These include use of explosives, drilling, hoisting, loading and haulage, and ventilation and lighting.

Explosives. The theory of detonation of high explosives is based upon the laws of conservation of mass, momentum, and energy applied to plane shock waves, combined with thermodynamics, equations of state for gases, chemical equilibria, and material-balance equations (see EXPLOSIVES). In a detonation wave, the energy of chemical reaction is utilized to heat the detonation products and to maintain the thermodynamic processes of shock-wave propagation at high temperatures (to 5,500° K [9,400° F]) and pressures (to 200,000 times atmospheric pressure). The distinguishing feature of a detonation is that it is a reactive shock—*i.e.*, a shock wave supported by an accompanying chemical reaction.

Most common commercial explosives are made up of compounds containing carbon, hydrogen, nitrogen, and oxygen, some of the compounds serving as fuels and some as oxidizers (agents that bring about chemical combination with oxygen). The compounds must be of such a character that they will react rapidly, releasing chemical energy at a very high rate. Thus, one stick (eight ounces, or 225 grams) of an average-energy dynamite may have a work capacity of 40,000 horsepower.

Ammonium nitrate–fuel oil explosives

Development of ammonium nitrate–fuel oil blasting agents in the late 1950s has reduced explosive energy costs to as little as one-third the cost of dynamite. Though it had been known since the late 1800s that ammonium nitrate mixed with a fuel would explode in large diameters, the corrosiveness, affinity for water, and tendency of ammonium nitrate to cake, plus its large critical diameter (the minimum diameter at which it will propagate a stable detonation), made it unusable. In the 1950s it was found that commercial-grade ammonium nitrate fertilizer prills (small spherical grains) would detonate in reasonably small diameter holes when they were mixed with finely divided carbon or about 6 percent by weight of fuel oil.

Whereas solid ammonium nitrate crystals are difficult to detonate, prills are cracked and fissured because the last 5 percent of moisture is evaporated after the ammonium nitrate is in prilled form. This leaves much more surface area exposed to chemical reaction, which is the primary reason for the success of ammonium nitrate–fuel oil as a blasting agent; *i.e.*, it results in a smaller critical diameter. Equivalent in strength to about a 40 percent dynamite, ammonium nitrate–fuel oil cannot be detonated by blasting caps but requires a strong booster to initiate an explosion. This feature classifies it as a blasting agent rather than an

explosive. Thus, it is safe to handle, can be mixed at or near the blasting site, can be loaded in dry holes in bulk from automatic loaders, and costs much less than dynamite. Disadvantages mentioned above include its affinity for water, corrosive action on metals, and tendency to cake. It cannot be used in wet holes because of its solubility except in waterproof bags or as a slurry.

While the solid density of ammonium nitrate is 1.725 grams per cubic centimetre, the bulk density of prills varies from 0.85 to 0.95 gram per cubic centimetre. Detonation velocity increases almost linearly with bulk density, and the question arose during its development whether the increase in density by filling pore spaces between prills with water could be compensated by other thermodynamic factors. It was found that, if ammonium nitrate, trinitrotoluene (TNT), and aluminum were mixed with water, the increase in density caused an increase in detonation pressure, and the favourable heat of reaction of aluminum plus other thermodynamic factors gave detonations of high velocity, higher pressure, but lower temperature. Because of these characteristics, slurries of various compositions have found wide application in rock and ore that is difficult to break. They may also be used in wet blast holes.

Blasting caps

Explosives are usually detonated with electric or nonelectric blasting caps that contain a small amount of powerful, relatively sensitive explosive. Detonating fuse, a train of explosive with a small critical diameter that will propagate a detonation, is also employed. Blasting agents, which are insensitive to blasting-cap initiation, are detonated by means of a booster, a charge of up to eight ounces (225 grams) of high explosive, which is itself initiated by a blasting cap.

An explosive confined in a borehole transmits much of its explosive energy to the surrounding rock in the form of a compressive "stress pulse." When this reflects from a rock surface in tension, it causes the rock to break in slabs, inasmuch as rock is only about one-tenth as strong in tension as it is in compression. The type, amount, and spacing of explosive charges are determined from experience or by experimentation.

Drilling. Drilling for blasting purposes (Figure 2) is performed with several types of drills. Percussion drills impact the rock with a chisel-shaped or button-faced bit

By courtesy of Gardner-Denver Company, Quincy, Ill.

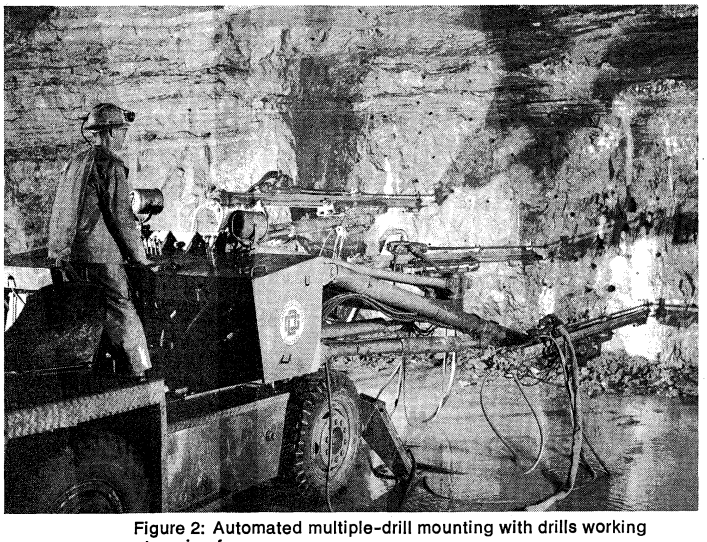

Figure 2: Automated multiple-drill mounting with drills working at a mine face.

(containing button-shaped inserts of extremely hard tungsten carbide) that chips the rock with repeated blows as it is rotated. This type of drill usually employs compressed air for power. Drag-bit rotary drills cut by shaving, plowing, or abrading with a rotating cutting head using blades, diamonds, or hard steel shot as cutting agents. Drag action is provided by thrust and rotation. Rotary-bit drills utilize a cutting head mounted with roller cones studded with teeth or hard metal buttons; they cut the rock by indenting, shaving, fracture, and crushing. Rotary–percussion is a combination of the two methods described above.

Factors influencing mechanical drilling are the condition of the equipment, depth, and diameter of the hole, rock properties, geologic conditions, and the stress in the rock.

In open pits, larger holes are drilled for explosives than underground; most large holes in surface mining are made with rotary bits. Some drilling a few decades ago was performed with churn drills, which fragment the rock in the bottom of a hole by repeatedly raising and dropping a heavy drill bit. Cuttings are removed from the hole with a long pipe with a closure device on one end. Until 1949 most rotary drilling employed drag bits. Modern rotary drills attack the rock with roller cones with hard teeth or knobs, the bit assembly being supplied with energy by means of rotating drill rods. Rock is broken by processes of abrasion, chipping, and scraping, or a combination of these. Circulating water is used to clean the hole and carry the cuttings to the surface. The drill is operated by a rig that may be mounted on a truck, trailer, or crawler. Power is furnished by a gasoline or diesel engine or electric motor. Hole diameters for surface mines may vary from nine to 15 inches (23–38 centimetres), with the spacing between holes being 15 to 40 feet (5 to 12 metres).

Flame-jet drilling

In hard rock that spalls (chips at the surface) readily when heated rapidly, flame-jet or jet-piercing drilling may be employed. The drill consists of a jacketed blowpipe that is water cooled. Fuel oil and oxygen are burned in a combustion chamber generating a high-temperature flame. The heat spalls the rock, and the cuttings are carried from the hole by the steam from the cooling water. Quartzitic rocks containing 20 percent or more of quartz are usually most favourable for spalling. Holes cut by flame jets may be somewhat irregular and require a free-flowing dry explosive or slurries to fill them completely. Flame jets may also be used to cut deep channels in dimension stone rock that spalls readily when attacked by heat.

Most underground drilling and blasting ulitizes small holes with diameters of one to three inches (3 to 8 centimetres), which are cut with either pneumatic or noncoring diamond drills, the latter often being employed for deeper holes. Also, both of these types of equipment can drill in any direction.

Pneumatic drills, powered by compressed air, consist of a heavy cylinder with a reciprocating piston that strikes a hollow drill rod with a bit on the opposite end. The drill rod fits into a chuck that rotates; water is conducted through the machine and drill rod to cool the bit and wash cuttings from the hole. Pneumatic drills may be hand-held (jackhammer) or mounted on a pneumatic leg (stopers) or on a column or jumbo (drifter). Modern jumbos for mounting drills are mobile, and the drilling by two or more machines may be controlled from a console on the vehicle. Pneumatic drills are employed primarily for shorter holes because of the inefficiency of transmitting impact energy through long rods.

For drilling very large holes, such as the shaft in a uranium mine, drills of the type shown in Figure 3 may be employed.

Hoisting. Hoisting from underground mines was first accomplished with a windlass. A later type of hoist was the horse whim, comprised of a rope or cable around a drum turned by a bevel gear attached to a sweep to which a horse was harnessed. Mechanical hoists are powered by internal combustion engines, compressed air motors, or —usually—by electric motors.

Most hoists have a double drum to hoist from a two-compartment shaft. The cables are wound on the two independent but mechanically connected drums in opposite directions to permit hoisting in balance. The cables run up over sheaves (grooved pulley wheels) on the top of a headframe to cages (see below) or skips attached on each. As one cage or skip is hoisted, the other descends, thus utilizing the weight of the empty to assist in hoisting the loaded one. To keep the peak power demand at a

lower level, a control device that utilizes energy stored in a large flywheel is employed on some hoists.

Hoisting drums may be either single or double and cylindrical or conical in shape. A conical shape permits a low starting torque on the motor and thus helps hold down the peak power load. If a single-compartment shaft is used, a counterweight may be employed, similar to that in a building elevator system, which in turn permits a smaller size motor.

Hoisting ropes

Most hoisting ropes are made of multiple-strand, twisted steel wire that must be strong enough to lift loaded skips and cages in addition to sustaining the acceleration and friction forces of the hoisting system. The hoisting drum must be large enough to keep the bending stresses of the cable around the drum below critical values. Hoisting ropes must be inspected frequently and discarded before they are weakened below the allowable strength.

Loading and haulage. Early loading of ore and rock was done by hand into baskets or similar containers that were then carried out of the mine. Wheelbarrows were employed in early mining and are currently used in small openings; animal haulage, which found early use, is still employed in small mining operations. Hand loading, or mucking, is likewise used at the present time, particularly where the cost of mechanical loaders is not justified.

Modern loading in horizontal room and pillar mines (in which a large horizontal ore body is mined, leaving some ore behind in the shape of pillars to support the roof), drifts (horizontal openings in or near an ore body and parallel to its long dimension), and tunnels is accomplished with various types of mechanical loaders mounted on either track, tractor tread, or rubber tires. Manual pushing of small cars on narrow-gauge tracks is called hand tramming. Broken ore and rock may also be moved along the floors of stopes or along tunnels by means of a scraper, a large hoe drawn back and forth by means of a cable through an anchored sheave (pulley wheel), the system being powered by a small hoist. Broken material is scraped into chutes or over ramps into mine cars.

Mine cars are heavy sheet-metal boxes on wheels with capacities from about 2,000 to 20,000 pounds (900 to 9,000 kilograms). They are usually drawn by electric locomotives, either battery-powered or powered through a trolley to an overhead wire. All are designed so that the broken rock or ore can be dumped outside of the mine or into a bin cut in rock, often lined with timber (skip pocket) at the hoisting shaft. For large mines on one level, truck haulage may be used. Sufficient ventilation must be provided to dilute or carry out the exhaust gases from the internal-combustion engines.

Ventilation and lighting. Underground mines must be adequately ventilated to provide a breathable atmosphere, to carry out noxious or explosive gases, and to provide cool air in hot mines. One primary purpose of mine ventilation is to make certain that there is enough oxygen in the working places for men to breathe. In gassy bituminous-coal mines, large amounts of air are required to dilute methane gas released from the coal. Noxious gases are generated in some metal mines by the action of acid water on rocks and minerals as well as by explosives used for blasting. Radon gas must be removed from uranium mines because of its radioactivity. Many mines are excavated in rock masses where temperatures are as high as 140° F (60° C) or more, sometimes with high humidity conditions. The air pumped through many such mines is cooled and dehumidified, a costly process.

The main ventilation system of a mine usually requires a minimum of two openings to the surface, with a fan at or near one opening. Air may either be forced through the mine by a positive pressure or pulled through by exerting suction on one opening. The fresh air is guided through the mine by stoppings, doors, and bulkheads. Auxiliary ventilation by small fans and ventilation ducts picks up fresh air and forces it into dead-end drifts, raises, stopes, and other areas that cannot be ventilated by the main air current. If fires are burning in a mine (old timbers, etc., in mined-out areas), these areas must be sealed off from the oxygen supply in the air currents and objectionable gases contained by bulkheads or stoppings.

Auxiliary ventilation

Costs of mine ventilation and air conditioning may constitute a significant part of the cost of producing ore, thus affecting the cost of the final mine product to the consumer, the grade of mineral that can be mined, and the margin of profit to the mining company.

For primary ventilation of a mine, a fan must be chosen that will deliver the necessary amount of air at the proper pressure. The amount of air a fan can deliver varies with the resistance to airflow encountered in the mine. This resistance changes with the extent of excavation, so fans have been designed whose characterstics can be changed by altering the pitch of their blades, or the fans may be designed to operate efficiently over a fairly wide range of pressure and quantity of air flowing.

Natural ventilation will take place in a mine if the two openings are at different elevations at the surface and if the outside temperature is different from the mine temperature, the flow being caused by the difference of weight of cold and warm air (thus producing convection currents). Natural air currents often reverse direction from summer to winter.

Air in workings must be treated to minimize the presence of harmful dust. Fine coal dust may cause "black lung" disease, while fine silica and asbestos may cause silicosis or asbestosis if breathed over a long period. Some dusts may be settled with a water spray, but others are difficult to remove from the atmosphere. Maintaining the quality of mine air is essential to the health of the miners and has been the subject of intensive research and development. Conditions have improved markedly in the past few years. Most countries have comprehensive legislation regarding health and safety in mines; labour unions may refuse to work under dangerous conditions. In view of the vital role that mining plays in the economic and strategic welfare of a country, the importance of supporting mining operations with competent scientific and engineering research is evident.

Most of the shaft stations and main haulage ways in mines are lighted with electric lights. Mine locomotives, trucks, and similar vehicles have lights comparable to those of transports operating on the surface at night. Workmen underground have lights, usually worn on their caps. Early lights were candles, wick lamps, or carbide lights. Most miners currently have electric lights powered from a battery on their belts through an electric cord. Good lighting is essential to safe working conditions as well as to efficient production.

MINING METHODS

In mining, the intervals between different underground levels and underground opening supports must be carefully selected. Mining methods include open stoping, sub-

level stoping, supported stopes, top slicing and sublevel caving, and block caving.

Intervals between levels. In ore deposits of hundreds of feet in vertical dimension, the interval between haulage levels should be the distance that gives the least cost per ton; that is, the value of ore to be mined from a given level must exceed costs of driving the level. The main cost items include sinking shafts and drifts (horizontal openings in or near an ore body, parallel to the course of its long dimension); making crosscuts to the ore; level equipment such as fans, track, air and water lines, and power lines; mining pillars; raises (vertical mine openings driven from one level to the other) and ore passes needed; maintenance of drifts, crosscuts, and raises for the life of the level; hoisting ore to the surface; pumping; handling ore and supplies in stopes; ventilation; waste filling; supervision; and interest on capital represented by broken ore in the stopes.

Underground opening support. In underground openings where the rock in the roof and walls is too weak to stand alone, it must be supported. The simplest type of timber support is a one-piece set called a stull or post (Figure 4A and B). Two-, three-, and four-piece sets

(Figure 4C and F) are employed in small drifts and tunnels. In stopes that require close support, square sets (Figure 4D) are employed, either in narrow veins, wide veins, or larger, irregular deposits. Timber support may also be required where horizontal openings meet the shaft at a shaft station that must usually provide for two hoisting compartments, a manway, and compressed air and water lines in the shaft, in addition to chutes to load ore and support for headroom for unloading materials. Many modern shafts are circular; support may be provided with steel or timber. Concrete may be used in shafts and permanent openings as well as steel sets. In very heavy grounds, collapsible steel arches or sets have been employed.

Rock bolting

Rock bolting has found broad application, particularly in openings that must be supported for long periods. A rock bolt is a steel rod, threaded on one end and provided with a means for anchoring in a hole in the rock on the other end. The bolt is anchored in the hole and a plate or other retainer pulled against the rock with a nut on the threaded end. Rock bolts are employed in drifts and other types of openings to hold the rock structure together, to reinforce strata, and to hold key pieces of rock in place and thus stabilize the structure.

A fine aggregate mixture of portland cement, sand, and water called shotcrete may be used to stabilize the rock around an opening when it is sprayed on in sufficient thickness, and it hardens in place. The shotcrete fills in small voids, holds key fragments in place, and furnishes arch support for the opening. It is used mostly in tunnels.

When a drift is driven in running (loose) ground, a method of timbering called spiling, or forepoling (Figure 4E), is used to provide close support to the ground.

Open stopes. Pillars of ore or waste rock are left to support the back of stopes in deposits of low-grade ore, in which it is cheaper to leave such pillars than to use artificial support. The required support depends on the depth of the deposit or the total weight on the pillars; the nature of the roof, which controls the length of unsupported span; the nature of the floor, which controls the bearing area and consequently the size of the pillar; and the strength of the ore, which determines the minimum size of pillars.

This method is applicable to geologic conditions that require a minimum of artificial support, the walls and roof span or both being self-supporting. Small ore bodies may be mined from wall to wall without pillars. Where ore bodies are larger, pillars of ore are left to keep the roof span to a safe dimension. Pillars may be spaced regularly, as in deposits of salt or phosphate, or randomly spaced in irregularly occurring ore (Figure 5), and the method may be applied to either horizontal or inclined deposits. Its greatest application is in flat-lying, bedded deposits.

The pillars are usually roughly circular, square, or rectangular in section and flared at the top and bottom to increase contact area with the roof and floor. In weak ground, the spacing is less, and the pillars are larger than in strong ground. The ore left in the pillars is sometimes recovered later. Some extraction of high-grade pillars has been accomplished with the roof supported by concrete columns, which must be preloaded by forcing them against the roof before it collapses.

In the development and mining of a flat-lying deposit, one or more openings are driven in a selected direction, and rooms are excavated usually at 90° to the openings. The pattern of layout of rooms may vary considerably, however. Pillar heights vary from a few to over 100 feet (30 metres), depending upon the thickness of the deposit.

The geology of typical open-stope mines is notable for simplicity of structure, lack of faulting, lack of alteration,

From R.S. Lewis, *Elements of Mining*, 3rd ed. (©1964); used with permission of John Wiley & Sons, Inc.

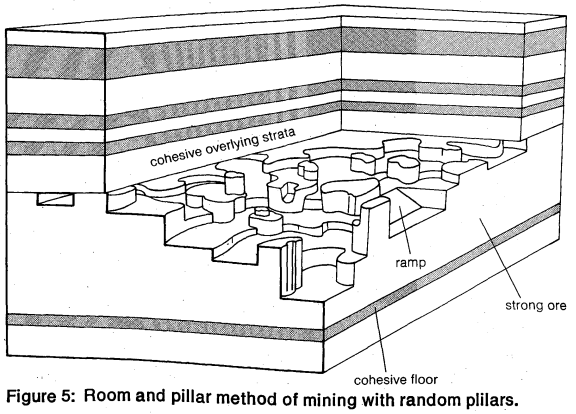

Figure 5: Room and pillar method of mining with random plilars.

and competency of the beds and the strength of the overall structure. Although dimensions of the deposits are variable, the method has uniform application throughout the deposits as long as the ore and rock are strong enough to support large openings. The placing or size of pillars is governed almost entirely by the presence of faults, fractures, or weak beds. Where weaknesses do not occur, the pillars may be placed regularly. Natural pillars may also be left to support the walls of a deposit that dips steeply. In this case, levels are driven from a shaft, and the ore is mined between the levels with natural inclined pillars left for support. Pillars may later be taken out ("robbed") and the walls allowed to collapse.

Robbing pillars

Sublevel stoping has many variations but is best suited to deposits that are steeply inclined and have strong ore and stope walls. In this method, there are two horizontal drifts (the main levels) 100 to 200 feet (30 to 60 metres) apart vertically. These drifts are connected by raises (vertical openings) that are separated about the same distance. At intervals of 20 to 25 feet, sublevel drifts, between the main horizontal drifts, are driven from the raise to the end of the stope. The main volume of ore is mined from the sublevel drifts. The ore and stope wall must be strong after the ore is excavated to furnish footing for workmen and support for sublevel drifts. After the main blocks of ore have been mined, the pillars are usually removed after which the walls may collapse.

Supported stopes. In shrinkage stoping the back (roof) of the stope, which is usually ore, is unsupported during mining, but the walls are supported by broken ore. Deposits may or may not need support during mining. The ore should be strong, but the walls may be weaker than those mined by sublevel stoping.

The first stages of shrinkage stoping are similar to those of sublevel stoping. There are no sublevels, however, and horizontal sections of the ore are mined from the bottom upward. The broken ore is left in the stope to support the walls during mining, and to serve as a floor for miners removing the ore overhead. Since the ore takes up more space when broken, about a third is drawn off as it is mined. After a stope is completed, the remaining ore is taken out.

Since the ore is unsupported during mining, it must be competent (*i.e.*, it must not yield or fail under stress). If walls are too weak, rock will slough off, diluting the ore. Hence, in deposits minable by shrinkage methods, the overall structure is slightly weaker than the ore and rock in which sublevel stoping is used. The footwall (the wall of rock under a vein of ore) of the stope should be steep enough to permit drawing the ore by gravity.

Shrinkage stoping has the advantage that blocks of ore may be quickly developed and mined, but considerable broken ore must be left in the stopes during mining, sorting may be difficult, and some sulfide ores may catch fire before they are removed.

Cut-and-fill method

In the cut-and-fill method (Figure 6), the ore is removed in parallel or stepped slices, and, as each slice is removed, a layer of waste (broken rock) fill is placed in the stope, leaving working headroom above it. Its applicability is similar to that of shrinkage stoping. The ore must be strong so that the miners can work under it. The walls do not need to be as strong, since the fill provides support. The fill may be in the form of broken rock from the mine. In some mines a sand and water mixture is pumped through pipelines into the stopes and the water is drained off. Because it settles less, sand fill is usually more satisfactory than broken rock. Sometimes the ore is of such a type that dilution cannot be allowed, and, if the ore oxidizes readily, causing difficulty in subsequent processes, shrinkage stoping cannot be used.

Shrinkage stoping is also used widely in steeply inclined deposits where broken ore can be removed by gravity and the stopes filled from the level above. In such deposits, even minimum subsidence (gradual settling) should not occur adjacent to the ore body; thus side support is given by immediate filling. Occasional slabs or loose sections of the back are supported by timbers placed on the fill. In large ore bodies, cut and fill stopes are kept small by spaced vertical pillars that are mined later, commonly by square-set stoping.

Before blasting, a horizontal or inclined layer of plank (lagging) is often laid over the waste to keep it from becoming mixed with the ore. The ore is drawn off at the level below and the waste is brought down from the level above.

Cut-and-fill stoping permits sorting and mining of irregular deposits and keeps ore dilution to a minimum. Ore production is intermittent, however, since filling is required, and the method is costly.

Square-set stoping, which employs timber frameworks (square sets) for support underground, is used most with ores that are weak, and the surrounding rock is also weak. The method is used when caving methods cannot be used, either because of the deposit or because of its high value or both. Sets can be extended vertically or horizontally depending upon the shape of the ore body, thus lending flexibility to operations. Basically the sets provide temporary support and a means of reaching the working face. Permanent support is accomplished by means of fill placed in the sets after a tier is worked out. Besides being used in mining heavy ground, square sets are commonly employed in mining pillars between cut and fill stopes. Sets are standardized as far as possible to simplify timber framing.

Among the advantages of square-set stoping are that irregular ore bodies may be worked while masses of waste or lean ore can be left in place; waste may be sorted out and left in the stopes; the grade of ore can be controlled, since each new face can be sampled and assayed before the ore is drilled (this flexibility is important in mines where the ore varies in value); and filling the sets as soon as possible leaves only a small space open at a time. Disadvantages include high cost; slow ore extraction and low productivity per man; large timber requirements and consequent fire hazard; and the highest accident rate of any underground-stoping method.

Disadvantages of square-set stoping

Under many geological conditions in which square set mining is employed, the ore and rock structure approach the behaviour of unconsolidated materials. The instability is caused by faulting, fracturing, and folding and the destructive alteration that accompanies mineralizing processes.

Top slicing and sublevel caving. In top slicing, horizontal slices are made, work proceeding downward from the top of the deposit. The capping or overburden, immediately above the top of the deposit, caves after each slice is removed. During ore excavation, the capping is supported by timber.

Top slicing is most adapted to deposits that are large, horizontal, and weak. It is essential that the capping be such that it will cave. Development openings consist of a series of drifts and crosscut drifts below the mining level and raises to the top of the ore. Sublevel caving is similar, but in sublevel caving, alternate slices are mined, and the weight of the capping is used to assist in mining of the ore. The capping should be somewhat stronger than that for top slicing.

From R.S. Lewis, *Elements of Mining*, 3rd ed. (©1964); used with permission of John Wiley & Sons, Inc.

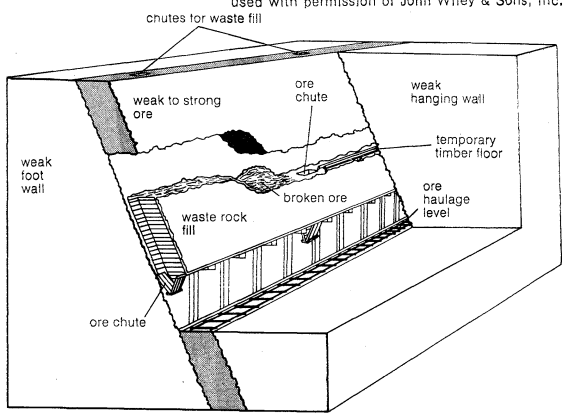

Figure 6: Cut-and-fill stoping, which is adapted to moderately weak ore and wall structures.

For both methods, the rock capping must be weak enough to cave when undermined. The caving formations should not be such that there could be sudden, dangerous collapses of large masses. Sublevel caving is more adaptable to irregular deposits than in top slicing.

Since considerable timber is used for supports in top slicing, an adequate supply of tough, low-cost timber should be available.

Development of top slicing

Top slicing was developed in the United States from caving methods used in iron mines of northern England. In the deposits, soft hematite was covered with glacial drift (loose soil and rock deposited when glaciers retreated). Initially, a longitudinal drift was driven through the ore body and raises containing a chute and a manway were placed at 100 foot (30 metre) intervals. From the top of each raise, a drift was driven a distance of 50 feet (15 metres) in either direction. The drifts were timbered. Slicing took the form of a succession of crosscuts and caves, a process that was repeated until an entire horizontal slice was removed.

Top slicing is safe for mining heavy ground and is economical where timber is plentiful and inexpensive. High extraction of ore is possible with little dilution. If the mine shuts down for any reason, stopes may be blasted down, and the ore body will remain in good condition for resumption of operations. Top slicing can be employed under loose material and does not require as clean a mat (mixture of broken rock and timber) as sublevel caving. On the other hand, top slicing cannot usually be employed without subsidence. Ventilation of such a mine is difficult, and large amounts of old timber create a fire hazard. Furthermore, the period of development prior to production is relatively long, and the rate of production is inflexible. Timbering and covering down (laying a rough timber floor) consume a large part of the work shift; hence, rock drills and scrapers are idle much of the time. Finally, sudden collapse of large blocks presents an element of danger; sorting of waste cannot be done in the stopes, nor can small blocks of waste be left in place.

Sublevel caving may have been developed from top slicing. In this method every other slice is mined by driving crosscuts (slice drifts). The ore between the crosscuts as well as that in the slice above is then mined and the overlying material caved. The method is applicable when the ore is weak and moderately soft and the capping material is hard enough to cave with a minimum of fine material. The method is used in irregular and inclined ore bodies that would not be suitable for working by top slicing. Because the ore must be removed before the capping caves, the capping must cave more slowly than is the case with top slicing.

The interval between levels ranges from 150 to 200 feet (45 to 60 metres). Sublevels are also driven from the tops of raises (vertical mine passages between levels) from the main and transverse haulage drifts. Raises are commonly spaced about 50 feet (15 metres) apart but may be farther apart in narrow ore bodies. Broken ore is pulled to the raises by scrapers. When all the ore is removed from a set and the capping is caved, the next set is caved, and so on, back to the raise at the sublevel.

The advantages of sublevel caving are that cost of mining heavy ground is comparatively low; cost of timber is lower and less development is required than for top slicing; ore may be mined more rapidly; the percentage extraction of ore may be high with little dilution; and the method can be applied to wet and sticky ore not suitable for block caving.

Disadvantages of this method include: there may be more dilution of the ore than in top slicing and square-set stoping; there is little sorting of ore in the stopes; stopes are difficult to ventilate; there is danger of fire from accumulation of timber; and low-grade ore in the capping or near the boundary of the deposits cannot be mined.

Block caving. The block caving method evolved from the methods used to mine pillars in Lake Superior iron mines. It is particularly applicable to very large ore bodies that have cappings that are sufficiently weak to be caved. Preliminary work consists of a series of evenly spaced crosscuts below the level of the ore body, from which a series of raises, known as main, branch, and finger raises, are extended up into the ore. The mass of the ore is then weakened by undercutting, and side cutting is sometimes necessary. The ore is further weakened, usually by blasting, just above the point where the ore is drawn off. The result is that the weight of the ore in addition to the weight of the capping crushes the ore and forces it down through the raises to the haulage way. The movement of the upper mass often affects the strength and stability of the lower mass.

Porphyry–copper deposits where both the ore and capping are weak lend themselves particularly to the block caving method. Large deposits of relatively strong ore are also mined by this method, using appropriate procedures.

Advantages of block caving

The cost of mining by block caving is low, approaching that for open-pit mining, and a high rate of production is attained once production is started. Mining conditions can be standardized, making for safe, efficient operation, and the accident rate is fairly low. On the other hand, capital expense is large, with a long period of time before a mine produces ore. Extracted ore is diluted with waste, and there is some loss of ore; drawing of the ore must be carefully controlled; and, finally, low-grade ore in the capping and at the margin of the ore body is lost.

III. Surface mining

BASIC OPEN-PIT MINING TECHNIQUES

Surface mining, or open-pit mining, is utilized to produce coal, copper, iron ores and nonmetallic mineral products such as clay, gypsum, phosphate rock, several types of stone, sand, and gravel. In recent years in the United States, as much as 88 percent of copper ore and 90 percent of the iron ore produced has been mined by open pit, whereas these values are 40 percent and 50 percent, respectively, for other countries.

Just as in underground mining, mineral deposits mined by surface methods are found by prospecting, evaluated by exploration, then developed, and finally placed in production.

For coal and metallic ores, the ratio of overburden to ore that can be moved is greater than for nonmetallics. Some of the factors that are important in excavation are drilling and blasting, cost of explosives, improvement of efficiency and size of excavation equipment, and methods of haulage.

Prospecting for deposits that may be mined by open-pit methods is conducted in much the same manner as for deeper deposits mined by underground methods. Surface geologic structures are mapped and studied. Drilling, geophysical methods, or both, may be employed to determine details of subsurface geology, to ascertain the presence of valuable minerals, and to make preliminary estimates as a basis for the exploration phase that follows.

When a new mineral deposit is found, it must be explored so that its size, value, shape, overburden, and other related factors can be determined. This information is utilized to ascertain whether it is economical to mine the deposit, to plan the method of operation, to predict profits, and to determine economical limits of mining and the other essential elements. Methods of drilling and sampling are adjusted to the type of deposit, and the results of sampling are evaluated by statistical methods to yield reliable evaluation. It is estimated that only one in 100 mining ventures develops into a successful operation. The exploration of a deposit, if properly done, will yield most of the information necessary to determine whether it may be mined at a profit.

Drilling programs

Drilling programs must be carefully planned; the type of drill chosen depends upon the material to be drilled. In reasonably intact rock and ore, diamond drilling yields more detailed geologic information as well as mineral value. Unconsolidated materials must be drilled by other methods. The first step of a drilling program is further verification of prospecting information; the second is outline drilling, a method of determining the approximate dimensions of the deposit; and the third step is sampling drilling, to yield enough detailed information about the deposit for economic appraisal. Drillings from all three phases are sampled and tested for valuable contents. Drill

holes must be properly spaced and values of samples correctly utilized to evaluate the deposit. Total ore reserves determine the life of the mine.

Factors that must also be considered in the overall operating feasibility of a prospect are geography, land and mineral rights, sociological and political factors, geology, mining conditions, ore-treatment requirements, and economic analysis.

Ownership of mineral land must be proven and stable before a deposit can be explored. Political and sociological factors must be conducive to profitable mining. Geological factors include the occurrence, size, mineral content, depth, and value of a deposit and must be evaluated sufficiently to justify expenditure of capital for development. Mining conditions refer to labour, working conditions, elevation, and related factors. Ore-treatment requirements are critical and include answers to questions of whether the ore must be concentrated before it is smelted or, if nonmetallic, whether treatment will be required before a marketable product can be produced. Finally, an economic evaluation of all of the above must be made, including investment costs, again taking into account that a mineral deposit is a wasting asset.

After a deposit has been explored and its grade, total tonnage, depth of overburden, size, shape, and other factors determined, pit layout must be planned and correlated with all mining operations. In addition to the factors described above, types of ore, cutoff (the lowest grade of ore that is profitable to mine), rate of production, pit slope, bench height (a bench is a level surface worked separately in an excavation), road grades, and related items must be considered. Careful sampling is required to fix the boundaries between capping and ore and to define waste inclusions. The ratio between worthless overburden and valuable ore must be calculated in order to ensure that a profit can be made. Flatbedded deposits are much easier to evaluate than irregular massive deposits. Pit slopes must be gentle so that rock and ore will not slide, and material near geologic fault planes sloping with the pit must be carefully excavated.

The industrial use of mined material determines some mining procedures. Concentration of low grade metallic ores requires that dilution be minimized. Nonmetallics that require purification are in the same category. Samples of the mined material must be representative for proper design of treatment processes. Some mining companies employ computers to calculate pit dimensions and other layout factors.

For stripping overburden and mining, ore equipment is purchased to suit operating conditions. Types of excavators include power shovels, draglines, scrapers, and bucket-wheel excavators. Haulage equipment includes bulldozers, scrapers, trucks, trains, and conveyors of various types. The combination of shovels and trucks is commonly selected.

The total production system usually includes drilling, blasting, loading, and haulage. Modern procedures include analyses of such cycles by advanced statistical techniques that require the use of computers. Successful open-pit mining thus requires modern management techniques and application of good industrial-engineering principles, particularly in large operations. Small or relatively simple operations do not require such complex analysis.

Production drilling is required to make holes for explosive in rock that is too hard to excavate without blasting. The two common methods of rock drilling are mechanical and thermal. Other novel methods, such as sonic, chemical, laser, electron beam, and water jets, are currently in the conceptual or research stage.

Blasting in an open-pit mine

In surface mines, blasting rounds (groups of holes) are spaced according to the size and shape of the benches, rock resistance, joint and fracture systems, and similar factors. Blasting is conducted to give the best breakage with a minimum displacement of the broken material. Large boulders require costly secondary breakage, and a pile of broken rock close to the new bench face is less expensive to load. If blasting is near populated areas, ground vibrations and air blast must be minimized.

Blasting with nuclear explosives is being considered for several purposes but mostly for large scale underground mining or for excavation of canals and harbours. Proper burial of the explosive device minimizes atmospheric radiation and the unit explosives costs decrease with increase of the size of the charge for nuclear explosives.

Pit operation is performed in cycles of drilling, loading explosives, blasting, and loading and haulage. In addition to power shovels, draglines and clamshells are employed in many countries, as are continuous excavators, consisting of a bucket wheel on the end of a long boom, which excavates loose material and dumps it in a conveyor system, which in turn conveys ore to haulage units and waste to a spoil bank.

Large mines are organized and equipped for maintenance of all types of mining equipment, while, in small mining operations, maintenance may be performed by operating crews.

Removal of water and flood control are important in many mines, depending upon rainfall and the presence of water-bearing rock. Slope stability in large mines may present problems. Research in rock mechanics and geology is often essential in preventing slides and predicting rock mass movement. In some mines, seismic Geophones have been installed in the rock at critical points to detect minute failures as evidenced by microseisms (tiny earth tremors). Their intensity and magnitude are indications of rock failure and possible slides.

Some valuable minerals, such as gold and cassiterite (tin mineral), are found in gravel deposits, where they have been deposited after being eroded from their place in primary deposits. Deposits of this type (placer deposits) are often exploited by dredges or hydraulic mining, as is overburden over iron-ore deposits in some countries.

Dredging

A dredge is a floating barge with a boom at one or both ends and engines and a concentrating plant if the latter is required in the barge or hull proper. A bucket-line dredge has one boom with a bucket line that may be lowered into the water in which the dredge floats. The dredge is pivoted about the far end on a spud (a heavy, pointed column driven into the floor of the water body), the bucket line continuously excavating material as it is swung by means of tension lines. The excavated material is conveyed through the concentrating plant if it contains valuable mineral; waste is conveyed up the rear boom to the top of the spoil bank. Dredges for moving waste material have no concentration plants on board. They are operated either in a pond in a gravel deposit (California, Malaysia) or offshore (Indonesia and the Philippines). Mined materials are screened and the valuable minerals recovered by washing the finer gravel over riffles, grooved sluices, where the heavy minerals settle out by gravity.

Hydraulic mining consists of washing the material from its position by a large stream of water under high pressure from a large nozzle (known as a hydraulic giant). It is used for mining terrace placer deposits that cannot be mined by dredging or other means. A large supply of water is necessary. Finer materials are transported to a sluice where valuable (heavy) minerals are recovered in riffles. Debris from the operation is accumulated downstream, preferably in ponds behind dams that will not be washed away by floods.

Recently, in the alluvial tin mines in Malaysia, mining practice has evolved almost entirely to an adoption of a system of breaking ground with water jets and removing the loosened material with gravel (suction) pumps.

Offshore operations include mining of gold in Alaska, tin-bearing sands off the coast of Thailand, tin off the shores of the Indonesia island of Sumatra, iron sands off the southwestern tip of Kyushu Island (Japan), cement sands (shell) west of Akranes (Iceland), and gravel from the English Channel.

