the Conquest to Magna Carta* (1963); C.H. HASKINS, *Norman Institutions* (1960); and *Regesta Regum Anglo-Normannorum*, vol 2, ed. by H.A. CRONNE and CHARLES JOHNSON (1956).

(C.W.Ho.)

Henry II of England

Henry II, king of England from 1154 to 1189, a man of great intelligence and ability, increased by war and diplomacy the dominions that he inherited and controlled finally continental territories wider than those of any other English medieval monarch. His greatest achievement was to strengthen the financial administration of the country, to rationalize tenurial and judicial procedure, and thus to control crime, to ensure peaceful possession of land, and to establish regular and equitable courts applying customary law.

Early life. Henry was born at Le Mans, France, in 1133. The claim of his mother, Matilda, daughter of Henry I, to the English crown had been set aside by her cousin, King Stephen. After receiving a good literary education, part of it in England, Henry became duke of Normandy in 1150, and count of Anjou on the death of his father, Geoffrey Plantagenet, in 1151. In 1152 he advanced his fortunes by marrying the beautiful and talented Eleanor, recently divorced from King Louis VII of France, who brought with her hand the lordship of Aquitaine. Henry invaded England in 1153, and King Stephen agreed to accept him as coadjutor and heir. When Stephen died the following year Henry succeeded without opposition, thus becoming lord of territories stretching from Scotland to the Pyrenees.

Accession in 1154

The young king lacked visible majesty. Of stocky build, with freckled face, close-cut tawny hair, and gray eyes, he dressed carelessly and grew to be bulky; but his personality commanded attention and drew men to his service. He could be a good companion, with ready repartee in a jostling crowd, but he displayed at times the ungovernable temper of a furious animal and could be heartless and ruthless when necessary. Restless, impetuous, always on the move, regardless of the convenience of others, he was at ease with scholars, and his administrative decrees were the work of a cool realist. In his long reign of 34 years he spent an aggregate of only 14 in England.

Reign. His career may be considered in three aspects: the defense and enlargement of his dominions, the involvement in two lengthy and disastrous personal quarrels, and his lasting administrative and judicial reforms.

Henry II (left) disputing with Becket (centre), miniature from a 14th-century manuscript. In the British Museum (Cotton MS. Claudius D.ii).

Dominions. His territories are often called the Angevin Empire. This is a misnomer, for Henry's sovereignty rested upon various titles, and there was no institutional or legal bond between different regions. Some, indeed, were under the feudal overlordship of the king of France. By conquest, through diplomacy, and the marriages of two of his sons, he gained acknowledged possession of what is now the west of France from the northernmost part of Normandy to the Pyrenees, near Carcassonne. During his reign, the dynastic marriages of three daughters gave him political influence in Germany, Castile, and Sicily. His continental dominions brought him into contact with Louis VII of France, the German emperor Frederick I (Barbarossa), and, for much of the reign, Pope Alexander III. With Louis the relationship was ambiguous. Henry had taken Louis's former wife and her rich heritage. He subsequently acquired the Vexin in Normandy by the premature marriage of his son Henry to Louis's daughter, and during much of his reign he was attempting to outfight or outwit the French king who, for his part, gave shelter and comfort to Henry's enemy, Thomas Becket, the archbishop of Canterbury. The feud with Louis implied friendly relations with Germany, where Henry was helped by his mother's first marriage to the emperor Henry V but hindered by Frederick's maintenance of an antipope, the outcome of a disputed papal election in 1159. Louis supported Alexander III, whose case was strong, and Henry became arbiter of European opinion. Though acknowledging Alexander, he continued throughout the Becket controversy to threaten transferrence of allegiance to Frederick's antipope, thus impeding Alexander's freedom of action.

Early in his reign Henry obtained from Malcolm III of Scotland homage and the restoration of Northumberland, Cumberland, and Westmorland; and later in the reign (1174) homage was exacted from William the Lion, Malcolm's brother and successor. In 1157 Henry invaded Wales and received homage, though without conquest. In Ireland, reputedly bestowed upon him by Pope Adrian IV, Henry allowed a expedition of barons from South Wales to establish Anglo-Norman supremacy in Leinster (1169), which the King himself extended in 1171.

Personal quarrels. His remarkable achievements were impaired, however, by the stresses caused by a dispute with Becket and by discords in his own family.

The quarrel with Becket, Henry's trusted and successful chancellor (1154–62), broke out soon after Becket's election to the archbishopric of Canterbury (May 1162, see BECKET, THOMAS). It led to a complete severance of relations and to the Archbishop's voluntary exile. Besides disrupting the public life of the church, this situation embroiled Henry with Louis VII and Alexander III; and though it seemingly did little to hamper Henry's activities, the time and service spent in negotiations and embassies was considerable, and the tragic dénouement in Becket's murder earned for Henry a good deal of damaging opprobrium.

More dangerous were the domestic quarrels, which thwarted Henry's plans and even endangered his life and which finally brought him down in sorrow and shame.

Family relations

Throughout his adult life Henry's sexual morality was lax; but his relations with Eleanor, 11 years his senior, were for long tolerably harmonious, and, between 1153 and 1167, she bore him eight children. Of these, the four sons who survived infancy—Henry, Geoffrey, Richard, and John—repaid his genuine affection with resentment toward their father and discord among themselves. None was blameless, but the cause of the quarrels was principally Henry's policy of dividing his dominions among his sons while reserving real authority for himself. In 1170 he crowned his eldest son, Henry, as coregent with himself; but in fact the young king had no powers and resented his nonentity, and in 1173 he opposed his father's proposal to find territories for the favoured John (Lackland) at the expense of Geoffrey. Richard joined the protest of the others and was supported by Eleanor. There was a general revolt of the baronage in England and Normandy, supported by Louis VII in France and William the Lion in Scotland. Henry's prestige was at a low ebb after the murder of Becket and recent taxation, but he reacted energetically, settled matters in Normandy and Brittany, and crossed to England, where fighting had continued for a year. On July 12, 1174, he did public penance at Canterbury. The next day the king of Scots was taken at Alnwick, and three weeks later Henry had suppressed the rebellion in England. His sons were pardoned, but Eleanor was kept in custody for 11 years.

A second rebellion flared up in 1181 with a quarrel between his sons Henry and Richard over the government of Aquitaine, but young Henry died in 1183. In 1184 Richard quarrelled with John, who had been ordered to take Aquitaine off his hands. Matters were eased by the death of Geoffrey (1186), but the King's attempt to find an inheritance for John led to a coalition against him of Richard and Philip II Augustus, the young king of France. Henry was defeated and forced to give way, and news that John also had joined his enemies hastened the King's death near Tours in 1189 (July 6).

Reforms. In striking contrast to the checkered pattern of Henry's wars and schemes, his governance of England displays a careful and successful adaptation of means to a single end—the control of a realm served by the best administration in Europe. This success was obscured for contemporaries and later historians by the varied and often dramatic interest of political and personal events; and, not until the 19th century, when the study of the public records began and when legal history was illuminated by the British jurist Frederic William Maitland and his followers, did the administrative genius of Henry and his servants appear in its true light.

At the beginning of his reign Henry found England in disorder, with royal authority ruined by civil war and the violence of feudal magnates. His first task was to crush the unruly elements and restore firm government, using the existing institutions of government, with which the Anglo-Norman monarchy was well provided. Among these was the King's council of barons, with its inner group of ministers who were both judges and accountants and who sat at the Exchequer, into which the taxes and dues of the shires were paid by the King's local representative the sheriff (shire-reeve). The council contained an unusually able group of men—some of them were great barons, such as Richard de Lucy and Robert de Beaumont, earl of Leicester; others included civil servants, such as Nigel, bishop of Ely, Richard Fitzneale and his son, Richard of Ilchester. Henry took a personal interest in the technique of the Exchequer, which was described at length for posterity in the celebrated *Dialogus de scaccario*, whose composition seemed to Maitland "one of the most wonderful things of Henry's wonderful reign." How far these royal servants were responsible for the innovations of the reign cannot be known, though the development in practice continued steadily, even during the King's long absences abroad.

In the early months of the reign the King, using his energetic and versatile chancellor Becket, beat down the recalcitrant barons and their castles and began to restore order to the country and to the various forms of justice. It was thus, a few years later, that he came into conflict with the bishops, then led by Becket, over the alleged right of clerks to be tried for crime by an ecclesiastical court. A result of this was the celebrated collection of decrees—the Constitutions of Clarendon (1164)—which professed to reassert the ancestral rights of the King over the church in such matters as clerical immunity, appointment of bishops, custody of vacant sees, excommunication, and appeals to Rome. The Archbishop, after an initial compliance, refused to accept these, and they were throughout the controversy a block to an agreement. The quarrel touched what was to be the King's chief concern—the country's judicial system.