QUARRYING

One meaning of the word quarry is "squared stone," hence, quarrying was initially applied to the mining of dimension (cut) stone. More recently, quarrying has been used to refer to the mining of several types of nonmetallic rock from shallow open-pit mines.

All three types of rock are quarried—igneous, metamorphic, and sedimentary. The most common igneous rock is granite; several sedimentary rocks are quarried, and marble, quartzite, and slate are common metamorphic types. The two products of quarrying are dimension stone and crushed stone. The former is employed for buildings, monuments, and decorative purposes. Such rock usually must be of uniform grain size, possess desirable coloration, and have lasting qualities related to its intended use. Sandstone is used for building, granite and marble for memorials, slate for roofing, and quartzite for flagging.

When usable rock is found, the first part of mining consists of stripping the overburden and weathered rock. Large blocks are then separated from the parent mass, sometimes with low-powered explosives. High-energy explosives shatter the rock and cannot be used.

Quarrying dimension stone

For most dimension-stone quarrying, the success of the art depends largely upon taking advantage of joints and cleavage planes in the rock. Granite has a "rift" along which it may be split with comparative ease. The planes perpendicular to the rift are the "head" and the "grain," along which it splits less easily. The rift of sedimentary rock is the bedding plane (*i.e.*, parallel to its layering), while some rocks, such as diabase, diorite, and porphyry (trap rock), have no rift. Joints in granite may be at obtuse angles, but, where they are perpendicular, the excavation is termed a block quarry.

A usual method of splitting granite by hand is to drill a row of holes about three-quarters of an inch (2 centimetres) in diameter, 3 to 5 inches (8 to 13 centimetres) deep and 6 to 8 inches (15 to 20 centimetres) apart. In each hole are placed two "feathers" and a plug. The feathers are half-round shims or wedges between which is placed a wedge plug. The plugs are successively driven with light blows of a hammer, creating a line of tensile stress between the holes that causes the rock to split. Granite and some limestone split with shallow holes, while sandstone and marble require deeper holes. Holes may be drilled with hand tools or with pneumatic drills. In softer rocks the holes may be farther apart.

Special quarrying methods

Special methods of quarrying include machine channelling, broaching, the Knox system, and flame-jet channelling. Machine channel bits are made of hard steel mounted to cut a channel in softer rock (that is, other than granite or hard metamorphic rocks). Broaching consists of drilling a row of holes and cutting the rock out between them. In the Knox system, deeper holes are drilled, grooved on opposite sides, and then loaded with black powder, which is fired to break the rock. For some types of rock containing quartz, flame-jet channelling has been employed. The rock must have the proper spallation (thermal breakage) characteristics for this method to be applied. Wire saws are also utilized; these employ a wire that runs as a belt over the rock, cutting by abrasion as sand or hard grains and water are fed onto it. Blocks are cut to the size desired, hoisted by derricks or other devices and transported away from the quarry for further cutting or sale.

Crushed stone is mined by the methods used in similarly shaped deposits of metallic ores; that is, the overburden is removed, then the rock is drilled and blasted. The broken material is loaded and hauled to a crusher, where it is crushed, screened, and sized. It is used for such purposes as road building, railroad ballast, and concrete aggregate. Some limestones have special uses, such as chemical applications, making portland cement, and for flux in blast furnaces.

IV. The mining industry

ORGANIZATION AND MANAGEMENT

The organizational structure of mining companies varies, but similar types are found in coal mining, open-pit mining, and underground mining. A large company usually has a corporate structure with departments or divisions for operations, engineering, sales, exploration, land, purchasing, financial, and legal aspects. All of these are administered by a centralized executive office headed by the president of the board and the president of the company.

A typical organization at a mine consists of a superintendent, an assistant superintendent, master mechanics, a chief electrician, pit or mine foremen, shift bosses, blasting foremen, engineers, clerical staff, and other assistants.

Strong support of research in various phases of mining has proved to be important to progressive management and successful operation of most mines. Most large mining companies throughout the world have research departments whose responsibility is to perform investigations that will solve problems in health and safety, rock mechanics, operations efficiency, and related matters.

CONSERVATION, ECOLOGY, AND MINING

The conservation of mineral resources, reduction and prevention of environmental pollution, and the preservation of wilderness areas are interrelated in varying degrees. Heavily populated countries are particularly concerned about the problems involved.

Inasmuch as mineral deposits are wasting assets that cannot be replaced, it behooves every nation to conserve them and use them wisely. An available quantity of minerals and mineral products is a vital factor in maintaining high national economic standards, in political power among the nations, and in the ability of a nation to develop its self-defense. Iron, coal, steel, copper, aluminum, and steel-alloying metals are basic necessities, with others of slightly less importance following. During wartime, many of the ores yielding these metals are classified as strategic minerals.

In the United States, many mining and smelting operations have contributed in the past to pollution of streams and the atmosphere. Legislation, both national and state, has been passed to improve these conditions, and many mining companies have taken steps to correct pollution problems. The Bureau of Mines is supporting research and development efforts to assist the mineral industries in the reduction of pollution due to mining and processing of minerals.

Effects of conservation regulations

Because of the nature of financial risks involved in the exploration and development of mineral deposits, many mining companies have found that regulations increase mineral-production costs; for example, regulations may prohibit temporary or permanent roads, aircraft landing strips or heliports, or the use of motorboats, motor vehicles, or other motorized equipment. An aircraft may not be allowed to drop equipment, supplies, or personnel. A permit is required for all types of prospecting except walking over the land. The validity of an unpatented claim may be contested, even though the valuable mineral may be far below the surface. Permits may be refused on the ground that the use of equipment is not consistent with desires to preserve various wilderness areas. Hearings may be called by interested groups to prevent the issuance of a permit, and repeated reconsideration of decisions may hold up prospecting indefinitely. (For further discussion of the ecological aspects of mining, see CONSERVATION OF NATURAL RESOURCES.)

BIBLIOGRAPHY. AGRICOLA, *De re metallica* (1556; Eng. trans. by H.C. and L.H. HOOVER, 1950), is a classic work on early mining in Europe. ROBERT PEELE and JOHN A. CHURCH (eds.), *Mining Engineers' Handbook*, 3rd ed., 2 vol. (1941), is a standard American work on basic surface and underground mining to 1941. SETH D. WOODRUFF, *Methods of Working Coal and Metal Mines*, 3 vol. (1966), gives a recent treatment. ROBERT S. LEWIS and GEORGE B. CLARK, *Elements of Mining*, 3rd ed. rev. (1964), is a general text that treats both theory and practice. GEORGE B. CLARK (ed.), *Symposium on Mining Research*, first to sixth (1956–61), deal with mining research, explosives, and blasting.

Recent works on surface mining include: EUGENE P. PFLEIDER (ed.), *Surface Mining* (1968); INSTITUTION OF MINING AND METALLURGY, *Symposium on Opencast Mining, Quarrying, and Alluvial Mining* (1965); and *Pit and Quarry Handbook* and *Purchasing Guide* (annual). MELVIN A. COOK, *The Science of High Explosives* (1958), is a comprehensive treatment of theory and experimentation. E.I. DUPONT DE NEMOURS AND COMPANY, *Blasters' Handbook*, 15th ed. (1966), deals with applied blasting techniques. JAMES TAYLOR and P.F. GAY, *British Coal Mining Explosives* (1958), discusses permissible explosives. U. LANGEFORS and B. KIHISTROM, *The Modern Technique of Rock Blasting*, 2nd ed. (1968), gives

an analysis of blasting theory and practice. KUMAO HINO, *Theory and Practice of Blasting* (1959), treats applications of experimental results. Two of the most recent books on mine ventilation are A. ROBERTS (ed.), *Mine Ventilation* (1960); and HOWARD L. HARTMAN, *Mine Ventilation and Air Conditioning* (1961).

Valuable journals and reports on mining theory, policy, research, and practice include: *Mining Magazine, Mining Journal, Mining Engineering, Canadian Mining Journal, Institution of Mining and Metallurgy Bulletin and Transactions, Mining Congress Journal,* Bureau of Mines publications (*Bulletins, Information Circulars,* and *Reports of Investigations*), *Annales des Mines, South African Mining and Engineering Journal, Transactions* of the *American Institute of Mining and Metallurgical Engineers,* and the *Engineering and Mining Journal.*

Minnesota

Near the heart of the North American continent, Minnesota lies at the headwaters of the Mississippi River, which flows southward to the Gulf of Mexico; of the Great Lakes, which drain eastward to the Atlantic Ocean; and of the Red and Rainy rivers, which flow northward into Hudson Bay. The state's 84,068 square miles (217,736 square kilometres) are bounded on the east by Lake Superior and Wisconsin, on the south by Iowa, and on the west by North and South Dakota. The northern boundary with the Canadian provinces of Manitoba and Ontario includes a small hump that makes Minnesota the most northerly of the 48 coterminous U.S. states. The state is dominated by a single large metropolitan area, the Twin Cities of Minneapolis and St. Paul (the capital) and their suburbs, in which nearly one-half of the 3,800,000 Minnesotans live.

In the popular image, Minnesota is a land of rugged winters, innumerable lakes, Scandinavians, flour mills, and iron mines. The variation from cold winters to warm summers and the nearly 5,000 square miles of inland water—more than that of any other coterminous state except Texas—do, indeed, serve as pacemakers for the style of life in Minnesota. About one in four Minnesotans has some Scandinavian blood, but Germans make up the largest ethnic stock. Flour milling, symbolic of the state's economic dominion over the vast grain belt to the west and northwest, reached its peak in 1920, when Minneapolis was the world's leading producer of flour; but since then it has declined into a relatively unimportant role in the economy. At one time Minnesota's Mesabi Range produced more than one-half of all the iron ore in the world, but the high-grade ores in the range have been almost completely depleted. (For information on related topics, see UNITED STATES; UNITED STATES, HISTORY OF THE; and NORTH AMERICA.)

THE HISTORY OF MINNESOTA

Diversity of Indian tribes

Until the mid-19th century, two major Indian tribes occupied what is now Minnesota: the Chippewa in the north and east, the Sioux in the south and west. Between the time of European exploration and statehood, the Chippewa had pushed the Sioux southward and southwestward onto the prairieland, with the Chippewa occupying the forested areas of the state. Indians of tribes from as far away as the Appalachians and the Rocky Mountains met in a sacred place of peace in southwestern Minnesota to quarry a hard red rock used for making peace pipes; this area is preserved as the Pipestone National Monument.

European settlement. The Kensington stone, found in west central Minnesota in 1898, bears inscriptions allegedly made by Norsemen who penetrated the continent in the 11th century, but its authenticity remains in doubt. The earliest verifiable Europeans in the area were the 17th-century French explorers searching for a Northwest Passage. The first white settlement was made where the French fur traders known as voyageurs had to leave Lake Superior to make a nine-mile portage (land detour) around the falls and rapids of the Pigeon River, the longest portage in their transcontinental water route.

The first permanent U.S. settlement was at Ft. Snelling, a military outpost established in 1819 overlooking the Mississippi and Minnesota rivers; the site has been restored as a state park. Immigration into the region was slow during the next 30 years, but, once the value of the vast forestlands of northern and central Minnesota was realized, lumbermen from New England, seeking to exploit the pine, balsam, and spruce forests that covered nearly 40 percent of the land, led a large wave of permanent settlers. An additional quarter of the state was covered with noncommercial hardwood.

Territory and state. Minnesota became a territory in 1849, its boundaries reaching as far west as the Upper Missouri River, but most of its 4,000 white settlers were located in the Fort Snelling–St. Paul area in the east. Lumbering grew rapidly, and major sawmills were built at Stillwater, on the St. Croix River, and at the Falls of St. Anthony, on the Mississippi, the major source of waterpower in central North America. The two villages at the falls merged in 1872, the village of St. Anthony on the east bank being absorbed into the larger and more aggressive city of Minneapolis on the west bank.

Minnesota became a state in 1858, its boundaries being cut back from the Missouri to the Red River, the present western boundary. The most rapid period of settlement in Minnesota was during the 1880s, when homesteaders—many recruited from Germany, Sweden, and Norway—rushed into western and southwestern Minnesota. In the same period, lumbering was at its peak and flour milling, using the power at St. Anthony falls, was becoming important. Both Minneapolis, as the lumber, milling, and retail centre, and neighbouring St. Paul, as the transportation, wholesaling, finance, and government centre, tripled in population during the 1880s. The rivalry between these two cities became particularly intense after the census of 1880, when Minneapolis surpassed St. Paul in population.

Tapping the ore beds

Commercial iron-ore production began in Minnesota in 1884 at Soudan, on the Vermillion Range. After the huge iron reserves of the Mesabi Range were discovered at Mountain Iron in 1890, large-scale production began, and the population along the Mesabi Range and in the port cities of Duluth and Superior grew rapidly in the next two decades. Most of the valuable pine, balsam, and spruce in central and northeastern Minnesota was cut before 1900, after which time lumbering declined rapidly in importance. Wood products, however, remained important in northern and northeastern Minnesota.

The 20th century. The mechanization of agriculture and changes in transportation technology had significant effect in Minnesota. The former allowed greater productivity for farm workers, resulting in increased farm size and a decline in farm population. New modes of transportation improved the accessibility of all parts of the state, thus accelerating urbanization and extending the commutation zones for many miles around the growing urban areas. These two factors have had a particularly important impact on the density and location of population and the economic activity in the state in the 20th century. The impact was apparent after World War I, with the great popularity of the automobile, but was repressed during the Depression years and World War I. Since World War II the impact of these factors has been particularly dramatic; urban areas have been growing while rural areas have been thinning out.

THE NATURAL AND HUMAN LANDSCAPE

Surface features. Although it straddles three continental watersheds, Minnesota's elevations range only from 600 feet above sea level, at Lake Superior, to 2,300 feet, at Eagle Mountain. Most of Minnesota was at one time covered with glaciers, and the surface of the land today has been shaped by the movement and the melting of those glaciers. Among the major remnants are the many thousands of lakes, 10,809 of which are more than 25 acres in area. The greatest glacial moraine development in Minnesota stretches from Albert Lea, in the south, northward to the Twin Cities; then westward and northward through Willmar, Glenwood, Alexandria, and Detroit Lakes; eastward to Park Rapids and Leech Lake; and, finally, south to Mille Lacs Lake. The greatest of the lake plains is that of Lake Agassiz, which existed in gla-

cial times along the Minnesota–North Dakota border and is now known as the Red River Valley. In northeastern Minnesota there are many areas of bare rock, stream valleys, and deep, clear lakes that were scoured by glaciers from the landscape. Extreme southeastern Minnesota was the only unglaciated part of the state. There, streams have cut their way through layers of limestone over many thousands of years, and steep, rocky bluffs rise 500 feet or more above the valleys.

Climate. The surprisingly great variations of temperature and growing season that occur not only seasonally but also from one part of the state to another reflect the fact that the state stretches from the edge of the sub-Arctic forest to the heart of the Corn Belt. The northeastern part of the state lies in the moist northern Great Lakes storm belt, while the western border lies at the edge of the semi-arid Great Plains.

In July, average daily maximum temperatures range from 85° F (29° C) in southern Minnesota to 80° F (27° C) in the northwest to 70° F (21° C) along the shore of Lake Superior; minimum in the same areas are, respectively, 60° F (16° C), 55° F (13° C), and 50° F (10° C). Average daily January highs range from 25° F (−4° C) in the south to 15° F (−9° C) in the north, minimums from 5° F (−15° C) to −5° F (−21° C). The average frost-free periods range from less than 90 days in parts of the north to more than 160 days in parts of the south. The average annual precipitation ranges from more than 30 inches (750 millimetres) in the southeast and the extreme northeast to less than 20 inches (500 millimetres) in the northwest. Average seasonal snowfall ranges from less than 40 inches (1,000 millimetres) in the western part of the state to more than 70 inches (1,800 millimetres) in the extreme northeastern tip. Most parts of Minnesota have continuous snow cover for at least 90 days, from about mid-December to mid-March.

Vegetation and soils. Minnesota stands astride one of the major physical geographic boundaries in the world, the sharp transition from forest to prairie in the heart of North America. The natural vegetation of Minnesota may be divided into three general categories: needle-leaf forests, hardwood forests, and tallgrass prairie. The needle-leaf forests originally occupied the northeastern third of the state and included pine, spruce, and fir, with tamarack in the bog areas. A belt of hardwoods extends from southeastern Minnesota to the Canadian border, passing through the Twin Cities and lying immediately to the south and west of the coniferous forest. Known as the big woods, this hardwood forest averages some 40 to 80 miles in width and consists primarily of oak, maple, and basswood. South and west of the hardwood forests lies the tallgrass prairie.

Belts of forest and prairie

The most fertile soils in the state are found in the grassland regions of the south and west, where they are rich in organic matter and high in soluble mineral plant food. Soils formed beneath the coniferous forest in northeastern Minnesota are light coloured, acidic, and low in organic matter, while those in the hardwood areas are intermediate in colour and natural fertility.

Human imprints. During a century of white occupancy, virtually all of the prairies have been cultivated. The coniferous forestlands, mostly cut over by 1920, are covered again by aspen, birch, and jack pine, while much of the big woods has been cleared for crops and pasture. Minnesota reached its peak in cultivated farmland in 1945. Since that time, the agricultural frontier has retreated, and farms have been abandoned in the less fertile areas in north central and northeastern Minnesota. The big woods area is now primarily a dairying area. Within 100 miles or so of the Twin Cities, dairying has intensified in recent years, but beyond that—and particularly in west central and northwestern Minnesota—dairying has declined in importance. The prairie areas of southern and southwestern Minnesota have a characteristically Corn Belt crop and livestock agriculture.

THE PEOPLE OF MINNESOTA

Ethnic and religious groups. The New England Yankees who first settled Minnesota were businessmen and lumbermen who helped establish the institutions and many of the traditions that remain important in Minnesota today. The first major immigrant groups in the latter half of the 19th century were German, Swedish, and Norwegian; they were primarily farmers and tradesmen.

The German settlers dominated the push up the Mississippi, continuing into the central and south central parts of the state. Norwegian settlers moved westward across the southern tier of counties, forming the major ethnic group in west central Minnesota and the Red River Valley. The major area of Swedish settlement is in five or six counties immediately north of the Twin Cities area. Substantial numbers of Finns live in northeastern Minnesota, Poles in central Minnesota, Bohemians south of the Twin Cities area, French and French-Canadians just north of the Twin Cities and in northwestern Minnesota, Dutch and Flemish in parts of southwestern Minnesota, Icelanders in northwestern Minnesota, and Danes and Swiss in scattered pockets.

The ethnic blend

These ethnic groups influenced the distribution of religious denominations throughout the state. Central and south central Minnesota are heavily Roman Catholic, reflecting the German, Polish, and Bohemian populations. A strip across southern Minnesota and through western Minnesota is heavily Evangelical Lutheran, reflecting the Norwegian population. Swedish communities are generally Augustana Lutheran. Many of these ethnic clusters have retained a high degree of purity in the rural areas. They have been sources of population movement to urban areas, but they have attracted few in-migrants to alter the original stock.

The larger and growing urban areas—the Twin Cities area, in particular—have been built from many different ethnic groups and have become major areas of cultural contact and variety. These urban centres also attracted populations not found in significant numbers in the rural areas: Ukrainians, Irish, Italians, Greeks, Jews, blacks, and Spanish-Americans. The Indian population, numbering about 23,000 in 1970, was primarily Chippewa; of that number, nearly one-half lived in urban Twin Cities neighbourhoods. Less than 1 percent of the population was black, over 90 percent of whom lived in the Twin Cities area.

Demographic trends. Although Minnesota has experienced a net out-migration during the middle decades of the 20th century, its population has grown through natural increase—the preponderance of births over deaths—and it has experienced population movements similar to those of the nation as a whole. The percentage of the population living in the Twin Cities metropolitan area is increasing because of natural increase and in-migration from the rural areas of surrounding states. In 1970, the Twin Cities area was the nation's 15th largest metropolitan area; only two larger metropolitan areas exceeded it in rate of growth over the 1960s. Most urban centres in the state with a population of more than 5,000 share in this rural-to-urban migration, while most towns of fewer than 1,000 inhabitants struggle for their existence. The lake region and other scenic areas of the state, meanwhile, are experiencing an increasing number of permanent year-round residents.

THE STATE'S ECONOMY

Basic resources. The economic growth of early Minnesota was related closely to the exploitation of the primary natural resources: agriculture, minerals, and timber. The activities, in turn, stimulated the growth of such ancillary activities as railroads, processing of natural-resource products, and services. Today, in Minnesota as throughout the nation, employment in the natural-resource-based activities, together with the railroads and associated manufacturing sectors, generally is declining. Nevertheless, about one in 15 employed persons in Minnesota is engaged in agriculture—more than twice the national average—and railroads account for about one in 75 employed persons. As recently as 1951, Minnesota produced 82 percent of the nation's iron ore, and, as the high-grade ores have been depleted, the seemingly unlimited reserves of low-grade ore, or taconite, have been

developed. Minnesota now supplies some 40 to 50 percent of the nation's iron-ore needs, mostly with low-grade processed ores. Other mining activities include sand and gravel, granite, and limestone quarrying.

Components and trends. Fewer than one in four employed persons in Minnesota is engaged in manufacturing (a figure slightly below the national average), but the rate of manufacturing growth exceeds that of the nation. The Twin Cities area dominates the state in manufacturing and accounts for over one-half of the state's employment, but in recent years growth has been greater outside this area. The service and government sectors have grown rapidly, with a modest growth occurring in most manufacturing not tied to natural resources. The net effect of these changes is an employment growth in Minnesota slightly below the national rate.

Minnesota is a net exporter of agricultural commodities, iron ores, and manufactured goods tied to natural resources, such as meat, dairy, and grain products, pulp and paper, and primary metals; it is a net importer of most manufactured goods not tied to natural resources —with such exceptions as electrical machinery and instruments. No coal, oil, or natural gas is produced in Minnesota, and the geologic formations are such that the discovery of such minerals is highly unlikely.

Multistate domination by Twin Cities

Probably no region in the country is so dominated by one urban centre as the upper Midwest by the Twin Cities in wholesaling, finance, and cultural activities. This multistate region includes western Wisconsin, Minnesota, northern Iowa, North and South Dakota, and eastern Montana. No urban area in this region has as much as one-tenth the population of the Twin Cities area. The continued rapid growth of the Twin Cities area has been partly a result of this regional dominance and partly a result of the diversified economic base that contributes to its own economic stability. At the same time, the Twin Cities area in many ways is becoming more closely tied economically to other major urban centres in the nation and the world and less directly dependent upon processing the products of the region and servicing the region.

Transportation. The movement of people and goods in Minnesota and the upper Midwest focusses on the Twin Cities area. Regional and transcontinental rail and highway systems radiate outward from the Twin Cities, tying the larger towns, smaller towns, and hamlets into one interdependent network. Independent of this major transportation network is the rail system of northeastern Minnesota, which brings iron ore and taconite products for transshipment by boat at the Lake Superior ports of Duluth and Superior. Wheat from the Dakotas and Montana also has been an important product transshipped from rail to boat at Duluth. Since the opening of the Great Lakes waterway to ocean vessels in 1959, products of the upper Midwest are carried directly to locations throughout the world.

River transportation was the first important mode for the movement of both people and goods in many parts of the state. Barges on the Mississippi now carry bulk products to and from the major inland ports at St. Paul and Minneapolis. Coming upstream are such bulk products as coal, oil, and salt; transported downstream are grain, sand, and gravel.

The Twin Cities area, also the air hub of the upper Midwest, is served by several scheduled commercial airlines. In 1970, more than 5,000,000 commercial passengers used the Minneapolis–St. Paul International Airport, which is supplemented by a satellite network of eight additional airports. Fourteen other communities in Minnesota are served by scheduled air service.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. *State level.* Minnesota's constitution, dating from the attainment of statehood in 1858, is lengthier than that of many states. The executive branch of government consists of the governor, a lieutenant governor, a secretary of state, an auditor, a treasurer, and an attorney general, all of whom are elected independent of one another for four-year terms. The heads of the 35 administrative agencies are appointed by the governor.

Executive, legislature, and judiciary

The Minnesota legislature meets in odd-numbered years for 120 legislative days. The House of Representatives comprises 135 members elected for two-year terms; the Senate, 67 members elected for four-year terms. Members of the legislature are elected without party designation but are organized into liberal and conservative caucuses.

The judicial branch comprises the Supreme Court, district court, probate court, municipal courts, and justices of the peace. Seven justices—a chief justice and six associates—constitute the Supreme Court; each is elected for a six-year term.

Local government. The state's 87 counties range in size from 155 square miles of land area to 6,092 and in population from about 3,400 to 960,000 in 1970. The 1967 Census of Governments reported 850 municipalities and 1,817 townships. Counties and municipalities provide most of the local governmental services, while the responsibilities of townships are limited to maintenance of local roads and certain welfare services. The number of school districts has been declining steadily through consolidation, especially in rural areas. Special districts, much fewer in number than in many states, provide for sewers, conservation, water supply, fire protection, parks, airports, and mosquito control.

Revenues and regional cooperation. One of the most difficult problems facing Minnesota is meeting the increasing cost of government and increasing the sources of revenue that support government. Traditionally, Minnesotans have been willing to tax themselves at a high rate to obtain needed public services, but inequities have existed in the abilities of local governments to provide those services. Several important legislative acts have been based on an equalization concept. In 1967 a bill establishing a metropolitan council in the Twin Cities metropolitan area was passed, and in 1969 the concept of regional cooperation was extended to ten other multicounty areas of the state. Gradually these other regions are becoming established on a voluntary basis. In 1971 a revenue-sharing bill required that 40 percent of the property-tax revenue from newly located industries within the seven-county Twin Cities metropolitan area be returned to the area and redistributed to municipalities and school districts. Another important tax bill passed in 1971 stipulated that state funds rather than local property taxes were to be used to pay most costs of operating local school districts.

The Twin Cities Metropolitan Council, the 15 members of which are appointed by the governor, is responsible for the development of certain area-wide services that local government is unable to provide, including sewage and water systems, transportation, and major land uses. In so doing, it plays a coordinating and regulatory role among the more than 300 local governmental jurisdictions within the Twin Cities area.

The social and political milieu. Among Minnesota's most significant characteristics is its political environment and high degree of citizen involvement in public affairs. These traditions were laid in Minnesota by the early settlers from New England, who brought their town-meeting form of government. This foundation was reinforced by the Scandinavian and German immigrants, with their ambition and high regard for education. As a result, government has always been accepted as the legitimate means for public decision-making in Minnesota. From those early years, business has played an important role as a strong participant in public decisions.

Citizen involvement in politics

The traditions of citizen involvement can be seen in the many neighbourhood and community organizations and ad hoc issue-related groups in the state and in the relatively large number of Minnesotans in national political prominence. Minnesota has been a leader in such national movements as those to guarantee the rights of women, homosexuals, and American Indians. The average Minnesotan is usually well informed about public issues. As a result, the political parties usually have focussed their attention on the visible public issues, thus bringing about a balanced political system in which neither major party has been dominant over an extended period.

Higher education. The University of Minnesota was established in 1851, with its main campus in Minneapolis.

Together with the smaller St. Paul campus, the Twin Cities campus has the largest daytime enrollment of full-time students on any campus in the country—over 50,000 in the early 1970s. Smaller branches of the university are located in Duluth and Morris, with four-year programs, and in Crookston and Waseca, with two-year programs.

To the six four-year Minnesota state colleges in smaller cities across the state, the legislature in 1971 added a seventh in the Twin Cities metropolitan area. This "college without a campus" utilizes diverse physical facilities throughout the area, bringing higher education to the neighbourhoods. In addition, the state operates large systems of junior colleges and of post-secondary vocational–technical schools. Fourteen private four-year colleges and four private junior colleges supplement the public system.

Health and welfare. The Twin Cities and Rochester serve as national health-care centres. The Mayo Clinic in Rochester, famous for its comprehensive approach to health care, has served patients from around the world since the late 19th century. The University of Minnesota Hospitals complex in the Twin Cities area has been a pioneer in medical research, while numerous hospitals across the state provide an effective network of medical care.

According to a study by the Midwest Research Institute, Minnesota ranks first among the U.S. states in the quality of its health and welfare. The report pointed out that a high standard of general medical services is provided in Minnesota, that children's health and welfare programs are among the best in the nation, and that Minnesota leads all states in old-age-assistance programs.

CULTURAL LIFE AND INSTITUTIONS

Recreation. Cultural life in Minnesota is highly diversified and seasonal. Many activities are outdoors oriented: swimming, boating, canoeing, camping, hunting, fishing, and winter sports. More fishing licenses are sold in Minnesota than in any other state, and Minnesota has more boats per capita than any other state. A high proportion of Minnesotans own second homes on one of the state's many lakes and streams, which are easily accessible to the population centres of the state. Voyageurs National Park, authorized by Congress in 1971, is being developed in the water wilderness along the Canadian border.

Prevalence of outdoor life

The arts. Whereas "outstate" Minnesota—beyond the Twin Cities area—serves as the outdoor playground for the state, the Twin Cities area serves as the centre of institutional culture. The best known musical organization is the Minnesota Orchestra, which was formed in 1903 as the Minneapolis Symphony Orchestra and acclaimed as among the finest symphony orchestras in the nation. Other important musical organizations include the Schubert Club, the Civic Orchestra of Minneapolis, the St. Paul Chamber Orchestra, the Center Opera Company, and the Duluth Symphony. Colleges and universities throughout the state make substantial contributions to the arts within their communities and regions.

In the early 1970s the Twin Cities had nearly a dozen resident professional theatres. The best known of these was the Tyrone Guthrie Theatre Company, formed in 1963. The Childrens Theatre Company is nationally recognized as one of the finest of its kind. The Minnesota Dance Theatre and the Northern Theatre Ballet Company are resident dance companies in the Twin Cities.

The Minneapolis Institute of Arts, the Walker Art Center, and the Minnesota Museum of Art are among the most important art museums in the state. Other major museums that serve the Twin Cities area include the St. Paul Arts and Science Center, the Bell Museum of Natural History, the Minnesota Historical Society, the American Swedish Institute, the Natural History Museum and Planetarium of the Minneapolis Public Library, the University of Minnesota Landscape Arboretum, and the Como Zoo and Conservatory.

The communications media. In the early 1970s, about 30 daily newspapers were published in Minnesota, while four other dailies published in urban centres in adjoining states had significant circulations in Minnesota; weekly or semi-weekly papers numbered some 350. The four Twin Cities dailies, particularly the Minneapolis newspapers, dominate circulation throughout Minnesota, western Wisconsin, northern Iowa, and most of North and South Dakota. Fifteen commercial television stations and three educational stations serve the state, and part of the state is served by nine commercial television stations and one educational television station in adjoining states. There are about 150 radio stations within the state, including nearly 60 FM broadcasters.

PROBLEMS AND PROSPECTS

In Minnesota's gradual shift away from a natural-resource-based economy, farms are growing larger, the farm population is declining, and the rural nonfarm population is increasing, particularly in the scenic lake areas of the state. Small towns struggle for their existence, while the Twin Cities metropolitan area is spreading and extending its influence into the rural areas of the state. The cores of Minneapolis and St. Paul are growing older and share most of the typical problems of urban areas across the country.

These changes across the state raise a number of questions that must be confronted during the 1970s: the density and distribution of population and economic activity; and the equitable provision for and financing of public needs in the areas of health care, education, transportation, communications, housing, and environmental management. The outcome of the legislative steps toward regional cooperation in these areas will be critical for Minnesota and may provide insights into issues of importance to the nation as a whole.

Minorities and Ethnic Groups

The phenomenon of culturally or racially distinct minority groups living in the midst of an alien society is a familiar one, but what exactly is meant either by "minority" or by "ethnic group" is something that scholars, politicians, and those who have to take practical action in social matters have seldom found easy to describe.

The nature of minorities. The most common general description of a minority group used is of an aggregate of people who are distinct in race, religion, language, or nationality from other members of the society in which they live and who think of themselves and are thought of by others, as being separate and distinct. Separation, too, often implies that the members of such a minority are excluded from taking a full share in the life of the society

because they differ in certain ways from the dominant group—a situation that tends to develop attitudes of discrimination and prejudice toward the minority in question, attitudes that may also be assumed by other groups or minorities in the society. The minority itself is likely to respond with strong attitudes of group loyalty and to develop forms of behaviour that, by design or not, help to segregate its members still further from the rest of society.

"Minority" and "minority group"

The sociological employment of the word minority, then, largely agrees with common usage in denoting a distinct, separate group of people who are different in certain easily recognized aspects from the majority. But the term minority group implies rather more; for to a sociologist a social group of any kind is an aggregate of people with defined aims and rules of membership and with its own obligatory rules of behaviour and a subculture that publicly mark it off from the rest of society. It is the use of particular forms of cultural behaviour, used as criteria or emblems, that marks off a minority group from other types of group.

The word minority denotes by implication a part of a larger whole, but a minority group in the sociological sense is not always a numerical minority of the population. In parts of the southern states of the U.S., blacks form a clear majority of the population, but they are nonetheless a minority group in relation to the numerically smaller dominant group of whites. A similar situation existed in East African towns under the former colonial rule of the British. Under British rule immigrants from India had settled in East Africa as traders and skilled artisans. Most of them lived and worked in the towns, where they formed the overwhelming majority of the population, although, in east Africa as a whole, the Indians numbered less than 1 percent of the total African population. Despite appearances in the towns, the Indians were clearly a "minority group." In South Africa, to take another example, the Bantu population, although many times more numerous than the dominant white group, are nevertheless a "minority group."

A minority group is generally but not always politically less influential than other sections of the population, but its political position is only one factor in distinguishing a minority from other types of grouping that may also occupy subordinate positions. What marks off a minority group in the eyes of members of a society are a number of other distinctive features: race (as, for example, in South Africa or the U.S.), culture, language, religion, or economic function. To ordinary citizens it is characteristics of this kind that matter when they think of minority groups. A few examples of different kinds of minority groups should make these various points clearer.

After the Norman conquest of England in AD 1066, the native Anglo-Saxon inhabitants still constituted the majority of the population, but their culture and the social forms sustaining it were subordinated to Norman-French political, social, and cultural institutions. Like Africans, many Asians, and American Indians under the former European colonial empires, they lived as a linguistic and cultural minority group.

Religious minorities

The demarcation of minorities by religion is possibly more familiar from historical sources than from contemporary situations, where, especially in the Western world, the adherents of separate religious persuasions are more commonly regarded as categories of the population than as coherent groups of people with distinctive religious, cultural, economic, and political aims, which they pursue in their own interests. But even today such situations are not uncommon. In the northern parts of west Malaysia, for example, Thai-speaking Buddhists form an important religious and cultural minority group, whereas a few miles across the border in southern Thailand it is the Muslim Malays who are a religious and cultural minority. In India and Pakistan the confrontation of Hinduism by Islām led to the emergence of minority groups whose differences, though expressed primarily in a religious idiom, had important political and economic aspects. When the English consolidated their conquest of Ireland in the 16th and 17th centuries, a small number of English-speaking Protestants gradually spread out through a much larger Irish-speaking population of Roman Catholics and subordinated them religiously, culturally, economically, and politically. But only in some contexts were the Irish regarded as a purely religious minority group: in most situations they were seen, and felt themselves, to be primarily political and economic subordinates.

Economic minorities

Any social group formed for particular aims is likely to develop distinctive cultural features, but a group whose ends are primarily economic seems to do so less frequently, unless its organization is also intimately associated with other principles, such as race or kinship. Shopkeepers in any society are people with a number of shared interests. They are usually united in common associations, such as chambers of commerce, but it is unusual for them to constitute a minority group in the strict sense. In certain circumstances, however, they may do so. During the 19th and 20th centuries large numbers of Chinese people emigrated to Southeast Asia. Their motives in leaving China were almost exclusively economic: it was hard for them to earn a living at home. In Southeast Asia most of them eventually became traders, forming closely knit economic groups. The indigenous inhabitants of Southeast Asia, however, as much as the Chinese themselves and their colonial rulers, always saw these groups as Chinese first and only secondly as economic. In other words, the immigrants lived as Chinese ethnic groups with economic functions rather than as economic groups, most of whose members happened to be foreigners.

During the same period there was also a large emigration from the subcontinent of India to places as far apart as the Caribbean, Fiji, East and South Africa, Mauritius, and Great Britain. Like the Chinese, these Indian emigrants left their homes for economic reasons and settled abroad as trading or labouring minorities, but, as in Southeast Asia, the people among whom they settled regarded them primarily as cultural and ethnic groups.

The form of a minority group and its position in a particular society depend on many variable factors. Its members, as has been seen, may be bound to one another by common religious ideals or by similar political, cultural, or economic interests, or the tie may be one of race. In East Africa the Indian immigrant settlers distinguished themselves from the Africans and the Europeans first by the differences of their Indian languages and their Indian culture, but they also used the criterion of race to separate themselves, especially from the Africans. In Great Britain the dominant English group uses race as the main criterion to segregate ethnic minorities such as immigrants from the Caribbean, India, Pakistan, or East Africa. But however a minority group may be demarcated, for it to maintain itself as a group its organization normally must include political, economic, and cultural aspects. The emphasis placed on these various factors determines the form that the minority group takes and the place that it is assigned in society. Further, the emphasis itself varies with factors such as the group's size, its ideology, and, to some extent the outcome of these two, its wealth and political power.

The nature of ethnic groups and other types of minority groups. A social group, as noted earlier, may be founded on almost any kind of common interest, but, as also noted, strict reference to minority groups should be made only when the interests that bind the members also serve to separate them from the rest of society in ways that are felt to be significant by everybody. In most Western countries Freemasons are an organized minority of the male population, but to most people their characteristics do not mark them off as a minority group in quite the same way as do the distinctions of race for blacks in the U.S., for example.

"Race" and ethnic groups

Physically men vary widely, and in some societies selected bodily characteristics, lumped together under the broad heading of "race," are used as marks of social differentiation and for the formation of minority groups. If race is thought to be important, then it is likely to be used in forming groups that today are more usually called ethnic groups than minorities. (Some writers, especially in the U.S., have applied the term ethnic group also to immigrant groups who are distinguished by cultural differences

in language and national origin but who have no distinguishing physical characteristics. They can, if they wish, sometimes shed their particular cultural characteristics and disappear into the wider population in ways not open to the members of ethnic or racial groups who carry the marks of difference on their persons.)

Not every society whose population is racially diverse elects to make use of race for social purposes. In much of the Greco-Roman world, in many parts of past and modern Islām, and in some areas of Latin America a man's racial attributes may have as little significance as does the possession in northern Europe of dark or fair hair. The variations in the use of physical characteristics for social purposes can be placed illuminatingly on a scale. At one end are those societies in which racial attributes, if they are noticed at all, merely place people in ethnic categories, in much the same way as the males and females of a population are often separated for social purposes. Among the ruling classes of Mexico, for instance, the physical differences between people of predominantly Caucasian and Amerindian descent are very apparent, but in many situations of social life they are unimportant compared with the possession of a common pattern of social positions in society and a shared culture based on the Spanish language. Such a society is at the opposite end of the scale contrasted to one like South Africa, which makes extensive use of racial criteria in the allocation of group membership.

An important characteristic of a social category is that it can easily become a group if its members are led to hold values in common and to follow rules binding on all members. In the same way a social group, whose members lose their common purpose and sense of corporate identity, can become no more than a social category or even disappear altogether. Indian immigrants in South Africa, for example, were heterogeneous in origin and social composition, and in the earlier stages of their settlement they were loosely united only by some common, but vague, qualities of "Indianness." Nevertheless, they did constitute a distinct and recognizable element in the population, thus making them a social grouping more cohesive than a mere category but less cohesive than a fully organized group. Later changes in South African law compelled the Indians to assume more and more common, obligatory rules of behaviour that were different from those of other sections of the population, thus consolidating them into an increasingly corporate and separate ethnic group.

CHARACTERISTICS OF CULTURAL DIVERSITY

It is clear that any society may include (and that most have and do include) a large number of subgroups, or constituent groups. The manner in which the constituent groups are arranged and related to one another determines the social form or structure of the society. Minority and ethnic groups do not in principle differ from other social subgroups; however, their aims, the rules by which they recruit members, and their internal organization may well be different and impose special forms of behaviour on their members. Just how a minority group is related to the other sections of a society depends in part on the structure of the society itself and in part on the structure of the minority group.

An integral aspect of the structure of any social group is the set of ideas and beliefs held by its members, which largely determines their aims and, to a greater or lesser degree, guides their actions. The ideology of a minority group is an important element in the place that it is allowed to occupy in a society, but as important, and often more significant, is the ideology of the dominant group in the society. Its members and those of the other constituent groups exercise all kinds of political, economic, and other pressures to produce a situation that as far as possible satisfies them. But it is rare for any group, whether dominant or not, to have the power to impose a situation that is wholly of its own choosing: the process is almost always a two-way, reciprocal one.

There are, roughly speaking, two ways in which the members of a society may try to solve the problems posed by the presence of a minority group. They may either attempt to eliminate it altogether or decide to tolerate it. Both methods, separately or combined, with good grace or bad grace, have been used many times in the past. They are still being used today.

Elimination of minorities: assimilation, suppression, ejection. When the physical features, aims, or behaviour of the members of a minority group are unacceptable to the rest of society, there may be attempts to get rid of the minority altogether—either by forcing or encouraging its members to adopt the dominant group's culture and so be assimilated or by completely ejecting the minority from the society.

Assimilation

Assimilation (sometimes called acculturation) has been defined as those phenomena that result when groups of individuals having different cultures come into continuous first-hand contact, with subsequent changes in the original culture patterns of either or both groups. The process is a familiar one in the modern world. During the 19th and 20th centuries very large groups of immigrants, many of them speaking foreign languages, were encouraged to settle in the United States, but the possibility that they might develop into permanent, compact minority groups was felt to be a threat by the largely Protestant, English-speaking dominant group of American society. Prolonged and successful efforts were therefore made by means of school education and ideological indoctrination to assimilate the immigrants and their children as rapidly as possible. A similar policy of directed acculturation has also been successfully followed in Thailand, where the governing elite felt that the large and economically powerful minority of immigrant Chinese traders presented a political and cultural danger to the Thai people. The government, therefore, by means of legal inducements and restrictions on business and family life, combined with compulsory Thai education, have, without physical force and in a relatively short time, almost completely eliminated the Chinese minority as an ethnic group.

Ejection and suppression

The contrasting method of ejecting an unacceptable minority (and coercing those who chance to remain) is perhaps only a little less common than peaceful assimilation. A combination of ejection and suppression has been used many times in many parts of the world. In the 17th century Protestants in France were banished or driven into concealment if they refused to change their religion. In the same century the small minority of Christians in Japan was proscribed and eradicated. In modern Indonesia the Chinese trading minority, as in Thailand, was seen as a threat to national interests; the traders were therefore violently driven out of the country or forced rapidly to adopt most aspects of Indonesian culture. In the newly independent countries of East Africa the dominant African group, considering the long-settled Indian traders to be a threat to their interests, physically ejected as many as they could and severely limited all spheres of activity open to those who remained. Perhaps the most dramatic example of extermination or attempted extermination was the fate of the Jews under Nazi rule.

Assimilation necessarily takes time. It is usually a reciprocal process, and it is not always the culture of the dominant group that survives. The Greek invaders who followed Alexander III's armies and set up independent kingdoms in northwestern India disappeared almost without trace. For 200 years after the Norman conquest of England, the French language and culture were supreme, but English, a modification of Anglo-Saxon, was the language finally spoken in the country. The dominant culture evolved into a combination of French, Norman, and Saxon institutions; the same eclectic process can be seen at work in any postcolonial country in the world today.

Pluralism: toleration of minorities. A minority may be tolerated either because its aims and organization are not felt to be sufficiently objectionable to be eradicated or because the dominant group in the society, even if it dislikes the minority, may think that it is unable for political or ideological reasons or that it is morally wrong to assimilate, eject, or suppress it.

The rulers of several countries in western Europe in the 12th and 13th centuries found it hard to tolerate Jews, but so many of the rulers relied on Jewish trade and finance

that they could not afford to destroy them. The rulers were consequently forced to allow Jews to live partly on their own terms, difficult though it was in that particular feudal society to accommodate non-Christian aliens or persons without feudal status. In England this was done by segregating them in ghettos; in Spain and Portugal, where the feudal system was less rigidly organized, their freedom was greater.

During the 20 years after 1950, immigrants from the Caribbean, Pakistan, and India settled in Britain. The British did not welcome their arrival, even though their services were essential for running the economic and social system, nor did the British like certain aspects of the immigrants' culture, which combined with their physical appearance made the new minority groups socially very visible. But the ideology of the British people made it equally difficult for them seriously to consider eliminating these new groups either by ejection or by assimilation, and so they were reluctantly compelled to accept forms of cultural, social, and ethnic heterogeneity that had not before existed in their society.

The toleration of ethnic and cultural minority groups can produce a wide range of different types of social organization, most of which involve some form of separation. A minority may be completely segregated (as in medieval Jewish ghettos) even when separatism may not otherwise be a major structural principle in the society. Alternatively, separatism may run right through the system, as it does, for example, in Switzerland. In that country separate linguistic and cultural groups are effectively segregated by living in different districts, although all are united by a central administrative system, which, unlike that in most multiracial and multicultural societies, is not controlled by one dominant group. Other less extreme forms of separatism are produced by discrimination of varying degrees of intensity and by excluding a minority group from goods valued by members of the society. A society divided into minorities resolves the problems of pluralism by balancing the factors that make either for the complete elimination of the minorities on the one hand, or for complete separatism, short of fragmentation of the whole society, on the other hand.

TYPES OF SOCIETIES WITH CULTURAL DIVISIONS

The pluralist model

Pluralistic situations are common in all parts of the world and have given rise to much discussion. The term pluralism is used by political scientists for the view that political, cultural, and social systems are most usefully considered as being made up of separate but interdependent groups whose qualities together produce a characteristic and valuable moral order or unity. After World War II, pluralism was used and developed to describe and interpret societies divided into cultural and ethnic minorities and held together by the political power of one dominant group. J.S. Furnivall, who first began to limit the term in this way, wrote in 1948:

> In Burma, as in Java, probably the first thing that strikes the visitor is the medley of peoples—European, Chinese, Indian and native. It is in the strictest sense a medley, for they mix but do not combine. Each group holds by its own religion, its own culture and language, its own ideas and ways. As individuals they meet, but only in the market-place, in buying and selling. There is a plural society, with different sections of the community living side by side, but separately, within the same political unit. Even in the economic sphere there is a division of labour along racial lines.

The stratification model

Whether or not such "plural societies" are usefully considered as a special type is a matter that has provoked much argument. For one thing, critics would contend that all complex societies are more or less culturally heterogeneous and that to list alternative values and institutions within individual societies does not often help to distinguish one type of complex society from another. For reasons of this kind most social scientists have preferred to use the traditional models of stratification in analyzing social diversity. A society in which technology and the economy are able to support a large population is usually divided into broad divisions or strata—classes, castes, or estates—that form a hierarchy of wealth, power, and prestige. Such strata are marked off from one another by special rules of behaviour or forms of subculture, which are to a greater or lesser extent obligatory on all the members of each stratum, and which give them a graded access to goods (such as wealth, power, and prestige) that are valued by everybody in the society. Even though these broad divisions may not always correspond with the sections of a plural society or with ethnic or minority groupings, they do correspond often enough to merit further consideration of stratified and unstratified forms of society in reference to minorities and ethnic groups.

Relatively stratified societies. In any system of stratification the forms of behaviour and the rights of graded access to valued goods, which mark off one stratum from another, must be both objectively observable and subjectively accepted by most of the members of the society, all of whom must also occupy only one place in the system at one time. These criteria are sufficient to distinguish a system of ranked social groups, as, for example, that of the upper, middle, and lower classes in England during the 19th century, from an ordering of ranked statuses or positions, such as was also found in England in the same period in the rules of precedence that placed the queen's subjects in descending order below her, from the degrees of peerage to the degrees of commoner status. These criteria alone are, however, insufficient for distinguishing different types of stratification, any of which may be found in a society where ethnic or other forms of minority group are component elements of the system.

Closed stratification. A system of social stratification may be closed or open. If an individual's place, once assigned, can in theory or practice never or rarely be altered, the system is closed. If, in contrast, social mobility from one stratum to another is permitted, then the system is open, and the relation of one stratum to another is necessarily competitive. In a closed system not only is place assigned but shares in scarce and valued resources are also differentially assigned to the separate strata. As places and resources are graded and fixed, it follows that if a closed system is to work the relations between the strata must be cooperative to a considerable degree.

Caste systems

A traditional Hindu caste system was a small self-contained hierarchy of endogamous groups in which an individual was given a permanent position at birth. Relations between the groups were governed by religious rules, the breach of which was believed to produce a state of dangerous impurity that carried ritual, legal, and other penalties.

The English word caste refers to two separate systems of social relations. In the one, the traditional fourfold division of Hindu society into four *varṇa* or castes (priests, soldiers and administrators, businessmen, and labourers) is sometimes described in Sanskrit literature in terms of what appear to be ethnic differences, but at least in historical times the *varṇa* have not constituted a system of stratification. Sociologically speaking they are categories of value, which refer to all parts of the Hindu world and which people use, among other things, for placing themselves and the subcaste group to which they belong in the hierarchy of districts outside their own local caste system.

The word caste also refers to the several thousand small, self-contained, local hierarchies of endogamous subcaste groups, or *jāti*, of which Hindu society was made up and of which a Hindu state might include a great many. Each *jāti* was named and ranked, though the ranking might not be the same even in adjacent local hierarchies. Traditionally each subcaste had a particular service assigned to it, so that the sons of goldsmiths or priests, for example, though not bound to follow these occupations, could prevent others from practicing them. In India neither castes nor subcastes were usually ethnic or cultural minority groups in the usual sense of the word, but in Iran and other parts of the Near East, cultural minorities are sometimes components in small-scale caste systems. It is possible, too, that in some areas of the southern states of the United States society could be most usefully described and interpreted by using a similar model of a local caste system.

Estate systems

If one is content to say, as are many, that in both South Africa and India social stratification is based on caste,

then the concept of closed stratification need be examined no further. But writers on India do not usually agree that "colour-bar" societies are necessarily caste systems, and certainly in South Africa, although individuals are assigned positions in ranked strata at birth, the society is large scale and is not made up of many small, local hierarchies. Most important, as in most industrial societies, the ties between individuals are not multiple: the fact that a man employs another does not usually mean that he is also his landlord, his creditor, his lawyer, a member of the same church congregation, and attached to the same political party. Thus in many of its aspects the South African system of closed stratified ethnic groups is nearer to the model of a feudal estate system than to that of a caste system.

In Europe feudal estates were defined and ranked by law, and penalties for a breach of the rules of rank were legal, not ritual as in a caste system. Admission to the estates was regulated by birth and a few other carefully stated criteria, so that a man's social standing as a noble, a cleric, or a commoner was legally defined and carried with its rights and duties shared by all members of his estate and not by others. Estates were also political in nature in that representatives for assemblies such as Parliament in England and France were recruited according to their rank. An estate was a closed group whose members could not in theory move out of it into another.

The population included in an estate system might, unlike that in a local caste system, be so large that the people in it did not have the multiple ties and close knowledge of one another, characteristic of a caste system and perhaps necessary for the working of the intricate and close-knit network of ties and regulations that held it together.

In writing of ethnic minorities in contemporary societies or of slaves in older societies, authors often speak of "caste"; and though they are generally aware of the fact that they are using an analogy, nevertheless misleading implications are frequently carried by the metaphor and are not always discounted. In analyzing the place of highly segregated minority groups in a large-scale society, a model based on a caste system is seldom as useful as one based on an estate system.

Social class system

Open stratification. In some situations and places, as in parts of the Caribbean, ethnic or culturally distinct groups are often treated as, and in fact may be, social classes. Sociologists generally consider a social class to be an aggregate of people in roughly the same social position, which is different from that of other social classes, and which, unlike position in a caste or an estate system, allows movement from one stratum to another. Because mobility is permitted it is not always easy to draw a boundary between one class and the next, nor is it always easy to decide how far the members of a class are bound to one another by ties that make the whole aggregate an institutionalized group. Furthermore, in an open system of stratification the scarce resources valued by the society are not overtly and explicitly allocated to each ranked stratum, and relations between classes are therefore necessarily primarily competitive, not cooperative as they often are in a closed system, where, within limits, an individual's share of resources is prescribed by his rank.

When some of the qualifications for belonging to a social class are also those for belonging to a minority group the difficulties of analysis may become very great indeed. In the later stages of the Spanish Empire in Mexico the qualities of being Indian—qualities such as physical appearance, the use of an Indian language, and a peasant or servile status—were also the marks of low class position. At a later period, with the acquisition of wealth, Spanish culture, and political influence, individuals from the lower classes could and did move in relatively large numbers from one social class to another. In the process the boundaries both between the social classes and between the ethnic groups often became blurred.

When social mobility in a system of stratification becomes very general and rapid, the system may sometimes change quite quickly into one of ranked individuals and not of ranked groups. In the opinion of some students of society, this condition has already been reached in the United States and may be a contributory factor in the difficulty that is sometimes met in absorbing certain minority groups. For instance, other members of American society are more likely to regard Negroes as stereotyped representatives of a minority group with prescribed social roles to play than they are to regard them as individuals making their own social roles outside fixed social groups. To the degree that Negroes are seen in this way they are encouraged to conform with the general view and assume stereotyped roles. Because they lack the greater freedom that other citizens have in choosing roles and in moving from one position to another, they often become even more effectively segregated.

The traditional models of stratified societies, which have been discussed here, are of course merely "ideal types" that have been constructed for studying social processes, which in different combinations produce different types of society. Any real-life society may in fact never quite match any of the ideal types, whose functions are simply to isolate the social processes that, acting together, produce particular situations. The models are useful in helping to think about such situations and in allowing a minority group to be placed in the structure of the society of which it forms a part. Much of the thought about minority groups in the past has been confused by focussing attention on inessential attributes. It is not the blackness of the Bantu in South Africa that is socially significant: it is their position in the formal structure of the society.

Relatively unstratified societies. In all societies there is a division of social labour and some diversification, but not all are stratified. Most of the discussion of pluralism has been of racially and culturally diverse populations within the jurisdiction of a central government—in such countries as Switzerland, Malaysia, and Canada. But there are other types of plural situations in which separate ethnic or cultural groups live within a common and accepted system of relationships that does not amount to either an effective central administration or a system of ranked groups. Systems of independent but allied groups of this kind were not uncommon, especially in tribal areas, before the expansion of European colonial regimes. In the eastern woodlands of North America, for instance, a group of Indian tribes known as the Iroquois had confederated for purposes of making decisions in common, even though central administrative control was lacking.

Unstratified societies with effective central administrative systems. In Switzerland, as has been noted, cultural and linguistic groupings are sharply differentiated and maintained. Within itself each group may be separately and differently stratified, but access to power in the wider society does not seem to be limited by local or cultural origins, nor does it seem to be limited by any ranking of the separate cultural groupings.

In western Malaysia the population is evenly divided between Malays and Chinese. There is also a small minority of Indians and even smaller ones of aboriginals, Thai-speaking Buddhists, and a few other small groups. The aboriginal population is almost wholly separated from the rest, and the majority of the Malays live in rural districts, whereas the Chinese are mostly urban dwellers. The ethnic groups are not segregated by law. The political constitution provides that the men who direct the machinery of government and hold legislative powers shall be impartially selected by voting. In practice electoral procedures and the staffing of the army and the civil service have put most political power in the hands of Malays. The greatest economic strength is in the hands of the Chinese. This distribution makes a permanent balance of power difficult. The fortunes of the Chinese could be threatened by political action, and they might use their wealth to upset the political balance and so threaten the Malays. Under the colonial rule of the British, the Malays, the Chinese, and the Indians were unorganized ethnic categories; but since independence the categories have for political purposes become more and more organized as corporate ethnic groups. Neither the Malay nor Chinese group is completely dominant, and in the strict sense neither is a minority group.

The situation in Malaysia, where no ethnic group is completely able to dominate the central government, is

exceptional. The situation in Kenya, Tanzania, or Uganda is more usual. Since independence the Africans have been the dominant group in all those countries, which also contain Arab, European, and Indian minorities. Like the Chinese in Malaysia, the Indians in East Africa are economically strong, but their numbers have always been far too few for them ever to think of making a bid to take over the central administration and run the country in their own interest. Indians, for various reasons, are now regarded by the Africans as an objectionable minority group, and for ideological reasons they are being driven out of Kenya and Uganda.

The effects of the rise of the nation-state

Toleration of minority groups depends in part, as noted earlier, on such factors, as size, wealth, access to power, and ideology. In modern nation-states wide differences of ideology are not as a rule very willingly permitted, possibly because the idea of a nation implies that if the nation and the dominant group controlling it are to survive, its citizens ought to hold strong, common, national values. The difficulties in deciding how far divergent minorities and ideas can be tolerated is not new, nor are they confined to new nation-states with ethnic and cultural minority groups held together only by the political power of a dominant group. In the 16th century France was divided between Roman Catholic and Protestant Christians, and each group, for its own safety, felt that it had to capture the central government. The victorious Roman Catholics, for their own sake and the safety of the French nation, as they saw it, did not cease their war until the Protestant minority was virtually eliminated.

The idea of a nation-state and the idea of tolerating a minority are to some extent in opposition to one another. The very long-standing solution to the problem reached by a country like Switzerland is unusual. The balance reached in such countries as Malaysia or Canada sometimes gives the impression of a temporary solution, which may at any time give way to a unitary state dominated by one group or to the secession of the minority to form a new nation. The dilemma is important in many parts of the world, especially in such areas as the Caribbean, the United States, and southern and southeastern Asia, where cultural distinctions have often fused with political hostility. It is this widespread fusion of ethnic and cultural hostilities as one of the main elements of political programs that has undoubtedly drawn many to the concept of a plural society. The concept does not give a satisfactory account of the structural characteristics of pluralistic societies, but what its advocates may be attempting to describe and analyze is a political situation in which ethnic and cultural loyalties are felt to be more important than the interests of class or party or any other group in society. This transformation of ethnic and cultural hostilities into political programs is closely related to the problems of minority groups and their place in society.

Unstratified societies without effective central administrative systems. In the past, pluralism has usually been discussed as if it were a feature only of societies with a central administration. It is, however, not uncommon to find ethnic and cultural groups, whether adjacent or intermingled, that live within a common system of relations constituting an alliance of some kind but not an effective central administration.

"Tribal pluralism"

In northern Thailand, Burma, Borneo, New Guinea, and other parts of the world small independent groups of ethnically and culturally distinct peoples were dispersed and mingled over wide areas without being subject in any effective sense to a central government. Among the Kachin of highland Burma, peoples of different languages and cultures, sometimes resident in the same villages, were united in a common network of marital, political, and trading alliances. On the Baram and Rajang rivers of Sarawak in Borneo, villages having different cultures and speaking different languages were interspersed along the banks. Each village was politically independent with its own characteristic social structure. In most villages the inhabitants were rigidly ranked: those of the lower ranks married and lived, for the most part, within their native villages; but those of the upper ranks, both men and women, married and often moved into other villages and other cultures for political and economic advantage. In most of these societies ranking was a fundamental principle of organization, but the different villages and cultures were not ranked against one another. Each was different from and none was considered better than the other. The system of alliances that held together a considerable population, culturally and linguistically divided, had certain similarities to the system by which modern nation-states maintain their independence and diversity.

THE FUNCTIONING OF MINORITIES AND ETHNIC GROUPS

Minority groups have performed almost every type of function in almost all known types of social system. Minorities have played economic roles as specialist bankers, traders, or craftsmen; more often they have been manual labourers, whether slave, serf, or free. As revolutionary groups they have acted as ideological leaders in political life; sometimes their function has been to hold the political balance; more often they have been the subject of exploitation. Some, because they have special skills, may be valued for their artistic contributions to social life and yet not be altogether socially acceptable to the rest of society. Earlier it was noted that the role played by a minority group within a society varies with such factors as its size, its skills, and its ideology and also with the roles of the dominant and other groups in the society. The amounts of wealth that the members of the group can accumulate and the political influence that they can exercise vary with the ways in which these factors arrange themselves. Factors such as these obviously work differently in different types of society, and even in the same type the balance is never likely to be identical in any two societies.

Their economic roles. *As specialists.* A division of labour is a feature of all societies, even the simplest, but unless the population is large enough to free specialists from the task of finding sufficient food and shelter for themselves and their dependents, the society is unlikely to be able to support wholly specialized groups. Without a sufficiently large population, too, a system of social stratification cannot develop; for a graded distribution of resources among the social strata is possible only if there is a sufficiency of basic goods for everybody.

In a system of closed stratification, in which movement from one stratum to another is forbidden, and in which resources are differentially allocated to the strata, functional specialization is likely to be a feature of the system. Specialized groups, handling resources that are the property, so to speak, of their members and of their stratum, are likely to resist change and defend their specialization and the resources that are needed for it. In an open system of stratification, on the other hand, where social mobility is the reward for talent of various kinds, the temptation to form perpetual, specialized minority groups is probably not so great.

In caste and estate systems

In a Hindu caste system the allocation of economic, political, and ritual roles is probably more formally and rigidly arranged than in almost any other kind of society; but it is not usual to consider the specialized subcastes, which make up the system, as minority groups. On the other hand, the outcaste groups, who were said by the Hindu to be altogether outside the system and whose menial occupations and servile structural position separated them, often physically, from the rest of society, are probably best understood when regarded as minority groups. Similarly, in a feudal system the roles of the estates were strictly prescribed: the nobles fought for all, the clergy prayed for all, and the commoners worked for all. Insofar as the nobles dominated society, both the clergy and the commoners could be considered minority groups, though it is not usual to call them so, for medieval European society had in it a number of smaller groups that were unambiguously minorities in the usual sense. The structure of a feudal system allows little place in it for trade, which indeed was not an approved activity in medieval Europe, though of course it was necessary and was carried on by specialized minority groups such as the Jews or by anomalous minorities such as the merchants in semi-independent towns.

In the colonial and postcolonial societies of the modern world, the population is more often than not ethnically and culturally diverse and is often also rigidly stratified. In these societies specialized minority groups are common. When the British established a colonial regime in East Africa at the end of the last century, the African population lacked most of the technical and trading skills that were needed to develop the area and produce a revenue for the administration. Immigrants from the west coast of India were therefore encouraged to move into the interior regions and set themselves up as a trading minority. They differed from the Africans and the Europeans in physique, language, religion, and culture. They were absorbed into the hierarchy of colonial society as a specialized minority group, with a virtual monopoly of retail trade and a position of wealth, influence, and prestige greater than that of the Africans but lower than that of the Europeans.

After independence the hierarchies in the East African countries were rearranged. The position of a non-African minority group with a major share of the country's retail trade was ideologically unacceptable to the new African rulers. The countries they ruled were ethnically and culturally highly diversified, and their main concern was to encourage the growth of a unified nation, whose citizens shared common, patriotic values, even, if need be, at the expense of equality of opportunity. The rulers therefore adopted policies designed to eliminate non-African minorities such as the Indians. With local variations the same situation can be found in all parts of Southeast Asia, where rulers of dominant groups have attempted either to absorb or to drive away Chinese and Indian minority groups that have specialized in trade or crafts.

As labourers. Minority groups have occupied servile or labouring positions in every type of society. The Bushmen of Botswana in southern Africa are a minority group loosely attached as herdsmen and servants to Tswana society. Pagan tribes, immigrants, and conquered groups have on many occasions been brought into Hindu society as servile minorities, usually as outcasts outside the caste system, but sometimes (though more rarely) they have been incorporated as subcastes on the lower rungs of the hierarchy. In England after the Norman conquest the servile roles of the feudal system were mostly occupied by the previously free Saxons, the Welsh, and other native minority groups. Ethnic and cultural minority groups of African slaves and Amerindians filled the lower strata of the rigidly organized class systems of the 18th century in the Caribbean area. In the less rigid class system of modern Britain immigrant minorities from the Caribbean, Pakistan, and India for the most part are labourers.

The labour of ethnic groups

Because the distinguishing marks of an ethnic group are physically carried by its members, it is harder for them to be assimilated. And if racial attributes are important in the ideology of the dominant group of the society, it may be easier for a cultural minority to improve its status than it is for an ethnic group. The Irish who settled in the United States as labourers and various eastern Europeans who followed them have found it possible (at least in the second or third generation) to be socially mobile by changing their cultural identities in a way that has not yet been really open to blacks. It is not entirely accidental that ethnic groups tend to be more segregated and restricted and therefore regularly found among the poorer classes of a society. As long as the ethnic groups reside in the lower ranks of the social system, the privileged classes —unthreatened—can talk easily and abstractly of the desirability of equality of opportunity and the undesirability of segregation and restriction of opportunity. If an ethnic minority does acquire wealth or influence, however, either through its own efforts within society or through circumstances outside it, then the dominant group is usually compelled to make the necessary changes in its practices as well as ideology to accommodate if not assimilate the minority. But the process is never easy and is seldom willingly undertaken.

Their political roles. The political roles open to a minority depend on many of the same factors as limit its economic opportunities. Its numbers may be too small, as were those of the Indian immigrants in East Africa, for it ever to contemplate making a bid for control of the central political machinery, whereas in Malaysia the Chinese were sufficiently numerous to threaten a takeover of the government and thus could protect themselves. In fact, they accomplished the takeover in Singapore. Many minorities, however—as, for instance, merchants whose main interest in a political system is the preservation of law and order needed for peaceful trading—do not possess an active political ideology. It is only if circumstances force them and the structure of the society permits it that they think of protecting themselves by direct action. A minority group by definition is subordinate, and its usual position is near the bottom of the power structure, especially if its values diverge markedly from those of the main body politic.

Minorities acquiring power and leadership

The opportunities for acquiring power depend not only on a minority's own characteristics but also on the nature of the larger society. In a Hindu caste system the hierarchy is one of ritual prestige. The priestly groups are endowed with the greatest sanctity and honour. But ideally secular power ought not to be in their hands. It is the prerogative of the administrative or warrior castes. In practice, political power under Hinduism has often been held by dominant priestly or merchant castes, and even by labouring castes, without wrecking the system. In theory, too, a society of feudal estates ought to be ruled only by nobles; but if, as happened at the Norman invasion of England, the conquerors were of mixed origins, they were soon attributed noble status and the system survived.

In an open class system, if a minority group achieves power in a modern society and displaces a dominant group, the distribution of roles among most of the ruled classes is unlikely to be fundamentally altered, whatever the fate of individuals. This situation can be documented from many parts of the Communist and the postcolonial worlds. In Ghana under the British colonial regime, the African elite was a minority group that was drawn from several indigenous linguistic and cultural groups and whose members were often foreign educated and English speaking. When this group took over the colonial administration from the British as the dominant group, the society in its broad essentials altered little, except that the Ghanian elite ceased to be a minority group.

As ideological leaders. A favourably placed minority may occupy a strategically important position in a political system without being the dominant group. After their defeat in the Boer War at the beginning of this century, the Afrikaners were sociologically speaking a minority group though numerically a majority of the white population of South Africa. Their ideology differed from that of the dominant English group, though both had much in common concerning ideas of race, stratification, and the political superiority of whites. These ideas were directly opposed to the idea of equality of opportunity, which was paradoxically held concurrently by the English. The ideology of the Afrikaners was less ambiguous, and in a real sense they were the ideological leaders of the whites in South Africa. When they eventually gained control of the central administrative system and, as the dominant group, began to put their ideas on race and minorities into practice, there was little real resistance.

In South Africa a linguistic and cultural minority was able, as in other parts of the postcolonial world, to become dominant without a military conquest or revolution. In the Soviet Union, in Mainland China, and in other Communist countries, the Communist Party has usually gained power by force. In all countries the party began as a minority group based on a political philosophy in which differences of race, language, and culture were not considered to be relevant criteria of membership. In the period before it gained control of the central administrative machinery, the party was undoubtedly, especially in many of the undeveloped tropical areas, a minority group that acted as an ideological leader and an instrument of social change.

As arbiters in balances of power. A minority group may be in an important political position in a society and yet not be able to take over the administration and rule it

in its own interests. In parts of the European colonial empires, for example, trading immigrants were disenfranchised minorities; but because their economic power was great in the countries in which they had settled, they could frequently persuade, and sometimes force, colonial rulers to modify policies unfavourable to trade, though possibly advantageous to the rulers or other groups in the society. In Hawaii in the 1890s the white men who dominated the economy even persuaded the United States to annex the islands after a new U.S. tariff had threatened their sugar exports.

In the latter part of the 19th century the Irish formed a minority group in Great Britain, and their parliamentary representatives in London were sufficiently numerous to hold the balance for a time in the political struggles of the rest of the United Kingdom. A not dissimilar position was held for a few years by the Cape Coloureds of the Cape Province of South Africa before their vote was removed.

The risks of arbitration

The role of arbiter, of choosing whether to give or refuse support, can be a dangerous one for a minority group. Even that of a "go-between" who mediates between the rulers and the ruled members of society may bring hatred and disaster in its train, as the Anglo-Indian community discovered when British rule ended in India; and as Chinese and Indian groups who had specialized in working with colonial civil services also discovered when former colonial territories gained independence. In situations where a minority holds a balance of power, it may feel obliged for the protection of its own interests, as were the Afrikaners, to become dominant in the society. On the other hand, it may be safer for the minority, if it can, to secede altogether and become independent before it is stripped, as was the Cape Coloured population of South Africa, of all political power. The Irish solved the dilemma by secession from the United Kingdom, and the Chinese of Singapore by secession from Malaysia.

As exploited groups. In the discussion of the economic functions of minority groups it was noted that most often they were servile or exploited and that both the form and function of the group largely depended on the form and ideology of the society of which they were a part. It was also seen that the degree of subordination or exploitation and the type of relation that a minority can have with a dominant group is variable. Thus, for instance, Brāhmaṇ priests in a caste system are the ritual servants of the other subcaste groups and may be exploited politically and economically by a lower ranked but dominant group, and yet the ritual relationship is not a servile one. Similarly in feudal Europe the nobles and the clergy exploited and segregated minorities such as the Jewish trading community, but the relationship differed in its degree of subordination and exploitation from the relationship of the nobles to serfs and slaves. Nor was the relationship of the Indian trading community in East Africa with the British rulers a wholly subordinate one, although the British exploited and used the Indians' commercial skills and political weakness. In British Guiana or Fiji the situation was different. There Indian coolies were imported as indentured plantation labourers when the suppression of the slave trade put an end to that source of cheap African labour, and as a result both the freed African and the indentured Indians, though not technically slaves, occupied an almost servile status.

Other roles. By its existence a minority group presents a challenge to the rest of society and its values. The challenge may be generated from within the society itself, as happened in England before the Reformation when Lollards formed themselves into minority groups for religious purposes without the approval of the church. On the other hand, the ideas through which a minority incorporates itself may come from outside the society. In the 19th and 20th centuries Christian missionaries have gone to countries in Africa and Asia with the deliberate intention of forming minority groups to transform the whole society. But whatever the sources from which a minority derives its existence, in coming to terms with it, the rest of society is challenged; and whether the society assimilates, tolerates, or eradicates the minority, the society is likely to be changed in the process.

A missionary group, whether religious or political, exists for the purpose of changing something in a society, but relatively few minority groups are missionary by intention. More often than not the changes that they bring about are, so to speak, inadvertent. In the late Middle Ages a minority group of Flemish weavers settled in England because it was possible to earn a good living there. The technical changes they caused helped transform the economic system of English society and its shape in the 16th century. In assimilating Jewish immigrants from Europe, the dominant Protestant culture of the United States has been modified in its business and artistic habits in more ways than is always apparent. In the United States, moreover, although the blacks have been segregated and barely tolerated by other groups in society, they have transmitted much of their music and many of their aesthetic ideas to the dominant group and from them to the rest of the world. In parts of Europe Gypsies have sometimes played a similar role.

The problems of cultural diversity and therefore of minority groups are inherent in the nature of social life. The structural adjustment of groups within a social system can, as has been noted, be attained in many different ways, but the fundamental problems of diversity remain, and in any foreseeable future probably must remain much the same as they have been in the past. With the growth of good communications and facilities for travel, racial and cultural diversity in societies all over the world is likely to increase rather than diminish. It is only by a clear understanding of the processes that make for diversity and by an ability to weigh the advantages and disadvantages of different answers to the problems of diversity that the people of the world, generation by generation, can learn to tolerate one another as well as, if not better than, their forebears.

BIBLIOGRAPHY. H. KOHN, *The Idea of Nationalism* (1944); L. WIRTH, "The Problem of Minority Groups" in R. LINTON (ed.), *The Science of Man in the World Crisis* (1945); and A.M. and C.B. ROSE (eds.), *Minority Problems* (1965), give a good background to the problems implicit in the ideas of nationalism and minorities, especially with reference to the West. L. KUPER and M.G. SMITH (eds.), *Pluralism in Africa* (1969), and H.S. MORRIS, *Indians in Uganda* (1968), examine the problem of ethnic and minority groups in non-Western societies and consider the subject of social and cultural pluralism in terms first raised by J.S. FURNIVALL in *Colonial Policy and Practice: A Comparative Study of Burma and Netherlands India* (1948). G.A. DE VOS and H. WAGATSUMA (eds.), *Japan's Invisible Race* (1966), discuss the same problems in a psychological rather than a sociological idiom. P. MASON, *Patterns of Dominance* (1970), treats a selected number of societies in different parts of the world and at different historical periods and evaluates various solutions for the problems of ethnic and cultural minorities. The discussion of ethnic and minority groups in terms of race relations is probably best looked at in A.W. LIND (ed.), *Race Relations in World Perspective* (1955). Of special interest for minority problems in the Western world are M. FREEDMAN (ed.), *A Minority in Britain: Social Studies of the Anglo-Jewish Community* (1955); E.J.B. ROSE *et al.*, *Colour and Citizenship* (1969); and C. WAGLEY and M. HARRIS, *Minorities in the New World* (1958). B. BENEDICT, *Indians in a Plural Society* (1961); F. and L.O. DOTSON, *The Indian Minority Zambia, Rhodesia and Malawi* (1968); S. PATTERSON, *Colour and Culture in South Africa* (1953); and D.E. WILLMOTT, *The Chinese of Semarang* (1960), give useful and illuminating descriptive accounts of ethnic groups and minorities outside Europe and America. The essays in F. BARTH (ed.), *Ethnic Groups and Boundaries: The Social Organization of Culture Difference* (1969), re-examine the traditional problems of maintaining ethnic or minority identities.

(H.S.M.)

Mirabeau, Comte de

Honoré-Gabriel Riqueti, comte de Mirabeau, was the greatest orator and probably the greatest political mind in the National Assembly, which governed France in the early phases of the French Revolution. Turning to politics after a dissipated youth, he advocated the course of constitutional monarchy, but his middle way was trusted by neither the court nor the radicals. His death in 1791 perhaps ended any possibility of moderation.

Mirabeau, portrait by Joseph Boze, 1789. In the Musée National de Versailles et des Trianons.
Giraudon

Troubled youth. Mirabeau was born at Bignon, near Nemours, on March 9, 1749. He was the elder son of the noted economist Victor Riqueti, marquis de Mirabeau, by his unhappy marriage to Marie-Geneviève de Vassan.

Ugly from birth and further disfigured by smallpox at the age of three, the precocious Honoré-Gabriel was soon on bad terms with his formidable father. At the age of 15 he was sent as a pupil to the strict Abbé Choquard in Paris, and at 18 he went as a volunteer to serve in a cavalry regiment at Saintes, where his father hoped that military discipline would curb him. His misbehaviour, however, led to his imprisonment on the Île de Ré, under a *lettre de cachet*, a written order permitting imprisonment without trial. Released to serve in Corsica with the rank of sublieutenant in the army, he distinguished himself there in 1769. Reconciled with his father, he married a rich Provençal heiress, Émilie de Marignane, in 1772, but his heavy spending and further misconduct led his father to have him imprisoned under another *lettre de cachet* in order to put him out of reach of his creditors. He was detained first at the Château d'If (1774), then at the Fort de Joux, near Pontarlier. Having obtained permission to visit the town of Pontarlier, he there met his "Sophie"—who, in fact, was the marquise de Monnier, Marie-Thérèse-Richard de Ruffey, the young wife of a very old man. He eventually escaped to Switzerland, where Sophie joined him; the couple then made their way to Holland, where Mirabeau was arrested in 1777.

Abduction of "Sophie"

The tribunal at Pontarlier had meanwhile sentenced him to death for seduction and abduction, but Mirabeau escaped execution by submitting to further imprisonment under a *lettre de cachet*. In the château of Vincennes he composed the *Lettres à Sophie*, some erotic works, and his essay *Des lettres de cachet et des prisons d'état* ("Of *Lettres de Cachet* and of State Prisons"). Released in December 1780, he finally had to surrender himself to arrest at Pontarlier in order to have the death sentence revoked; but by August 1782 he was entirely free. He now became involved in a lawsuit against his wife, who wanted a judicial separation. Pleading on his own behalf, he gained the sympathy of the public but lost his case (1783). Rejected by his wife and by his father, he had to renounce the aristocratic society into which he had been born.