The judicial system

Anglo-Saxon England had two courts of justice—that of the hundred, a division of the shire, for petty offenses, and that of the shire, presided over by the sheriff. The feudal regime introduced by the Normans added courts of the manor and of the honour (a complex of estates). Above all stood the royal right to set up courts for important pleas and to hear, either in person or through

his ministers, any appeal. Arrest was a local responsibility, usually hard upon a flagrant crime. A doubt of guilt was settled by ordeal by battle; the accused in the shire underwent tests held to reveal God's judgment. Two developments had come in since William the Conqueror's day: the occasional mission of royal justices into the shires and the occasional use of a jury of local notables as fact finders in cases of land tenure.

Henry's first comprehensive program was the Assize of Clarendon (1166), in which the procedure of criminal justice was established; 12 "lawful" men of every hundred, and four of every village, acting as a "jury of presentment," were bound to declare on oath whether any local man was a robber or murderer. Trial of those accused was reserved to the King's justices, and prisons for those awaiting trial were to be erected at the King's expense. This provided a system of criminal investigation for the whole country, with a reasonable verdict probable because the firm accusation of the jury entailed exile even if the ordeal acquitted the accused. In feudal courts the trial by battle could be avoided by the establishment of a concord, or fine. This system presupposed regular visits by the King's justices on circuit (or, in the technical phrase, "on eyre"), and these tours became part of the administration of the country. The justices formed three groups: one on tour, one "on the bench" at Westminster, and one with the King when the court was out of London. Those at Westminster dealt with private pleas and cases sent up from the justices on eyre.

Equally effective were the "possessory assizes." In the feudal world, especially in times of turmoil, violent ejections and usurpations were common, with consequent vendettas and violence. Pleas brought to feudal courts could be delayed or altogether frustrated. As a remedy Henry established the possessory writ, an order from the Exchequer, directing the sheriff to convene a sworn local jury at petty assize to establish the fact of dispossession, whereupon the sheriff had to reinstate the defendant pending a subsequent trial at the grand assize to establish the rights of the case. This was the writ of Novel Disseisin (*i.e.*, recent dispossession). This writ was returnable; if the sheriff failed to achieve reinstatement, he had to summon the defendant to appear before the King's justices and himself be present with the writ. A similar writ of Mort d'Ancestor decided whether the ancestor of a plaintiff had in fact possessed the estate, whereas that of Darrein Presentment (*i.e.*, last presentation) decided who in fact had last presented a parson to a particular benefice. All these writs gave rapid and clear verdicts subject to later revision. The fees enriched the treasury, and recourse to the courts both extended the King's control and discouraged irregular self-help. Two other practices developed by Henry became permanent. One was scutage, the commutation of military service for a money payment; the other was the obligation, put on all free men with a property qualification by the Assize of Arms (1181), to possess arms suitable to their station.

The ministers who engaged upon these reforms took a fully professional interest in the business they handled, as may be seen in Fitzneale's writing on the Exchequer and that of the chief justiciar, Ranulf de Glanville, on the laws of England, and many of the expedients adopted by the King may have been suggested by them. In any case, the long-term results were very great. By the multiplication of a class of experts in finance and law Henry did much to establish two great professions, and the location of a permanent court at Westminster and the character of its business settled for England (and for much of the English-speaking world) that common law, not Roman law, would rule the courts and that London, and not an academy, would be its principal nursery. Moreover, Henry's decrees ensured that the judge-and-jury combination would become normal and that the jury would gradually supplant ordeal and battle as being responsible for the verdict. Finally, the increasing use of scutage, and the availability of the royal courts for private suits, were effective agents in molding the feudal monarchy into a monarchical bureaucracy before the appearance of Parliament.

Results of Henry's measures

Significance. Henry II lived in an age of biographers and letter writers of genius. John of Salisbury, Thomas Becket, Giraldus Cambrensis, Walter Map, Peter of Blois, and others knew him well and left their impressions. All agreed on his outstanding ability and striking personality and also recorded his errors and aspects of his character that appear contradictory, whereas modern historians agree upon the difficulty of reconciling its main features. Without deep religious or moral conviction, Henry nevertheless was respected by three contemporary saints, Aelred of Rievaulx, Gilbert of Sempringham, and Hugh of Lincoln. Normally an approachable and faithful friend and master, he could behave with unreasonable inhumanity. His conduct and aims were always self-centred, but he was neither a tyrant nor an odious egoist. Both as man and ruler he lacked the stamp of greatness that marked Alfred the Great and William the Conqueror. He seemed also to lack wisdom and serenity; and he had no comprehensive view of the country's interest, no ideals of kingship, no sympathetic care for his people. But if his reign is to be judged by its consequences for England, it undoubtedly stands high in importance, and Henry, as its mainspring, appears among the most notable of English kings.

BIBLIOGRAPHY. W.L. WARREN'S *Henry II* (1973) is the one full biography (with bibliography). The best short accounts are still those of KATE NORGATE in the *Dictionary of National Biography*, vol. 26 (1891); and DORIS M. STENTON in the *Cambridge Medieval History*, vol. 5, ch. 17 (1929), both with full bibliographies. The classical essay by WILLIAM STUBBS, his introduction to the *Gesta Henrici* ("Rolls Series," 1867), was reprinted by A.H. HASSALL in his collection of *Historical Introductions to the Rolls Series*, pp. 89–172 (1902). Many contemporary sources are translated in D.C. DOUGLAS and G.W. GREENAWAY (eds.), *English Historical Documents II* (1952), including the whole of the *Dialogue of the Exchequer* (*Dialogus de Scaccario*), of which the best edition, with translation, is that by CHARLES JOHNSON (1950). For Henry's judicial reforms, the best account is still that in F. POLLOCK and F.W. MAITLAND, *The History of English Law Before the Time of Edward I*, 2nd ed. (1898). See also D.M. STENTON, *English Justice Between the Norman Conquest and the Great Charter, 1066–1215* (1965).

Henry V of England

In his nine-year reign (1413–22), King Henry V of England renewed the Hundred Years' War (*q.v.*), reduced France to his mercy, and made England the strongest kingdom in Europe. The hero of the Battle of Agincourt (1415), Henry was popular as a warrior and among the ablest of England's medieval monarchs. Henry, eldest son of Henry, earl of Derby (afterward Henry IV), by Mary de Bohun, was born at Monmouth in 1387, probably on September 16. On his father's exile in 1398, Richard II took the boy into his own charge, treated him kindly, and knighted him in 1399. Henry's uncle, Henry Beaufort, bishop of Winchester, seems to have been responsible for his training, and despite his early entry into public life, he was well educated by the standards of his time. He grew up fond of music and reading and became the first English king who could both read and write with ease in the vernacular tongue. On October 15, 1399, after his father had become king, Henry was created earl of Chester, duke of Cornwall, and prince of Wales, and soon afterward, duke of Aquitaine and Lancaster. From October 1400 the administration of Wales was conducted in his name, and in 1403 he took over actual command of the war against the Welsh rebels, a struggle that absorbed much of his restless energy until 1408. Thereafter he began to demand a voice in government and a place on the council, in opposition to his ailing father and Thomas Arundel, archbishop of Canterbury. The stories of Prince Henry's reckless and dissolute youth, immortalized by Shakespeare, and of the sudden change that overtook him when he became king, have been traced back to within 20 years of his death and cannot be dismissed as pure fabrication. This does not involve accepting them in the exaggerated versions of the Elizabethan playwrights, to which the known facts of his conduct in war and council

provide a general contradiction. Probably they represent no more than the natural ebullience of a young man whose energies found insufficient constructive outlet. The most famous incident, his quarrel with the chief justice, Sir William Gascoigne, was a Tudor invention, first related in 1531.

Henry succeeded his father on March 21, 1413. In his early years his position was threatened by an abortive Lollard rising (January 1414) and by a conspiracy (July 1415) of Richard of York, earl of Cambridge, and Henry, Lord Scrope of Masham, in favour of Edmund Mortimer, earl of March. On each occasion Henry was forewarned and the opposition was suppressed without mercy. Neither incident long distracted him from his chief concern: his ambitious policy toward France. Not content with a demand for possession of Aquitaine and other lands ceded by the French at the Treaty of Calais (1360), he also laid claim to Normandy, Touraine, and Maine (the former Angevin empire) and to parts of France never in English hands. Although such demands were unlikely to be conceded even by the distracted government of France, Henry seems to have convinced himself that his claims were just, and not a merely cynical cover for calculated aggression. Yet if "the way of justice" failed, he was ready to turn to "the way of force," and warlike preparations were well advanced long before the negotiations were finally broken off in June 1415.