For the next five years Mirabeau lived the life of an adventurer. He was employed sometimes as a hired pamphleteer, sometimes as a secret agent. He came into contact with Louis XVI's ministers Charles-Alexandre de Calonne; Charles Gravier, comte de Vergennes; and Armand-Marc, comte de Montmorin-Saint-Hérem. He also made an enemy of the Swiss banker Jacques Necker, at that time director of the finances, and engaged the playwright Pierre-Augustin Caron de Beaumarchais in controversy. His activities necessitated much travelling. In London he was introduced into the best Whig society by Gilbert Elliot (later 1st earl of Minto), who had been his fellow pupil under the Abbé Choquard; he had to take refuge in Liège when his *Dénonciation de l'agiotage* (against stockjobbing) annoyed Calonne; and he undertook a secret mission to Berlin in 1786. With the active assistance of a Brunswick friend, Jakob Mauvillon, he wrote *De la monarchie prussienne sous Frédéric le Grand* (1788; "The Prussian Monarchy Under Frederick the Great"), which he dedicated to his father; but *Histoire secrète de la cour de Berlin* ("Secret History of the Court of Berlin"), in which he made unscrupulous use of material derived from his mission in Germany, created a scandal in 1789.

Election to the States General. Within France, affairs were moving toward a crisis. The country, bankrupted by its 18th-century wars, was burdened with an archaic system of taxation and social privilege. The States General, an assembly of the three estates of the realm—the clergy, the nobility, and the commons Third Estate—was summoned to meet in Paris in May 1789 in an attempt to implement the necessary reforms. It was that meeting that set in motion the great French Revolution of 1789. (See FRANCE, HISTORY OF.) When the States General were summoned, Mirabeau hoped to be elected as a deputy for the nobility of Provence. For this he needed his father's support. Pleased by the book dedicated to him, the Marquis had summoned Mirabeau to Argenteuil in the autumn of 1788 but had not given him any real help. Mirabeau presented himself in the chamber of the nobility in the estates of Provence in January 1789 and uttered violent diatribes against the privileged classes but was not elected deputy, as he held no fief. Turning reluctantly to the Third Estate he was elected to represent both Marseilles and Aix-en-Provence, choosing to represent Aix.

Outbreak of the Revolution

Mirabeau came to the States General without any precise constitutional doctrine. An avowed enemy of despotism (he had written *Essai sur le despotisme* ["Essay on Despotism"] before he was 25), he was, nevertheless, a firm supporter of the monarchy and of the executive power. Without expressly adhering to the English system, he wanted representative government. A nobleman rejected by his class, he opposed the idea of an aristocratic second chamber. Like most of his contemporaries, he had no political experience, but his intelligence and his knowledge of men made him supremely capable of acquiring such experience rapidly. Lack of money, however, exposed him to pressure and to temptation.

From May to October 1789 Mirabeau played a decisive part in the battle between the Third Estate and the privileged orders. His aim was to become the spokesman of the nation to the King and at the same time to moderate the expression of the nation's wishes. Thus, on June 15 and 16 he was careful not to suggest the name National Assembly, which was the rallying cry of the Third Estate in its revolutionary debate of June 17, when it set itself up as representative of the whole nation. Yet, at the ending of the "royal session" of June 23, when Henri Évrard, marquis de Dreux-Brézé, in the King's name, ordered the assembled estates to return each to its separate chamber, Mirabeau's answer did much to confirm the deputies in their resolution to disobey and establish the National Assembly; and, in the feverish atmosphere of the early days of July, his speeches inspired the Assembly to demand the dispersal of the troops concentrated around Paris. After the fall of the Bastille (July 14), he urged the Assembly to demand the dismissal of the ministers who were to blame for the disorders. His popularity in Paris was then considerable. On the other hand, he disapproved of the Assembly's precipitate action in abolishing feudalism (on the night of August 4) and of the abstract Declaration of Rights; and, while he was openly against a second chamber, he yet wanted the king to have an absolute veto. In October, when the Parisians marched on Versailles and took Louis XVI back to Paris, Mirabeau's attitude was ambiguous and gave rise to the suspicion that he might be plotting against the King. To clear himself and to keep open the door to the court's favour, he addressed a memorandum to the King, advising him to leave Paris for Rouen, to secure the support of a small army, and to appeal to the provinces.

Contacts with the court

Mirabeau's prime concern, however, was to win "the battle of the ministry." Ostensibly a supporter of Necker, Mirabeau, in fact, did his utmost to destroy him: his brilliant speech on the bankruptcy of the nation was a masterstroke against this minister. Furthermore, he tried skillfully to induce the Assembly to grant to the king the option of choosing members of it to be his ministers; but the Assembly's decree of November 7, 1789, which precluded all deputies from the ministry for the duration of the session, frustrated his hopes of ministerial office for himself.

Intrigue with the court. From November 1789, notwithstanding his oratorical triumphs of January–April 1790 in the cause of the Revolution, Mirabeau was a prey to despondency and aimlessness until his friend Auguste, prince d'Arenberg, comte de La Marck, with the approval of Florimund, Graf Mercy d'Argenteau, Austrian ambassador to Paris and confidant of the queen, Marie Antoinette, approached him with the proposal from Louis XVI and the Queen that he should become their secret counsellor. Mirabeau accepted with delight: "I shall make it my chief business to see that the executive power has its place in the constitution" (letter of May 10). Part of the promised remuneration was to be the paying-off of his debts. In May 1790, when the Assembly was debating the king's right to make war and peace, Mirabeau successfully opposed the left-wing orator Antoine Barnave, whom he challenged with the words: "Tell us that there should be no king, do not tell us that there should only be a powerless, superfluous king." He impeded the progress of the Jacobins but risked his own popularity, and a pamphlet accusing him of treason was circulated ("Trahison découverte du comte de Mirabeau" ["The Uncovered Treason of the Comte de Mirabeau"]).

From June to October he had to work to recapture his prestige. This was the more necessary because the King and the Queen, despite their secret interview of July 3 with Mirabeau at Saint-Cloud, took little notice of his advice and continued to be influenced by his rival for court favour, the Marquis de Lafayette, who had scorned Mirabeau's offer of alliance. In October 1790 the Assembly further disappointed Mirabeau by refusing, after more discussion, to revoke the decree of November 1789 on the noneligibility of its members for the ministry.

While the court was displeased by some of Mirabeau's outbursts and by his "incurable mania of running after popularity," Mirabeau, for his part, was enraged to see a new ministry formed under the influence of his rivals Lafayette and Alexandre, comte de Lameth. By the end of November 1790 his relations with the court were severely strained. He restored them by submitting to the King's adviser Montmorin a "Plan" concocted for bringing pressure to bear by various means on the Assembly, on Paris, and on the provinces so as to coordinate "the means of reconciling public opinion with the sovereign's authority." The plan was perfect in theory but very difficult to put into practice. From January 1791 it was clear that Mirabeau had no intention of doing anything that might compromise his own popularity, though he was willing enough to sabotage the Assembly by getting it to adopt ill-considered measures of religious persecution and was eagerly and adroitly working to discredit Lameth's faction at court. His popularity rose to its zenith, and the eyes of all Europe were on him. As spokesman of the diplomatic committee, on January 28, 1791, he made a speech that bore the unmistakable stamp of statesmanship. Anxious to avoid anything that might compromise France's relations with neighbouring countries, particularly with England, he yet would not repudiate any of the Revolution's political victories or allow any necessary military precautions to be overlooked. On the following day he at last became president of the Assembly for a fortnight. In this office, from which he had been so long excluded, his control of the debates was masterly.

President of the Assembly

Mirabeau's problem was to know how and for how long his Machiavellian game could be continued before his intrigue with the court would be exposed. The people of Paris were restless, worried by rumours. Mirabeau's position was made difficult by his intervention on behalf of the King's aunts (who had fled from Paris), by his hostility to the law against the *émigrés*, and by his harsh words against the Lameths and their satellites in the Assembly ("Silence to the factious! Silence to the 33!"). On February 28 he was sorely pressed to justify himself to the Jacobins after a pitiless attack by Alexandre, comte de Lameth. The newspapers of the left redoubled their accusations of treason against him, and in March he experienced some notable reverses in the Assembly.

Death may have saved him from political defeat. Gravely ill since his presidency of the Assembly, he worsened his condition by excessive indulgence. He took to his bed on March 27 and died on April 2, 1791. The people's grief for him was boundless; he was given a magnificent funeral; and it was for him that the new church of Sainte-Geneviève was converted into the Panthéon, for the burial of great men. In the insurrection of August 10, 1792, however, papers proving Mirabeau's relations with the court were found in an iron chest in the Tuileries Palace; and on September 21, 1794, his remains were dislodged from the Panthéon by order of the Convention.

Assessment. As a statesman, Mirabeau failed in his main object, that of reconciling the monarchy with the Revolution and a strong executive with national liberty. He was too much of a monarchist for the Revolution, too revolutionary for the monarchy. As an orator he was unsurpassed. Even though his eloquence was fed by material gathered from every quarter and by a "workshop" of collaborators, it was Mirabeau who found the striking images and expressions that give to his speeches their brilliant individuality. Generally bad at extemporizing, Mirabeau could be moved by anger or by injured pride to an impassioned tone that would carry the Assembly with him.

BIBLIOGRAPHY. Still valuable are the 19th-century accounts of ETIENNE DUMONT, *Souvenirs sur Mirabeau* (1832, new ed. 1951; Eng. trans., *Recollections of Mirabeau*, 1832); M. LUCAS DE MONTIGNY, *Mémoires biographiques, littéraires et politiques de Mirabeau*, 8 vol. (1834–35; Eng. trans. of vol. 1–4, 1835), an uncritical work by Mirabeau's adopted son that should be read with LOUIS DE LOMENIE, *Les Mirabeau*, new ed., 5 vol. (1889–91); and ALFRED STERN, *Das Leben Mirabeaus*, 2 vol. (1889). Later accounts include JEAN-JACQUES CHEVALLIER, *Mirabeau, un grand destin manqué* (1947); O.J.G. WELCH, *Mirabeau: A Study of a Democratic Monarchist* (1951); ANTONINA VALLENTIN, *Mirabeau avant la révolution* and *Mirabeau dans la revolution* (1946–47; Eng. trans., 1948); RENE DE LA CROIX, *Mirabeau: ou, l'echec du destin* (1960); and J.J. CHEVALLIER, "The Failure of Mirabeau's Political Ideas," *Review of Politics*, 13:88–107 (1951).

Miracle

Miracles are extraordinary and astonishing happenings that are attributed to the presence and action of an ultimate or divine power. This article treats the nature, functions, and sources of miracles; it then attempts to discover the place of miracles in the religions of the world and the variety of interpretations given to them. It considers miracles mainly as seen, experienced, and interpreted in the religious context, irrespective of the scientific or philosophical judgment passed on them from the outside.

NATURE AND SIGNIFICANCE OF MIRACLES

Etymology and definition

A miracle is generally defined, according to the etymology of the word—it comes from the Greek *thaumasion* and the Latin *miraculum*—as that which causes wonder and astonishment, being extraordinary in itself and amazing or inexplicable by normal standards. Because that which is normal and usual is also considered as natural, miracles have occasionally been defined as supernatural events, but this definition presupposes a very specific conception of nature and natural laws and cannot, therefore, be generally applied. The significance of a miraculous event is frequently held to reside not in the event as such but in the reality to which it points (*e.g.*, the presence or activity of a divine power); thus, a miracle is also called a sign—from the Greek *sēmeion* (biblical Hebrew *ot*)—signifying and indicating something beyond itself. Extraordinary and astonishing occur-

rences become specifically religious phenomena when they express, reveal, or signify a religious reality, however defined.

Belief in miraculous happenings is a feature of practically all religions, and the incidence of miracles (*i.e.*, of belief in and reports regarding miracles) is universal, though their functions, nature, purpose, and explanations vary with the social and cultural—including theological and philosophical—context in which they appear. However inexplicable, all miracles have an explanation in the sense that they are accounted for in terms of the religious and cultural system that supports them and that, in turn, they are meant to support. Without such an accompanying—explicit or implicit—theory (*e.g.*, the presence, activity, and intervention of such realities as gods, spirits, or magical powers), there would be no miracles in the aforementioned sense but only unexplained phenomena.

TYPES AND FUNCTIONS OF MIRACLES

There is no general rule determining the types of occurrences that can be classified as miracles; they vary according to the cultural matrix of beliefs and assumptions. The mythological accounts of the origins of the gods and their activities in the primeval past, as well as accounts of the activities of other primeval beings, such as first ancestors and culture heroes, should, perhaps, not be classed as miracles, and the term is better reserved for outer, objective events—as distinct from such phenomena as inner experiences and visions—regarded as divine interventions or as manifestations of divine or supernatural powers. In many cultures, primitive as well as some more highly developed, such as the ancient classical and Oriental civilizations, the operation of extraordinary forces was taken for granted and was integrated into the total world picture and into the procedures and modes of action—*e.g.*, magic, oracles, divination, and shamanism—of ordinary life. Certain kinds of divine or spirit action and of cosmic operation were considered part of the normal order of things, even though it was generally admitted that priests and shamans would often resort to deception in their diverse activities, which included prophecy, oracles, healing, magic, and judgment by ordeal.

Purposes of miracles

Revelation and signification. The purpose of a miracle may be in the direct and immediate result of the event—*e.g.*, deliverance from imminent danger (thus, the passage of the children of Israel through the Red Sea in the Old Testament book of Exodus, chapter 14), cure of illness, or provision of plenty to the needy. Nevertheless, the ultimate purpose frequently is the demonstration of the power of the god or of the saint, the "man of God" through whom the god works, to whom the miracle is attributed. Thus, the crossing of the Red Sea by the Israelites is described not solely in terms of salvation from great danger but as a revelation of the saving presence of God and of the consequent obligation to serve and obey him; according to the account in Exodus: "and Israel saw the great work which the Lord did against the Egyptians, and the people feared the Lord; and they believed in the Lord and in his servant Moses." The purpose of a miraculous occurrence is thus often to reveal a divine reality or numinous dimension. The occurrence may be an event concerned with natural needs or situations, such as illness, hunger, or distress, or a specifically religious event that effects some form of salvation or revelation, such as the theophany on Mt. Sinai in which God gave to Moses the Ten Commandments, the Resurrection of Jesus Christ, or the revelation of the Qur'ān to Muḥammad. Even in these specifically religious events, the miraculous element is not necessarily of the essence but occurs as merely an accompanying circumstance designed to arrest the attention and to impress on everyone the unique character and significance of the occasion. Thus, theoretically at least, the theophany at Mt. Sinai could have taken place without thunder and lightning; Jesus need not have been born of a virgin; Muḥammad need not have made his miraculous journey to heaven. In actual fact, however, the very nature and quality of a religious event attracts miraculous elements, elaborations, and embellishments; and thus, for example, the founders of almost all religions are at the centre of great miracle cycles, and miracles occur as a rule in connection with persons and objects of religious significance, such as saints, sacraments, relics, holy images, and the like.

Authentication. In practice it is difficult to distinguish the revelatory or signifying miracles from miracles of authentication—*i.e.*, miraculous happenings that serve: (1) as credentials for claimants to religious authority in the form of leadership (*e.g.*, in Exodus, chapter 4, Moses convinces the Israelites of the authenticity of his mission by miraculous performances) or prophecy (*e.g.*, in Deuteronomy, chapter 18, it is said that a prophet is disqualified if the sign that he has predicted does not come to pass); (2) as demonstration of the superior power of a particular god (*e.g.*, in Exodus, chapter 7, Aaron's staff swallowed up the staffs of the Egyptian magicians, showing the superiority of the God of the Israelites); (3) as proof of the sanctity of a holy man, a holy site, or a holy object; or (4) more generally as evidence of the truth of a particular religion.

SOURCES OF MIRACLES

Spiritual sources. The source of miracles is always a divine, spiritual, supernatural, sacred, or numinous power that may be conceived in personal form (*e.g.*, God, gods, spirits) or impersonal form (*e.g.*, mana or magic).

Natural phenomena accompanied by special circumstances

The sacred may manifest itself in natural phenomena, such as thunderstorms or earthquakes, that evoke appropriate feelings of awe, but these are not usually considered miracles unless attended by special circumstances—*e.g.*, being predicted by a "man of God" or coinciding with an event of religious significance. As reported in the Gospel According to Matthew, chapter 27, at the moment of Jesus' death on the cross, "the curtain of the temple was torn in two, from top to bottom; and the earth shook, and the rocks were split; the tombs also were opened, and many bodies of the saints who had fallen asleep were raised, and coming out of the tombs after his resurrection they went into the holy city and appeared to many." The belief that thunder and lightning are manifestations of divine powers is very common, and many deities have been interpreted as personifying them or at least as being symbolized by them. Even in the Old Testament, thunderstorms and lightnings appear as manifestations or messengers of God. In this respect, the account of the theophany granted to the prophet Elijah in I Kings, chapter 19, marks a milestone in the history of religions, for "behold, the Lord passed by, and a great and strong wind rent the mountains, and broke in pieces the rocks before the Lord, but the Lord was not in the wind; and after the wind an earthquake, but the Lord was not in the earthquake; and after the earthquake a fire, but the Lord was not in the fire; and after the fire a still small voice" in which Elijah heard God.

In most cases theophanies and divine manifestations occur for a specific purpose: giving laws (*e.g.*, Moses and the theophany at Mt. Sinai; events in the lives of Numa Pompilius of Rome, Minos of Crete, and Lycurgus of Sparta, the ancient lawgivers in classical legend); saving interventions (*e.g.*, the voices resounding from the temple of Athena Pronaea in Delphi that caused the Persians to retreat); and the founding of cults (*e.g.*, the appearances of Mary, the mother of Jesus, at Lourdes, France, and Fatima, Portugal). Gods would appear to their devotees in visions and dreams, but these experiences should, perhaps, not be treated under the same general heading with other miracles. Immediate divine action was often perceived in omens preceding important undertakings, in apparently natural phenomena occurring providentially at critical moments or in miraculous—*i.e.*, sudden and seemingly impossible—cures. In most cases, however, such divine interventions took place through some form of mediation, human or inanimate: oracles are usually connected with certain sanctuaries, statues, or priestly functionaries; miraculous cures are effected through the intercession of particular saints, pilgrimages to certain holy sites, or rituals at certain sanctuaries (*e.g.*, at the temples of Asclepius, the Greek god of medicine, especially at Epidaurus).

Human and inanimate sources. Man can be the object of miracles, as when his disease is miraculously healed, or their subject, as when he performs miracles, such as healing others, in the name of whatever power is moving him. The two aspects cannot always be strictly distinguished, as is seen in the case of saints whose bodies are immune from corruption after death or founders of religions whose birth is attended by supernatural manifestations. Generally speaking, however, it is the role of holy personages—and of their tombs and relics—as sources of miracles that are of importance in the history of religions and more especially in the history of popular cults.

Subjects of legends

Founders of religions. The attitudes of the founders of the great religions to miracles vary considerably, but all have become the subject of legends of the most fantastic kind in popular belief, and much of this legendary material has been subsequently canonized in scripture and tradition. Moses is described as the man of God who performs miracles—occasionally with his miraculous staff—as the messenger and servant of the Lord; the fact that his place of burial is unknown rendered further miracles impossible. The ministry of Jesus was accompanied by many miracles and signs (*sēmeia* in Greek), and the sites and objects associated with his life and Passion have become centres of pilgrimages, objects of veneration, and sources of miracles. Muḥammad, though rejecting the demand to vindicate his ministry by signs, nevertheless became the subject of many miraculous accounts. The same applies to the Buddha, whose birth and passing away are said to have been accompanied by the most extraordinary phenomena: among other things, music resounded, and flowers descended from the heavens; jewel-laden trees sprouted, and perfumed rivers flowed from the Earth.

Holy persons. Much closer to the lives and devotion of ordinary folk than the superhuman figures of the founders are the saints, monks, ascetics, and diverse kinds of holy men and women. The attitude to saints and their miracles is very much the same on the popular levels of all religions, although the theoretical interpretations on the more theological level vary considerably. In Far Eastern religions it is often difficult to distinguish between saints and hero gods, because great men of renowned virtue can be deified and venerated and even receive officially approved state cults. Miracles occur as a matter of course at their tombs and relics. In Muslim as well as in Christian belief, the occurrence of miracles is part of the requirements for official recognition of sainthood and is interpreted as a special intervention by God, who thereby manifests his esteem for the saint or, more essentially, his salvific presence as realized concretely in the life and virtues of the saint. In Indian—Hindu and Buddhist—belief, miraculous powers are the "natural" result of ascetic practice and spiritual realization and can thus be considered as an almost natural manifestation of magical or spiritual causes. Among the many types of miracles ascribed to saints are not only those that are concerned with helping the needy or assisting persons in grave danger but also performances that demonstrate the powers or special status of the thaumaturgist, or miracle worker—*e.g.*, levitations and flying in the air. Thought or mind reading is another miraculous faculty ascribed to saints, but this is often made to serve a spiritual purpose—especially in Christian and Jewish legends—by being a means to turn sinners to repentance.

Relics, images, and amulets

Sacred objects. Because the life-span even of saints is limited, most of the miracles attributed to them occur through their inanimate remains at their tombs or through their relics. These relics may be parts of their bodies—often deliberately dismembered for wider distribution, so that a bone may be in one place, a hair in another, and the heart someplace else—or objects or parts of objects associated with their lives (*e.g.*, the shroud of Christ or fragments of the True Cross). The possession of relics was important for the reputation, prosperity, and safety of their place of preservation, and thus cities and churches would often compete for them or even steal them from each other (*e.g.*, there are legends concerning the transferral of the bodies of St. Mark to Venice or of St. Nicholas to Bari, Italy). Relics of the Buddha are preserved in several places (*e.g.*, the sacred tooth at Kandy in Sri Lanka) as are hairs of the Prophet Muḥammad. Very often these relics are simply objects of pious veneration rather than sources of constant miracles; nevertheless, popular belief and devotion frequently ascribe to them quasi-magical virtues.

Not all miracle-working objects of veneration are relics. Statues and icons can work miracles, and in many Christian countries images and icons of the Virgin Mary are especially famed for their miraculous virtues. In the Christian Middle Ages the veneration of the sacrament of the Eucharist brought about a proliferation of miracles. Here, as in the case of images, a distinction can be made between the magical character of folk beliefs and the diverse theological doctrines concerning these religious objects; only rarely have religious authorities opposed the cult of saints, images, and relics and the concomitant belief in miracles—an exception is classical Protestantism, which in the 16th century rejected such cults.

Although they are not strictly sources of miracles, talismans and amulets—*i.e.*, objects believed to possess magical virtues as good-luck charms or as protecting the bearer or owner from all kinds of danger—should be mentioned in this connection. They are found in diverse forms and sizes and in all kinds of material: as natural objects or artifacts; as relics; or as pieces of paper, parchment, or metal inscribed with verses from Holy Scriptures, religious invocations, or magic formulas. In many primitive religions such objects form part of the recognized cultic paraphernalia—*e.g.*, African fetishes and the medicine bundles of many American Indian tribes. In some religions what seems to be objectionable magic practice may be integrated with the normative religious system by the blessing of medals and similar objects.

Sacred places. Miracles are often connected with special sacred places. Normally these are natural shrines, such as sacred groves, or temples and sanctuaries in which a god or spirit lives or has manifested himself or in which his statue, his symbol, his holy objects, or his relics are enshrined. Holy places, such as Mecca and the Kaʿbah in Islām or the Buddhist stupas, are centres of pilgrimages and veneration because of their religious significance and the religious values that they symbolize and not necessarily because miracles are wrought there; yet, popular devotion associates miracles with many of these holy sites.

MIRACLES IN THE RELIGIONS OF THE WORLD

It has already been suggested that the mythologies of primitive and ancient religions should not be designated miraculous insofar as they deal with mythical origins and ages; frequently they attempt to explain how certain regularities and what is now considered the normal course of things have come into being. The crucial distinction lies between religion on the popular primitive level and the more highly developed forms of religious belief. The tendency of the former is to relate to a concrete, magical presence of the sacred and to envisage the possibility of using this presence for the achievement of such desired ends as healing, blessing, or success in an undertaking. The higher forms of religion—though recognizing miracles or even demanding dogmatic affirmation of belief in them—exhibit a far more differentiated and complex attitude.

Hellenistic religion

Hellenistic religion presents one of the best examples of a civilization in which miracles play a major part. The intervention of the gods in the affairs of the Homeric heroes takes place in a cosmos in which the divine and human spheres still interact. Later Hellenistic syncretism conceived of the sublunar world as a distinct sphere, though higher powers could miraculously irrupt into it. Miraculous cures (*e.g.*, at the sanctuary of Asclepius at Epidaurus), divine manifestations of various kinds (*e.g.*, voices, dreams, and theophanies), and even virgin births and resurrections were widely reported. Some statues of gods were said to have descended from above and to move when they wished to communicate an oracle. Miraculous cures, resurrections of the dead, and other ex-

traordinary feats were attributed to great thaumaturgists, among whom Simon Magus, mentioned in the New Testament Acts of the Apostles, and especially Apollonius of Tyana, a Neo-Pythagorean sage of the 1st century AD, are the best known. In the world of Hellenistic syncretism, belief in miracles and in magic merge and can hardly be distinguished.

Religions of the East. In the great religions of the East the belief in miracles is closely connected with the theory that ascetic practices and the knowledge of mystical formulas, such as the Sanskrit *mantras*, can give the practitioner unlimited magical powers.

Religions of India. India has become the classic land of wonders not because of the accounts of fantastic actions of divine beings or semidivine heroes and avatars (incarnations of Hindu gods) related in Indian mythology but because both popular religion and philosophical theory set no bounds to the magical powers that can be attained by great ascetics and yogins (adherents of Yoga, the Hindu philosophy teaching the suppression of all activity of mind, body, and will in order that the self may realize its distinction from them and attain liberation). Even if these magical powers are considered insignificant in higher religion and spiritually negligible, their reality is never doubted. The *Upaniṣad* and the *Brāhmaṇa*—ancient Sanskrit writings of the Vedic period—may consider the heights of religious insight and mystical experience as man's supreme aim, but neither the later classical sources nor contemporary Hindu belief ever question the miraculous powers of a holy man. The same attitude is shared by the other religions of Indian origin: Jainism and Buddhism. According to the earliest Buddhist accounts, Gautama Buddha deprecated the miraculous powers that he possessed as being devoid of spiritual significance; nevertheless, miraculous accounts of the circumstances attending his conception, birth, life, and death proliferated as time went on. Miracles also occurred in connection with his relics, which became centres of veneration. Miraculous and magical elements are especially prominent in the *Mahāyāna*, or Greater Vehicle, forms of Buddhism.

The Buddha

The Buddha himself refused to spread his teaching by impressing his audience with miracles. According to the Aṅguttara Nikāya, one of the collections of the Buddha's sayings, there are three kinds of miracles—the miracle of magic, the miracle of thought reading, and the miracle of instruction—and of these the last is the most wonderful and excellent, whereas the other two are not much better than a conjuror's tricks. Yet the same text also describes what is implied by the miracle of magic: "there is one who, . . . having been one becomes many, . . . appears and vanishes, unhindered he goes through walls. . . . He dives in and out of the earth as if it were water. Without sinking he walks on water as if on earth. Seated cross-legged he travels through the sky like a winged bird. With his hand he touches and strokes the sun and the moon. . . ." The same text also asserts that not only was Gautama endowed with these powers but so also were hundreds of monks of his order. The tendency to denigrate the spiritual value of miraculous powers is illustrated by the story of the Buddha's meeting, at the bank of a river, with an ascetic who had practiced austerities for 25 years and who claimed that he was at last capable of crossing the river by walking on the water. The Buddha's reaction was to express regret at the waste of so much time and effort, because for "one penny" the ferry would take him across the river.

Religions of China. In China, although Confucianism in the strict sense has little room for miraculous elements, Taoism has produced a rich crop of thaumaturgy and magic on all levels of folk religion. No doubt the teaching of the Tao (literally, the Way) can be interpreted in terms of a sublime moral and perhaps even mystical doctrine. In actual fact it was one of the main sources of Chinese magic in all its forms, including the quest for the elixir of life. Religious Taoism, with its theory of a balance and interaction of cosmic forces, lent itself to elaboration and expression on all levels—from philosophy to pseudo-science to magic.

Religions of the West. In Western monotheistic religions it is necessary to distinguish between the role of miracles on the level of popular beliefs and practices and the theory of miracles propounded by the theologians. Belief in a personal, omnipotent Creator who exercises his providence over his creatures implies a concept of miracle as a deliberate intervention in the course of events by the same sovereign God who also assures their normal regularity.

Judaism. Miracles are taken for granted throughout the Old Testament. God does "wondrous things" according to Psalms, chapter 72, and "great things and unsearchable, marvellous things without number" according to the Book of Job, chapter 5; these things are done in his creation in general and in the history of his people in particular (*e.g.*, the ten plagues of Egypt and the events of the Exodus). A list of the great wonders done by God is given in Psalms, chapter 136; their purpose is to make his creatures praise him, acknowledge his rule, and "know that I am the Lord." God's wondrous deeds range from the normal regularities of creation to extraordinary interventions that run counter to ordinary experience and thus serve as signs of his greatness and providence in wreaking vengeance on the wicked and giving salvation to his elect. Very few miracles—apart from prophetic experiences and visions—are told of the great literary prophets; the cycles of legends the heroes of which are the early prophets Elijah and Elisha, however, are closer to the traditions of folk religion.

The Old Testament and rabbinic Judaism

Later rabbinic Judaism took the occurrence of miracles for granted. It assumed a natural order in which things worked and within which man was supposed to discharge his duties; thus, to rely on miracles was nothing short of sinful. In special circumstances, however, or in connection with persons of extraordinary saintliness, God would intervene or spectacularly answer their petitionary prayers. It was not so much a matter of suspending as of relativizing nature, the normal course of which was just one possible expression of the divine will; *e.g.*, in the legend of the lamp into which vinegar had been poured by mistake instead of oil: "He who has commanded the oil to burn will also command the vinegar to burn—and the lamp burned for a whole day." It was only in the Middle Ages and under the influence of Greco-Arabic philosophy that the problem of miracles was systematically discussed on a philosophical and theological level. Normative, rabbinic Judaism, being mainly concerned with doing God's will as revealed in his Law, had little interest in miracles, though it accepted, as a matter of course, the veracity of the miracles recorded in scripture and in the Talmud (the collection of Jewish lore, legend, and law). On the level of popular piety both magic and the belief in miracles always flourished, especially under the influence of Kabbala, the esoteric, mystical movement within Judaism; the Ḥasidic movement (a pietist movement that arose in eastern Europe in the 18th century) in particular produced a rich crop of beliefs and legends concerning the miraculous virtue—through prayer, intercession, or magical power—of the great Ḥasidic saints and rabbis.

Christianity. New Testament accounts of the advent, birth, life, Passion, and Resurrection of Christ include many miracles. Jesus is reported in the Gospels to have performed miracles of diverse kinds: raising the dead, healing the sick, casting out demons, and causing nature miracles, such as the multiplication of loaves and the turning of water into wine at the town of Cana. New Testament scholars are still conducting detailed research as to which accounts are early and which developed later, which grew on original Jewish soil and which evolved under the influence of the Hellenistic genre of miracle legends. There seems little doubt, however, that Jesus impressed many of his contemporaries more by his power to work miracles than by his preaching. Unlike the Buddha and Muḥammad, Jesus had an ambiguous attitude toward miracles: on the one hand he performed them as a sign of his mission and of the impending coming of the Kingdom; on the other hand he reproved the desire for wonders and repeatedly forbade the disciples to publicize his miracles, insisting that it was faith alone that worked

Jesus Christ

miracles. In fact, because miracles could also be explained by attributing them to demonic agency, it was ultimately faith that determined the quality and function of the miracle.

Early Christianity developed in the atmosphere of Hellenistic, Greco-Roman culture, which was full of miraculous accounts and legends. These no doubt influenced Christian traditions and forms of devotion, especially as popular religion always hankered after miracles, and—at the conclusion of the Gospel According to Mark—Christ himself had promised the continuance of miracles in his church. In a world in which only a few critical minds doubted the reality of miracles, the similarity of the Christian signs to those reported in pagan legend was attributed to demonic imitation and counterfeit; St. Augustine, the great theologian of the early Western Church, held that "the miracles of the [pagan] gods are vanquished by those of the [Christian] martyrs." The problem of distinguishing between the two sources of miracles—because the devil often disguises himself as an angel of light—frequently solicited the attention of theologians and mystics. Whereas for the theologians a miracle was a sign of God's saving presence and design, for the mass of believers it was the manifestation of a sacred power inherent in individual persons, places, and objects. Spectacular miracles were reported occurring in connection with the sacraments of Baptism and the Eucharist, with the tombs of martyrs and saints, with relics and holy images; certain saints acquired a special reputation as thaumaturgists.

Medieval theologians—and specifically St. Thomas Aquinas—taught that as all knowledge was derived from sensible facts, so also "a certain degree of supernatural knowledge of the objects of faith" could be brought about "by certain supernatural effects that are called miracles." This doctrine already assumes a system of natural causality that God—though he normally works through the natural law of which he is the author and Creator—can temporarily set aside. It also assumes that—at least in theory, if not always in practice—natural and supernatural effects can be distinguished. Thus, in 1870 the first Vatican Council declared: "If anyone should say that no miracles can be performed, . . . or that they can never be known with certainty, or that by them the divine origin of the Christian religion cannot be rightly proved—let him be anathema." (Anathema is a solemn ban or curse pronounced by ecclesiastical authority.) Belief in miracles is thus obligatory in the Roman Catholic Church, although belief in any specific miracle is not necessarily so. In fact, miracles form part of the career, in life as well as after death, of Christian saints and their occurrence continues; proof of miracles is among the requirements for the process of canonization, in which a person is formally proclaimed a saint. Classical Protestantism, however, has confined its belief in miracles to those recorded in scripture.

Islām. Muslim religion assumes, as a matter of course, that Allāh works miracles and has done so in the past; *e.g.*, through Moses, Solomon, and Jesus but significantly not through the Prophet Muḥammad. According to the Qur'ān, Muḥammad explicitly rejected the idea of proving his vocation by signs and miracles: the Qur'ān itself was the greatest miracle, and he was but a human messenger and preacher of repentance. Nevertheless, subsequent narratives invested his birth and life with superlatively miraculous details.

The Prophet Muḥammad

Muslim popular religion, particularly under Ṣūfī (Islāmic mysticism) influence, abounds in miracles, pilgrimages to the tombs of wonder-working saints, and the like. Dogmatic theology, too, recognizes miracles as facts. The peculiar feature of Muslim theology is that, unlike Christian theology, it did not accept the idea of nature as an entity operating according to fixed laws ordained by the Creator. Because the universe is constantly being re-created by Allāh in successive time atoms, natural regularity is nothing but the regularity of Allāh's habit in re-creating the universe. Thus, a miracle is the omnipotent God's departure from his habit but no different, in principle, from the latter. Muslim dogmatics distinguishes between miracles (*karāmāt*), with which Allāh surrounds his saints (*awliyā'*) as a mark of distinction, and signs (*āyāt*, also *mu'jizāt;* literally, "acts of an overwhelming nature"). The latter are wrought by Allāh to prove the genuineness of his messengers and to overwhelm and reduce to silence their opponents. Such miracles, which deviate from the usual course of things and are of such nature that others cannot produce their like, are Allāh's testimony to the sincerity of his apostles. The problem is nevertheless complicated by the fact that Satan too can perform miracles. Generally speaking, miracles do not play a role in the continued life of orthodox Islām, though they loom large in popular belief and piety, especially in the cult of saints who—in life as well as after death at their tombs—have the power to impart *barakah* ("blessing"). Orthodox zealots, such as the Wahhābīs, have not hesitated on occasion to destroy the tombs of saints because they considered their cult as incompatible with true Islām.

INTERPRETATION OF MIRACLES

All of the more fully developed theologies have formulated a doctrine of miracles in the context of their beliefs regarding God, the world, the operations of nature, and causality. The emergence of the concept of nature as a closed system functioning in accordance with strict causal laws created problems more than once, but medieval Christian and Jewish thought had no difficulty in maintaining that the order created by God could also be suspended by him.

In classical antiquity. Miracles were denied even in classical antiquity. Thus, Cicero asserted that "nothing happens without a cause, and nothing happens unless it can happen. When that which can happen does in fact happen, it cannot be considered a miracle. Hence, there are no miracles." Cicero qualified this statement, however, by saying that miracle stories may be necessary for the piety of ignorant folk. The 2nd-century pagan philosopher Celsus is less dogmatic in his attacks on Christianity: the Christian miracles are insufficiently attested and most improbable, but, even if they were genuine, they could hardly offset the miracles of the pagan world—*e.g.*, the healings of Asclepius. This was the standard pattern of many religious polemics: miracles as such were not necessarily denied; only those claimed by the adversary were denied. When these could not be denied, they were ascribed to diabolic agency or to the fraudulent practices of priests or occasionally to a misinterpretation of essentially natural phenomena.

In the 18th and early 19th centuries. Rationalist criticism, although not completely absent in the Middle Ages, became a major factor in the 18th and 19th centuries. David Hume, a British Empiricist and a Skeptic, in the chapter "On Miracles" in his *Enquiry Concerning Human Understanding* argued that, given the general experience of the uniformity of nature, miracles were highly improbable and that the evidence in their favour was far from convincing. It should be emphasized that Hume, whose criticism led him to a denial of causality, did not dismiss miracles because they were inconsistent with causal law—as many other thinkers did, notably the Deists (those, especially British, who advocated a natural religion). Instead Hume insisted on the probability factor and thus on the importance of assessing historical evidence. Because all Christians agreed that biblical religion and the scheme of salvation set forth in it could be maintained only by stressing prophecy and miracle, there developed a vast body of literature, especially among Protestants, proving the authenticity of the Christian faith on the basis of the miracles recorded in the Bible. For many 18th-century thinkers, however, the vastness and complexity of the order of nature were even more impressive than any alleged exceptions to it. Thus, belief in miracles, although remaining an essential element of faith to good Christians, appeared as sheer superstition to the eyes of the torchbearers of Rationalist enlightenment. Deism and subsequently liberal Protestantism, each in its own way, defined religion or reinterpreted biblical religion in ways that dispensed with miracles. Sometimes the facts alleged

Rationalist criticisms

in the Bible were partly admitted, but a natural explanation was substituted for the miraculous one.