The French wars

Henry V's true genius is revealed in the planning and execution of his subsequent campaigns for the conquest of France. Before hostilities began, his diplomatic skill was exerted in an effort to secure the support or at least the neutrality of John the Fearless, duke of Burgundy. His attempts to deprive France of maritime assistance show an awareness of the importance of sea power unusual in medieval kings, and after the Battle of the Seine (August 1416), England's naval mastery of the Channel was not seriously disputed. At home, Henry turned to the systematic financing of his projected invasion, partly through large-scale borrowing, partly through parliamentary taxation, the generosity of which reflects his success in arousing national enthusiasm for the war. Henry began the struggle with the wholehearted support of the magnates and the backing of a united nation. His military strategy was conceived with equal ability. It stands in marked contrast with the haphazard and spasmodic operations of the English in France in the previous century. His main objective, to which the winning of battles was largely irrelevant, was the systematic reduction of the great towns and fortresses of northern France. These, kept as headquarters of permanent English garrisons, would become focal points for the subjection of the surrounding countryside; behind the soldiers were to come administrators and tax collectors, who would make the war pay for itself. Despite the forethought and grasp this plan displayed, its execution took longer than Henry had anticipated. It absorbed his energies for seven years and brought him to an early grave.

His first campaign brought the capture of Harfleur (September 1415) and the great victory of Agincourt (October 25, 1415). This resounding triumph made Henry the diplomatic arbiter of Europe: it won him a visit (1416) from the Holy Roman emperor Sigismund, with whom he made a treaty of alliance at Canterbury (1416) and whose influence was used to detach Genoa from its naval alliance with France. The cooperation of the two rulers led directly to the ending of the papal schism through the election of Martin V (1417), an objective that Henry had much at heart. Thereafter he returned to the long, grim war of sieges and the gradual conquest of Normandy. Rouen, the capital of northern France, surrendered in January 1419, and the murder of Duke John of Burgundy by the Dauphin's partisans in September 1419 brought him the Burgundian alliance. These successes forced the French to agree to the Treaty of Troyes on May 21, 1420. Henry was recognized as heir to the French throne and regent of France, and Catherine, the King's daughter, was married to him on June 2. He was now at the height of his power: but his triumph was short-lived. His health grew worse at the sieges of Melun and Meaux. He died of camp fever at Bois de Vincennes, August 31, 1422.

Character and ability

Henry's character is by no means wholly admirable. Hard and domineering, he was intolerant of opposition and could be ruthless and cruel in pursuit of his policy. His lack of chivalrous qualities deprives him of any claim to be regarded as "the typical medieval hero." Yet contemporaries united in praising his love of justice, and even French writers of his own day admired him as a brave, loyal, and upright man, an honourable fighter, and a commanding personality in whom there was little of the mean and the paltry. Although personally lacking in warmth, he had the capacity to inspire devotion in others, and he possessed high qualities of leadership. His piety was genuine, and on his deathbed he expressed a last wish that he might live to rebuild the walls of Jerusalem in a new crusade. In respect of ability, he must rank high among English kings. His achievement was remarkable: it has been rightly observed that "he found a nation weak and drifting and after nine years left it dominant in Europe." The tragedy of his reign was that he used his great gifts not for constructive reform at home but to commit his country to a dubious foreign war. His premature death made success abroad unlikely and condemned England to a long, difficult minority rule by his successor.

Henry VII of England

By his victory over King Richard III at Bosworth Field in 1485, Henry Tudor, earl of Richmond, became king of England as Henry VII and thereby ended a long period of dynastic civil wars between the houses of Lancaster and York, later known as the Wars of the Roses. Henry VII (reigned 1485–1509) restored stable and efficient government, and by his caution and thriftiness laid the foundation for the achievements of the Tudor dynasty.

Henry, son of Edmund Tudor, earl of Richmond, and Margaret Beaufort, was born at Pembroke Castle on January 28, 1457, nearly three months after his father's death. His father was the son of Owen Tudor, a Welsh squire, and Catherine of France, the widow of King Henry V. His mother was the great-granddaughter of John of Gaunt, duke of Lancaster, whose children by

Henry VII, painting by an unknown artist, 1505. In the National Portrait Gallery, London.

Catherine Swynford were born before he married her. Henry IV had confirmed Richard II's legitimation (1397) of the children of this union but had specifically excluded the Beauforts from any claim to the throne (1407). Henry Tudor's claim to the throne was, therefore, very weak and of no importance until the deaths in 1471 of Henry VI's only son, Edward, of his own two remaining kinsmen of the Beaufort line, and of Henry VI himself, which suddenly made him the sole surviving male representative of the House of Lancaster.

Early life. As his mother was only 14 when he was born and soon married again, Henry was brought up by his uncle Jasper Tudor, earl of Pembroke. When the Lancastrian cause crashed to disaster at the Battle of Tewkesbury (May 1471), Jasper took the boy out of the country and sought refuge in the duchy of Brittany. The House of York then appeared so firmly established that Henry seemed likely to remain in exile for the rest of his life. The usurpation of Richard III (1483), however, split the Yorkist party and gave Henry his opportunity. His first chance came in 1483 when his aid was sought to rally Lancastrians in support of the rebellion of Henry Stafford, duke of Buckingham, but that revolt was defeated before Henry could land in England. To unite the opponents of Richard III, Henry had promised to marry Elizabeth of York, eldest daughter of Edward IV; and the coalition of Yorkists and Lancastrians continued, helped by French support, since Richard III talked of invading France. In 1485 Henry landed at Milford Haven in Wales and advanced toward London. Thanks largely to the desertion of his stepfather, Lord Stanley, to him, he defeated and slew Richard III at the Battle of Bosworth on August 22, 1485. Claiming the throne by just title of inheritance and by the judgment of God in battle, he was crowned on October 30 and secured parliamentary recognition of his title early in November. Having established his claim to be king in his own right, he married Elizabeth of York on January 18, 1486.

Battle of Bosworth

Yorkist plots. Henry's throne, however, was far from secure. Many influential Yorkists had been dispossessed and disappointed by the change of regime, and there had been so many reversals of fortune within living memory that the decision of Bosworth did not appear necessarily final. Yorkist malcontents had strength in the north of England and in Ireland and had a powerful ally in Richard III's sister Margaret, dowager duchess of Burgundy. All the powers of Europe doubted Henry's ability to survive, and most were willing to shelter claimants against him. Hence, the King was plagued with conspiracies until nearly the end of his reign.

The first rising, that of Lord Lovell, Richard III's chamberlain, in 1486 was ill prepared and unimportant; but in 1487 came the much more serious revolt of Lambert Simnel. Claiming to be Edward, earl of Warwick, the son of Richard III's elder brother, George, duke of Clarence, he had the formidable support of John de la Pole, earl of Lincoln, Richard III's heir designate, of many Irish chieftains, and of 2,000 German mercenaries paid for by Margaret of Burgundy. The rebels were defeated (June 1487) in a hard-fought battle at Stoke (East Stoke, near Newark in Nottinghamshire), where the doubtful loyalty of some of the royal troops was reminiscent of Richard III's difficulties at Bosworth. Henry, recognizing that Simnel had been a mere dupe, employed him in the royal kitchens.

Then in 1491 appeared a still more serious menace: Perkin Warbeck, a handsome young Fleming who had been coached by Margaret to impersonate Richard, the younger son of Edward IV. Supported at one time or another by France, by Maximilian I of Austria, regent of the Netherlands (Holy Roman emperor from 1493), by James IV of Scotland, and by powerful men in both Ireland and England, Perkin three times invaded England before he was captured at Beaulieu in Hampshire in 1497. Apparently the Spanish monarchs, Ferdinand and Isabella, were still so doubtful of Henry's survival that in 1499 he had to resort to the judicial murder of Perkin Warbeck and the unfortunate Earl of Warwick before they would allow their daughter Catherine to come to England to marry Prince Arthur.

Even after this Henry was worried by the treason of Edmund de la Pole, earl of Suffolk, the eldest surviving son of Edward IV's sister Elizabeth, who fled to the Netherlands (1499) and was supported by Maximilian. Doubtless the plotters were encouraged by the deaths of Henry's sons, the infant Edmund in 1500 and Arthur in 1502, and of his wife, Elizabeth, in 1503. It was not until 1506, when he imprisoned Suffolk in the Tower of London, that Henry could at last feel safe. When he died on April 21, 1509, his only surviving son, Henry VIII, succeeded him without a breath of opposition.

Foreign policy. In the early years of his reign, in a vain attempt to prevent the incorporation of the duchy of Brittany into France, Henry found himself drawn along with Spain and the Holy Roman emperor into a war against France. But he realized that war was a very hazardous activity for one whose crown was both impoverished and insecure; and in 1492 he made peace with France on terms that brought him recognition of his dynasty and a handsome pension. Thereafter, French preoccupation with adventures in Italy made peaceful relations possible; but the support that Maximilian and James IV gave to Warbeck led to sharp quarrels with the Netherlands and Scotland. The economic importance of England for the Netherlands enabled Henry to induce Maximilian and the Netherlands to abandon the pretender in 1496 and to conclude a treaty of peace and freer trade (the Intercursus Magnus) that was beneficial to both countries.

Efforts to avoid war

With Scotland, the long tradition of hostility was harder to overcome; but Henry eventually succeeded in concluding in 1499 a treaty of peace, followed in 1502 by a treaty for the marriage of James IV to Henry's daughter Margaret. James's consent to the match may have been fostered by the arrival in England of Catherine of Aragon for her marriage with Prince Arthur in 1501. Spain had recently sprung into the first rank of European powers, so a marriage alliance with Spain enhanced the prestige of the Tudor dynasty, and the fact that in 1501 the Spanish monarchs allowed the marriage to take place is a tribute to the growing strength of the Tudor regime in the eyes of the European powers.

After Arthur's death in 1502, Henry was in a strong position to insist on the marriage of Catherine to his surviving son, Henry (later King Henry VIII), since he had possession both of Catherine's person and of half her dowry, and Spain needed English support against France. Indeed, in these last years of his reign, Henry had gained such confidence in his position that he indulged in some wild schemes of matrimonial diplomacy. But the caution

of a lifetime kept him from involvement in war, and his foreign policy as a whole must not be judged by such late aberrations. He had used his diplomacy not only to safeguard the dynasty but to enrich his country, using every opportunity to promote English trade by making commercial treaties (including agreements with Spain, the Netherlands, Florence, and Denmark). He made his country so prosperous and powerful that he was able to betroth his daughter Mary to the archduke Charles (afterward Emperor Charles V), the greatest match of the age.

Government and administration. In home affairs Henry achieved striking results largely by traditional methods. Like Edward IV, Henry saw that the crown must be able to display both splendour and power when occasion required. This necessitated wealth, which would also free the king from embarrassing dependence on Parliament and creditors. Solvency could be sought by economy in expenditure, such as avoidance of war and promotion of efficiency in administration, and by increasing the revenue. To increase his income from customs dues, Henry tried to encourage exports, protect home industries, help English shipping by the time-honoured method of a navigation act to ensure that English goods were carried in English ships, and find new markets by assisting John Cabot and his sons in their voyages of discovery. More fruitful was the vigorous assertion of royal fiscal rights, such as legal fees, fines and amercements, and feudal dues. This was largely achieved by continuing Yorkist methods in ordering most of the royal revenue to be paid into the chamber of the household, administered by able and energetic servants and supervised by the king himself, instead of into the royal exchequer, hidebound by tradition. So efficient and ruthless were Henry's financial methods, especially in his latter years, that he left a fortune to his successor and a legacy of hatred for some of his financial ministers.

Growth of crown's wealth

In restoring order after the civil wars, Henry used more traditional methods than was once thought. Like the Yorkist kings, he made use of a large council, presided over by himself, in which lawyers, clerics, and lesser gentry were active members. Sitting as the Court of Star Chamber, the council dealt with judicial matters, but less than was formerly thought. Nearly all the heavy fines levied for the illegal retaining of armed men toward the end of his reign were imposed in the Court of King's Bench and by the justices of assize. Special arrangements were made for hearing poor men's causes in the council and for trying to promote better order in Wales and the North by setting up special councils there; and more powers were entrusted to the justices of the peace. The King, moreover, could not destroy the institution of retainers since he depended on them for much of his army and society regarded them as natural adjuncts of rank. So Henry's government was conservative, as it was in its relations with Parliament and with the church.

Character. The whole of Henry's youth had been spent in conditions of adversity, often in danger of betrayal and death, and usually in a state of poverty. These experiences, together with the uncertainties of his reign, taught him to be secretive and wary, to subordinate his passions and affections to calculation and policy, to be always patient and vigilant. There is evidence that he was interested in scholarship, that he could be affable and gracious, that he disliked bloodshed and severity; but all these emotions had to give way to the needs of survival. The extant portraits and descriptions suggest a tired and anxious-looking man, with small blue eyes, bad teeth, and thin white hair. His experiences and needs had also made him acquisitive, a trait that increased with age and success, and one that was opportune for both the crown and the realm.

Henry VIII of England

As king of England from 1509 to 1547, Henry VIII presided over the beginnings of the English Reformation, unleashed by his own matrimonial involvements, even though he never abandoned the fundamentals of the Roman Catholic faith. Exceptionally well served by a succession of brilliant ministers, he turned upon them all; those he elevated, he invariably cast down again. Attracted to humanist learning and something of an intellectual himself, he was responsible for the deaths of the outstanding English humanists of the day. Six times married, he left a minor heir and a dangerously complicated succession problem. Of his six wives, two joined a large tally of eminent persons executed for alleged treason; yet otherwise his regime observed the law of the land with painful particularity. Formidable in appearance, in memory, and in mind, and fearsome of temper, he yet attracted genuine devotion and knew how to charm people. Monstrously egotistical and surrounded by adulation, he nevertheless kept a reasonable grasp on the possible; forever taking false steps in politics, he emerged essentially unbeaten and superficially successful in nearly everything he attempted to do. It is no wonder that this embodiment of personal monarchy, so mixed in all that touched him, has divided opinion ever since his death; and the debate is far from over.

Henry VIII, painting by Hans Holbein the Younger, *c.* 1538. In the collection of the Duke of Rutland.

Accession to the throne. Henry was born at Greenwich on June 28, 1491, the second son of Henry VII, first of the Tudor line, and Elizabeth, daughter of Edward IV, first king of the short-lived line of York. When his elder brother, Arthur, died in 1502, Henry became the heir to the throne; of all the Tudor kings, he alone spent his childhood in calm expectation of the crown, which helped give an assurance of majesty and righteousness to his self-willed and ebullient character. A child of

Childhood and first marriage

quick-witted intelligence, he excelled in book learning as well as in the physical exercises of an aristocratic society, and, when in 1509 he ascended the throne, great things were expected of him. Six feet tall, powerfully built, a tireless athlete, huntsman, and dancer, he promised to bring to England the joys of spring after the long winter of Henry VII's reign. Yet those who lavishly praised his milk-and-roses beauty, his lively mind, and his affability overlooked the suspiciousness lurking at the back of his close-set, small eyes and the ready temper flaring up at even small checks.

Observers ought also to have taken note of the manner in which this early popularity was turned to political use. Henry and his ministers exploited the dislike inspired by his father's energetic pursuit of royal rights by sacrificing, without a thought, some of the unpopular institutions and some of the men that had served his predecessor. Yet the unpopular means for governing the realm soon reappeared because they were necessary. Soon after his accession, Henry married Catherine of Aragon, Arthur's widow, and the court embarked on a round of lavish entertainments that ate into the modest reserves accumulated in the previous reign.

More serious was Henry's determination to engage in the other proper avocation of kings, military adventure. Europe was being kept on the boil by rivalries between the French and Spanish kingdoms, mostly over Italian claims; and, against the advice of his older councillors, Henry found occasion in 1512 to enter upon the scene as the ally of his father-in-law, Ferdinand II of Aragon, against the ancient enemy, France, and ostensibly in support of a threatened Pope, to whom the devout King for a long time paid almost slavish respect.

The war was something of a farce. Henry himself displayed no military talent in a campaign that included the fortuitous rout of a French force and led to the capture of Tournai in northern France, occupied until 1518, while a real victory was won by the Earl of Surrey at Flodden (1513) against a Scottish invasion. Despite the obvious pointlessness of the fighting, the appearance of success was popular. Moreover, in Thomas Wolsey, who organized his first campaign in France, Henry discovered his first outstanding minister. By 1515 Wolsey was archbishop of York, lord chancellor of England, and a cardinal of the church; more important, he was the King's good friend, to whom he gladly left the active conduct of affairs. Henry never altogether abandoned the positive tasks of kingship and often interfered in business; though the world might think that England was ruled by the Cardinal, the King himself knew that he possessed perfect control any time he cared to assert it, and Wolsey only rarely mistook the world's opinion for the right one.

Wolsey's ascendancy

Nevertheless, the years from 1515 to 1527 were marked by Wolsey's ascendancy, and his initiatives set the scene. The Cardinal had some occasional ambition for the papal tiara, and this Henry supported; Wolsey at Rome would have been a powerful card in English hands. In fact, there was never any chance of this happening, any more than there was of Henry's election to the imperial crown, briefly mooted in 1519 when the emperor Maximilian I died, to be succeeded by his grandson Charles V. That event altered the European situation. In Charles, the crowns of Spain, Burgundy (with the Netherlands), and Austria were united in an overwhelming complex of power that reduced all the dynasties of Europe, with the exception of France, to an inferior position. In celebrating, in 1518, the London treaty of universal peace—a multilateral covenant based on the new concept of collective security—Wolsey had been able to display an effective English initiative; a year later, the new situation so far circumscribed freedom of action that Henry's allegedly independent role ceased to convince the experts. The fact was briefly disguised when he was wooed by the Emperor and the King of France as they moved into position for a showdown; in 1520 and 1521 a series of public and private negotiations, including the lavish splendour of a meeting with Francis I of France at the so-called Field of Cloth of Gold near Calais (1520), seemed to show Henry as a monarch equal to the greatest that Europe could produce. But there was little meaning in it. From 1521, Henry became an outpost of Charles V's imperial power, which at Pavia (1525), for the moment, destroyed the rival power of France. In a desperate attempt to escape from this domination, Wolsey tried to reverse alliances at this unpropitious moment. This policy brought reprisals against the vital English cloth trade with the Netherlands and lost the advantages that alliance with the victor of Pavia might have had. It provoked a serious reaction in England, nor did the fact that he had helped to inspire it prevent Henry from concluding that Wolsey's usefulness might be coming to an end.