Criticism of the concept of miracle was articulated in more than one way. There was philosophical and scientific criticism to the effect that miracles were impossible and that even epistemologically (*i.e.*, within the limits of knowledge) the occurrence of a miracle could never be established; at most, these critics maintained, there were merely as yet unexplained natural phenomena. (This view comes close to the religious assertion that faith precedes the experience of a miracle and that the factuality of a miracle can never precede faith.) There was historical and philological criticism, arguing that the actual occurrence of miracles is unsubstantiated and analyzing the growth and evolution of the legends and texts reporting miracles. There was psychological criticism, arguing that some people want to believe in miracles and so produce imaginative creations answering their psychological needs. There was also a type of religious criticism implying that the truly spiritual has no need of miraculous supports. One suggested solution to the problem was the assertion that the term miracle does not describe an objective event but a subjective mode of experience: the more religious one is, the more one sees miracles everywhere. This view of Friedrich Schleiermacher, an early-19th-century Protestant theologian and philosopher, identified miracle with a religious understanding of any aspect of the world.

Liberal and Neo-orthodox Protestantism

In the late 19th and 20th centuries. Later 19th- and 20th-century liberal Protestant thinkers, such as Rudolf Bultmann, a German New Testament scholar, discarded the traditional notion of miracle together with other elements of what they termed the mythological apparatus of the Bible. Many of these liberal theologians sought the evidence for Christianity in the moral and religious transformation it brought to people's lives or interpreted the doctrine of salvation in Existential terms. The early decades of the 20th century, however, also witnessed a return to a more orthodox theological climate—as, for example, in the thought of Karl Barth, a Swiss Protestant theologian—and a new readiness to accept miracles as meaningful signs of God's salvific activity. This change of climate coincided with certain developments in science that appeared to question a too rigid and mechanical concept of causal determinism. It was argued that the discoveries of physics on the atomic level and particularly of Werner Heisenberg's Principle of Uncertainty (*i.e.*, that it is impossible to specify or determine simultaneously both the position and velocity of a particle with full accuracy) allowed for divine action in the form of noncausal miracles, though this argument was also judged by some as a misinterpretation both of science and of the religious meaning of miracle. The problem was complicated for modern theological apologetics by the compulsion of many people to believe in miracles—although their actual philosophical, intellectual, and even religious sensibility inclines them to dispense with this belief—simply because miracles are recounted in their hallowed scriptures and traditions; not everyone is prepared to abandon or "explain away" parts of his hallowed tradition.

Orthodox Jews, Christians, and Muslims still believe in the literal occurrence of the miracles recorded in their scriptures and traditions; Catholics, furthermore, believe in the continued occurrence of miracles, defining them as a direct divine effect upon nature. The liberal attitude—whatever the variations in detail and in sophistication of the explanation—is essentially similar to that propounded by Schleiermacher.

Miracles hold a prominent place in the history of religions; the encounter with the reality posited by religion (God, the gods, transcendence, the holy, sacred, or numinous) is essentially wonderful and transcending normal reality. Thus, religious experience tends to crystallize in miraculous accounts. The religious pattern of experience easily combines with the primitive yearning after the miraculous, born of the human desire to master ordinary needs, uncertainities, fears, and sufferings with a magical short-cut to greater powers. Whereas some theological systems assert that miracles both produce and confirm faith, many students of religion agree with Goethe's description of the miracle as "the dearest child of faith."

Miró, Joan

A Spanish artist whose paintings, sculptures, and drawings are continually surprising in their playful simplicity, their wit, and their richness of imagination, Joan Miró creates works that haunt the spectator like a dream. Miró's ultimate artistic style was the outcome of many stages of development that were, from the outset, directed toward discovering in the hackneyed appearance of the visible world the pristine condition of myth. Through all the phases of modern art through which he has lived, he has never become outmoded. The latest trends in art and anti-art always seemed to have been anticipated in his works. Miró's work disowns all tradition and penetrates to the origins of art.

Youth in Barcelona

Joan Miró was born on April 20, 1893, in the old town of Barcelona. His father was a watchmaker and goldsmith, and his forefathers had also been artisans from the Tarragona region of Spain and the island of Majorca. Both the artisan tradition and the austere Catalan landscape were to prove of the greatest importance to his art. From his father he learned a love of astronomy and a sense of the infinity of the cosmos.

Miró's artistic development did not progress with the triumphant directness of his countryman Picasso, who could draw like a master while still a boy. Instead of being allowed to go to an art school, Miró was expected to complete high school, though he failed to do so. He then attended a commercial college and worked for two years as a clerk in an office, until he had a mental and

physical breakdown. His parents took him for convalescence to an estate, Montroig, near Tarragona, which they bought especially for this purpose, and finally allowed him to attend an art school in Barcelona. His teacher at this school, Francisco Galí, showed great understanding for his 18-year-old pupil, advising him first to touch the objects he was about to draw, a procedure that strengthened Miró's feeling for the spatial quality of objects. Galí introduced his pupil to examples of the latest schools of modern art from Paris and showed him the churches and chapels of the region, with their Byzantine-influenced frescoes. Finally, he introduced him to the fantastic world of the buildings of Antonio Gaudí, Barcelona's famous Art Nouveau architect.

Miró's development as an artist differed from that of other modern artists: whereas artists of the contemporary Fauve and Cubist schools deliberately attempted to destroy the canons of tradition in order to attain a new kind of pristine vision, Miró possessed such a vision naturally. In his paintings and drawings he sought above all to establish means of metaphorical expression—that is, to discover signs that stand for concepts of nature in a transcendent, poetic sense. He wanted to depict nature as it would be depicted by a primitive man or a child equipped with the intelligence of a 20th-century adult; in this respect, he had much in common with the Surrealists and Dadaists, two other schools of modern artists, who were striving to achieve similar aims by more intellectual means than Miró used. Miró's art developed slowly from his first clumsy attempts at expression to the apparently playful masterpieces of his later period. His fanatical honesty and his conscientious craftsmanship compelled him to work on many of his pictures for years.

From 1915 to 1919 Miró worked in Barcelona, at Montroig, and on Majorca, painting landscapes, portraits, and nudes in which his interest centres on the rhythmic interplay of volumes and areas of colour. His colours were still dark and heavy, though he delineated details with a frenzied concentration as if superimposing on a heavy earthly ground a filigree of luminous leaves and blossoms. His manner was the same in landscapes, portraits, and nudes.

Miró was one of many artists who made their way from abroad to Paris during the first two decades of the 20th century and enriched French painting, which was to influence the art of the whole world. Most of these foreign artists elected to become Frenchmen after coming into contact with the French artistic metropolis, but Miró remained attached to his Catalan homeland, in his choice both of dwelling places and of subjects for his pictures.

From 1919 onward Miró lived alternately in Spain and Paris. In the works he produced in the period between World Wars I and II—the great still lifes, landscapes, and phantasmagorias set free from both space and time—he gradually removed the objects he portrayed from their natural context and reassembled them as if in accordance with a new, mysterious grammar, creating a ghostly, eerie impression.

Dream pictures and imaginary landscapes

From 1925 to 1928, under the influence of the Dadaists, Surrealists, and Paul Klee, he painted "dream pictures" and "imaginary landscapes" in which the linear configurations and patches of colour look almost as though they were set down randomly. After a trip to The Netherlands, where he studied the 17th-century Dutch realist painters in the museums, the figurative elements in his pictures once more assumed a firmer shape. But, when a tendency toward beautiful, tasteful forms emerged in his works, he countered it with more brutal signs, collages, and objects made up of the waste products of industry.

By the 1930s, Miró's artistic horizons were expanding. He designed decor for ballets. His paintings began to be exhibited regularly in French and U.S. galleries. In 1934 he designed tapestries, and that led to an interest in the monumental and in murals.

At the time of the Spanish political turmoil and Civil War in the late 1930s, Miró was living in Paris. In their demonic expressiveness, his pictures of this period mirrored the fears and horrors of those years. At the Paris World Exhibition of 1937, he painted for the pavilion of the Spanish Republic a mural, "The Reaper," containing a strong element of social criticism.

During World War II, Miró returned to Spain, where he painted his "Constellations," symbols of the happy collaboration of everything creative, of the elements and the cosmos. They represent a challenge to the anonymous powers of corruption in social and political life, the cause of misery and wars. During the last year of the war, Miró together with his potter friend Artigas, produced ceramics that revealed a new impetuosity of expression.

From 1948 onward he once more divided his time between Spain and Paris. That year saw the start of the series of very poetic works the symbols of which were based on the theme of woman, bird, and star. Pictures wildly spontaneous in character came into being alongside others whose forms were executed with punctilious craftsmanship. Both approaches were also combined in Miró's sculptures; in them all his earlier figurations were happily amalgamated to form erotic fetishes or signals towering into space.

Postwar fame

In the years following World War II, Miró became world famous; his sculptures, drawings, and paintings, as well as books he had illustrated, were exhibited in many countries. In 1950 he painted a wall for Harvard University. His ceramic experiments were crowned by the great ceramic wall in the UNESCO building in Paris (1958), for which he received the Great International Prize of the Solomon R. Guggenheim Foundation. In 1962 Paris honoured him with the first major exhibition of his collected works in the Musée National d'Art Moderne. The architect José Luis Sert built for him on Majorca the large studio of which he had dreamed all his life.

In spite of his fame, however, Miró continued to devote himself exclusively to looking and creating. A taciturn, introverted man of short stature, Miró had not found it easy to attain the wisdom permeated by irony that ultimately characterized his work. From his youth on, he had felt compelled by an almost anarchic obstinacy to keep his eyes firmly fixed on his goal despite the resistance offered by society or by the prevailing artistic theories. His late works manifest an even greater simplification of figure and background than his early ones. In order to realize his inner visions, it was enough now for Miró to set down a dot and a sensitive line on a sea-blue surface; in this the spectator could still find himself in a state of total enchantment. His early work anticipates the representational techniques of his later art style; thus, although the former playful or aggressive irony gives way to a quasi-religious meditation, all of his works form a coherent whole manifested by a common quality of rejuvenation and deepening.

MAJOR WORKS

"Self-Portrait" (1919; Pablo Picasso Collection, France); "The Farm" (1921–22; Ernest Hemingway Collection); "Carnival of Harlequin" (1924–25; Albright Knox Art Gallery, Buffalo, New York); "Dog Barking at the Moon" (1926; Philadelphia Museum of Art); "Dutch Interior" (1928; Museum of Modern Art, New York); "Woman in the Night" (1940; Mme Duchamp Collection, New York); "The Red Disc in Pursuit of the Lark" (1953; Galerie Maeght, Paris); "Blue II" (1961; Galerie Maeght, Paris); "Personage and Bird" (1965; private collection); "The Ski Lesson" (1966; Galerie Maeght, Paris); "Red Accent in the Quiet" (1968; private collection); Mural for the "Labyrinthe" of the Fondation Maeght, Saint-Paul, France (1968).

BIBLIOGRAPHY. J.J. SWEENEY, *Joan Miró* (1941), the first comprehensive presentation of Miró's life and work, written for a retrospective exhibition at the Museum of Modern Art in New York; WALTER ERBEN, *Joan Miró* (Eng. trans. 1959), a monograph that reproduces many different examples of the artist's work at his home and studio on Mallorca; JACQUES DUPIN, *Miró* (1961; Eng. trans., 1962), the standard work, written by an art historian and poet who has been a friend of the painter for many years—contains a detailed bibliography of writings on Miró as well as a catalog of his pictorial and sculptural works; MICHEL TAPIE, *Joan Miró* (1970), French text with many illustrations, especially of his later works, and an enlarged bibliography up to 1968.

Mississippi

General character of the state

Originally part of America's Old Southwest, Mississippi became the 20th state of the Union in 1817. Its name has long been symbolic of many of the characteristics attributed, correctly or incorrectly, to the Deep South. As it entered the last quarter of the 20th century, the state was engaged in efforts to alter economic and social patterns of the past and present. Through the inevitable confrontation of the forces of tradition and change, Mississippians had become conscious of their image as portrayed on the national scene.

For decades, an unusually large dependent population, above or below employment age, as well as a predominantly agricultural economy, helped to keep per capita income low and to create inadequate levels of living for many families. Though more than half of the 2,216,912 Mississippians counted in the 1970 census were still rural —but not necessarily on farms—the state ranked low in many economic indexes. During the 1960s, the industrial income surpassed the agricultural income for the first time.

Throughout most of its 47,716 square miles (123,584 square kilometres)—from Tennessee in the north to Louisiana and the Gulf of Mexico in the south, from Alabama on the east to Louisiana and Arkansas on the west —much of Mississippi's soil is rich and deep, and its low-lying landscape is laced with many rivers. Almost inevitably it became an agricultural state. The long dominance of a rural, unhurried way of life has contributed much to the problems of present-day Mississippi. This way of life has also left a sense of history among some Mississippians, whose ancestors created a culture of gentility that is still evident in the many historic mansions located in such old towns as Columbus, Biloxi, Natchez, and Holly Springs. (For information on related topics, see the articles UNITED STATES, HISTORY OF THE; CIVIL WAR, U.S.; MISSISSIPPI RIVER; MEXICO, GULF OF; and NORTH AMERICA.)

THE HISTORY OF MISSISSIPPI

Pre-Civil War days. The original Mississippi Territory created by Congress in 1798 was a strip extending about 100 miles north to south and from the Mississippi River to the Chattahoochee, on the Georgia border. The territory was increased in 1804 and 1812 to reach from Tennessee to the Gulf. In 1817 the western part achieved statehood as Mississippi (the eastern part became the state of Alabama in 1819). Natchez, the first capital, was replaced by Jackson in 1822.

The 1820s and 1830s were marked by the decline of the Jeffersonian Republicans, the ascendancy of the Jacksonian Democrats, and the removal of the Indians to Oklahoma.Those were the days of the steamboats, land speculation, and the growth of a plantation-based cotton economy, with its concomitant slave population. Slave owning, however, was not common among the small landowners, who became more numerous than the large planters but had little influence on public affairs for many years.

Sectionalism in both North and South had been growing for some time. Its ill feelings, though fed by many issues, gradually became dominated in both North and South by slavery. In January 1861, a convention adopted an ordinance of secession, and within a year the state was in the midst of war. The people suffered much privation, and the land, great devastation; by 1865 the state was in economic ruin.

Aftermath of war. Many historians consider that the Reconstruction period that followed was as bad as the war. Political control passed to a group comprising Radical Republican carpetbaggers, black freedmen, and scalawag whites. The excesses and abuses of Reconstruction ended by 1876, but the seeds of new problems had been planted. Controversy over the sharecropping system, ideas of "white supremacy," and economic policies would plague the state for 100 years.

Mississippians hoped to find economic salvation in the coming of industry and the railroads, but the hope was only partially realized. Emancipation had made the former slave free to go where he would, but most remained and eventually were absorbed into the tenant-farming system. The continued economic interdependence of the two races kept many of the customs and social systems intact. The constitution of 1890 effectively disfranchised most of the Negro population.

Hardening of rural dominance and social traditions

World War I hastened the end of Mississippi's physical and psychological isolation, and most of the bitterness remaining from the Civil War was lost in a surge of patriotism. Between the wars, the state was affected by the agricultural depression of the 1920s, the devastating 1927 flood, the Great Depression of the 1930s, the coming of farm-production controls, and the beginnings of new industrialization. After World War II, government farm programs and mechanization on a broad scale created another agricultural revolution.

Civil rights movement. After the war, a series of events developed that may be characterized as a revolution in race relations. Many long-accepted practices, customary throughout much of the South, received their first major jolt in 1954 with the United States Supreme Court decision declaring racially segregated schools to be unconstitutional. That was followed by years of increasing protest against other aspects of segregation and by large-scale registration of black voters. Within the black community, leaders emerged who sometimes were aided by whites, often from outside the state.

Tensions between tradition and change

The white Mississippians felt the entire fabric of their lives threatened by demands for massive and immediate change. They reacted strongly to what they believed was the duress imposed upon them by outside governmental forces and private reform groups alike. Pressures, publicity, and recrimination were accompanied by bitter words, confrontations, name-calling, sit-ins and boycotts by blacks, and even acts of violence. Among these were the murder of civil rights workers and the bombing of black churches. These acts of militance by both sides made international headlines. Yet the slow process of historical change saw the people of the state adjusting to many new laws and to new interpretations of long-standing laws. By the early 1970s a much changed, more tranquil atmosphere existed. Many observers found Mississippi's schools to be the most integrated in the nation, and blacks had been elected to a number of local offices.

In politics, disaffection developed between the state and national Democratic parties. Traditionally Democratic, Mississippians broke the trend and voted for other presidential candidates who appeared to be more conservative or more favourably disposed toward the region. Some feeling existed that increasing urbanization of the state, economic changes, and the growing role of the blacks might move the state toward a more conventional two-party system.

THE NATURAL AND HUMAN LANDSCAPE

Mississippi is a low-lying state, its highest point (in the northeast) reaching only 806 feet (246 metres) above sea level. Its major soil areas encompass hills, plains, prairie, river lowlands, and pine woods. The traditional regions relate generally to physiographic regions. Discernible differences exist, however, in life-styles, political persuasions, economic characteristics, and general cultural variations.

The Delta

Physiographic regions. In the northwest, the great fertile crescent called the Delta is the old floodplain of the Yazoo and Mississippi rivers, comprising 4,000,000 acres of black alluvial soil many feet in depth. Once subject to disastrous floods, the land is now protected by levee and reservoir systems. Though the Delta was only sparsely settled in antebellum days, it is today a region of highly mechanized farming.

East of the Delta looms the high wall of loess bluffs, marking the beginning of the highlands, or hills. One first encounters a brown loam belt of varying width extending from Tennessee to Louisiana. Most of southern Mississippi, from the brown loam belt to Alabama, lies in the high and rolling Piney Woods. Though settled early, the area did not prosper until the early 20th century, when the great virgin pine forests were exploited

and heavily decimated. Today it is a prosperous area based on diverse forest industries, cattle, and some specialty farming.

The coastal area, sometimes called the Coastal Meadows, or Terrace, borders the Gulf of Mexico. The soil is sandy and not well suited to crops, but its location, climate, and industrialization have made the region important.

Along the northern edge of the Piney Woods lies the narrow Central Prairie, separated from the Black Prairie by a section of hills and woods. The two prairies, with fertile black soil that is excellent for many types of agriculture, were once the site of cotton plantations. East of the Black Prairie, in the extreme northeast, are the Tennessee Hills. Arching between Tennessee and Alabama, these hills form the only area in Mississippi in which terrain and people are reminiscent of the southeastern mountains.

West of the Black Prairie another highland area, the Pontotoc Ridge, ranges south from the Tennessee border. This great ridge, averaging 400 to 600 feet above sea level, is one of the state's most distinctive topographic features. Its fertile sandy loam soil is excellent for orchards. A low-lying region called Flatwoods skirts the western edges of the Pontotoc Ridge and the Black Prairie. Its heavy clay soils drain poorly, and the area has never developed a prosperous economy. The North Central Hills range through northern and central Mississippi and eastward to Alabama. Their red clay soil, though not fertile, supports small farms. Before scientific farming methods were widely adopted, erosion ruined thousands of acres in these hills.

The natural environment. *Rivers.* Mississippi has many rivers, creeks, bayous, and other drainage. The state has five principal river systems, in addition to some important smaller ones. Except for a small area in the northeast that drains into the Tennessee River, these streams empty into the Gulf, either directly, or through the Mississippi and other rivers.

Climate. Mississippi's location endows it with a very favourable climatic range. The growing season is long (virtually year-round on the coast), rainfall is abundant, and extreme temperatures are unusual. Summers are warm, with temperatures sometimes exceeding 95° F (35° C). Autumn's bright, crisp days have the least rain and are usually the most agreeable of the year. January temperatures average from 42° F (6° C) to 50° F (10° C). Snowfall is rare but does occur. Supplies of water are abundant, and rainfall is usually adequate for replacement. The state's annual average is more than 50 inches (1,270 millimetres), varying by region. The coastal area is subject to hurricanes from June to October.

Vegetation and animal life. The mild climate, long growing season, and abundant rainfall provide Mississippi with a remarkable variety of plant and animal life. Live oaks and palms vary the landscape of the southern counties, and fruit trees and hardwoods thrive in the north. The magnolia and pecan trees are favourites throughout the state. More than half the land area is in forests, and both natural and cultivated floral displays are diverse and abundant.

Opening land to farming and heavy hunting reduced the once-abundant wildlife to near extinction. The wolf and panther (cougar) are gone, the bobcat is rare, and the bear even rarer. Yet deer are once more abundant and wild turkeys are increasing. The state has a great variety of resident and migratory birds. Some game fish can be taken throughout the year, with catfish, bream, bass, and perch the leading freshwater species. The Gulf is rich in shrimp, oysters, and fish, which are the mainstays of extensive commercial fishery.

Traditional regions. Almost every Mississippian knows and uses such regional designations as the Delta and the Hills; South Mississippi and the Coast; the Prairie or the Black Belt; and North Mississippi and the Northeast. The landscape of Mississippi is mainly one of forest, fields, and towns. Cities and factories take a lesser place. Cotton is king no more, and soils unsuited to row crops may support tree farms, pastures, or orchards. The two Standard Metropolitan Statistical Areas are Jackson, with nearly 260,000 inhabitants, and coastal Biloxi–Gulfport, with nearly 135,000.

Regional distinctions

Delta and hills. Geographers may speak of the Yazoo Basin, but to the people of the state it is the Delta. The Deltans pay homage to aristocratic plantation traditions, tend to be politically conservative, and usually display more solidarity than most other regions. The leading families are patrons of the arts and letters and tend to be well-read and travelled. The Hill people, however, do not defer to the Deltans, many of whose families originally came from the Hills.

South Mississippi and the Coast. What historians call the Piney Woods, covering most of the state south of Jackson, the people call South Mississippi. Its population and prosperity are growing. Change seems to come easier here than in most other regions. The farmer is fast being replaced by the worker in commerce and industry.

The coastal area is atypical of the state as a whole. More Catholic and Mediterranean than upstate, it blends French, Spanish, Latin American, Dalmatian, and British heritages in the most heterogeneous of Mississippi's regions.

Prairie and northeast. The Prairie region has some of the ways and style of both the Delta and the Hills. Its lands, however, are more productive than the Hills, its people are somewhat more expansive, and some traditions from the antebellum era remain. Northeast Mississippi developed as an area of small family farms and few plantations, and it has the lowest nonwhite population in the state.

THE PEOPLE OF MISSISSIPPI

Ethnic and religious characteristics. The white population of Mississippi is remarkably homogeneous. More than 98 percent native-born of native stock, they are predominantly of British, Irish, and northern European ancestry. The black population is of old stock and almost entirely native-born.

Until about 1940, blacks were in the majority, but by 1970 they made up about 37 percent of the population. About 4,000 Choctaw Indians remained, living on or near their reservation. Other groups are represented but in such small numbers that they are not conspicuous.

Various Protestant denominations dominate Mississippi's religious life, most notably the Baptists and Methodists. The Catholic population tends to be in the urban centres and the southernmost areas, especially the coastal counties. The Jewish congregation is almost entirely urban.

Demography. Like many predominantly rural areas, Mississippi has relatively low death rates and high birth rates. Birth rates, which, in the 1960s, averaged 22 per 1,000 inhabitants—17.4 for whites, 28.2 for blacks—were higher in only five other states. The overall fertility ratio—the number of children under five per 1,000 women of childbearing age—was 468 in 1970, a significant drop from 670 in 1960. The death rate was 9.6 per 1,000 in the 1960s: 9.2 for whites, 10.4 for blacks.

Mississippi has no great extremes of population concentration, nor are there extensive uninhabited areas in the state. Since 1950 there has been a slow but steady loss of farm population and a decline of smaller towns, and most of the centres of over 10,000 inhabitants have experienced significant growth. The average population density is 50 persons per square mile, ranging from 245 in Hinds County to seven in Issaquena County.

Patterns of migration

Mississippians, who inherited the frontier tradition of "moving on," have become as mobile as most Americans. Frequent movement by sharecroppers and tenant farmers from one farmstead to another was commonplace before 1920, at about which time the economic focus (and the locus of emigration) shifted to the cities and towns. About three-fourths of the white emigrants moved to one of the other Southern states, whereas the same proportion of black emigrants left the South entirely. The net loss by emigration has largely offset Mississippi's high rate of natural increase. If Mississippi is able to retain more of its youth, it is possible that the growth, com-

position, and distribution of the population will depart from the past experience and the current projections for the future.

THE STATE'S ECONOMY

In many economic indexes, Mississippi ranks low in its region and in the nation. During most of the 1950s and 1960s, personal income ranged from only 50 to 60 percent of the national average. This can be explained in part by the smallness of industrial employment, by the great numbers of dependent persons under 15 and over 65, and by poor re-employment opportunities for an increasing surplus farm population. Where agricultural employment continues, it is often seasonal or on a daily basis.

Personal income

There has been some improvement in employment, wages, and personal income; but the proportionate national and regional growth has been even greater, and the relative economic disadvantage continues. Nearly 90 percent of personal income is derived from eight sources. Manufacturing is the largest single source, though it falls short of the national average. The other main sources are the federal government, property, farms, state and local governments, wholesale and retail trade, operation of nonfarm commercial enterprises, and personal and business services.

Natural resources. Mineral fuels account for over four-fifths of the value of all minerals. In 1971 Mississippi ranked ninth and 16th, respectively, in petroleum and natural-gas production among the states. Important nonmetallic minerals include sand and gravel, clays, and magnesia. Iron has been mined intermittently since 1887. Aluminum ores are low in quality and little exploited.

Approximately 55 percent of the land area is in commercial forests that produce lumber, paper pulp, naval stores, and other forest products. Seafoods from Gulf waters are processed in coastal plants.

Electrical power produced within the state is from steam-generating plants. Hydroelectric power is brought in from Tennessee Valley Authority dams or through interconnections with power companies in other states. Two private companies, numerous rural cooperatives, and several municipal generating systems are in operation. Several large transmission facilities bring gas into and through the state.

Economic management. State agencies administer regulatory functions in the area of utilities, transportation, oil, gas, insurance, and pollution. The Agricultural and Industrial Board both seeks new businesses and aids in expanding existing ones by such means as loans to train and recruit workers. It is aided by the Mississippi Research and Development Center through research in economic development. The several economic-development districts promote activities in their constituent counties. Private enterprise also advertises the state's advantages.

Labour-union membership

Labour-union membership is relatively small, although widely dispersed. In 1968 unions reported 76,000 members, accounting for 13.8 percent of workers in nonagricultural employment, compared to the national level of 28.4 percent. Most large employers have a union membership, though Mississippi has a "right-to-work" law that prohibits compulsory union membership.

Transportation. The declining fortunes of rail transportation and the existence of obsolete segments of the state's highway system represent problems for transportation. Relief is hoped for, however, in the four new highways of the interstate system and in the program of highway improvement voted by the legislature. The heaviest volume of traffic is along the Gulf Coast, where it merges into the flow from the numerous upstate north–south and east–west patterns. The 200-mile Natchez Trace Parkway, part of the National Park Service, is protected from commercialization and truck traffic. Peaceful and bucolic, it preserves the natural surroundings and encompasses many sites of historic and other interest. Eventually, it will extend from Natchez to Nashville, Tennessee.

Commercial transportation, in addition to highway trucking, is very diversified. Of the 16 railways in the state, seven are entirely intrastate. Three scheduled airlines serve Mississippi, and 13 airports are certified for commercial service. Several interstate bus companies maintain service through the state, and almost all major cities and towns are served by one or more bus lines. Gulfport and Pascagoula can accommodate oceangoing ships, and low-draft oceangoing vessels can travel up the Mississippi to Natchez, Vicksburg, and Greenville. Barge traffic moves on the Mississippi, Pearl, and Yazoo rivers. The Gulf Intracoastal Waterway passes just off the coast across the Mississippi Sound.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of state government. The state government has the traditional executive, legislative, and judicial branches, but it differs from some states in that most heads of executive departments are elected rather than appointed. The bicameral legislature, which meets in limited annual sessions, comprises a 122-member House of Representatives and a 52-member Senate.

Executive, legislature, and judiciary

Persons elected to statewide offices serve four-year terms, and the governor and treasurer cannot immediately succeed themselves. In addition to commanding the National Guard, the governor may call upon a volunteer state guard and an unorganized militia, the latter potentially comprising all able-bodied men of military age.

Justice of the peace courts have original jurisdiction in misdemeanor matters and may have concurrent jurisdiction with county or circuit courts where fines, sentences, and judgments do not exceed prescribed limits. Chancery courts have jurisdiction over matters of equity, probate, juvenile delinquency (where county courts do not exist), divorce, and mental competence. The Circuit Court is the main trial court for major suits, criminal cases, and appeals from justice and county courts. The Supreme Court is the court of appeals; its nine justices are elected, from three judicial districts, for staggered terms of eight years.

Local government. Each county's governing body is a board of supervisors. The sheriff formerly functioned also as the tax collector and was compensated on a fee basis. Beginning in 1972, tax assessment and collection were combined on a salaried basis. Municipalities may be incorporated as villages, towns, or cities, though no new villages may be chartered. Governments of these units are of the mayor–council type with aldermen, the commission type with three commissioners (including the mayor), or the city-manager type, in which the manager is appointed by the council.

Politics. State and county officials are elected in the November general election. Under a system adopted by the legislature, all candidates must stand in a preferential primary in October. If no person receives a majority, the two candidates with the highest number of votes are placed on the ballot in the November election.

By 1875 Democrats had won most of the offices from the carpetbag rule that had prevailed for about a decade. Until the late 1940s, Mississippi was a one-party state, in which the Democrats usually won. Disaffection with the national party broke the pattern in following decades, when, except for 1952 and 1956, states'-rights candidates and other conservative presidential candidates received the state's electoral ballots. For offices below the national level, major consideration is focussed on personality and political philosophy on local issues.

Race and politics

In effect, Mississippi now has two Democratic parties. The traditional state party structure is conservative and has official recognition in the state. The Loyalist Democratic Party, allied with the more liberal national party, symbolizes the increased importance of the black voter. An increasing impact has been felt from drives to register black voters, court decisions banning literacy and other tests, and redistricting under court order. Beginning in the 1960s, blacks won election to an increasing number of municipal and county posts throughout Mississippi.

Finances. Sales taxes are the state's major source of revenue, followed by personal and corporate income taxes and gasoline taxes. Local governments derive their greatest income from property taxes. Considerable

amounts of federal monies are provided through numerous federal and state agencies.

Social services. Education, health, welfare, and other measurements of the quality of life in Mississippi necessarily must be considered in the perspective of the state's long history of segregation and the nearly equal number of people of each race to which that segregation was, in part, a response. Though segregation is by no means limited to the South, let alone Mississippi, the nearly equal numbers of whites and blacks in the state have intensified the actions and reactions on both sides and made the state a national scapegoat in the eyes of some and a symbol of the problem in the eyes of others. Certain researchers have pointed out that although the level of educational attainment of white Mississippians is among the highest in the nation, the inclusion of the black population in this index relegates Mississippi virtually to the bottom of the national scale. Analogous conditions prevailed in other areas.

Education. In 1957 a process of enlarging and consolidating public school districts was nearly completed. In addition, the years of confusion and emotion since the reversal of the separate but equal doctrine in 1954 have altered the Mississippi schools in a drastic manner. The year-by-year changes brought on by integration have produced a condition of semipermanent flux. The very low per pupil expenditure by the state is in large measure the result of the low tax bases that exist and the high proportion of school-age persons in the population. In terms of money spent for instruction, as distinct from buildings and utilities, the state ranks much higher than the comparative national figures indicate.

Despite its present problems, Mississippi has a distinguished history in education. In 1884 it established what was probably the first U.S. state-supported institution granting diplomas to women. The University of Mississippi, in Oxford, was chartered in 1844 and opened in 1848. In addition, the state supports 18 junior colleges, five four-year colleges, three universities, a medical centre, the Gulf Coast Research Laboratory, and the Universities Marine Center.

Health and welfare. Cases of dietary imbalance, hunger, and malnutrition found in Mississippi are associated with an overall cultural, economic, and social picture, as is the rate of infant mortality—the lowest in the state's history in the early 1970s but still nearly 60 percent above the national average. Almost all counties have some form of relief or welfare programs, many of which involve federal funds. In addition, welfare services include aid to the blind and disabled, the elderly, and dependent children. Health programs are administered by several state agencies, including the Board of Health, which dates from 1877. Historically, the state has been in the vanguard of various public health services. The causes of pellagra were discovered in 1915, through experiments at the penal farm. A model mosquito-control program eradicated malaria and yellow fever, and the state tuberculosis sanitorium is recognized nationally. Pioneer work was done and continues in educating blind and deaf children.

CULTURAL LIFE AND INSTITUTIONS

The cultural milieu

Before the Civil War, the "Planter Society" and those who identified with it had a highly developed sense of gentility. The life-style to which they aspired made patronage of the arts obligatory. They built their Georgian mansions and furnished them with art objects and fine furniture; their children were tutored in the social graces and the arts; and hospitality became an art in itself. This rural gentry, however, was only a part of the total society. The small landowner and slave alike fashioned simple, sturdy furniture, made their own oxbows and spinning wheels, or patiently crafted musical instruments. When they rested, they heard folk songs, ballads, or African lullabies. Their literature was myth, legend, and tall tale, and their dances were traditional or improvised.

From these varied sources came the present-day cultural and artistic heritage of Mississippians. In the 20th century, technology, mobility, and mass communication have created an adherence to a homogenized national culture. A freshening sense of history is evident, however, in the efforts to preserve historic landmarks and in the intensity of the collectors of the artifacts and furnishings of the past—of folk songs, implements and utensils, furniture, and manuscripts.

The arts. Mississippi has been a vital part of the flowering of Southern literature during the 20th century. The mythical county of Yoknapatawpha and the generations of its people were created by William Faulkner in a celebrated series of novels. The works of this Nobel Prize-winning Mississippian are often ranked among the highest attainments in American literature. Other natives of international literary renown include novelist Eudora Welty, novelist-critic Stark Young, and playwright Tennessee Williams.

In music, both white and black folk traditions are found: in English and Scottish ballads, and in blues, spirituals, and sacred harp singing (religious hymns or songs sung to the accompaniment of a harp). In the classical vein, the state has eight symphony orchestras, an opera guild in Jackson, and extensive musical activities at several colleges. The theatrical tradition dates from 1800, when a Natchez audience saw the first dramatic production to be presented west of the Alleghenies. Today, more than 20 community theatres and 30 colleges and universities offer dramatic fare, in addition to a semiprofessional company in Jackson.

Communications. Newspapers and broadcasting are and have long been a vigorous and important part of Mississippi's cultural life. Newspapers came on the scene in territorial days, with the appearance of *The Mississippi Gazette* at Natchez in 1799. In the early 1970s there were 19 daily and 114 weekly newspapers in the state. The *Woodville Republican*, founded in 1824, is the oldest paper continuing publication. *The Delta Democrat-Times*, edited and published in Greenville by Hodding Carter, gained national recognition through its liberal editorial policies. The state has more than 102 radio stations and 19 television stations, including the first colour educational television station in the country.

The press

Prospects. On balance, Mississippians are optimistic about the future. They are keenly aware of the state's needs, problems, and potentialities and of how these will affect their ability to retain the finer elements of their heritage and to attain a more prosperous and harmonious future. They are proud, too, of the many positive aspects of life in Mississippi: its clear air and water, its easy access to recreation and open spaces, and its low incidence of crime. In the early 1970s, Mississippi's economy was at its highest level in history, and its racial problems, though far from solved, were being confronted in an atmosphere of generally increasing goodwill.

BIBLIOGRAPHY. HODDING CARTER, *Lower Mississippi* (1942), is an interesting study by a major journalist. The classic definition of the Delta appears in DAVID COHN'S autobiographical *Where I Was Born and Raised* (1948), containing his earlier *God Shakes Creation* (1935). ARTHUR H. DE ROSIER, JR., *Removal of the Choctaw Indians* (1970), is a scholarly contribution. HORACE S. FAULKERSON, *Random Recollections of Early Days in Mississippi* (1885), contains stories from a time when vices and virtues were exaggerated. WILLIAM L. GILES, "Agricultural Revolution in the Delta," *Journal of Mississippi History*, 31:79–88 (1969), is essential for an understanding of contemporary plantation agriculture. LOUISE H. MOREHEAD, *Old Spanish Trail Along the Mississippi Gulf Coast* (1955), provides colourful material, as does W.A. PERCY, *Lanterns on the Levee* (1941). WILLIE MORRIS, *North Toward Home* (1967), is the autobiography of the former editor of *Harper's* magazine; and his *Yazoo: Integration in a Deep-Southern Town* (1971), continues his brilliant reportage. Research and opinion includes MISSISSIPPI STATE COLLEGE, AGRICULTURAL EXPERIMENT STATION, *Mississippi's Counties: Some Social and Economic Aspects*, ed. by WILLIAM A. STACEY, TOMMY W. ROGERS, and CARLTON R. SOLLIE, 3rd ed. (1966); VERNON L. WHARTON, *The Negro in Mississippi, 1865–1890* (1947); and JAMES W. SILVER, *Mississippi: The Closed Society*, new enl. ed. (1966), an unfriendly account by a noted scholar.

(J.N.B.)

Mississippi River

Paramount among North American rivers, the Mississippi combines with its major tributaries to form the world's fifth largest drainage system in area (approximately 1,244,000 square miles, or 3,221,000 square kilometres). As the central river artery of a highly industrialized nation, the Mississippi has become one of the busiest commercial waterways in the world; and as the unruly neighbour of some of the continent's richest farmland it has been subjected to a remarkable degree of man-made control. Furthermore, the river's unique contribution to the history and literature of the United States has woven it like a bright thread through the folklore and national consciousness of North America, linking the names of two U.S. Presidents—Abraham Lincoln and U.S. Grant—with that of the celebrated author Mark Twain. Draining all or part of 31 U.S. states and two Canadian provinces, the outline of the Mississippi system resembles a sturdy tree with two main lateral branches, the Ohio to the east and the Missouri to the west. Only a thin line carries the name of the parent trunk northward to the river's source at Lake Itasca, Minnesota.

Although the Mississippi can be ranked as third longest river in the world by adding the length of the Missouri (2,466 miles or 3,969 kilometres) to the Mississippi downstream of the Missouri–Mississippi confluence, the 2,348-mile (3,779-kilometre) length of the Mississippi proper is comfortably exceeded by at least a dozen other rivers. In volume of discharge, however, the Mississippi's 350,000,000,000 gallons per day is eighth greatest in the world (for further information see NORTH AMERICA).