Loss of popularity. While the greatness of England in Europe was being shown up as a sham, the regime was also losing popularity at home. The fanciful expectations of the early days could not, of course, endure; some measure of reality was bound to intrude. As it was, those influential shapers of posterity's opinions—journalists and writers—continued to be full of hope for a king who, from 1517, commanded the services of a new councillor, Sir Thomas More, one of the outstanding minds of the day. But More soon discovered that Henry found it easy to keep his enjoyment of learned conversation apart from the conduct of policy. Nothing for the moment could dent the strength of Wolsey's ascendancy, and this had serious drawbacks for the King who supported him. The country was showing increasing signs of its unwillingness to endure priestly rule; there were riots against the clergy, foreign merchants, tax gatherers, and exploiting landlords; and Wolsey's efforts to remedy grievances—always promising fairer than he could perform—only exasperated men of influence without bringing satisfaction to the poor. In the early 1520s, plague and trade depression afflicted the country, and Wolsey's always expensive foreign policy absorbed large sums in the equipping of futile expeditions to France (1522) and larger ones in subsidies to unreliable allies. Feelings came to the boil in the years 1523–24. Although he disliked Parliaments, Wolsey had to agree to the calling of one in 1523, but the taxes voted—with great difficulty—were well below what was required. Next year, the attempt to levy a special tax led to such fierce resistance that Henry rescinded it, he and the Cardinal both trying to take the credit for the remission of what they had been jointly responsible for imposing. While he had Wolsey to take the blame, Henry could afford such fiascoes; the Cardinal could not.

By 1527 a government policy that, though seemingly Wolsey's, was really the King's was facing bankruptcy; ineffective abroad, unpopular at home, it made the regime look as empty of positive purpose as in fact it was. At this point, the King entered affairs unmistakably and spectacularly, to prove that 16th-century politics were bound to revolve around the personal affairs of monarchs. Among his failures so far had been his or Catherine's inability to provide a male heir to the throne; several stillbirths and early deaths had left only a girl, the princess Mary (born in 1516), to carry on the line, and no one relished the thought of a female succession with all the dynastic and political uncertainties it would bring. Being the man he was, Henry could not suppose the fault to be his. His rapidly growing aversion to Catherine, six years older than himself and aged even more by her experiences, received powerful assistance from his infatuation with one of the ladies of the court, Anne Boleyn, the sister of one of his earlier mistresses. Henry was no profligate, and the stories of his sexual adventures are wildly exaggerated. Indeed, he had a strong streak of prudery and is thought by some to have been sexually timid. But he was a passionate man in the prime of physical condition, and he sought the occasional relief from marriage to a worthy but ailing wife to which princes have generally been held entitled. In Anne he met his match; this 20-year-old girl, brought up in a tough school of courtly intrigue, would be more than a king's mistress. It took Henry, who in any case needed to marry her if the expected issue was to solve the succession problem, some six years to achieve their joint purpose. Inadvertently, he provoked a revolution.

Anne Boleyn

From 1527 Henry pursued what became known as "the

Divorce from Catherine

King's great matter": his divorce from Catherine. He convinced himself that his first marriage had been against the divine law; that is, against the biblical injunction (Lev.) forbidding marriage with a brother's widow. The deaths of the children proved God's judgment on the union. With his characteristic readiness to convert his own desires into the law of God, Henry rapidly assured himself that he was living in mortal sin with Catherine and must find relief if he was again to become acceptable to God. So quickly did he arrive at this immovable position that he bypassed without notice a neat device of Wolsey's that might have solved his trouble painlessly but on a lower plane of conscientious conviction. He appealed to Rome for a declaration of annulment. Popes had usually obliged kings in such matters, but Henry had picked both his time and his case badly. He was asking Pope Clement VII to help him discard the Emperor's aunt, but Clement, the Emperor's prisoner in 1527–28, never thereafter dared resist Charles, whose powerful feelings of familial honour and public prestige barred any concession to Henry's wishes. Moreover, the Pope's reluctance was increased by the fact that he was being asked to declare illegal an earlier exercise of papal power —which had licensed Henry's marriage to his brother's widow—of a kind that brought a good deal of money to the papal coffers.

Thus Henry's attempts to solve his dilemma in the accepted legal way were doomed from the start. Wolsey, in a worse dilemma, since only success in the impossible could keep him in power, obtained a trial of the case in England, but this was frustrated by his fellow judge, Cardinal Campeggio, on orders from Rome (1529). Within weeks, Wolsey was ousted; 15 years of high-handed activity rose up against him, and, though the King spared his life, the Cardinal was stripped of power and possessions, to die a year later while being brought to London for further persecution. But Wolsey's disappearance solved nothing, and the councillors who succeeded him could offer little help to their king, who knew only what he wanted, not how to get it.

The chancellorship went to Thomas More, who had told Henry that he did not approve of the divorce and who wished to devote himself to a fight against Lutheran heresy, the alleged dangers of which had driven everything else from a mind once dedicated to rational reform. His policy of assisting the bishops and maintaining the privileges of the church was hampered by the violent hostility of the influential part (nobility, gentry, and mercantile interest) of the nation, now effectively represented in the Parliament that Henry called in November 1529, in order to have backing for his battle with the Pope. The anticlericalism of the Commons increased the pressure on Rome, threatened with loss of power and revenue, even possibly with secession, but it conflicted with the renewal of bigoted orthodoxy urged on by More. Confusion, in fact, was the keynote of policy for some three years, while the King dithered between hope that Rome might yet be forced to let the formal trial of his first marriage take place in England and stirrings of a more radical nature—to reject Rome outright. But though he occasionally talked of doing just that, neither he nor anyone else knew how to convert talk into action.

The breach with Rome. Action called for a revolution, and the revolution required a man who could conceive and execute it. That man was Thomas Cromwell, who, in April 1532, won the battle for control of the council and thereafter remained in rarely troubled command for some eight years. The revolution consisted of the decision that the English Church should separate from Rome, becoming effectively a spiritual department of state under the rule of the king as God's deputy on earth. It was accomplished by a massive burst of parliamentary legislation in the years 1533–36. The revolution that he had not intended gave the King his wish: in January 1533 he married Anne Boleyn; in May a new archbishop, Thomas Cranmer, presided over the formality of a trial that declared the first marriage annulled; in September the princess Elizabeth was born. The Pope retaliated with a sentence of excommunication; it troubled no one.

Head of Church of England

The supreme headship on earth over the Church of England, though he had not sought it, represented Henry's major achievement. It had very wide ranging consequences, but those that immediately concerned the King were two. In the first place, the new title consolidated his own concept of kingship, his conviction that (as he once said) he had no superior on earth. It rounded off the majestic image of divinely instituted royal rule that it was Henry's constant ambition to present to an awed and obedient world. But, in the second place, it created a real personal problem for a king who in 1521, in his book against Luther (*Assertio septem sacramentorum adversus Martinum Lutherum*, certainly Henry's own work), had expressed a profound devotion to the papacy and been rewarded with the title of Defender of the Faith. Now he had thrust out the Pope, and the language used was even more abusive than that employed before had been respectful. In the 1530s, turning against the pope was equal to encouraging the Protestant Reformation, a thing attractive to Cranmer and Cromwell (and perhaps Anne Boleyn), but not to Henry, who never forgot Luther's rude contempt for him. The religion of the newly independent church was for its head to settle: where was he to take his stand? For the rest of his life, Henry, who justly prided himself on his theological learning, was to give much time and thought to the nature of the true religion. With the exception of the papal primacy, he never gave up the main tenets of the faith in which he had grown up, but he changed his mind on details and arrived at an eclectic amalgam of his own in which transubstantiation (the doctrine that the bread and wine used in Holy Communion are changed into the body and blood of Christ) and clerical celibacy mingled with radical views about the worldly authority of the church and man's ability to seek salvation without the aid of priests.

Domestic reforms. Cromwell's decade, the 1530s, was the only period of the reign during which a coherent body of policies was purposefully carried through. Cromwell's work greatly enlarged Henry's power, especially by transferring to the crown the wealth of the monasteries, dissolved in 1536–40, and new clerical taxes; but it also, more explicitly than ever, subjected the King to the law and to the legislative supremacy of Parliament. Since Henry knew how to work with parliaments, the immediate effect was to make him appear more dominant than ever and to give to his reign a spurious air of autocracy—spurious because in fact the rule of law remained to control the sovereign's mere will. The appearance of autocracy was misleadingly emphasized by the fact that all revolutions have their victims. As heads rolled, the King's earlier reputation as a champion of light and learning was permanently buried under his enduring fame as a man of blood. Old friends such as More, refusing to accept the new order, fell before the onslaught, as did some 50 other men caught by the treason laws. Between 1538 and 1541 the families of Pole and Courtenay were destroyed by the axe for treasons linked with efforts abroad to reverse the course of events in England but mainly because they could claim royal blood and represented a dynastic danger to the unprolific Tudor line.

Later marriages

The King now embarked on the series of matrimonial adventures that made him appear both a monster and a laughingstock. He soon tired of Anne, who failed to produce a male heir; in 1536 she was executed, with other members of the court, for alleged treasonable adultery. Catherine of Aragon, rejected but unbowed, had died a little earlier. Free at last, Henry immediately married Jane Seymour, who bore him his son Edward but died in childbirth (1537); she not only escaped the fates of her fellow wives but remained the sentimental King's one remembered attachment. The next three years were filled with attempts to replace her, and the bride chosen was Anne, sister of the Duke of Cleves, a pawn in Cromwell's policy for a northern European alliance against dangers from France and the Emperor. But Henry hated the first sight of her and at once demanded to be freed, an end achieved by the divorce to which the lady obligingly consented, in return for a sizable estate, upon which she settled in happy obscurity.

Physical and mental decline. The Cleves fiasco destroyed Cromwell; it enabled his many enemies to turn the King against him, and in July 1540 his head fell on the scaffold. There is no doubt that Henry had by now become truly dangerous. He had always been secretive and suspicious, trusting no one and determined to know the inmost thoughts of all other men. Now he was beginning to show paranoiac tendencies. Convinced that he controlled everyone, he was in fact readily manipulated by those who knew how to feed his suspicions and pander to his self-righteousness. Full of experience—the oldest king in Europe—and increasingly competent in the routine of rule, he lacked the comprehensive vision and large spirit that would have made him a great man, instead of the image of greatness painted on a Tudor canvas. His temperamental deficiencies were aggravated by what he regarded as his undeserved misfortunes and by ill health. Ever since a fall in his last tournament in 1536, he had suffered from headaches. In the late 1530s he developed the ulcer on his leg (not syphilitic) that was to keep him in agony for most of his remaining days. No longer able to subject his splendid body to the strenuous exercises to which it had been accustomed, he grew enormously fat. Fifty was a good age in the 16th century, but even so Henry aged faster than he should have done. His mind did not weaken; there was no senility. But he grew restless, peevish, and totally unpredictable; often melancholy and depressed, he was usually out of sorts and always out of patience. In 1540–42 he briefly renewed his youth in marriage to the 20-year-old Catherine Howard, a promiscuous young woman whose folly in continuing her adventures, even as queen, brought her to the block. The blow finished Henry. Thereafter, he was really a sad and bitter old man, and, though he married once more, to find a measure of peace with the calm and obedient Catherine Parr, his physical ruin was complete, and behind the trappings of capricious authority there was only a sick man frightened of the coming dissolution.

But he was still the king and, from Cromwell's fall (which he regretted too late), the only maker of policy. Policy in the hands of a sick, unhappy, violent man was not likely to be either sensible or prosperous, and so it proved. Left to himself, Henry concentrated on keeping the realm united, despite the growing strife between the religious factions, and on keeping before the world his own image as the glorious monarch of the age. The first resulted in frequent explosions against the ingratitude of subjects who dared maintain their petty squabbles when he had told them what to believe and in frequent outbursts against his councillors, whose careers in the 1540s became unprecedentedly precarious and variable. The second brought him back to his first love—war and conquest, the sport of kings.

Military successes

In 1542 the Emperor and the King of France resumed hostilities. After a pretense of independence, Henry again joined in on the side of the former, which promptly brought in the Scots on the side of their allies, the French. Now it was success in war that was to cause trouble. The Scots were routed at Solway Moss (1542), and their king died soon after: this opened the possibility of subjugating that country permanently by means of a marriage alliance between the infant heirs to both thrones. In France, an English army conquered Boulogne. But the Scottish dream quickly collapsed as Henry's crude handling of that nation gave control to a pro-French party, determined to resist even an alliance with England; physical conquest was beyond the King's means. Boulogne, a useless prize, was expensive to keep but—since honour was involved—almost impossible to give up. Henry personally managed both the war and the subsequent negotiations, and he displayed amazing energy for so sick a man. But energy is not the same thing as competence. The war proved ruinous. Heavy taxation and borrowing did not suffice to cover its cost. Thus, money had to be raised by selling off the monastic lands, which had brought a good income, so that the financial improvement made by Cromwell was quickly lost. The desperate expedient of debasing the coinage, though it brought temporary succour, led to a violent inflation that made things worse. Yet, even after the Emperor made peace with France behind his back (1544), Henry would not let go; it was only two years later that he could be brought to end the pointless struggle.

As the year 1546 drew to a close, it was apparent to all observers that the King had not long to live. Not that it was clear to the man most concerned; he continued as before, lamenting religious dissension, attending to the business of government, continuing the pretense of deathless majesty, destroying the powerful Howard family, whom he suspected of plotting to control his successor. Conscious almost to the very end, he died on January 28, 1547. He left the realm feeling bereft and the government the more bewildered because, to the last, he had refused to make full arrangements for the rule of a boy king.

Assessment

Immediately and ever since, the impact of that overpowering personality maintained the achievement of which he himself was proudest: Henry VIII has always seemed the very embodiment of true monarchy. Even his evil deeds, never forgotten, have been somehow amalgamated into a memory of greatness. He gave his nation what it wanted: a visible symbol of its nationhood. He also had done something toward giving it a better government, a useful navy, a start on religious reform and social improvement. But he was not a great man in any sense. Although a leader in every fibre of his being, he little understood where he was leading his nation. But, if he was neither statesman nor prophet, he also was neither the blood-stained monster of one tradition nor the rowdy *bon vivant* of another. Cold, self-centred, ungiving, forever suspicious of the ways of the world, he could not live down to the second stereotype; despite a ruthlessness fed by self-righteousness, he never took the pleasure in killing required of the first. Simply, he never understood why the life of so well-meaning a man should have been beset by so many unmerited troubles.

BIBLIOGRAPHY. J.J. SCARISBRICK, *Henry VIII* (1968), supersedes all earlier biographies, especially that by A.F. POLLARD, *Henry VIII* (1902, reprinted 1966). LACEY BALDWIN SMITH, *Henry VIII: The Mask of Royalty* (1971), though inclined to overdramatize, interestingly discusses the King's last years. The often discussed medical problems are best studied in A.S. MACNALTY, *Henry VIII: A Difficult Patient* (1953). A.F. POLLARD, *Wolsey* (1929, reprinted 1965), still gives the most searching account of the first half of the reign; G.R. ELTON, *The Tudor Revolution in Government: Administrative Changes in the Reign of Henry VIII* (1953), and *Policy and Police* (1972), provide the best analysis of the Cromwell era. For the religious setting, see especially A.G. DICKENS, *The English Reformation*, rev. ed. (1964).

(G.R.E.)

Henry IV of France

The first of the Bourbon kings of France, Henry IV brought unity and prosperity to the country after the ruinous 16th-century Wars of Religion. Though not a great strategist, his gallantry made him a great military leader; though never an efficient administrator, his political insight and understanding of his people (he is credited with having promised them a chicken to eat every Sunday) made him an efficient ruler. He is one of the most popular figures in French history, for his amorous as well as his political achievements. He deserved to be called Henry the Great and good king Henry.

Prince of Béarn. Henry de Bourbon-Navarre was born on December 13, 1553, at Pau, near the Franco-Spanish border. The son of Antoine de Bourbon, duc de Vendôme, and Jeanne d'Albret, queen of Navarre from 1555, Henry, through his father, was in the sole legitimate line of descent from the Capetian kings of France. It was scarcely to be expected, however, that he would one day succeed to the throne of France, since Catherine de Médicis had already borne three sons to the reigning king, Henry II, and would soon bear him a fourth. Prince Henry spent most of his early childhood in Béarn. From 1561 to 1567 he lived with his second cousins, the children of the King of France, among whom was his future wife Marguerite.

Henry IV of France by Frans Pourbus the Younger (1569–1622). In the Louvre.
Giraudon

The religious crisis between Roman Catholic and Protestant forces was then coming to a head, leading to the long period of civil war. Antoine de Bourbon temporarily allied himself with the Protestants but changed sides and was mortally wounded in battle against them. Henry's mother, Jeanne d'Albret, held firm and publicly announced her Calvinism on Christmas 1560.