The character and physical appearance of the Mississippi proper divides into three stages. From the source to the head of navigation at St. Paul, Minnesota, it is a clear, fresh stream winding its unassuming way through low countryside dotted with lakes and marshes. From St. Paul to the mouth of the Missouri it grows into the powerful dominating river immortalized in Mark Twain's *Tom Sawyer* and *Huckleberry Finn*. Flowing past steep limestone bluffs, it is in these reaches, where it gathers in the streams and rivers of Minnesota, Wisconsin, Illinois, and Iowa, that the river assumes the character that led Algonkian-speaking Indians to name it the "Father of Waters" (literally *Misi*, "big"; *Sipi*, "water"). Its union with the Missouri changes the Mississippi completely. The turbulent, flotsam-laden Missouri, especially when in flood, adds impetus as well as enormous quantities of silt to the clearer Mississippi. Beyond the junction with the Ohio at Cairo, Illinois, the Mississippi swells to its full grandeur. Often a mile and a half from bank to bank, it becomes a brown flood, descending with deceptive quiet toward the Gulf of Mexico.

Regional divisions

To geographers, the lower Mississippi has long been a classic example of a river in "old age"; that is, it loops and curls extravagantly along its channel, leaving behind meander scars, cutoffs, oxbow lakes, and swampy backwaters. More poetically, Mark Twain compared its shape to "a long, pliant apple-paring." Today the sunlight glittering on the twisted ribbon of water remains one of the most distinctive landmarks of a transcontinental flight. Now largely curbed by an elaborate system of embankments (levees) and spillways, this lower section of the Mississippi was the golden, sometimes treacherous, highway for the renowned Mississippi steamboats, those "palaces on paddlewheels" that so fired public imagination. From the explosive master pilot Horace Bixby portrayed by Mark Twain, down to the nostalgic lyrics of Oscar Hammerstein's "Ol' Man River," the creations of that era on the Mississippi have added colour to America's heritage.

THE PHYSICAL ENVIRONMENT

The geology and physical geography of the Mississippi drainage area are essentially those of the Interior Lowlands and Great Plains of North America. Fringes also touch upon the Rocky and Appalachian mountains and upon the rim of the Laurentian Shield to the north. The focus of the system, the floodplain of the lower Mississippi, is of particular interest in that the geology and physical geography of the region are of the river's own making. Like a huge funnel, the river has taken silt and debris from contributory areas near the lip of the funnel and deposited much of the product in the alluvial plain of the funnel's spout, illustrating the interdependence of the entire Mississippi system.

The most significant contributory area in recent times has been to the west of the river. Rising in western uplands, notably in the foothills of the Rockies, rivers like the Red, Arkansas, Kansas, Platte, and Missouri remove considerable silt loads from the rolling expanses of the Great Plains. A wide, gently sloping mantle of unconsolidated materials, laid down over rock beds of the Cretaceous Period (100,000,000 years ago), allows for each river to pick up an independent course toward the Father of Waters. Rainfall in these western areas is meagre, usually less than 25 inches a year; but because at least 70 percent of this precipitation falls between April and September, the erosive capability of the rivers is enhanced. The prairie soils, moreover, offer little resistance to erosion, so that the rivers are not only incised and braided in their courses but their silt load is high in relation to their volume. The Red River, for example, takes its name from the distinctive stain given to its waters by the red-brown soils of its upper course.

Contributory areas

The Mississippi's eastern contributory rivers drain the well-watered Appalachian Plateau. Most of this group, including the Kentucky, Green, Cumberland, and Tennessee rivers, flow via well-defined valleys into the Ohio and thence into the Mississippi. The erosive capacity of these rivers varies in relation to the geological structure of their basins. These consist of harder rocks in the higher plateau and a softer sill of limestone of the Carboniferous Period, 300,000,000 years ago, lying below the 1,000-foot line between the Ohio and Tennessee rivers and the glaciated area of the Ohio's right bank tributaries.

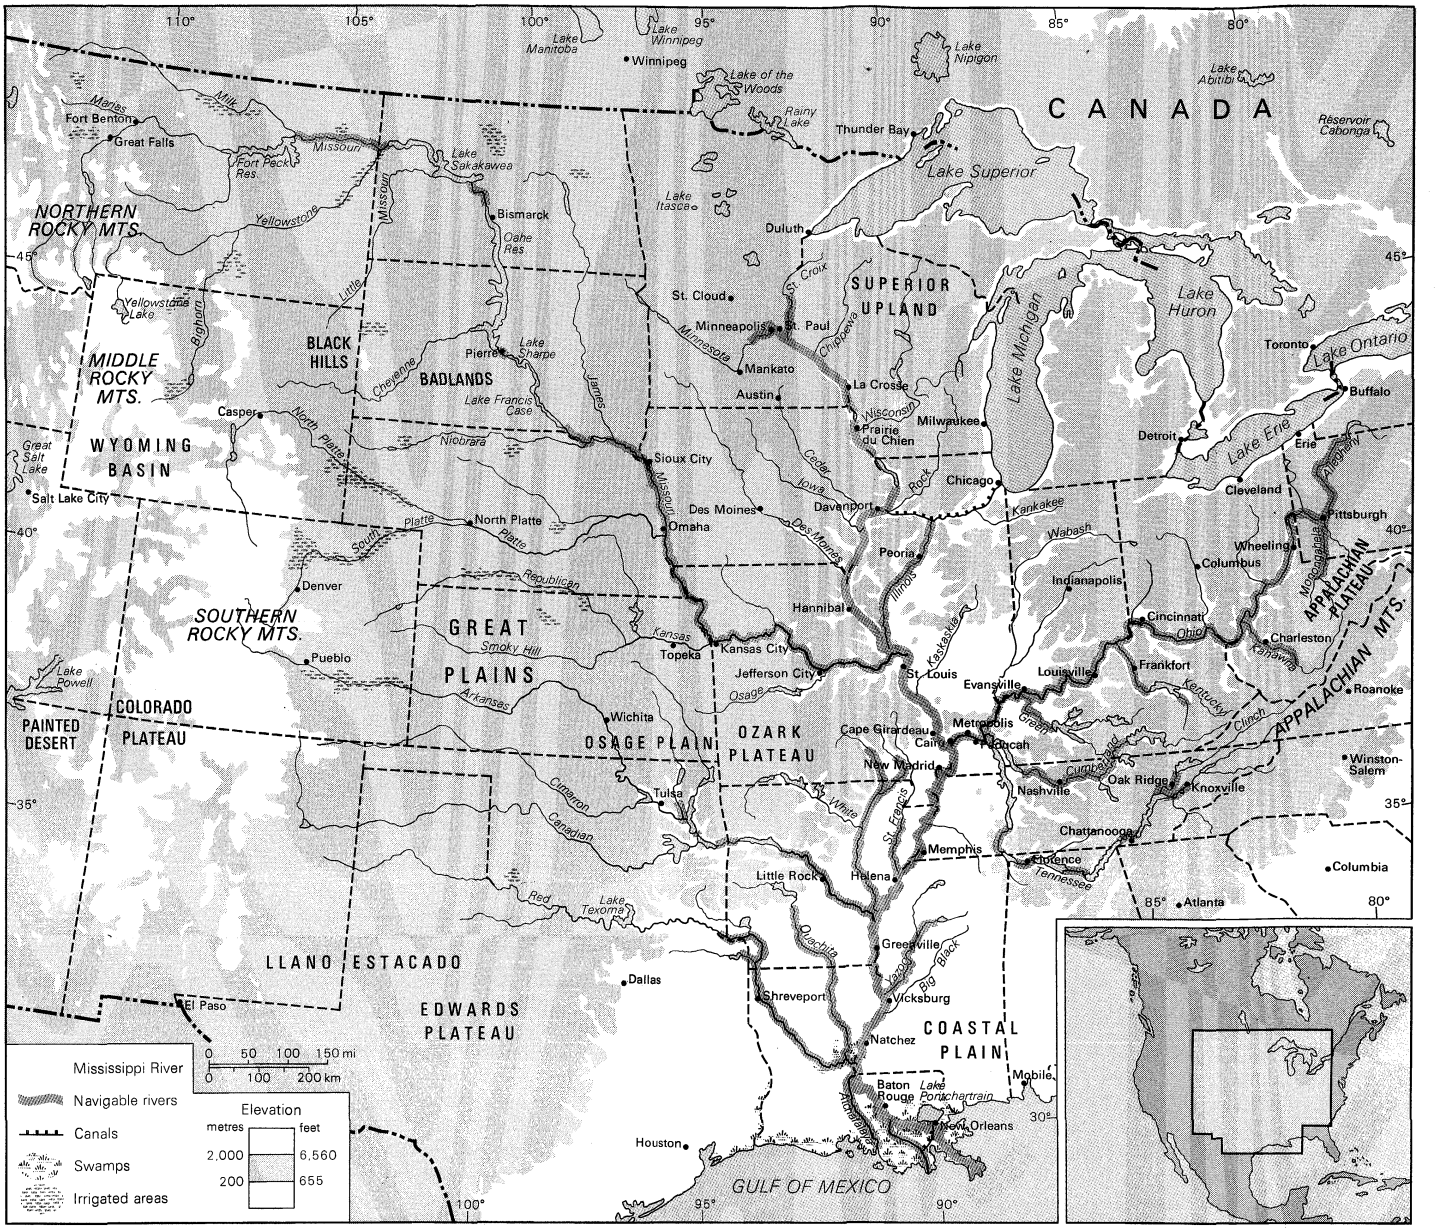
The third contributory area of the Mississippi differs, once again, from the other two. The upper Mississippi gathers its strength in a region marked and scarred by glacial action. After the great ice sheets had put down layers of glacial debris across much of Minnesota, Wisconsin, Illinois, and upper Iowa, huge quantities of meltwater flowed south, washing distinct channels through this debris. Today the upper Mississippi and its tributaries, the Wisconsin, St. Croix, Rock, and Illinois rivers, all trace the lines of these former glacial sluiceways.

Pouring southward the glacial meltwaters were joined by the proto-Missouri and Ohio rivers. The combined flood then gouged out the great north–south trough along which the lower Mississippi now flows. Six hundred miles long, this trough is from 25 to 200 miles wide and bounded by escarpments rising up to 200 feet above the valley floor. Geological studies have revealed that the floor of the glacial trough was later buried by a deep layer of material washed out from the ice sheet, and dumped to a thickness of 100–200 feet in the central section.

The delta

The Mississippi's delta is an even more striking monument to the river's constructive work. Here, at the tip of the drainage funnel, millions of years of sedimentation have spilled out across the floor of the Gulf of Mexico a great cone of sediment 300 miles in radius and 30,000 square miles in area. The surface expression of this cone (slightly to the east of its apex) is the Mississippi's present delta with an area of 10,100 square miles. Stretching into the Gulf the "fingers" of its levee-building distributaries, the Mississippi piles up 495,000,000 tons of sediment each year and inexorably advances its delta shoreline six miles seaward every century.

Understandably, the hydrology of so powerful a river as the Mississippi has been the subject of intense study. In the 19th century, Mark Twain described with considerable wit how the pilots of the Mississippi paddle-wheelers banded together to run a common information service about changing conditions along the channel. Today the Mississippi River Commission is responsible for river work and considers it worthwhile to maintain a working scale-model of the river so that its engineers can test new plans in miniature before embarking on expensive, full-scale projects. Indeed, by the 1920s it was generally held



The Mississippi River Basin and its drainage network.

that enough was known about the river's hydrology and enough control structures had been built to have tamed the river. Then, in 1927, came the most disastrous flood in the recorded history of the lower Mississippi Valley. More than 26,000 square miles of land were flooded. Communications, including roads, rail, and telephone services, were cut in many places. Farms, factories, and whole towns went temporarily under water. In modern values, something like $1,000,000,000 worth of damage was done, and 214 people lost their lives. The river engineers took another look at the hydrology of the Mississippi.

Mean water discharge data

Since the freak conditions of 1927, the mean discharge of water into the lower Mississippi by its major tributaries has been monitored as follows (in cubic feet per second): Arkansas 41,500; Illinois 20,700; Upper Mississippi 92,600; Missouri 70,600; Ohio 259,300; Red 49,300; White 30,200. The mean discharge of the main river past Vicksburg, Mississippi, is calculated at 548,160 cubic feet per second. These statistics, however, conceal all-important variations in river flow linked with the fluctuating state of the Mississippi's larger tributaries.

Broadly speaking, the western tributaries are the most irregular. They reach a spring or early summer peak that is up to three or four times as great as their winter contribution. The upper Mississippi and its tributaries reach their maximum flow about the same time (March–June), when melting snows are followed by early summer rains. The winter runoff from this area is, however, substantial. The crest of the Ohio's flow occurs slightly earlier. At Metropolis, Illinois, just short of the confluence with the Mississippi, the greatest monthly discharge is usually recorded in March, at which time the Ohio may be providing over 60 percent of the water being monitored past Vicksburg in the lower river. From these figures it is clear that the Ohio is chiefly responsible for the lower Mississippi flood situations, which may be aggravated by such factors as early rains in the Great Plains, a sudden hot spell melting the northern snows, and heavy downpours throughout the lower valley. Under such conditions the lower river will rise over its banks and put pressure against the levees. Tributaries will back up and form lakes on the far side of these same levees. The current, which normally runs no more than two to 3½ knots (2½ to four miles per hour), may then double at constricted points along the main channel. Thus the monitoring station at Vicksburg, which, at low water 1936, recorded as little as 93,800 cubic feet per second, measured 2,060,000 cubic feet per second at high water stage the following year, a daily flow of about 1,300,000,000 gallons.

Although the natural vegetation of the Mississippi's immediate valley is the product of climate and soil, rather

than of the river, the Mississippi's swamps and backwaters are ecologically noteworthy. Threaded along the river, from the wild rice marshes of Minnesota to the coastal wetlands of the delta, are pockets of thriving plant–animal associations. Here the abundance of natural cover, the comparative isolation, and the food provided by such plants as sedges, pondweeds, and millets encourages regular colonization by waterfowl. The path of these birds, as they move up and down the river with the seasons, has been called the "Mississippi Flyway," an appropriate name for the vast aerial highway that reaches from the delta to the distant summer nesting grounds in northern Canada. An estimated eight million ducks, geese, and swans winter in the lower part of the flyway, and many more birds use it en route to Latin America. Typical flyway migrants are Canada and lesser snow geese, large numbers of mallard and teal, black duck, widgeon, pintail and ring-necked ducks, and coots.

Ecology

The most important varieties of fish found in the river include several types of catfish (some of which grow to considerable size and are fished commercially by local concerns along the middle and lower river); walleyes and suckers, which thrive in the upper river and provide the basis for a sport fishing industry in Minnesota and Wisconsin; carp; and garfish. Alligators are now rare, being found only in the most isolated backwaters, while the shrimp and crab fisheries of the brackish waters are in decline.

HUMAN GEOGRAPHY

As its respectful Indian name indicates, the Mississippi played an important role in the lives of the aboriginal peoples settled on its banks. To the Indians of the river, the Mississippi was both highway and larder. On it they paddled their cottonwood dugouts and their bark canoes, and from it they took the fish that was a mainstay of their diet. Constant shifts of migration, local or large scale, interwove tribal languages and cultures. By the time the white man arrived, the Sioux who had originally lived on the upper river had withdrawn west to give place to Ojibwa, Winnebago, Fox, and Sauk. Lower down, the Illinois tribe had established prosperous agricultural communities. And in the lower valley itself lived clans of Choctaw, Koroa, Taensa, Chickasaw, Tunica, Yazoo, Pascagoula, Natchez, Biloxi and Alibamu.

The explorer Hernando de Soto, commander of the first white expedition to penetrate to the river, had high hopes of plundering the southern tribes. In May 1541 his Spanish raiding force reached the river at a point near Memphis, Tennessee. But the "Rio Grande," as the Spaniards called it, provided the newcomers with small profit and much grief. The river Indians launched repeated attacks; the Mississippi floods caught the Spanish unawares; and, ironically, de Soto, white discoverer of the river, was buried in its waters, after which the rest of his disappointed expedition retreated to the sea, their homemade boats under a running fire from the Indians.

Early exploration

The next white explorers of the river appeared in 1673 out of French Canada—two canoe loads of voyageurs commanded by Louis Jolliet, a French government agent, and Father Jacques Marquette, a Jesuit priest. Portaging from the Fox River to the Wisconsin, they paddled down the Mississippi as far as the mouth of the St. Francis River in present-day Arkansas. Nine years later the famous French explorer René Robert sieur de la Salle reached the delta itself, having opened up the even easier portage from the Great Lakes via the Illinois River. He grasped at once the strategic significance of the huge drainage system and promptly claimed the entire Mississippi Basin for France. Within a generation the Mississippi was a vital link between France's Gulf settlements and Canada, and La Salle's claim was vaguely designated as "Louisiana."

But France's grasp on the Mississippi was never firm. French traders settled the upper river, establishing towns like St. Louis and Prairie du Chien, whose names survive to this day. But the lower river passed into Spanish hands in 1769; the Treaty of Paris (1783) optimistically declared the river as the western boundary of the United States; and republican France re-acquired the much-bartered stream only long enough to sell it to the United States as part of the Louisiana Purchase (1803). This last move recognized what had been obvious for a quarter of a century—the growing domination of the river by the Americans. They came by raft, flatboat, and ark (a "raft with a rim"), built and loaded on the left bank tributaries that were in the forefront of the westward expansion of the United States. Unwieldy and expendable, these craft floated downstream to leave their cargoes and occupants as advance guards of American political and economic expansion. Only the long, slim keelboats made the return trip. They were worked upcurrent under pole, paddle, sail, or by the back-breaking "cordel," a system under which the crew went ashore with a long bow hawser and pulled the vessel upstream by brute strength.

The torch of exploration also passed to the Americans after the Purchase. In 1805–06 the pioneer expedition of Lieut. Zebulon M. Pike struggled to within 80 miles of the river's source, and in 1832 Henry Schoolcraft, an Indian agent for the U.S. government, identified and named Lake Itasca (Latin *veritas caput*, "true head") as the Mississippi's starting point.

Built in Pittsburgh in 1811, the "New Orleans" was the first steamboat to appear on the river. Like some fearful omen, her maiden voyage coincided with the series of earth tremors known as the New Madrid earthquake, the cause of much flooding and sudden relocation of sections of the main channel. But the "New Orleans" won through, and within a decade her successors had wrought a revolution on the Mississippi. In 1814 only 21 steamboats called at New Orleans, whereas 191 arrived during 1819, and 14 years later more than 1,200 cargoes were unloaded in the year. As the freight rate by steamer between Cincinnati and New Orleans plummetted from nine cents a pound to less than half a cent, it became cheaper to send freight to the east coast via the Mississippi and the long sea passage than to send it a tenth the distance over the Appalachians.

The coming of the steamboats

With the introduction of larger, high-pressure engines and more streamlined hulls, the steamboats extended their range, and the Mississippi became economic overlord to half the country. In 1820 the "Western Engineer" probed up the Missouri. In 1823, the "Virginia" churned her way up to Fort Snelling at the junction of the Mississippi with the Minnesota River. The steamboats brought an era of unprecedented prosperity to the river. Town after town grew up, dependent on the regular arrival of packet boats bringing mail and passengers or freight boats that took on local produce and left off manufactured goods. Riverbank plantations maintained their own landings so they could ship crops direct, and riverside towns vied with one another to provide services such as fuelling and warehousing. The waterfront at New Orleans, with its double line of twin-stacked steamers mingled with ocean-going ships, was among the busiest in the nation.

Then came the Civil War and, at once, a sharp struggle for control of this vital waterway, a struggle culminating in Grant's siege of Vicksburg helped by the fortified gunboats and armoured steamers of the Union. When Vicksburg and the river fell into northern hands, the South was dealt a heavy commercial and strategic blow. Lincoln, who himself had been a Mississippi flatboat man, could report "the Father of Waters flows unvexed to the sea."

The years immediately after the Civil War saw a brief but glorious revival in river traffic. New and faster steamboats were built and operated, often in rivalry to one another, a rivalry made famous by the three-day race, commencing June 30, 1870, between the "Natchez" and the "Robert E. Lee." The latter won by dint of stripping out all her unnecessary superstructure and taking on her extra fuel supplies from tenders while steaming at full speed upriver. Yet even as the river was at its most flamboyant, the same westward expansion that had brought its development now passed it over. With the construction of east–west railroads and canals, the Mississippi's north–south alignment came to be regarded as a nuisance. Towns that had once sought to be staging posts up and down the river now competed to become crossing

points. Commercial traffic dwindled, and the grand luxury paddle-wheelers gave way to sombre, more prosaic towboats with blocks of barges.

World War I produced a major resurgence in river trade. As other lines of transport became congested, the river was recognized as an increasingly valuable asset. With federal initiative, new barge lines were organized, and by 1931 the annual barge traffic moving along the river was twice the volume moved in any single year during the previous century. In 1917, for instance, the steamer "Sprague" established a new world record for size of tow. Her raft of 60 coal barges weighed 67,307 tons and covered an area of 6.5 acres.

"Sprague's" record is unlikely to be matched by any other paddle-wheeler, for the remaining steamboats are mostly showpiece examples, and the modern Mississippi towboat is of radically different design from her forebears. Screw-driven and diesel-engined, the modern towboat is made fast to the stern of her tow. Ahead stretches a rigid platform of barges as much as 1,500 feet long and with a designed draft of nine feet. Most barges are built for specific cargoes. If for dry cargo, they average 1,500 tons capacity and measure 195 feet long by 35 feet wide; for liquid cargo the proportions are about 2,500 tons capacity and 295 feet by 50 feet. To aid navigation, the towboat captain has at his disposal electronic depth finders, radar, contraguide rudders, a sophisticated system of river bank lights and markers, and radio telephone to warn other river users of his approach in narrow passages. Among the most recent cargoes to be carried along the river in this fashion are the booster rockets for space research, which are so bulky as to be unsuitable for any other mode of transport.

Responsibility for overseeing the maintenance and improvement of the Mississippi as a commercial waterway, as well as the related tasks of flood control and bank protection, falls upon the Mississippi River Commission. Created by act of Congress in 1879, the commission has supervised a massive program of river work that has profoundly reshaped the character of the Mississippi. The main stages of the navigation improvement program include a channel nine feet deep and 250 feet wide at low water between Cairo and Head of Passes (Gulf) authorized in 1896; a widening of this channel to 300 feet, approved in 1928; and its deepening to 12 feet put in hand in 1944 and still under way. Farther upriver, the outstanding achievement has been the construction of 26 locks and dams on the upper river to take the nine-foot channel up to Minneapolis-St. Paul. Connecting into the Mississippi is a vast complex of related waterways—from the Intracoastal Waterway in the south stretching between Florida and the Mexican border, to the nine-foot channels that lead up the Ohio to its tributaries and through the Illinois waterway to the Great Lakes and St. Lawrence Seaway.

Commercial use of the Mississippi waterway has shown sturdy growth. By the early 1970s traffic on the river between Minneapolis and the Gulf exceeded 230,000,000 tons a year, a 65 percent increase over the totals for a decade earlier. Between Baton Rouge and New Orleans it increased 153 percent to over 120,000,000 tons annually. Leading cargoes, by bulk, were petroleum and products, coal and coke, iron and steel, chemicals, sand and gravel, and sulfur. An increasing emphasis on bulk handling has inevitably meant the rapid growth of a few key port cities at the expense of their rivals. The chief winners in this changing relationship between river and population, with a comparison of tonnages, are given in the Table.

Commercial Tonnages Transported

	1959	1969
Minneapolis	849,865	1,687,949
St. Paul	3,592,913	4,474,863
St. Louis	9,254,125	10,463,032
Helena (Ark.)	1,970,158	2,087,259
Greenville (Miss.)	1,380,787	1,563,750
Vicksburg (Miss.)	881,120	1,569,311
Baton Rouge (La.)	25,672,105	40,845,124
New Orleans	50,441,941	113,426,557

Flood control

Flood control along the river dates back to the foundation of New Orleans by the French, who built a small levee to shelter their infant city. Over the next 200 years a complex array of riverbank structures was erected along the river to contain or divert floods. But it was not until after the catastrophic flood of 1927 that the federal government became committed to a definite program of flood control. Today the target is an integrated flood-control system able to master "project flood," the largest theoretical flood expected along the river. This program has altered the face of the river even more than the navigation program, with which it is linked, has altered its bed.

In principle, the Mississippi's floods are either constricted by levees, hastened out of danger zones by floodways and improved channels, dissipated down spillways and into reservoirs, or starved by the impounding of tributary floods. From Cape Girardeau to the sea, the river is virtually "walled in" by a vast line of main stem levees, now 1,870 miles long and planned to extend 2,192 miles. This stern concrete barrier has, incidentally, isolated the river from much of the surrounding countryside and many former riverbank towns are severed from their natural setting. In the event that the main levees are threatened, the excess floodwater drains away down spillways (*e.g.*, from north of New Orleans it is diverted past the city by spillways leading directly to the Gulf) or it bursts "fuse plugs," the specially weakened sections of levee leading to harmless floodways or reservoirs. A major example of this type of floodway occurs at New Madrid, just south of the Ohio confluence. Elsewhere, a massive program of bank strengthening using mattresses of concrete blocks has reduced lateral erosion and increased channel stability. The careful positioning of underwater dikes to deflect the current, the cutting through of oxbow bends at their necks, and a continuous dredging schedule have all helped to reduce flood levels. Tested by excessive high water stages in 1945 and 1950, the Mississippi flood-control system has noticeably reduced the risk of inundation.

PROBLEMS AND PROSPECTS

The Mississippi flood-control program is not without its lessons for the future. It has been increasingly necessary, now that the river is caught behind the main stem levees, to attend to the isolated tributaries. In some cases costly pumping stations must be installed to lift the impounded water over the levees and into the main river. More dramatic was the penalty for using the Atchafalaya River as a convenient spillway for floods on the lower river. The Mississippi threatened to divert permanently into this secondary channel, inundating the lower Atchafalaya, bypassing New Orleans, and rendering millions of dollars worth of flood-control works useless. Only at the cost of a vast and complex lock and barrage system has the danger been averted. For the future it is evident that now the Mississippi's delicate hydrology has been disturbed, the program of river work must continue for many years to come, readjusting the interplay of waters. Similarly, it is clear that no single stretch of the commercial waterway can be neglected in favour of other sections. Traffic will use the river only if the entire system is open to a common draft, and with the increasing trend to bulk transport the demands on the waterway are liable to increase.

The same situation applies to the problem of river pollution. Water samples at New Orleans show a relatively high dissolved oxygen content, mostly in the 6.0–10.0-milligrams-per-litre range, and low biochemical oxygen demand; so, by these traditional indices, the river cannot be considered polluted to any great extent. Moreover, federal water-pollution-control legislation should prevent further degradation of the water quality. On the other hand, it remains to be seen whether the current standards will be acceptable either to recreational users of the river in the future or to industries that must inevitably turn to the Mississippi as one of the nation's largest reserves of freshwater.

BIBLIOGRAPHY. MISSISSIPPI RIVER COMMISSION, *Mississippi River Navigation* (annual), a brief history, with emphasis on the development of navigation, commerce, federal par-

ticipation in waterways development, navigational details for part-time pilots, and a bibliography of charts and film material available, and *Flood Control in the Lower Mississippi Valley* (annual), information on flood-control plans, drainage statistics, and a summary of legislation on the Mississippi River and Tributaries Project; W.D. THORNBURY, *Regional Geomorphology of the United States* (1965), general data on the geology and geomorphology of the Mississippi system, with particular reference to the lower valley and marine delta formation; MARK TWAIN, *Life on the Mississippi* (1883), a classic humorous account of river conditions and of the life of a river pilot in the mid-19th century that is invaluable for background detail to the river's history; TIMOTHY SEVERIN, *Explorers of the Mississippi* (1967), a popular history of the exploration of the river.

(G.T.Se.)

Missouri

Located near the geographical centre of the conterminous United States, Missouri is the meeting place of the timberlands of the East and the prairies of the West, of the cotton fields of the South and the cornfields of the North. It has represented the political and social sentiments of a border state since its admission as the 24th member of the Union in 1821. The question of its admission as a slave or free state produced in Congress the Missouri Compromise (1820), regulating the spread of slavery in America's western territories.

Missouri was the westernmost state of the nation until the admission of Texas in 1845, and for decades it served as the eastern terminus of the Santa Fe and Oregon trails, over which tens of thousands of explorers and settlers plunged deeper into the frontier. For the West, St. Louis, Missouri's largest city, long was its closest contact with the more settled society and the culture of the East, and for the East the state had a reputation as the chief gateway to the West.

The Missouri River cuts across the state from Kansas City in the west, through Jefferson City (the state capital) in the centre, to just above St. Louis in the east, where the river joins the Mississippi. With the exception of Tennessee, Missouri has more neighbouring states than any other American state. To the north lies Iowa; across the Mississippi River to the east, Illinois, Kentucky, and Tennessee; to the south, Arkansas; and to the west, Oklahoma, Kansas, and Nebraska. According to the census of 1970, there were more than 4,600,000 Missourians inhabiting the state's 69,686 square miles (180,487 square kilometres), more than 60 percent of them living either in St. Louis or Kansas City and their surrounding counties and about another 10 percent in smaller urban areas.

Comparisons with neighbouring states

Among its neighbouring states, Missouri ranks second only to Illinois in its degree of urbanization and its amount of industrial and economic activity, though it maintains a vigorous and diversified agriculture and, in its rugged Ozark Plateau, a scenic beauty and many lively folk traditions. Missouri retains numerous conservative characteristics of the rural life that predominated prior to the 1930s. In Missouri, as in the southern states, the Democratic Party does not necessarily represent more liberal political philosophies than the Republicans. As in such other border states as Kentucky and Tennessee, Republicans have begun to make sharp inroads into the traditional Democratic orientation. Continuing low tax bases prevent the elaboration of social services, a problem felt most acutely in the two major cities, which have experienced an increasing loss of wealth to the suburbs, coincident with greatly expanding needs within the city itself. (For information on related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; NORTH AMERICA; and MISSISSIPPI RIVER.)

THE HISTORY OF MISSOURI

Before the coming of white explorers, and for long thereafter, the land that was to become Missouri was the home of a diverse group of Indian tribes whose mounds and other remains dot the state. One of the tribes was called the Missouris.

Exploration and settlement. The recorded history of the region dates from the settlement of some French lead miners and hunters from Kaskaskia in the Illinois country at Ste. Genevieve, on the western bank of the Mississippi around 1735. At some distance from its original site, Ste. Genevieve remains the oldest continuously inhabited white settlement in Missouri. Some 30 years later, Pierre Laclede, a French fur trader from New Orleans, founded St. Louis. At the time of the Louisiana Purchase in 1803, most of the 10,000 settlers were Frenchmen from the Illinois country, but some Americans had come in from Kentucky and Tennessee, which, with Virginia, were the major immediate sources of settlers in following decades.

Statehood and growth. The "pull of the West" solidified Missouri's position as a land of passage after it achieved statehood as a slave state in 1821. Migrants bound for Texas outfitted in Missouri, and later, thousands poured through Saint Joseph, Independence, Westport Landing, and the City of Kansas (Kansas City) bound for Oregon or for California gold.

Role in the Civil War

The 1850s were years of increasing dissension, worsened by the Kansas-Nebraska Act of 1854 that set slave- and free-state advocates at one another's throats for control of those adjoining territories. Border skirmishes with Kansas became commonplace. Missouri already was moving toward a free-state economy, however, and a wave of immigrants from the northeast and from Europe in the 1850s was influential in keeping the state within the Union during the Civil War. Missourians in the Union Army outnumbered those in the Confederate Army by nearly four to one. Considerable conflict occurred in the state, much of it guerrilla warfare along the Kansas border. After the war, Confederate sympathizers were dealt with harshly; overall, however, Reconstruction was not as severe as in states in the Deep South.

The continued growth of Missouri in the late 19th and early 20th centuries was celebrated in the famous St. Louis Exposition in 1904. The state remained heavily rural and agricultural until the Great Depression of the 1930s and World War II brought about vast movements of people from the land to the cities.

THE NATURAL AND HUMAN LANDSCAPE

The natural environment. *Physiographic regions.* North of the Missouri River, Missouri's landscape is characterized by gently rolling hills; open, fertile plains; and well-watered prairie country. South of the Missouri, except in the extreme southeastern corner of the state and along the western boundary, the land is rough and hilly, with some deep, narrow valleys and clear, swift streams. This is a region abounding with caves and extraordinarily large natural springs. Much of the land is 1,000 to 1,400 feet (300 to 425 metres) above sea level. Near the western border, however, the elevation rarely exceeds 700 to 800 feet, and southeastern Missouri is a part of the alluvial plain of the Mississippi, less than 500 feet.

Soils and waters. Drainage and soil conditions permit farming in all of Missouri's counties, though thin soils make the Ozark Plateau a subsistence-farming region. Northern Missouri is generally well drained, much of it covered by rich soils. The alluvial soils in the bottomlands along the many rivers and streams, which some soil experts believe to be the most extensive in the nation, also add to the farming potentiality. Except for the rivers that flow southeasterly into the Mississippi, many through Arkansas, the Missouri drains most of the state. Missouri's many lakes have been created by damming rivers and streams. The Lake of the Ozarks is a large artificial lake, with an area of 65,000 acres (26,000 hectares) and a shoreline of 1,672 miles. Most have been built to furnish hydroelectric power and to prevent flooding, but they provide Missouri with excellent recreational resources. Many natural springs, some of them among the largest in the world, have a daily flow in excess of 1,000,000 gallons (about 4,000,000 litres) each.

Climate. Missouri's midcontinental location makes it susceptible to the influences of cold Canadian air; of warm, moist air from the Gulf of Mexico; and of drier air from the southwest. Though winds are variable throughout the year, summer winds generally blow from the south and southwest, whereas winter winds come from

the north and northwest. Rainfall, usually sufficient for crops, varies from around 35 inches (890 millimetres) in the north and northwest to 45 or more inches in the extreme southeast. About one-third of it falls in April, May, and June. Heavy snows are unusual, most often occurring in February and March. While Missouri does not have as many tornadoes as Oklahoma and Kansas, it does lie in "Tornado Alley," the zone of maximum occurrence, and experiences an average of 27 tornadoes annually. Maximum January temperatures range from about 35° F (2° C) in the north and northwest to 48° F (9° C) in the southeast. The extreme northwest usually experiences cooler summers than the southeast, but summer temperatures well above 100° F (38° C) may occur in any part of Missouri.

Vegetation and animal life. Originally, about two-thirds of Missouri was forested, and the remainder was covered with prairie grasses. The river bluffs and canyons of the Ozark Plateau offered, as they still do, a wide variety of unusual plants. Fameflower, royal catchfly, Trelease's larkspur, coneflower, gayfeather, and fringed poppy mallow are limited in their normal distribution to the Ozark Ridge. Trelease's larkspur and the coneflower are found only in Missouri. Elk, deer, bison, and bear once were plentiful, as were such smaller animals as beaver, otter, and mink. After settlement and the development of agriculture, most of the larger animals, with the exception of deer, disappeared, and the animals valuable for their fur were trapped out of existence.

Human settlement and exploitation. Missouri's traditional regions reflect accidents of geography, topography, and economic pursuits, or of the ethnic origin or religious or political persuasion of their inhabitants. The "Bootheel" in the extreme southeast was settled by planters from the South and was appended to Missouri at the time of statehood through the great influence of one planter; it remains today as the centre of Missouri's cotton culture, which is now declining due to cotton disease and is being replaced by the cultivation of soybeans and sweet corn. The Ozark Mountains, whose rugged terrain is unsuited to extensive agriculture and which lack roads and railroads, historically have been among the poorer regions of Missouri. Today the Ozarks constitute one of the great tourist attractions of the state. "Little Dixie" is a block of counties that lies generally north of the Missouri River and extends westward along its banks to the middle of the state. It was initially settled by persons sympathetic to the South, to slavery, and to Democratic politics. Some of the finest examples of antebellum residences are found here. South of Little Dixie, on the bluffs and uplands south of the Missouri River and west of St. Louis, is a concentration of German settlements, known traditionally as the "Missouri Rhineland." In the western part of the state, north and east of the Missouri River, is "Mormon Country." There, followers of Joseph Smith settled around 1831, first at Independence and subsequently in other counties, until they were driven out by hostile neighbours. In the centre of the state, around Boonville, Franklin, and Columbia, is the "Boone's Lick Country," where the frontiersman Daniel Boone and his sons moved from Kentucky to make salt.

The "Bootheel," the Ozarks, and other regions

Human settlement has altered Missouri's landscape significantly. Only one-third of the state remains forested, mostly on the hills and slopes of the Ozarks. Nearly all of the prairie land has been brought under cultivation. The damming of streams has produced numerous lakes and reservoirs, and in the southeast, drainage systems have converted former swamps into one of the state's richest agricultural regions. Traditionally, agriculture has been characterized by family-owned farms, but, as elsewhere in the nation, the number of farms has been decreasing for decades, while acreage and productivity have been increasing. Urbanization also has eaten into the amount of land available for agriculture. Although urban settlements are scattered throughout the state, Kansas City and St. Louis are Missouri's important centres of commerce and manufacturing and the nuclei of large metropolitan areas that extend into Kansas on the west and Illinois on the east.

THE PEOPLE OF MISSOURI

Ethnic and religious groups. After the early French settlers, immigration came largely from states to the east and northeast, as well as from the South, with the implantation of its type of economy and society in the Bootheel and in Little Dixie. The first immigrants from abroad—particularly Germans, Irish, and English—came in great numbers after 1820. By 1860, large groups of Germans had settled in St. Louis and immediately to the west, while many Irish had settled in the city. Between 1860 and 1870 the immigration from Ohio, Illinois, and Indiana exceeded that from the Upper South, while an increasing number of immigrants from Germany arrived, most of them settling in urban centres. Subsequently, both St. Louis and Kansas City attracted sizable colonies of Italians and Greeks as well as Poles and Jews.

Patterns of immigration

During the middle of the 20th century, Missouri has been affected by the northward migration of many Negroes from the rural South. From 1940 to 1960, the white population increased by 11 percent, whereas the nonwhite population increased 62 percent. By 1970, Negroes made up nearly 11 percent of the state's total population; but in St. Louis and Kansas City they comprised 41 and 22 percent, respectively. This growth has had enormous consequences, as it has had for urban centres throughout the nation.

It is not unusual that a crossroad state should exhibit great religious diversity. The Roman Catholic Church, dominant until the Louisiana Purchase, remains powerful, particularly in the two major cities. After 1803, the chief Protestant denominations as well as many smaller sects established themselves. Jewish communities have flourishing congregations in the larger cities.

Demography. Population density varies enormously, from around 10,000 per square mile in St. Louis proper to seven in Shannon County in the Ozarks. Slightly more than 70 percent of the Missourians live in urban areas. The birth rate for Missouri in 1970 was 18.0 per 1,000, as compared with the national rate of 18.2. Missouri's death rate stood at 11.3, as compared with a national rate of 9.4.

Though the trend of population movement from rural to urban areas undoubtedly will continue, the 1970 census revealed that St. Louis is losing population to its suburbs, and that Kansas City's modest gain is probably attributable to its large land area, the sixth-largest of any city in the nation. The older sections of both cities are losing population. Though Missouri has grown modestly over past decades, it nevertheless has been a population-exporting state, a pattern more characteristic of heavily rural or economically less developed states. Nothing in the present economic, political, and social conditions in Missouri suggests that this exodus of young Missourians will soon be reversed. The proportion of older inhabitants among the population will probably continue to rise, perhaps producing a simultaneous rise in conservatism and need for social services.

THE STATE'S ECONOMY

Although agriculture has remained important as an income-producing activity, manufacturing has forged ahead since World War II. Missouri has become the commercial and industrial leader among all its adjacent states, except Illinois. In some types of manufacture, particularly in the production of aerospace and transportation equipment—including automobile assembly—Missouri ranks second in the nation. Kansas City and St. Louis have always been important trading and commercial centres for large regions reaching into neighbouring states. They rank among the foremost grain and cattle markets of the nation.

Economic resources. The state's variety of resources includes lead and iron ore, limestone, timber, animal hides, vegetable fibres, hydroelectric power, natural transportation routes, and labour in abundance. Its chief sources of income are, in order, manufacturing, agriculture, and tourism. Manufacturing is led by the production of aerospace and transportation equipment, followed by the processing of food and kindred products and the

production of chemicals. Agricultural production is valued at over $1,000,000,000 annually, and tourism produces income in the millions of dollars.

Minerals

Mineral-rich Missouri leads the nation in lead production, and continuing new discoveries of lead, as well as iron ores, assure this position. About two-thirds of the forest stand lies in the Ozarks, and since the 1950s industry has made increasing use of these resources. The acreage of many marginal farms in the Ozarks is being given over to tourism, one benefit of which is their return to forest.

Finance and planning. Missouri ranks among the top ten states in banking and financial institutions of all kinds. Federal reserve banks are located in both St. Louis and Kansas City, and the Internal Revenue Service offices in Kansas City serve much of the Middle West.

Workers in Missouri have enjoyed the benefits of an expanding economy, and per capita income has kept pace with national averages. Unions have had great influence in increasing the salaries of teachers and clerical workers as well as those of workers in the trades and crafts. In spite of favourable comparisons with other states in income and revenue, Missouri has consistently ranked near the bottom in terms of state tax revenue per $1,000 of per capita income. As a result, it has suffered even more than many other states from a lack of sufficient tax revenue to meet the critical needs and services that modern governmental agencies are expected to provide.

A state Department of Business and Administration includes several divisions and commissions that have had a significant influence upon the state's economic development. Many industries have located new plants in Missouri, creating thousands of new jobs. Local chambers of commerce and private financial groups also have stimulated the state's economic growth.

Transportation. Though even the most remote towns and villages are not far from modern, hard-surfaced highways, the major flows of traffic within the state are from east to west along the Missouri Valley and southward along the Mississippi. Missouri has more than 30,000 miles of state-controlled highways and is served by seven interstate highways. Its some 7,000 miles of railroads link up with most of the nation's major trunk lines. St. Louis, Kansas City, and Jefferson City are served by Amtrak passenger service. The Mississippi and Missouri rivers, providing 1,000 miles of navigable waterways within the state, connect waterborne traffic with New Orleans. St. Louis is served by 14 airlines, Kansas City by eight. Public mass-transit facilities, however, have continued to decline in the face of the private automobile, further contributing to the decline of the city cores.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. Missouri is governed under its fourth constitution, ratified in 1945, but the basic structure of government has remained constant since the first constitution of 1820. The governor, elected for a four-year term and able to succeed himself, has the unusual power of "item veto," by which he may strike individual provisions from any appropriation bill, except those for public school support. He thus exercises enormous control over fiscal affairs. In the General Assembly, each senator represents equivalent population units, whereas each county has one representative, regardless of its population. In the early 1960s, voters in 42 rural counties had as many representatives as nearly ten times the number of citizens living in St. Louis, St. Louis County, and Kansas City and surrounding Jackson County. Missouri has yet to come forward with an acceptable plan for redistribution to meet the 1965 order of the U.S. Supreme Court for equality of representation.

The judicial system is similar to that of most other states, with a supreme court as the highest tribunal. Below it are three courts of appeals, 42 circuit courts, and a probate court in each county. An unusual feature of Missouri's judicial system is a method of selecting judges by merit. Known as the Missouri Plan, it virtually eliminates partisan political considerations, and it has been adopted by several other states. Under this plan, the governor fills a vacancy in the court by appointing one of a three-man panel selected by a nonpartisan judicial commission. When the appointee's term is about to expire, his name must appear on the next election ballot to be voted on. To remain a judge, he must first be appointed and then elected.

The city and the county are the most important units of local government. The state has 114 counties plus the city of St. Louis, which is independent of surrounding St. Louis County. Counties are administered by a county court of three elected judges, who have no judicial authority but are responsible for administering county affairs. Counties with a population of more than 85,000 may adopt their own charters. In the early 1970s, St. Louis and Jackson counties were the only home-rule counties. Missouri, the first state in the nation to permit cities to adopt their own governing charters, today has several cities with home-rule charters.

In common with other border states, Missouri usually votes Democratic, but in the 1940s the Republicans elected governors and returned Republican majorities to the General Assembly on a number of occasions. Both parties contain factions espousing liberal and conservative approaches to social and economic questions. The Democratic Party is somewhat stronger in the two large metropolitan centres, but the Republicans have considerable strength there as well.

Social conditions. In spite of its high degree of urbanization and its relatively high economic ranking, Missouri retains a strong conservative bent that is nowhere so evident as in its handling of social issues.

Conservatism in social issues

Missouri retained discrimination against Negroes long after World War II. In 1957, however, the General Assembly established the Commission on Human Rights; and in 1961 it enacted the Fair Employment Practices Act, which made discrimination on racial or religious grounds unlawful in firms employing 50 persons or more. Four years later it passed a public accommodations law, forbidding any business offering goods or services to the general public from practicing discrimination based on "race, color, creed, sex or ancestry." While some discrimination still exists, particularly in housing, Missourians generally have shown a willingness to conform to these laws. Blacks have become increasingly conscious of their rights, and in major cities there have been numerous minor confrontations and occasional serious riots. Kansas City was the scene of a serious disturbance in April, 1968. Fortunately, these disturbances have not reached the magnitude of similar outbreaks in other large cities.

Education. Since 1945, many small school districts have consolidated into fewer large ones, and school enrollments and revenues have increased. Despite the growth, however, Missouri has lagged behind other states in support of public education. In 1970, Missouri ranked 33rd nationally with respect to expenditure per pupil. After 1954, schools were desegregated rather smoothly, except in the Bootheel region, where the process lagged.

Higher education has expanded both in the public and private institutions. The University of Missouri has campuses in Kansas City, St. Louis, and Rolla, in addition to the main and oldest campus in Columbia. There are also seven state colleges plus Lincoln University, founded originally for Negroes but now enrolling whites. Among the more than 20 private institutions are Washington University and Jesuit-run St. Louis University, both nationally recognized universities in or near St. Louis. Financial support of higher education consistently has been less than its needs.

Health, welfare, and living standards. The state Department of Public Health and Welfare provides for the ill and the indigent, especially in mental-health services. Progress in the latter slowed in the early 1970s, however, because of revenue problems. In cooperation with federal agencies, St. Louis and Kansas City have undertaken massive urban-renewal programs to help relieve the problems of inner-city blight and congestion.

Though costs of living have risen, especially in the larger population centres, per capita income also has risen. Pockets of poverty exist in depressed rural areas and

in city slums, but Missouri generally has not experienced the severe poverty of states with more heavy industrialization or a greater amount of subsistence farming. The disparities between rich and poor are greatest in and around St. Louis and Kansas City. Missouri has five Standard Metropolitan Statistical Areas: St. Louis, Kansas City, Springfield, St. Joseph, and Columbia. Because those of St. Louis and Kansas City cut across state lines, their problems of metropolitan government and management are compounded.

CULTURAL LIFE AND INSTITUTIONS

The cultural milieu. Diversity characterizes Missouri's cultural milieu, from the centres of fine art, music, and theatre along the St. Louis–Kansas City axis to the folk culture and native crafts of the Ozarks.

The state has furthered cultural opportunities through the Missouri State Library, established in 1946, and the Missouri State Council on the Arts, created in 1965, the second such body in the nation established with legislative support. The state library has been responsible for the rapid growth of county and regional libraries. The larger cities have their own library systems. The council on the arts has stimulated communities to expand their cultural resources.

The arts. From the state's beginnings, the arts have flourished in Missouri. In painting, George Caleb Bingham and Thomas Hart Benton have been pre-eminent. Samuel Langhorne Clemens, known as Mark Twain, remains Missouri's most distinguished literary figure, both for his world-renowned works and for his immortalization of mid-19th-century life in Hannibal and along the rivers. Schools of art and design exist in St. Louis and Kansas City, and music flourishes in both. St. Louis' Gateway Arch, designed by Eero Saarinen, is the most spectacular of the diverse architectural styles in evidence throughout the state.

Folk traditions and crafts

The Ozarks abound in folk traditions, tales, and ballads. The growth of tourism there has generated a revival of culture and native crafts. The Ozark Ridge was settled primarily by pioneers from the southern Appalachians, who brought with them traditional songs and ballads, some of which had been brought over from England and Scotland in the 17th century. Native crafts once practiced out of necessity by the pioneers have begun to flourish again in recent years in response to the interest of tourists and also because of recognition of the intrinsic merit of the objects made. Weaving, basketmaking, and pottery are among some of the most important crafts, and their development is encouraged through the Missouri Federation of Arts and Crafts.

Cultural institutions. Besides its universities and colleges, Missouri has outstanding cultural institutions, among them the St. Louis Symphony Orchestra, the second-oldest and one of the major musical ensembles in the nation. In Kansas City, the William Rockhill Nelson Gallery and Atkins Museum of Fine Arts owns one of the finest collections of Oriental art in the Western Hemisphere, and the Linda Hall Library of science and technology has an outstanding scientific collection. Independence is the home of the Harry S. Truman Library and Museum. Fulton, where the British leader Winston Churchill made his famous "Iron Curtain" speech, has a collection of Churchilliana in the St. Mary Aldermanbury Church, whose stones were reassembled there after its destruction in the World War II bombings of London.

Recreation. Kansas City and St. Louis are the homes of major-league baseball and football, along with other professional sports. Increased leisure time and increased mobility have stimulated an enormous interest in recreation in Missouri. The State has developed a superb system of state parks and historic shrines and memorials, which are attractive to residents and visitors alike. Numerous manmade lakes afford fishing and water skiing, while the clear cool rivers of the Ozark Plateau offer pleasure to canoeists, fishermen, and campers.

Press and broadcasting. The Missouri Press Association, established in 1867, has had an important effect upon the development of the press in the United States. It was responsible for establishing, at the University of Missouri, the world's first school of journalism and for founding the Missouri State Historical Society, with the largest membership in the nation. In addition to numerous local newspapers and journals, Missouri publishes newspapers of national distinction, including the *St. Louis Post-Dispatch*, made famous by Joseph Pulitzer, and the *Kansas City Star* and *Times*. There are more than 160 commercial radio stations and 24 television outlets, both commercial and educational.

Prospects. Since the end of World War II, social and economic conditions have been transformed by the forces associated with the technological revolution. Manufacturing has supplanted agriculture as the chief income-producing activity, population has become concentrated in urban areas, and important advances have been made in education, health, and welfare. In spite of this progress, in the early 1970s Missouri had lost some of its forward momentum, and its rate of growth was falling behind states of similar wealth and resources. One of the most critical problems is the conservatism of Missourians, who tend to dislike large legislative appropriations and tax increases to support their institutions. Reflecting the same conservatism is the steady refusal to call for a new constitution, more adequate to present conditions. Unless rapid changes come about, many observers believe that the future may see retreat rather than advance in Missouri's progress.

Mithradates VI Eupator

Mithradates VI Eupator, called the Great, ruled from 120 to 63 BC over the kingdom of Pontus, one of the small, superficially Hellenized states that grew up in Anatolia in the wake of the conquests of Alexander I the Great. Under Mithradates VI's energetic leadership, Pontus expanded to absorb several of its small neighbours and, for a brief while, contested Rome's hegemony in Asia Minor.

Mithradates the Great was the sixth—and last—Pontic ruler by that name. Mithradates (often misspelled Mithridates and meaning "gift of [the god] Mithra") was a common name among Anatolian rulers of the age. When Mithradates VI succeeded his father, Mithradates Euergetes, in 120 BC, he was then only a boy, and for a few years his mother ruled in his place. About 115 BC, she was deposed and thrown into prison by her son, who thereafter ruled alone. Mithradates began his long career of conquest by dispatching successful expeditions to the Crimea and to Colchis (on the eastern shore of the Black Sea). Both districts were added to the Pontic kingdom. To the Greeks of the Tauric Chersonese and the Cimmerian Bosporus (Crimea and Straits of Kerch) Mithradates was a deliverer from their Scythian enemies, and they gladly surrendered their independence in return for the protection given to them by his armies. In Anatolia, however, the royal dominions had been considerably dimin-

ished after the death of Mithradates V: Paphlagonia had freed itself, and Phrygia (*c.* 116 BC) had been linked to the Roman province of Asia. Mithradates' first move there was to partition Paphlagonia and Galatia between himself and Nicomedes III of Bithynia; but next, he quarrelled with Nicomedes over Cappadocia. Successful at first on two occasions, he was on both deprived of his advantage by Roman intervention (*c.* 95 and 92). While appearing to acquiesce, he resolved to expel the Romans from Asia. A first attempt to depose Nicomedes IV of Bithynia, who was completely subservient to the Romans, was frustrated (*c.* 90). Then Nicomedes, instigated by Rome, attacked Pontic territory, and Mithradates, after protesting in vain to the Romans, finally declared war (88).

The First Mithradatic War

Nicomedes and the Roman armies were defeated and flung back to the coasts of the Propontis and the Aegean. The Roman province of Asia was occupied and most of the Greek cities in western Asia Minor allied themselves with Mithradates, though a few held out against him, such as Rhodes, which he besieged unsuccessfully. He also sent large armies into Greece, where Athens and other cities took his side. But the Roman generals, Sulla in Greece and Fimbria in Asia, defeated his forces in several battles during 86 and 85. In 88 he had arranged a general massacre of the Roman and Italian residents in Asia (80,000 are said to have perished), in order that the Greek cities, as his accessories in the crime, should feel irrevocably committed to the struggle against Rome. As the war turned against him his former leniency toward the Greeks changed to severity; every kind of intimidation was resorted to—deportations, murders, freeing of slaves. But this reign of terror could not prevent the cities from deserting to the victorious side. In 85, when the war was clearly lost, he made peace with Sulla in the Treaty of Dardanus, abandoning his conquests, surrendering his fleet, and paying a large fine.

In what is called the Second Mithradatic War, the Roman general Lucius Licinius Murena invaded Pontus without provocation in 83 but was defeated in 82. Hostilities were suspended, but disputes constantly occurred, and in 74 a general war broke out. Mithradates defeated Marius Aurelius Cotta, the Roman consul, at Chalcedon; but Lucullus worsted him outside Cyzicus (73) and drove him, in 72, to take refuge in Armenia with his son-in-law Tigranes. After scoring two great victories at Tigranocerta (69) and Artaxata (68), Lucullus was disconcerted by the defeat of his lieutenants and by mutiny among his troops. In 66 Lucullus was superseded by Pompey, who completely defeated both Mithradates and Tigranes. Mithradates established himself in 64 at Panticapaeum (Kerch) on the Cimmerian Bosporus and was planning an invasion of Italy by way of the Danube when his own troops, led by his son Pharnaces II, revolted. After vainly trying to poison himself, Mithradates ordered a Gallic mercenary to kill him (63 BC). His body was sent to Pompey, who buried it in the royal sepulchre at Sinope, the Pontic capital.

Assessment

Mithradates was a man of great stature and physical strength, a brave fighter, and a keen hunter. The ancient historians have invested him with a halo of romance, and many strange stories are told of his life. Particularly famous is his supposed self-immunization against poison, which he achieved by administering to himself increasingly large nonlethal doses. Whatever the truth of these stories, there can be no doubt that he had some of the worst traits often associated with the Oriental despot—cruelty and sensuality, in particular. On the other hand, it cannot be denied that Mithradates was a ruler of astonishing energy and determination, or that he possessed political skill of a high order. The fact that he was one of the few men to offer a serious challenge to the Roman Republic is sufficient testimony to his ability. He organized the forces at his disposal very effectively, and he had a good grasp of strategy. He was unlucky in having to face three exceptionally brilliant Roman generals; unlucky, too, in coming to power at a time when the Hellenistic world was in the final stage of its collapse. It is quite conceivable that had he been born a century earlier he could have constructed an enduring Greco-Asiatic empire. A cunning, brutal tyrant, he concerned himself solely with maintaining and strengthening his own power. He posed as the champion of Hellenism, but this was mainly to further his political ambitions; it is no proof that he was deeply imbued with Greek culture or that he felt a mission to promote its extension within his domains. Hellenism made advances in Pontus during his reign, as it had under his predecessors, but this was a natural process. He treated all alike; Greek, Roman, and Asiatic were welcome at his court provided that they could be of use to him (his military subordinates were mostly Greeks, though in later years he employed several Roman renegades); but he trusted no one. Just as it is impossible to speak of his favouring one religion or culture above another, so it is impossible to believe that he had any notion of bringing Greeks and Asiatics closer together in a new kind of political and social system. His posing as a liberator of the Greeks from Roman oppression and, later, his encouragement of social revolution in the Greek cities of the province of Asia can only be interpreted, in both cases, as the actions of an opportunist seeking immediate political advantages.

BIBLIOGRAPHY. T. REINACH, *Mithridate Eupator, roi de Pont* (1890), gives a full account and analysis of the historical sources for Mithradates' life (in French). M. ROSTOVTZEFF in the *Cambridge Ancient History*, vol. 9, ch. 5 (1932), describes the Pontic kingdom, its institutions, and its history; the available evidence derives mainly from Mithradates' own reign. Volume 1 of D. MAGIE, *Roman Rule in Asia Minor* (1950), provides a narrative account of Mithradates' reign; vol. 2 consists of critical footnotes—an examination of the literary and archaeological evidence. See especially chapters 9, 14, and 15.

(R.H.S.)

Mithraism

Mithraism was the worship of Mithra, the Iranian god of the sun, justice, contract, and war in pre-Zoroastrian Iran, known as Mithras in the Roman Empire during the 2nd and 3rd centuries.

HISTORY

The pre-Zoroastrian period. Before Zoroaster (6th century BC or earlier), the Iranians had a polytheistic religion and Mithra was the most important of their gods. First of all, he was the god of contract and mutual obligation. In a cuneiform tablet of the 15th century BC that contains a treaty between the Hittites and the Mitanni, Mithra is invoked as the god of oath. Furthermore, in some Indian Vedic texts the god Mitra (the Indian form of Mithra) appears both as "friend" and as "contract." The word

mitra may be translated in either way, because contracts and mutual obligation make friends. In short, Mithra may signify any kind of communication between men and whatever establishes good relations between them. Mithra was called the Mediator. Mithra was also the god of the sun, of the shining light that beholds everything, and hence was invoked in oaths. The Greeks and Romans considered Mithra as a sun god. He was probably also the god of kings. He was the god of mutual obligation between the king and his warriors, and hence the god of war. He was also the god of justice, which was guaranteed by the king. Whenever men observed justice and contract, they venerated Mithra.

Sacrifice of the bull

The most important Mithraic ceremony was the sacrifice of the bull. Opinion is divided as to whether this ceremony was pre-Zoroastrian or not. Zoroaster denounced the sacrifice of the bull, so it seems likely that the ceremony was a part of the old Iranian paganism. This inference is corroborated by an Indian text in which Mitra reluctantly participates in the sacrifice of a god named Soma, who often appears in the shape of a white bull or of the moon. On the Roman monuments, Mithra reluctantly sacrifices the white bull, who is then transformed into the moon. This detailed parallel seems to prove that the sacrifice must have been pre-Zoroastrian. Contract and sacrifice are connected, since treaties in ancient times were sanctioned by a common meal.

The Achaemenid period. Beginning with Darius (522–486), the Persian kings of the Achaemenid dynasty were Zoroastrians. But Darius and his successors did not intend to create political difficulties by attempting to eradicate the old beliefs still dear to the heart of many nobles. Thus, the religion of Zoroaster was gradually contaminated with elements of the old, polytheistic worship. Hymns (the Yashts) were composed in honour of the old gods. There is a Yasht dedicated to Mithra, in which the god is depicted as the all-observing god of heavenly light, the guardian of oaths, the protector of the righteous in this world and the next and, above all, as the archfoe of the powers of evil and darkness—hence, the god of battles and victory.

Decline of knowledge about Persian Mithraism

In the mixed religion of the later Achaemenid period, however, the Zoroastrian aspects clearly dominate the heathen aspects. The sacrifice of the bull, abhorred by every Zoroastrian, is never mentioned. When Alexander the Great conquered the Persian Empire about 330 BC, the old structure of society appears to have broken down completely and about the worship of Mithra in Persia no more is heard.

The Hellenistic period. Local aristocrats in the western part of the former Persian Empire retained their devotion to Mithra. The kings and nobles of the border region between the Greco-Roman and the Iranian world still worshipped him. When Tiridates of Armenia acknowledged the Roman emperor Nero as his supreme lord, he performed a Mithraic ceremony, indicating that the god of contract and of friendship established good relations between the Armenians and the mighty Romans. The kings of Commagene (southeast of Turkey) venerated Mithra. Mithradates VI of Pontus may have been a worshipper of the god, and his allies, the Cilician pirates, are known to have performed Mithraic ceremonies (67 BC). The worship of Mithra, however, never became popular in the Greek world, because the Greeks never forgot that Mithra had been the god of their enemies, the Persians.

The Roman period. There is little notice of the Persian god in the Roman world until the beginning of the 2nd century but, from the year AD 136 onward, there are hundreds of dedicatory inscriptions to Mithra. This renewal of interest is not easily explained. The most plausible hypothesis seems to be that Roman Mithraism was practically a new creation, wrought by a religious genius who may have lived as late as *c.* AD 100 and who gave the old traditional Persian ceremonies a new Platonic interpretation that enabled Mithraism to become acceptable to the Roman world.

Roman Mithraism

Roman Mithraism, like Iranian Mithraism, was a religion of loyalty toward the king. It seems to have been encouraged by the emperors, especially Commodus (180–192), Septimius Severus (193–211), and Caracalla (211–217). Most adherents of Mithra known to us from inscriptions are soldiers of both low and high rank, officials in the service of the emperor, imperial slaves, and freedmen (who quite often were very influential people)—persons who probably knew which god would lead them to quick promotion.

Mithraic sanctuaries and dedications to Mithra are numerous at Rome and Ostia, along the military frontier, in Britain, and on the Rhine, Danube, and Euphrates. Few dedications are found in peaceful provinces; when they do occur the dedicator is usually a provincial governor or an imperial official. Within a few generations, the Roman world had completely assimilated the Persian god. When Diocletian attempted a renewal of the Roman state and religion, he did not forget Mithra. In the year AD 307, in a dedication from Carnuntum (at the Danube, near Vienna), Diocletian and his colleagues dedicated an altar to Mithra, as the patron of their empire (*fautori imperii sui*). But in 312, Constantine won the battle at the Milvian Bridge under the sign of the cross. Instantaneously, the dedications to Mithra ceased, even though there was no immediate public interdiction of Mithraic ceremonies. The worship seems to have collapsed quite suddenly when imperial favour ceased to be with the Mithraists. Dedications to Mithra, it is true, appear again between about 357 and 387, but only at Rome. The dedicators all come from the old pagan aristocracy of the city of Rome, which in this period was in open opposition to the new Christian emperor at Constantinople. In these inscriptions, however, Mithra is only one of many traditional pagan gods who were worshipped by the Romans. The Mithraic mysteries had gradually faded long before. And when the Roman opposition was defeated, pagan worship was suppressed altogether.

MYTHOLOGY AND THEOLOGY

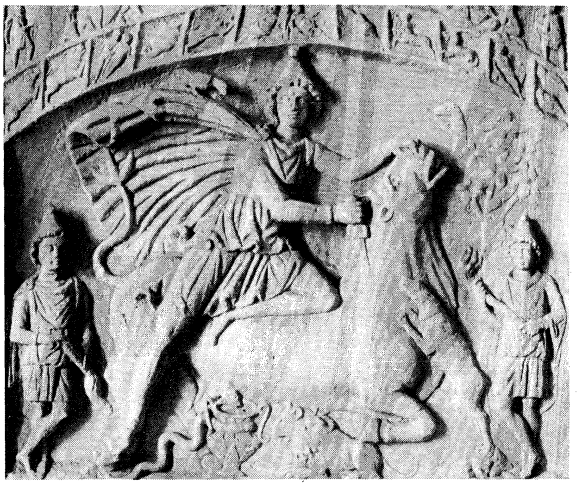
Creation myths

Mythology. The creation of the world is the central episode of Mithraic mythology. According to the myths, the sun god sent his messenger, the raven, to Mithra and ordered him to sacrifice the bull. Mithra executed the order reluctantly; in many reliefs he is seen turning aside his face in sorrow. But at the very moment of the death of the bull, a great miracle happened. The white bull was metamorphosed into the moon; the cloak of Mithra was transformed into the vault of the sky, with the shining planets and fixed stars; from the tail of the bull and from his blood sprang the first ears of grain and the grape; from the genitals of the animal ran the holy seed which was received by a mixing bowl. Every creature on earth was shaped with an admixture of the holy seed. One Mithraic hymn begins: "Thou hast redeemed us too by shedding the eternal blood." The plants and the trees were created. Day and Night began to alternate, the Moon started her monthly cycle, the Seasons took up their round dance through the Year, and thus Time was created. But, awakened by the sudden light, the creatures of the dark emerged from earth. A serpent licked the bull's blood. A scorpion tried to suck the holy seed from the genitals. On the reliefs, a lion often is also seen. With the bull's death and the creation of the world, the struggle between Good and Evil began: thus is the condition of man's life. The raven symbolizes Air, the lion Fire, the serpent Earth, and the mixing bowl Water. So the four elements (air, fire, earth, and water) came into being, and from them all things were created. After the sacrifice, Mithra and the sun god banqueted together, ate meat and bread, and drank wine. Then Mithra mounted the chariot of the sun god and drove with him across the ocean, through the air to the end of the world.

Theology. The myth was interpreted by the Roman Mithraists in terms of Platonic philosophy. The sacrifice took place in a cave, an image of the world, as in the simile of the cave in Plato's *Republic*. Mithra himself was equated with the creator (demiurge) of the *Timaeus:* He was called "demiurge and father of all things," like the Platonic demiurge. The four elements, the mixing bowl, the creation of Time, the attack of the wicked animals upon the newborn creature are well-known features of the

Timaeus. The Mithraic doctrine of the soul is intimately linked with the myth of creation and with Platonic philosophy. As in the *Timaeus*, the soul of man came down

Bavaria-Verlag



Mithra slaying the bull, flanked by two torchbearers. Below the bull is a group composed of a serpent, an urn, and a lion; the signs of the Zodiac are depicted on the arch. Bas-relief, 2nd century AD. In the Städtisches Museum, Wiesbaden.

from heaven. It crossed the seven spheres of the planets, taking on their vices (*e.g.*, those of Mars and of Venus) and was finally caught within the body. The task of man is to liberate his divine part (the soul) from the shackles of the body and to reascend through the seven spheres to the eternal, unchanging realm of the fixed stars. This ascension to the sky was prefigured by Mithra himself, when he left the earth in the chariot of the sun god.

WORSHIP, PRACTICES, AND INSTITUTIONS

The Mithraic sanctuaries were subterranean caverns, which presented obvious limitations of size. None of the many excavated shrines could receive more than a hundred persons, and most even fewer. All ceremonies were of necessity enacted in artificial light. The cavern always contained a well. Access to the cavern often consisted of a system of subterranean passages, which were used in the initiation ceremonies. Men only were admitted to this religion of soldiers, and no organizational hierarchy seems to have existed.

Initiation rites

The initiates were organized in seven grades: *corax*, Raven; *nymphus*, Bridegroom; *miles*, Soldier; *leo*, Lion; *Perses*, Persian; *heliodromus*, Courier of (and to) the Sun; *pater*, Father. To each rank belonged a particular mask (Raven, Persian, Lion) or dress (Bridegroom). The rising of the Mithraist in grade prefigured the ascent of the soul after death. The series of the seven initiations seems to have been enacted by passing through seven gates and climbing a ladder of seven steps. Each grade was attributed to one of the seven planetary gods. The zealous Mithraist gradually passed the spheres of these minor deities and finally reached the region of the fixed stars. Little is known about initiation ceremonies. Ancient texts refer to ablutions (baptism) and purifications and chastisements, to fetters and liberation, and to certain ceremonial passwords. Frescoes at Capua (Italy) show the initiates blindfolded, kneeling, and prostrated. A simulated death and resurrection was probably part of the ceremony. Tertullian, the 2nd century North African Christian theologian, describes the test of courage to which the *miles* (Soldier) was subjected. Weapon in hand, he had to force his way—probably by a sham duel—to a wreath. When he had succeeded, an officiant offered to crown him with the wreath. But the candidate had to decline, saying that Mithra alone was his wreath; and throughout the rest of his life, he never again bore a wreath.

The Mithraic caverns were decorated with frescoes, reliefs, and statues of minor deities and of the planetary gods. A narrow aisle was flanked on both sides by a broad, raised bench on which the worshippers kneeled or reclined. At one end of the aisle (often apselike) there was always a relief or fresco representing the sacrifice of the bull. Sometimes, the relief could be turned on a pivot; the back of the stone represented the repast of Mithra and the sun god. While it is unlikely that the ceremony of the bull's sacrifice was frequently performed, the common meal of the initiates was a regular feature of Mithraic worship.

MITHRAISM AND CHRISTIANITY

There are obvious similarities between Mithraism and Christianity; however, they should not be overestimated. Mithraism permitted only male devotees, and the social strata to which it appealed included mainly soldiers, officials, and men in imperial service. Christianity, on the other hand, was primarily the religion of the poor or of the lower classes. If there was competition between the two, it was for the favour of the emperor rather than for followers. The Christian Church triumphant ultimately destroyed pagan worship and sanctuaries everywhere. The Mithraic shrines were pillaged, and on the spot of the former caverns Christian basilicas were built.

BIBLIOGRAPHY. *The Avestan Hymn to Mithra* was edited and translated from the Iranian text by ILYA GERSHEVITCH (1959). For the Roman mysteries, the fundamental work is FRANZ CUMONT, *Textes et monuments figurés relatifs aux mystères de Mithra*, 2 vol. (1894–1900). His conclusions are available in English, *The Mysteries of Mithra* (1903), and *The Oriental Religions in Roman Paganism*, ch. 6 (1911). Cumont's work is now partly replaced by the monumental work (in English) of MAARTEN VERMASEREN, *Corpus inscriptionum et monumentorum religionis Mithriacae*, 2 vol. (1956–60). Vermaseren also published a popular account, *Mithras, de geheimzinnige God* (1959; Eng. trans., *Mithras, the Secret God*, 1963). For the monuments in Britain, see EVE and JOHN R. HARRIS, *The Oriental Cults in Roman Britain*, pp. 1–54 (1965). See also LEROY A. CAMPBELL, *Mithraic Iconography and Ideology* (1968). On the creation myth and the Platonizing theology, see R. MERKELBACH, "Die Kosmogonie der Mithrasmysterien," in *Eranos-Jahrbuch*, 34:219–257 (1965).

(R.Me.)

Modern Dance

The art form that came to be known as modern dance emerged in the early years of the 20th century as a protest against the prevalent forms of theatrical dancing. Led by innovators in central Europe and the United States, the movement was aimed at making dance a more viable, contemporary art. Leaders of the movement objected, basically, to two forms then prevalent. On the one hand there was the classical ballet, which, its detractors felt, had reached a low point in its artistic development and had become largely an empty display of technical virtuosity. On the other hand there was the so-called interpretive dance, which they recognized as being often full of feeling but found devoid of a basic concern for communicating with an audience.

In the words of the critic John Martin, modern dance aimed "to externalize personal, authentic experience." Modern dance evolved as a means of projecting feeling that was deeply, personally experienced but that also communicated a wider, more universal experience to the theatre audience.

PRINCIPLES UNDERLYING MODERN DANCE

Ballet and modern dance. In the beginning, there was a complete rejection of the vocabulary of the balletic tradition as it had formed in the late 17th and 18th centuries to embody ideals of aristocratic elegance and decorum. In the 19th century, ballet had become a vehicle for pure virtuosity, sacrificing even its original nobility for spectacle and display. By the start of the 20th century, dance innovators felt they could not communicate with techniques that expressed values they saw as alien to contemporary society. They sought to return to the most primitive, most basic, most human function, the immediate communication of significant feeling; and they believed that to be significant the feeling had to be contemporary.

In line with the tendencies of modern painting, sculpture, and music, choreographers stripped the dance to the essentials of movement, which could be inherently expressive when not obscured by artificial ornament.

New approaches to dance

For their themes, the modern dancers turned away from the fairy tales and romantic legends of the ballet to primitive ritual and classic myth and to the social and psychological problems that beset their own time. With themes that allowed the choreographer to comment on the most basic needs and aspirations of man, the subject of the dance was no longer incidental to the dance: it was the vital core and substance of the work.

For the modern dance, movement was motivated by message and strict economy was observed. The approach was functional; if a dancer leaped or turned, it had to be for an emotional, dramatic reason, never for mere display. Taking a serious theme and presenting it sparsely, choreographers of modern dance often met with charges of obscurity and drabness. But because their objective was to develop an art that the audience must make an effort to understand, they remained adamant and made no attempt to adorn their works with graceful but irrelevant movements to capture the fancy of a broad public.

In contrast to the pleasing symmetrical design of ballet, modern dance movements struck many as ugly, gross, distorted. New ideas of physical beauty, derived in part from Picasso and primitive artifacts, favoured expressiveness over charm. In terror the body curled inward on itself; in daring assault it reached outward precariously and fell heavily to the ground; anger made the dancer jerk in violent spasms to jagged rhythms.

Similarly, there was no compromise with the demands of spectacle in stage design. Costumes were most often of plain black jersey; the feet were bare, exposed. Scenery was sparse; the music was often dissonant when not dispensed with altogether. The aim of all appeared to be to startle the audience into an awareness that was frequently unpleasant. Modern dance thus understood has never been a form of popular art.

Intellectual and artistic influence. If ballet of the late 19th century was a negative influence on the modern dance, there were positive ones as well. Some of these came from other arts in which the revolt against romanticism had already established modernist tendencies by 1900. Others came from changes in the social and intellectual environment. Although dance was among the last of the arts to be affected by these changes, it may have been the one most drastically altered by them.

Impacts of psychology and anthropology

Of primary importance for the dance were developments in two areas: psychology and anthropology. In the former, the writings of Sigmund Freud were prompting people to look not so much to man's actions as to the motives that allegedly led him to those actions. Nineteenth-century thought held that intense emotions were best hidden from view and preferably not even admitted to exist. Fighting the denial of these basic human drives, Freud's followers urged frank and honest emotional revelation. Modern dance choreographers, in their turn, began to rediscover the power of movement in communicating subjective experience, and their new directions were reflected in both subject matter and structure. The use of naturally expressive gesture, known to the ancient Greeks, had long been lost to an art that had adopted a strict code of graciousness and good manners.

The themes of modern dance dealt with intimate human relations and passions. The action of a dance could centre not on a series of adventures culminating, for example, in a wedding but on an internal change, a recognition of a significance or truth. In structure, modern dance abandoned the series of decorative movements hung upon a feeble thread of a plot and created works in which every moment was both dance and drama, every movement served to express feeling. The anthropological revolution, stirred by the publication of Sir James George Frazer's *Golden Bough* (1890; expanded 1907–15), led the modern dance to investigate the forms of primitive ritual. For three centuries theatrical dancing had been derived from a refinement of patterns originating in folk dance, once seriously social in function but long since reduced to a more or less formal kind of play. Modern dance turned instead to the older concept of dance as an instrument of magic and religion, as a means for the survival of a community through the proper performance of sacred rites designed to banish evil spirits or to promote growth and fertility. This recalling of dance to its original seriousness was congenial to choreographers eager to make the public aware of the social significance inherent in their work. For their contemporary world, they saw the theatre as potentially a place of magic in which the souls of men could be purified and refreshed through the vigorous, direct qualities of movement found in primitive dance.

Impact of other arts

The modern dance found sources of technical inspiration in developments within the other arts. In the early 20th century, serious painters and sculptors had moved away from the concept of art as decoration or as an attempt to reproduce the literal forms of nature toward an increasing abstraction that centred on such movements as Cubism, Expressionism, and Fauvism. Like these visual artists, modern dancers sought the essence of form and emotion underlying the literal: they stripped away the superfluous, they used sharp body angles and off-balance positions for the direct expression of emotion. And as the painter found a new aesthetic in his materials—in the textures and colours of his paints, canvases, and multimedia collages—so the choreographer asserted the inherent beauty of the human body with its joints and its natural weight subject to the pull of gravity.

Like the musical composers who in the early 20th century were introducing new ideas of tonality, rhythm, and structure, modern dancers turned from the romanticism of the past with its rich, sweet harmonies and its even, pleasing rhythms. As Igor Stravinsky and Béla Bartók experimented with polytonal and polyrhythmic structures, so the choreographer looked for new principles by which to order his composition. His performers moved to dissonant music with uneven measures. Sometimes dispensing with musical accompaniment altogether or using only percussion for a skeletal score, he juxtaposed one violent rhythm against another. Like the musician who refused to confine himself to the traditional major and minor scales and who refused to end every phrase with a consonant chord, the choreographer sought freedom in structuring his sequences of movement.

Unrestricted by a limited vocabulary of steps and positions and thus able to draw instead on a whole range of possibilities in human movement, choreographers could use their freedom and personal temperament to select the range of movements most appealing to them as individuals. Thus some dealt with the sombre, introverted aspects of human nature, others with man's more outgoing, social nature; some were happiest identifying with past times and distant cultures, others felt only for the concerns of the present. The concept of what was personal and authentic in experience naturally differed with each artist. Modern dance became a multifaceted form, but a form with a cohesion rooted in a conviction about the function of dance as an art capable of expressing thoughts and feelings relevant to contemporary society.

HISTORICAL DEVELOPMENT

Modern dance, as here understood, began in two areas, Europe and the United States. The Europeans tended to abstract concepts of the body in relation to the space surrounding it, the Americans to turn for inspiration to cultures that they felt were superior to their own. Consequently two modern dance movements developed almost simultaneously but practically independently of one another. They held the belief in common that dance, freed of its restrictive vocabulary, could express a personal, relevant, contemporary view of life.