Henry had just turned 13 when his mother brought him back to Béarn. At a crucial age in his intellectual development, he was brought up in the strict principles of Protestantism. About the same time he began his military education. In the autumn of 1567, he served as nominal head of a punitive expedition launched against the rebellious Catholic gentry of lower Navarre, which ended in an easy victory. Less than a year later Jeanne d'Albret, who had remained neutral during the first two religious wars, readily entered the third. She proceeded to La Rochelle, where she put her son into the charge of her brother-in-law Louis I de Bourbon, prince of Condé, who was leader of the Protestant (Huguenot) forces.

The Protestants were surprised and defeated near Jarnac on March 13, 1569, by the duc d'Anjou, the future Henry III, and Condé was killed. Jeanne d'Albret immediately hastened to the scene and proclaimed her son head of the army, though actual command was exercised by Gaspard de Coligny, from whom Henry would receive his military education. Henry and his cousin, Henri, the young prince of Condé, were present on October 3 at the Battle of Moncontour, when the Protestants were again defeated. Coligny, however, forbade Henry to draw his sword.

The 16-year-old general received his baptism of fire near Arnay-le-Duc on June 26, 1570, when he led the first charge of the Huguenot cavalry. The long campaign through the ravaged provinces, extending from Poitou to the heart of Burgundy, forged in him the soldierly spirit that he would retain throughout his life and made him reflect on the disaster that had befallen the kingdom.

King of Navarre. Peace was concluded in August 1570, and a very liberal edict was granted the Protestants. Many persons, including Catherine de Médicis, hoped the civil war had come to an end. In order to strengthen the peace, the Queen sought to arrange a marriage between Prince Henry and her daughter, Marguerite de Valois, a project that had first been considered during Henry II's lifetime, when the future couple were still children. After difficult negotiations, which lasted until the spring of 1572, the Queen Mother and the Queen of Navarre reached an agreement. The latter, who preceded her son to Paris, had scarcely arrived when she died June 9 of a respiratory illness. Prince Henry thereby became king of Navarre and sovereign lord of Béarn. He and Marguerite exchanged vows August 18 before the main portal of Notre Dame, but only Marguerite attended mass with the royal family.

St. Bartholomew's Day Massacre

On August 24 came the St. Bartholomew's Day Massacre, in which thousands of French Protestants were cut down by royal forces. The marriage was publicly styled the "scarlet nuptials" because of the bloodshed. Ordered by his brother-in-law Charles IX to abjure his Protestant faith, Henry yielded. His conversion was obviously of dubious sincerity, and he was therefore held for three and a half years at the courts of Charles IX and then Henry III. Careful to restrain his impatience, he hid his forceful personality from his detainers. The wily Catherine de Médicis was deceived along with everyone else, and it was with her secret consent that her son-in-law escaped from the court at the beginning of 1576.

Once free, the Prince displayed his sharp intellect and political acumen in his role as protector of the Protestant churches. His common sense—one of his outstanding traits, except in love affairs—manifested itself when civil war broke out anew at the end of 1576. The Huguenots fared badly, and Henry, evaluating the situation, was able to persuade his coreligionists to give up the struggle and accept the Treaty of Bergerac on September 17, 1577, despite the sacrifices it imposed on them.

In the meantime, Catherine de Médicis went to Guyenne to return Marguerite to her husband, who had left her with alacrity, and, more important, to seek a lasting peace. While this subject was being negotiated at Nérac, Henry learned that the Catholics had seized the Château de La Réole on the Garonne. His response, a crushing surprise attack on Fleurance, revealed him to be a born military leader. In the spring of 1580, after five days of furious street fighting, which delighted him, he subdued Cahors, emerging from battle "all blood and powder," in his own words. When his town of Mont-de-Marsan was not returned to him, he stormed it by night (November 1583) without firing a shot.

War and politics were not enough, however, for this restless man, and Henry enjoyed romantic as well as territorial conquests. In the summer of 1583, he began a love affair that lasted for several years with Corisande d'Andouins, comtesse de Guiche; a member of the highest nobility of Béarn, she was a young and beautiful widow, saluted by the essayist Michel de Montaigne as "the great Corisande."

Heir presumptive to the throne. On the death of Henry III's brother, François, duc d'Anjou, in 1584, Henry de Bourbon-Navarre became the heir presumptive to the throne of France. He was irrevocably opposed, however, by the militant Catholics of the Holy League, who were unwilling to accept a Protestant king, and by the Pope, who excommunicated him and declared him devoid of any right to inherit the crown. Headed by Henri, duc de Guise, and his brothers, the League claimed to be the defender of the ancestral faith of France, but its increasing reliance on Spanish support rapidly became a serious threat to French independence. Henry III lacked the strength to contain the League's overwhelming influence.

The Holy League

The King of Navarre himself could rely only on the grudging support—peppered with shrewd demands—of Elizabeth of England and on the distant German Protestant princes. In France, in addition to the Huguenots, a few enlightened and liberal Catholics, such as Montaigne, supported him. Ultimately he could depend only on himself. In this crucial episode of French history, in which the very independence of the nation was at stake, Henry's activity was the essential factor. Although too prone in peace to neglect public affairs for private pleasure, he was an unrivalled leader in times of peril. Quick to grasp the significance of every situation, he was equally prompt to act, and victory was invariably the reward of his bold swiftness. He was not a brilliant strategist but had the ability to inspire men to action, as much by his own example as by the spoken or written word. Four centuries later, his notes and speeches still have the impact and clarity of a clarion call.

The military situation drew and held Henry within an extended radius of his base at La Rochelle. Though this town was a symbol of Protestant resistance, as well as a fortress, its extreme religious atmosphere could not keep Henry away from amorous escapades.

War of the three Henrys

In the fall of 1587, the outcome of the war hinged on the impending encounter between Henry and the army of the French king Henry III, who came increasingly under the influence of the League. The King placed another brother-in-law, Anne, duc de Joyeuse, in command of the army. The battle took place on October 20 on the outskirts of Coutras about 30 miles northeast of Bordeaux. Joyeuse was killed, and his troops were cut to pieces. The significance of the event was more political than military, for two of the young Catholic stepbrothers of the Prince of Condé had fought with the King of Navarre.

It became clear that the struggle, initially a religious conflict, had become dynastic and national when the League accepted the daughter of Philip II of Spain and Elisabeth de Valois as the next ruler of France. Henry III had the merit to grasp the full meaning of the situation for the future of France and, after long hesitation, had the Duc de Guise assassinated. The logic of the events left him with no choice but reconciliation with the King of Navarre, which took place April 30, 1589.

The united forces of the two princes laid siege to Paris on July 30, but on August 1 Henry III, the last of the Valois, was stabbed in his headquarters at Saint-Cloud. He died the next day, after staunchly proclaiming the head of the House of Bourbon, first prince of the blood, as his successor in accordance with dynastic law.

Henry IV. Henry IV was now king of France, but it would take him nine years to conquer his kingdom. Many of the Catholic gentry who had remained loyal to Henry III deserted him, and his army was growing exhausted. He had to withdraw from the outskirts of Paris. A few weeks after his accession, he fought Charles de Lorraine, duc de Mayenne, in sight of the Château d'Arques in Normandy. Mayenne, who had become head of the League on the death of his brother Guise, suffered a more serious defeat at Ivry on March 14, 1590. It was at Ivry that Henry IV issued his famous call to his troops: "If your cornets fail you, rally to my white plume—you will find it on the path to honour and victory!" He was unable to break the resistance of the capital, however, despite the terrible famine that came in the wake of his long siege. He then laid siege to Chartres, which capitulated April 10, 1591. During the siege of Chartres, Henry IV became involved with Gabrielle d'Estrées, who of all his women was to exert the most influence over him.

Soon after Chartres, Henry IV captured Noyon, but he could not conquer Rouen. The war dragged on interminably, and the King realized that it had to be ended at any cost. After long hesitation, he abjured Calvinism on July 25, 1593, in the basilica of Saint-Denis, the sepulchre of the kings of France.

Abjuration of Calvinism

Though many remained unconvinced of his sincerity, the monarch's conversion still brought quick results. Important towns, notably Orléans and Lyons, submitted in growing numbers. Reims remained loyal to the League, so the King was crowned at Chartres on February 27, 1594. The conversion removed all legitimate pretext for resistance, and on March 22 he finally entered Paris. Whether or not he made the comment attributed to him —"Paris is well worth a mass!"—he went, amid cheers, to hear the Te Deum at Notre Dame. He was, as he wrote, "in his triumphal chariot."

During the spring and summer, many League towns hastened to acknowledge royal authority. Laon, however, submitted only after a difficult siege. Even after Pope Clement VIII removed the ban of excommunication from Henry IV on September 17, 1595, Brittany remained in the hands of Philippe-Emmanuel de Lorraine, duc de Mercoeur, the younger brother of Guise and Mayenne.

Brittany was held by the League only through Spanish support. In order to bring this situation to an end, the King had declared war on Philip II in January 1595. On June 5 at Fontaine-Française in Burgundy, he overwhelmed the Spanish cavalry. In return, Philip II's forces seized Cambrai and then Calais and Ardres. Henry succeeded, after a six-month siege, in taking La Fère, but, on the night of March 11–12, 1597, panic swept Paris, for Spain had taken Amiens by surprise.

Henry quickly responded to the situation, exclaiming, "Enough of being king of France, it is time to be king of Navarre!" He lacked both men and money but was able to raise both as if by a miracle; as one of his chief ministers, Nicolas de Neufville, seigneur de Villeroy, wrote in a private letter, "The king has enough courage for everyone." He succeeded in forcing the Spaniards to surrender Amiens on September 19, and the treaty between France and Spain was concluded at Vervins on May 2, 1598. Spain kept Cambrai, which was not returned to France until 1677.

Henry also prepared to unseat the duc de Mercoeur in Brittany. He was able to come to a bloodless agreement by arranging a marriage between Françoise de Lorraine and César de Vendôme, the eldest of his two sons by Gabrielle d'Estrées; at that time César was about four years old. The high point of Henry IV's visit to Brittany was at Nantes, where Gabrielle gave birth to a daughter, and, on April 13, 1598, Henry signed the famous edict bearing the name of the city. The Edict of Nantes proclaimed freedom of conscience and granted many places of worship and nearly a hundred places of refuge to the Protestants.

Edict of Nantes

Henry IV had united the kingdom and achieved peace at home and abroad. During the remainder of his brief reign, he devoted himself to healing France's wounds. He faced the risk of having his work undone, however, should he die without leaving a universally accepted successor. Blinded by an unlucky passion and exploited by the coterie that had gathered around Gabrielle, Henry nearly married his mistress, which would have made César, the son of their double adultery, heir to the crown of Saint Louis. Such an act could not have failed to provoke a war of succession when the King died. Gabrielle's death in childbirth on April 10, 1599, however, removed all reason for Pope Clement VIII's reluctance to annul the marriage of Henry IV and Marguerite de Valois. The annulment made it possible for the King to marry the princess of Tuscany, Marie de Médicis, in October 1600, despite the protests of his new mistress, Henriette d'Entragues. Continuing his effort to unify the kingdom, Henry went on to subdue Charles-Emmanuel, duc de Savoie, forcing him to cede Bresse and Bugey to France. The new queen gave birth on September 27, 1601, to the Dauphin, the future Louis XIII, and eventually to four other children. Henriette d'Entragues, Jacqueline de Bueil, and Charlotte des Essarts also bore him many children.

Even after unification of the kingdom, Henry IV's reign was not tranquil. More than a century of impassioned religious conflict had torn France asunder, and peace was not to be easily regained. Political intrigue was closely intertwined with the religious struggle, as in the treason case of the marshal de Biron, who was decapitated in 1602, and the conspiracy of the Entragues and Charles, comte d'Auvergne, the illegitimate son of Charles IX. There was more than one attempt on Henry's life. In December 1594, Jean Châtel wounded the King with a dagger. Châtel was tortured, and his crime was used as a pretext to expel the Jesuits from the kingdom. The regicide attempts were born of the still-widespread belief that, behind the mask of his hypocritical conversion, Henry intended to ensure the triumph of heresy.

Achievement of the reign

Nonetheless, France flourished anew. Maximilien de Béthune, duc de Sully, the most renowned of Henry's councillors, reorganized the national finances, stabilized the economy, and the country prospered. The groundwork was laid for the splendour of the next two reigns. Although Henry IV never became a sedentary or reflective man, his remarkable political insight enabled him to govern efficiently. His interest in maritime and colonial expansion led him to support Samuel de Champlain's exploration in Canada.

Henry's folly in affairs of the heart continued to stand in contrast to his wisdom in affairs of state. He finally

grew tired of the malicious and scheming Henriette d'Entragues, now marquise de Verneuil, or perhaps he was motivated by a predilection for young girls: at the age of 55, he became infatuated with Charlotte de Montmorency, then 15 years old, the daughter of his close friend the constable of France. Henry conceived of marrying Charlotte to his cousin the young Condé, Henri II, who was supposedly not interested in women. Once married, however, the Prince prevented the King from seeing his wife by taking her to Brussels, the capital of the Spanish Netherlands. Henry IV became furious. The argument made by many historians that the war he then prepared to launch against the Habsburgs had its cause in this unfortunate love affair is, however, unconvincing. Difficulties had arisen with the Clèves–Jülich succession. After some hesitation, Henry finally decided on a military expedition to expel the imperial troops from Jülich. He had long decided on May 19, 1610, as the date of his departure to take command of the army of the east, one of three armies he had formed for this expedition to the Rhine. Early on the afternoon of May 14, he entered his coach with the intention of visiting the ailing Sully. The coach had not gone far from the Louvre when a traffic congestion in the narrow Rue de la Ferronnerie obliged the coachman to slow down. Suddenly a certain François Ravaillac, a fanatic, dashed out, leaped onto Henry's carriage, and stabbed the King twice with a long knife. Henry died on the way back to the palace.

Henry IV died a victim of the fanaticism he wanted to eradicate. Centuries ahead of his own time, he said, "Those who follow their consciences are of my religion, and I am of the religion of those who are brave and good." Too often misunderstood during his lifetime, his tragic end seemed finally to have opened the eyes of his people. They soon bestowed on him the appellation Henry the Great.

BIBLIOGRAPHY. After those of Napoleon I, the Revolution, and Louis XIV, the bibliography concerning Henry IV is the most abundant of any in French history, to the point that it fills an entire volume of the classic work of HENRI HAUSER, *Les Sources de l'histoire de France au XVI^e siècle*, vol. 4 (1915). PIERRE DE VAISSIERE, *Henri IV* (1928), is a study that remains today the best informed in its entirety; it may be supplemented by the recent work of the DUC ANTOINE DE LEVIS-MIREPOIX, *Henri IV, roi de France et de Navarre* (1971), a brilliant and lively evocation of the personality and of the great events of his life and reign; and that of ROLAND MOUSNIER, *L'Assassinat d'Henri IV, 14 mai 1610* (1964). Among the testimonies of contemporaries are: P. DE L'ESTOILE, *Mémoires-Journaux*, 12 vol. (Brunet edition, 1875–96), by a Parisian, curious and informed about everything, who has left us the richest treasure of anecdotes and miscellaneous facts relating to Henry IV; the *Chronologie septenaire* (1605) and the *Chronologie novenaire*, 3 vol. (1608), by P.V. PALMACAYET, who had been the Calvinist minister attached to the household of Catherine de Bourbon, the sister of Henry IV, and knew the prince well; J.A. DE THOU, *Histoire universelle . . .*, 16 vol. (1734), which continues to be the most serious and the most fruitful source for works of all kinds about Henry IV; and RAYMOND RITTER (ed.), *Lettres du cardinal de Florence sur Henri IV et sur la France (1596–1598)* (1955), the day-to-day notes, valuable because of their sincerity, of a Medici, a papal legate, who understood and defined the exceptional merits of the monarch. Particular points of the political history of the reign are discussed in MARTIN PHILIPPSON, *Heinrich IV and Philipp III*, 3 vol. (1870–73); L. ANQUEZ, *Henri IV et l'Allemagne* (1887); E. ROTT, *Henri IV, les Suisses et la haute Italie* (1882); and L.A. PREVOST-PARADOL, *Elisabeth et Henri IV (1595–1598)* (1855), which may be supplemented by J. NOUAILLAC, *Villeroy* (1909). More instructive are the writings of Henry himself in the *Recueil des lettres missives de Henri IV*, 9 vol. (1843–76), by M. BERGER DE XIVREY (finished by J. GUADET), and the numerous documents of the same nature that have followed and continued since the last quarter of the 19th century. Little has been published on Henry IV in English; however, HESKETH PEARSON, *Henry of Navarre: The King Who Dared* (British title, *Henry of Navarre: His Life;* 1963), is of interest.

(R.Ri.)

Henry, Patrick

Patrick Henry was one of the outstanding orators and civil leaders of the American Revolutionary period. He was largely responsible for the passage of the Bill of Rights—the first ten amendments to the Constitution, guaranteeing individual rights and limiting the power held by government over individuals.

Patrick Henry, portrait by Thomas Sully, 1815. In the Colonial Williamsburg Collection.

Patrick Henry was born at Studley, Hanover County, Virginia, on May 29, 1736, the son of John Henry, a well-educated Scotsman who served in the colony as a surveyor, colonel, and justice of the Hanover County Court. Before he was ten, Patrick received some rudimentary education in a local school, later reinforced by tutoring from his father, who was trained in the classics. As a youth, he failed twice in seven years as a storekeeper and once as a farmer; and during this period he increased his responsibilities by marriage, in 1754, to Sarah Shelton. The demands of a growing family spurred him to study for the practice of law, and in this profession he soon displayed remarkable ability. Within a few years after his admission to the bar in 1760 he had a large and profitable clientele. He was especially successful in criminal cases, where he made good use of his quick wit, his knowledge of human nature, and his forensic gifts.