Pioneers. In Europe two men had experimented with new forms of body movement, although one was concerned only with singers and actors, the other only with musicians. François Delsarte (1811–71), disturbed by the artificial mannerisms he saw on the Parisian stage, worked out a system of gesture by which the performers' movements could more naturally express the meanings behind his words, not merely adorn them. In Switzerland,

Experiments of Delsarte, Dalcroze, and Laban

Émile Jaques-Dalcroze (1865–1950) pioneered the teaching of eurythmics, the representation of musical rhythms in movement. He found that musicians could improve their sense of rhythm if trained to respond to music through movement. His exercises evolved into forms also useful for the dancer and were presented in performance-demonstrations. Both men revealed the possibilities of a freer kind of theatrical movement, and dancers began to explore its significance for their own art.

Working in Switzerland during World War I, the Hungarian dancer Rudolf Laban (1879–1958) experimented with the spatial and directional possibilities of the body's movement. With the dancer Kurt Jooss (1901–), he codified principles of physical expression based on analyses of the coordination of mind, nerves, and muscles. He sought primarily to establish the full range of human movement, believing that once the dancer mastered this vast repertory he would be free to utilize any range within it to express whatever inner motivations impelled his dance.

The dance of Wigman, Duncan, and St. Denis

Laban's pupil Mary Wigman (1886–), who also had studied with Dalcroze, saw more forcefully and successfully the dramatic use to which his theories could be put. In her work, a dancer related his person to a surrounding space that was either hostile or amiable so that space became a character and a dramatic relationship was established. Wigman's dance was an objectified telling of universal, deep-rooted experience. "Beyond the personal interpretation underlying the dancer's gesture," she wrote, "there is always the responsibility and obligation to make clear the universal, super-personal meaning—which the dancer can neither change forcibly nor exchange arbitrarily without endangering the general validity of his message." (From Mary Wigman, *The Language of Dance*, translated by Walter Sorell, Wesleyan University Press, 1966.)

In America, where the experimentation had begun shortly after the turn of the century, the foundations of modern dance were different. Isadora Duncan (1878–1927) found in the culture of ancient Greece the counterpart of her self-proclaimed devotion to the good, the true, and the beautiful. In antique sculpture she found representations of the kind of dance she wanted to see and to perform: the beautiful, natural body clothed in loose robes and with bare feet, its movements echoing the swaying of trees, the ebb and flow of the waves of the sea. She was inspired too by music, especially that of Beethoven, Schubert, and Chopin. She sought a dance "that might be the divine expression of the human spirit through the medium of the body's movement." She would not teach technique as the ballet taught it, believing that it only disfigured the natural grace of the body. She told her pupils:

> Listen to the music with your soul. Now, while listening, do you not feel an inner self awakening deep within you—that it is by its strength that your head is lifted, that your arms are raised, that you are walking slowly toward the light? (From Isadora Duncan, *My Life*, Garden City Publishing Co., Inc., 1927.)

From her ideas came a basic characteristic of the American modern dance: movement emanating from individual feeling. As she said in the same source:

> My art is just an effort to express the truth of my Being in gesture and movement. . . . I have given [the public] the most secret impulses of my soul. From the first I have only danced my life.

Unfortunately the genius of Duncan fell into disrepute for a long period through the teachings of many of her followers, who tended to emphasize pure, unstructured feeling at the expense of carefully articulated communication through movement, an uncomfortably close approach to the earlier interpretive dance from which Duncan had raised the art.

Meanwhile another young American was longing "to translate into rhythmic patterns a spiritual significance." The motivation of Ruth St. Denis (1877–1968) was personal, an "inward impulse" she called it, but she felt impelled to represent her feeling more objectively than Duncan had. Dance, she said, "can be expressive of the whole range of thought and philosophy." The civilizations of the East provided her with concepts of spirituality that she found lacking in America; as well, they provided her with themes, characters, and episodes and with ideas for costumes and settings. She never pretended that her works were authentic reconstructions of Eastern styles, only that they were based on those styles. But the East provided her with vast resources for ideas of movement for which she could feel a personal affinity.

The late 1920s and after. Thus audiences were gradually exposed to new forms of movement. The negative aspects of the freedom opened by Delsarte, Dalcroze, and Laban were becoming focussed in positive directions: for each it was a personal search for a means to communicate significant values. In a sense, however, it was still escape. Seeking to ennoble the dance, the innovators saw little of dignity or stature in their immediate surroundings, and for all their claims to revolution, much of romanticism remained in their work. Duncan echoed the idealism of Walt Whitman and danced to the heroic strains of Tchaikovsky's *Marche Slave*; St. Denis portrayed goddesses in *Egypta* and *Radha*, while her partner-husband Ted Shawn told a tale of ancient Mexico in *Xochitl* and mourned the fate of the American Indian in *The Feather of the Dawn*. Wigman was not without her mystical strain: she had her demonic *Witch Dance* and her ecstatic *Seraphic Song*.

Where these early innovators had looked to the glory of Greece and the mysticism of the East, to the romanticism of Whitman and Schubert, the next generation was to become more fully aware of its own present, of the writings of Freud and T.S. Eliot, of the music of Bartók and the painting of Picasso. In addition, society was becoming aware of Hitler, who banished modern dance from Germany, and of the rising labour agitation that reached its peak in the depression of the 1930s. Such consciousness, in dancers and in audiences, would breed a choreography far different from that of Duncan and St. Denis.

Second generation: Graham, Humphrey, and Limón

Modern dance was still concerned with externalizing personal experience: Martha Graham (1893–) called it "making visible the interior landscape." But the exponents of the late 1920s and the 1930s had new ideas about what kind of experience was important. Rejecting not only the ballet but also Duncan and her own mentor St. Denis, Graham wrote:

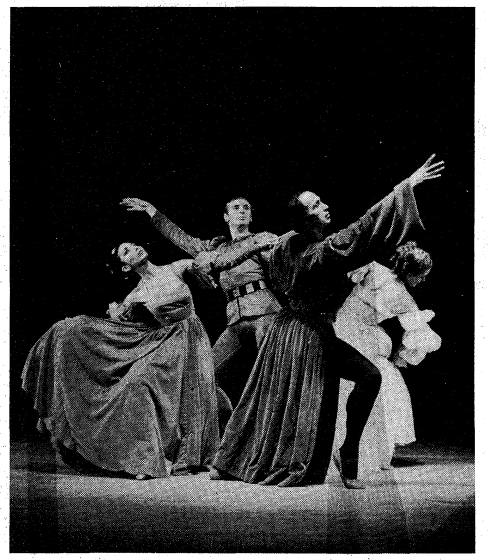
> I do not want to be a tree, a flower, or a wave. In a dancer's body, we as audience must see *ourselves*, not the imitated behavior of everyday actions, not the phenomena of nature, not exotic creatures from another planet, but something of the miracle that is a human being, motivated, disciplined, concentrated. (In Frederick Rand Rogers, ed., *Dance: A Basic Educational Technique*; The Macmillan Co., 1941.)

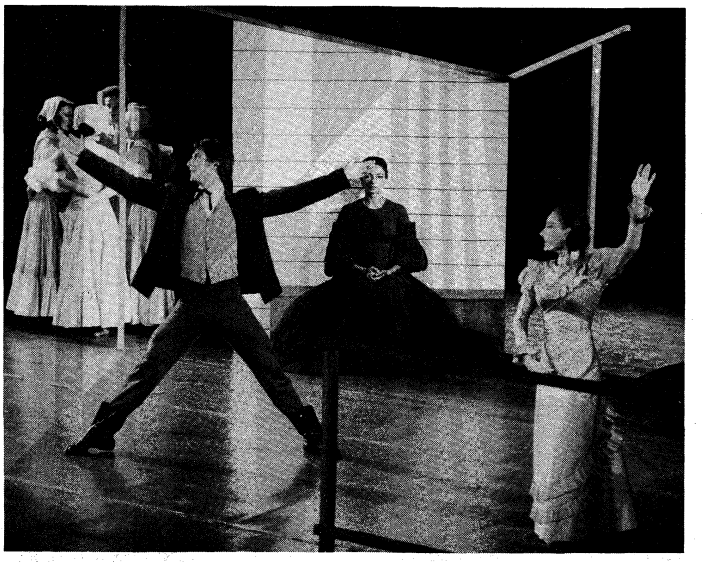
Doris Humphrey (1895–1958) chose another way to break away from the bases of her training in the company of St. Denis and Shawn. "I knew something about how the Japanese moved, how the Chinese or Spanish moved, but I didn't know how I moved or what the American heritage should be." (From Doris Humphrey, "New Dance: An Unfinished Autobiography," in *Dance Perspectives 25*, 1966.) In seeking her identity, she also found her own way of dance: It

> is composed as an expression of American life as I see it today. . . . I believe that the dancer belongs to his time and place and that he can only express that which passes through or close to his experience. The one indispensable quality in a work of art is a consistent point of view related to the times. (From Doris Humphrey in *Dance: A Basic Educational Technique*.)

The vocabulary of ballet was unsuited to the communication of ideas "related to the times" but so were the idioms of the first innovators. If form was to follow function, as modern dancers had proclaimed, still other kinds of movement had to be found to embody the new directions.

Graham asserted that she had found a guiding principle for her work in the act of breathing. The body contracted in inhalation, released in exhalation, and by intensifying the act, the dancer could use the breath as a force to send him into a turn, a leap, a fall. The movement could be sharp and spasmodic, signifying agony or terror or ecstasy, or it could be controlled and lyrical. For her, movement spoke always of basic passions: it was at once savagely of the ground but aspiring to the sky. "Your spine,"





Modern dance of the early 20th century.

she told her students, "is the line connecting heaven and earth."

Where Graham saw the struggle within the person, Humphrey looked outward—to the environment and the society that surrounded the dancer. She saw movement as generated by efforts to resist the pull of gravity, of those forces that threaten man's security. The dancer fell, crushed by hostile antagonists, but always rose again, sustained by his will to persist and conquer. Her approach was inherently dramatic, for it was based on a fundamental human conflict: the longing for progress and change pitted against the desire for stability. She believed that without the daring, there is no action, no life, and "Dance," she said, "takes place within the arc between two deaths."

Changes in the approach to dance did not necessarily involve a shift to contemporary subject matters, and in fact such subjects were rarely used. (Notable exceptions were Graham's *Immediate Tragedy*, which dealt with the Spanish Civil War, and Charles Weidman's *Lynch Town*.) But the point of view was contemporary. Graham saw social cohesiveness founded on the act of ceremony in *Primitive Mysteries*. She approached the legends of Greece with Freudian insight in a great cycle that was climaxed with *Clytemnestra* in 1958. Humphrey commented on democracy through the complex relations of group and individual in *New Dance* and on social injustice through her treatment of an episode from 19th-century England in *Inquest*.

Grief for contemporary turmoil made some choreographers look to the past, not with nostalgia but with a view to its relevance for their own problems. Graham recalled the courage of pioneers in *Appalachian Spring*; Humphrey evoked the fervour of a religious sect in *The Shakers*. Such subject matter was not romanticized: the past was viewed both sympathetically and critically.

When modern choreographers found that they had made their point about the capacity of dance to express the darker, more ruthless part of man's nature, they felt able to deal with his nobler aspects without harming their own cause, but they never were quite able to return to the sanguine views of the earlier years. José Limón (1908–72) wrote that he tried to compose works that were involved with

> man's basic tragedy and the grandeur of his spirit. . . . I reach for demons, saints, martyrs, apostates, fools and other impassioned visions. (S.J. Cohen [ed.], *The Modern Dance*, pp. 23–24.)

He turned to Shakespeare's tormented lovers in *The Moor's Pavane* and to heroism in wartime in *Missa Brevis*. Even Graham, while continuing her concern with man's animal drives, created in 1948 *Diversion of Angels* about the joy and sadness of being in love. A contemporary and unsentimental lyricism had evolved.

Broadening subject and technical repertoires

An expanded range of subject matter required a correspondingly larger repertoire of technical means in terms of movement and theatrical spectacle. The early modern dance had rejected the ballet vocabulary, but the ballet itself had entered an era of creative rejuvenation in the early decades of the century. Modern dance choreographers began to adapt certain of its elements as they found it possible to accommodate some of the ideas it represented. Technical skills, it was felt, were not necessarily inexpressive; they had only been made so by having been exploited for their own sake, and they could as well depict important aspects of personal experience—youth, joy, dreams. In time some choreographers reinstated costume and decor and even romantic music. These elements were used, however, in fresh ways: never decoratively, always for the sake of expression. Modern dance, while changing, retained its identity.

Renewed searches for new forms. But as modern dance seemed to become richer, some critics in fact began to find it poorer. Though the repertory of technique had been expanded, it was still limited by the dictum that the movement of the dancer must be meaningful. The dance, it was felt, was becoming too literary in its concerns, and bodily movement was a means to an end rather than an end in itself. At the same time, many dancers were undertaking fresh experiments with movement, not for its balletic qualities of brilliance but for its values of pure shape, rhythm, and texture. To develop dance as an independent art, free of drama, free of music, beholden to nothing but itself, became a new avenue for exploration.

Experiments of Cunningham and Nikolais

Choreographers who felt thus had to search for new movements and new ways of combining them. Because they rejected dramatic motivation, they had to look elsewhere for their initiating impulse. The acknowledged leader of the group, Merce Cunningham (1919–), wrote:

> I start with a step. . . . This is not beginning with an idea that concerns character or story, a fait accompli around which the actions are grouped for reference purpose. I start with the movement, even something moving rather than someone (pillows in the air). . . . But then out of this the action begins to assume its own proportions, and other possibilities appear as the dance proceeds. New situations present themselves—between the dancers and the space, the space and

the time. It can take a momentum of its own. . . . I have a feeling it produces some kind of atmosphere. (Merce Cunningham *et al.*, "Time To Walk in Space," in *Dance Perspectives*, 34, 1968.)

To ensure independence of personal choice or subjective motivation, Cunningham at times introduced chance elements into his work, including improvisation and dances performed in random sequences, to discover new patterns and combinations of movement; at other times he used elaborate mathematical charting techniques.

Other devices have been employed by Alwin Nikolais (1912–). Granting that movement is naturally expressive, he tried taking it out of the context with which it is normally associated. He would, for example, in the instance of a man reaching for a box, remove both the box and the man's purpose. This allows the spectator to look only at the quality of the action of reaching. Analyzing the movement's qualities, he would combine it with other movements quite unrelated to it emotionally. To assure that the audience saw the movements for their own sake without reference to any potentially dramatic situation, he characteristically clothed his dancers in a variety of unrevealing shapes or sacks, often attaching them to inanimate objects to alter further their configuration in space. He called the result not dehumanization but depersonalization. His works were not dances, he asserted, but rather "theatre pieces of light, color, motion, and sound." He is thus characteristic of the newer generation of choreographers who have readmitted scenic values and technological potentialities into modern dance.

Other choreographers, notably Ann Halprin and Yvonne Rainer, worked with the idea of what were called "task movements." Each performer was given a task—*e.g.*, carrying a load of objects along a specified path—and the motions resulting from the execution of the task constituted the dance. They and others, such as Meredith Monk and Twyla Tharp, let their dances develop as responses to the environments, utilizing whatever space happened to be available—an expanse of grass, a museum, a gymnasium.

Modern dance continued, however, to be a many-faceted art. Holding to the original concept of representing personal experience, some choreographers continued to create in the dramatic vein. Anna Sokolow and Pauline Koner persisted in the belief that dance is an embodiment of human values, a representation of human actions and passions. Others, like Paul Taylor, who began as a member of the Martha Graham company, turned to dramatic dance after experimenting with nonrepresentational forms. Still others, such as Alvin Ailey and Donald McKayle, borrowed elements of ethnic dance from Africa and the West Indies, combining them with modern dance techniques to develop individual styles of expressive jazz. Their work differed from that of Pearl Primus and Katherine Dunham, both of whom performed a theatricalized "ethnic dance" quite apart from the mainstream of modern dance.

Interactions with ballet and musical comedy

Since influences upon these modes of choreography frequently came from such other art forms as painting, music, and theatre, the ballet was open to them as well. Some of the works created by George Balanchine for the New York City Ballet were as abstract in structure as those of Cunningham. The original opposition of the classical ballet and modern dance broke down in this way, and distinctions between the forms blurred for other reasons as well. As modern dance incorporated technical elements from the ballet, the reverse also occurred. Some choreographers, such as Antony Tudor and Jerome Robbins, although trained within the ballet idiom and eager to use its repertory of physical skills, wished to make dances that were serious, expressive, and relevant to their own time. As their purpose approached that of the modern dance, they assimilated elements from its store of techniques.

Further influences resulted from the use of dance by the musical theatre and films that employed both ballet and modern dance choreographers. Among the most notable of these were Agnes deMille, whose choreography of *Oklahoma!* (1943) significantly altered the face of the musical comedy; Helen Tamiris, who choreographed the dances in *Annie Get Your Gun*; Hanya Holm, a student of Mary Wigman, who did *My Fair Lady*; and Robbins with *West Side Story*. The attitude of modern dance that allows character and situation to dictate movement was found most appropriate to the musical stage and film.

Modern dance today. By the middle of the 20th century modern dance was an almost exclusively American form. Wigman and others toured or worked in the United States following the German political suppressions

of the 1930s. After World War II the void in European dance was filled by the resurgence of ballet as an authentic form. In England modern dance was restricted to educational institutions, where adaptations of Laban's techniques were not of a serious artistic calibre. The work of the Martha Graham school in London—the London School of Contemporary Dance, founded in the late 1960s—indicated that American influences might initiate a fresh beginning.

Companies and festivals

Even in America, by the 1970s modern dance companies were existing precariously, many performing only a few months each year. There was no central organization for, or cooperation among, these companies, and only two dance festivals were well established. The Jacob's Pillow Dance Festival in Lee, Massachusetts, was guided by Ted Shawn from the early 1940s; it staged a repertory of ballet and ethnic and modern dance. The only festival devoted entirely to modern dance was begun in the late 1940s at Connecticut College in New London.

After the mid-1950s, despite the work of Taylor, Ailey, and others, the trend in modern dance was toward the abstract. At the beginning of this period of nonrepresentational dance, the concern was to draw attention to movement for its own sake. After the first decade or so some exponents began to draw on such other idioms as eurythmy, the interpretation in movement of a spoken or sung accompaniment, and the film, slide, and light projections characteristic of such contemporaneous multimedia forms as the rock-and-roll discotheque, the seemingly improvised "happenings" that were carefully prepared for presentation on city sidewalks or college campuses, and similar phenomena associated with "pop art" culture. Practitioners of other arts such as the painter Robert Rauschenberg began experiments with choreography that utilized their proved skills in combination with dance. Experiments in linking art and engineering drew electrical technicians into the dance theatre. New art forms combined with the new technology to represent an integral part of contemporary man's experience. By the early 1970s there were signs of another kind of development. Growing protest of social and political origin found its way into dance works and started a trend, once again, away from the abstract and toward a more emotionally, if not dramatically, oriented dance theatre. With actors like James Cunningham turning to choreography, at least one facet of the modern dance concerned itself with arousing the emotions and intellect of its audiences. The modern dance, attempting to relate to its time, appeared headed again toward growing social involvement.

Modes, Musical

In musical theory and analysis, the term mode has been employed in a variety of more or less correlated meanings. Mode designates particular aspects of melodic construction; its meaning ranges from strictly defined scales whose identity stems from the position of given intervals (distances between notes) in the sequence of tones (see SCALES, MUSICAL) to broadly delineated melody types and constellations of motivic figures (brief, identifiable melodic fragments) that may serve as bases for improvised or written compositions. Throughout the history of Western and non-Western art music, various modal systems have been formulated by theorists. The use of modal concepts in the analysis of the vast bodies of Western and non-Western folk music, including that of tribal cultures, substantially advances the understanding of this music.

This article covers the ancient Greek modes, Jewish liturgical modes and reciting formulas, Eastern and Western church modes, and it briefly touches upon non-Western modal systems (see also ISLAMIC PEOPLES, ARTS OF: *Music*; MUSIC, EAST ASIAN; SOUTH ASIAN PEOPLES, ARTS OF: *Music*; SOUTHEAST ASIAN PEOPLES, ARTS OF: *Music*). The term rhythmic mode refers to the 13th-century system of simple rhythmic patterns in three-beat, or ternary, metre (see MUSICAL RHYTHM) and, occasionally, to longer rhythmic patterns in non-Western music.

Ancient Greek modes. The modes of Greek antiquity were placed by theorists in orderly fashion within a larger context. Although the modes were a series of seven-note diatonic scales (*i.e.*, containing five whole tones and two semitones), the nucleus of the tone system was the tetrachord—a group of four consecutive notes (as, from C to F on the piano) comprising the interval of a fourth. Except in late antiquity, the notes were always arranged in a descending order, the basic tetrachord consisting of two whole tones and one semitone: E–D–C–B. Two such tetrachords, separated from one another by a whole tone, formed the so-called Greek Dorian mode: E–D–C–B A–G–F–E. The Dorian mode was taken as a basis for the construction of the larger system. Its single-octave range was extended by the addition of a third tetrachord, A–G–F–E, on top and of a fourth tetrachord, E–D–C–B, at the bottom. In contrast to the two inner tetrachords, which were separated by a whole tone (disjunct tetrachords), each outer tetrachord was linked with the neighbouring inner one by a shared note (conjunct tetrachords):

A G F E D C B A G F E D C B.

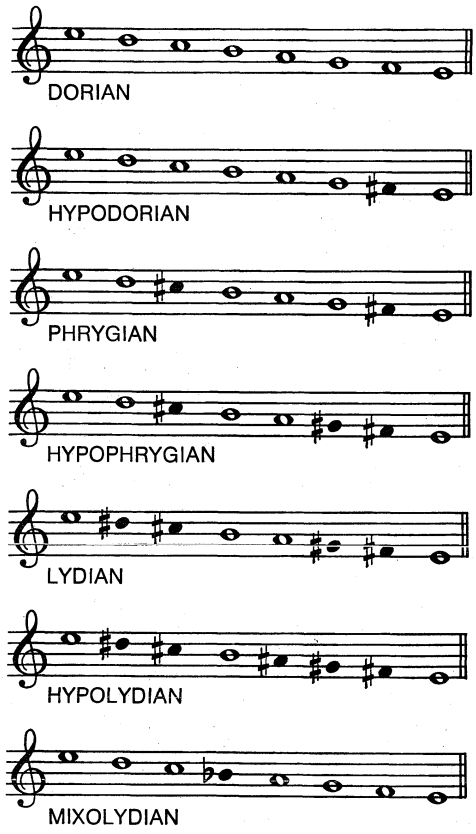
Because the combination of the four tetrachords yielded a range of two octaves minus one whole tone, a low A was added by theorists to achieve the following diatonic two-octave system: A G F E D C B A G F E D C B A. This two-octave row, or disdiapason, was called the Greater Perfect System. It was analyzed as consisting of seven overlapping scales, or octave species, called *harmoniai*, characterized by the different positions of their semitones. They were termed as follows (semitones shown by unspaced letters):

The Greater Perfect System

A G FE D CB A	Hypodorian
G FE D CB A G	Hypophrygian

FE D CB A G F	Hypolydian
E D CB A G FE	Dorian
D CB A G FE D	Phrygian
CB A G FE D C	Lydian
B A G FE D CB	Mixolydian

Although the names of the *harmoniai* were identical with those of the Greek modes, the *harmoniai* represented not the modes themselves but were instead projections of the interval patterns of the modes into the more extensive Greater Perfect System. The modes proper were termed *tonoi*, their essence being their interval pattern. On the kithara or *lyra* (the two basic plucked string instruments of ancient Greece) the *tonoi* were produced either by the basic tuning or by the raising or lowering of one or more of the strings by a semitone. Thus, the seven *tonoi* would sound within the octave E–E as follows (black notes indicate changes from the Dorian tuning):



Greek theory distinguished three different genera of tetrachords, producing an additional variety of modes. The previously described tetrachord (two descending whole tones plus one semitone) was called diatonic. There were also chromatic and enharmonic genera. The two tones bounding the tetrachord were fixed and always formed a perfect fourth; the two inner tones were movable. The chromatic tetrachord consisted of a minor third (encompassing 1½ whole tones) plus two semitones, the enharmonic tetrachord of a major third (encompassing two whole tones) plus two approximate quarter tones:

Also prominent in Greek music was the concept of ethos, which ascribed certain ethical characteristics to the different modes. The Dorian mode was preferred because of its strong and virile character; the Phrygian mode was ecstatic and emotional, the Lydian mode intimate and lascivious. In *The Republic* Plato stressed the educational values of the Dorian mode and warned against the softening influence of the Lydian mode.

In early Greek antiquity a system of modal categories developed, referred to as *nomoi* (singular, *nomos*, "law"). The *nomoi* represented modes in that they were characterized by distinctive melodic formulas suited to different song types. The performers were free to improvise within the boundaries of these modal formulas.

Jewish and Eastern Christian chant. Ancient Hebrew music followed well-established modal patterns. According to Abraham Zevi Idelsohn, a musicologist whose comparative research in the early decades of this century established modern understanding of the Hebrew modes,

> A mode . . . is composed of a number of motives (*i.e.* short music figures or groups of tones) within a certain scale. The motives have different functions. There are beginning and concluding motives, and motives of conjunctive and disjunctive [*i.e.*, convergent and divergent] character. The composer operates with the material of these traditional folk motives within a certain mode for his creations. His composition is nothing but his arrangement and combination of this limited number of motives. His "freedom" of creation consists further in embellishments and in modulations from one mode to the other.

The modal Hebrew music strongly influenced early Christian chant. This correlation can be illustrated by comparing a Gregorian chant Kyrie, in the third mode, with a Babylonian Jewish melody for a phrase from Exodus:

Eastern church chants

Syria played an important part in developing early Christian chant by integrating both Hellenistic and Hebrew elements. The Syrians devised a musical system called *oktōēchos*, a term suggesting a classification into eight *ēchoi*. The Syrian *ēchoi* are modes, although there is no consensus on whether they represented modes in a specifically technical sense, comparable to the Greek *tonoi*, or melodic formulas, comparable to the Greek *nomoi*.

Byzantine chant molded the features of early Christianity with Hellenic and Oriental traits, including the Syrian *oktōēchos*, and achieved a brilliant and distinctive style that served as a prototype for the chant of the Greek Orthodox Church. The eight *ēchoi* of the Byzantine *oktōēchos* were divided into four authentic and four plagal (derived) forms. The most common classification of the Byzantine modes was in terms of typical initial and final notes of melodies in a given mode, with the characteristic distinctions as follows (the orderly progression of notes in each series should be observed).

	Ēchos	Initial Note	Terminal Note
Authentic	I	a′	a′ or d′
	II	b′ or g′	e′ or b′
	III	c″ or a′	f′ or c″
	IV	d″ or g′	g′ or d″
Plagal	I	d′ or g′	d′
	II	e′ or g′	e′
	III	f′ or a′	f′
	IV	g′, a′, or c″	g′

The above classification reflects only two of various characteristics (not all completely clarified by modern scholars) that gave the modes their identity.

Even before the foundation of the Byzantine Empire, Armenia adopted Christianity as a state religion (AD 303). Although the early Armenian chant did not survive, the arrangement of the hymns of the Armenian Church in the comprehensive collection, *Sharakan*, indicates that the Armenians used an *oktōēchos* classification the modal characteristics of which seem to have been defined by melodic formulas rather than by scalar distinctions.

Another variety of the *oktōēchos* occurs in Russian Church chant. Although a concept of eight *ēchoi* points to the Byzantine system, the Russian *ēchoi* show a different structure. The melodic motives characteristic of the *ēchoi* are called *popievki*; but similar *popievki* could be employed in more than one *ēchos*. The use of some *popievki* is limited to the beginning, the middle, or the end of a chant. Occasionally, two *popievki* are merged into a compound *popievka*.

Gregorian chant. Gregorian chant, or plainsong, which forms the core of the musical repertoire of the Roman Catholic Church, consists of some 3,000 melodies collected and organized during the reigns of several 6th- and 7th-century popes. Most instrumental in codifying these chants was Pope Gregory I.

Melodically, Gregorian chants are based on eight different modes, often called church modes. Seven of them were given names identical with those used in the musical theory of ancient Greece: Dorian, Hypodorian, Phrygian, Hypophrygian, Lydian, Hypolydian, and Mixolydian, while the name of the eighth mode, Hypomixolydian, was adapted from the Greek. Each mode comprises a diatonic scale with the compass of one octave. The modes are classified by their *finalis*, the usual final note of a melody in that mode. Each of the four notes of the tetrachord D–E–F–G serves as the *finalis* of an "authentic" mode (see chart below).

Structure of Gregorian modes

An authentic mode consists of a pentachord (a succession of five diatonic notes) followed by a conjunct tetrachord, for example:

D E F G A B C D.

But the tetrachord may be added below rather than above the pentachord, thus generating a "plagal" mode:

A B C D E F G A.

In either case the *finalis* falls on the lowest note of its pentachord. Each authentic mode has a correlated plagal mode, which is identified by the prefix *Hypo*. In the following chart of the eight church modes the *finalis* is marked by a capital letter:

1. Dorian		D e f g a b c d
2. Hypodorian	a b c	D e f g a
3. Phrygian		E f g a b c d e
4. Hypophrygian	b c d	E f g a b
5. Lydian		F g a b c d e f
6. Hypolydian	c d e	F g a b c
7. Mixolydian		G a b c d e f g
8. Hypomixolydian	d e f	G a b c d

The tones of the Hypomixolydian mode are identical with those of the Dorian, but the two modes differ in the location of their *finalis*. The character of the church modes was further determined by a number of distinctive melodic formulas, and sometimes a particular ethos was attributed to the different modes.

Contrary to the Byzantine classification, which lists first the four authentic and then the four plagal modes, the Roman classification alternates the authentic and the plagal modes, so that modes with similar *finalis* follow each other. This principle underlies the medieval fourfold system of the so-called *maneriae* (Latin: "manners"), a division of the modes into four pairs. The first pair, or *protus maneria*, includes the Dorian and Hypodorian modes; the second, or *deuterus*, the Phrygian and Hypophrygian; the third, or *tritus*, the Lydian and Hypolydian; and the fourth, or *tetrardus*, the Mixolydian and Hypomixolydian modes.

Although Greek names were sometimes applied to the church modes and the principle of diatonic octave scales is found in both systems, certain significant discrepancies seem to belie any direct historical connection. Most conspicuous is the different meaning attributed to the names of the Greek octave species and of the church modes. Comparing the two systems provides a plausible explanation: medieval theorists apparently assumed wrongly that the Greek octave species were named in ascending rather than descending order. The Greek octave species Dorian (E–E), Phrygian (D–D), Lydian (C–C), and Mixolydian (B–B) thus appeared in the church modes as Dorian (D–D), Phrygian (E–E), Lydian (F–F), and Mixolydian (G–G).

Gradual emergence of major and minor tonality

The strict consistency of the system of church modes was gradually weakened by the appearance of B♭ in addition to B♮, although the two notes never occurred in succession. The main reason for the use of a tone not included in the basic scale pattern was that medieval musicians sought to avoid the tritone F–B. The tritone (so called because it includes three whole tones) was considered an undesirable interval sharply contrasting with the perfect fourth F–B♭. The substitution of B♭ for B♮ changed the character of a mode. For example, the Lydian mode with a flattened B was identical with the modern major mode, specifically, with the F-major scale (F G A B♭ C D E F); and the Dorian mode with a flattened B generated a minor mode corresponding to the natural D minor scale (D E F G A B♭ C D).

Nevertheless, for centuries medieval theorists considered these alterations as special forms of the Lydian or Dorian mode rather than as new modes. The reluctance to acknowledge the existence of additional modes is reflected in the so-called musica ficta. According to this practice, musical notation appears to conform strictly to the system of church modes but presupposes that the performer makes certain adjustments by raising or lowering a note through the insertion of a sharp or flat.

Two different developments occurring between the 12th and the 16th centuries resulted in a radical change in modal theory: an infiltration of folk music into the ecclesiastical and secular art forms and the steadily evolving fabric of harmony destined to unify the growing complexity of polyphonic (many-voiced) musical texture. Finally, a theorist, Heinrich Loris, commonly known by his assumed name Henricus Glareanus, sanctioned the coexistence between the old church modes and the emerging major and minor modes. In his *Dodecachordon* (1547; from Greek *dōdeka*, "twelve," and *chordē*, "string"), perhaps the most significant musical treatise of his time, Glareanus enlarged the system of the eight church modes by adding the following four:

9. Aeolian		A b c d e f g a
10. Hypoaeolian	e f g	A b c d e
11. Ionian		C d e f g a b c
12. Hypoionian	g a b	C d e f g

The Ionian and Hypoionian correspond to the major mode, the Aeolian and Hypoaeolian to the "natural" minor mode. The 12 modes of the *Dodecachordon* comprise authentic and plagal structures with tonal centres on C, D, E, F, G, and A, without recourse to sharps or flats. Glareanus mentions another two modes: the Locrian and the Hypolocrian, having B as their tonal centre. But because in these two modes B and the fifth degree above it, F, form a "false" (*i.e.*, diminished, or flattened) fifth (another form of the tritone), Glareanus states that for practical purposes only 12 modes are available.

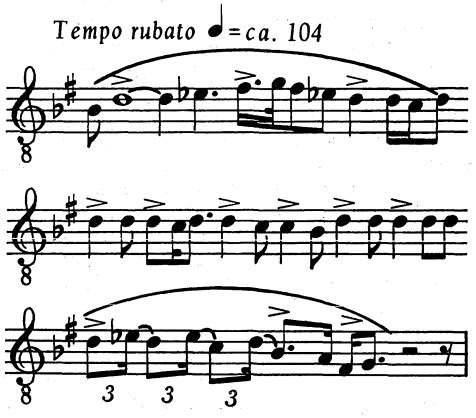
The growing complexity of polyphonic music caused the distinction between authentic and plagal modes to become more and more irrelevant, and as a result, the number of modes was virtually reduced to six. The further development of Western art music is characterized by the gradual abandonment of the old church modes in favour of the dual major–minor system that dominated 18th- and 19th-century harmony. This system is often termed tonal, in contradistinction to that of the church modes; in fact, some 20th-century works reviving the patterns of the old church modes, as well as folksongs that occasionally use them, are often termed modal. Nevertheless, major and minor have all essential characteristics of modes and should therefore be evaluated as such.

Non-Western modes and melody types. Modal concepts permeate all manifestations of Oriental art music. They represent a synthesis of well-established systems both of scalar construction and of a variety of melodic formulas and motivic configurations. The amalgamation of these elements yields specific melody types that are imbued with ethical, emotional, and cosmological connotations and form the basis of musical creation. Whereas the Western composer strives for originality and individual expression, his Eastern counterpart submits to the limitations of existing melody types, seeking to excel in an exploitation of their potentials.

The *rāga* and the *maqām*

The most elaborate modal concepts are those of the Indian *rāga* and of the Arabian–Persian *maqām*. They correspond to the Javanese *patet*, the Jewish *nigun*, and the aforementioned Greek *nomos*. The Oriental musician first exposes the characteristic features of a particular melody type in a free, improvisatory prelude leading to the more formalized section of the composition. These improvised introductions developed into a specific art form, called in India *ālāpa* ("conversation"), in Java *bebooka* ("guide"), in Iran *mukhtaṣarī* ("summary"), in Egypt and Turkey *taqsīm* ("dissection, analysis"), and in northwestern Africa *istahbar* ("information"). The following example (recorded by G. Schünemann, transcribed by R. Lachmann)—the first of four phrases constituting an introduction to a Tunisian art song composed in the *maqām raṣd ad-dīl*—illustrates this aspect of modal exposure.

From Robert Lachmann, *Musik des Orients* (1929); Ferdinand Hirt



*Rāga*s and *maqāmāt* embrace a wide variety of emotional content. They can be courageous, amorous, melancholy, cheerful, soothing, or ecstatic and are capable of conveying these qualities to the listener. Some melody types are supposed to influence illnesses, calm storms, tame wild animals, and increase the fertility of the soil. Others have pernicious power; for example, a certain *maqām* attracts evil spirits, while a certain *rāga* may cause fire. According to an ancient legend, a singer who performed such a *rāga* under the reign of Emperor Akbar (1556–1605) was reduced to ashes although he had submerged his body in the Ganges River. Cosmological connotations have caused melody types to be assigned to different parts of the day; for example, a mid-morning *rāga* may not be performed during the evening. The Westernized younger generation, however, tends to disregard these traditional restrictions.

The music of many tribal societies shows well-organized scalar and modal patterns, but they have not been explicitly formulated and systematized by the peoples involved. A comparative analysis reveals that, in spite of a great structural diversity, scalar and modal correlations exist not only among culturally unrelated tribal societies but also among tribal, Western folk, and Eastern art music. Modal systems and their unconscious counterparts thus may be said to have substantially contributed to the structure of a vast amount of the world's music.

BIBLIOGRAPHY. GUSTAVE REESE, *Music in the Middle Ages* (1940), provides a competent account and critique of a wide variety of modal concepts prevailing during the Western Middle Ages and discusses their origins and repercussions. WILLI APEL, "The Tonality," in *Gregorian Chant*, ch. 3 (1958), describes thoroughly the system of church modes. EGON WELLESZ, *Eastern Elements in Western Chant: Studies in the Early History of Ecclesiastical Music* (1947, reprinted 1967), discusses the modal structure of the melodies of Byzantine hymns and compares them with those of the Western Church. ABRAHAM Z. IDELSOHN, *Jewish Music in Its Historical Development* (1929, reprinted 1967), an authoritative work on Jewish music, contains chapters on "The Modes of the Bible" and "The Modes of the Prayers." EGON WELLESZ (ed.), *The New Oxford History of Music*, vol. 1 (1957), includes the following chapters discussing modes: ARNOLD BAKE, "The Music of India," CARL H. KRAELING and LUCETTA MOWRY, "Music in the Bible," ERIC WERNER, "The Music of Post-Biblical Judaism," ISOBEL HENDERSON, "Ancient Greek Music," and HENRY G. FARMER, "The Music of Islam." MIECZYSLAW KOLINSKI, "Classification of Tonal Structures, Illustrated by a Comparative Chart of American Indian, African Negro, Afro-American and English-American Structures," *Studies in Ethnomusicology*, 1:38–76 (1961), comprises a new system of modal classification accommodating a wide range of Western and non-Western modal patterns. ROBERT LACHMANN, *Musik des Orients* (1929, reprinted 1966), is the first scholarly survey of the music of Eastern cultures.

(M.Ko.)

Modigliani, Amedeo

For the importance and quality of his work, as well as for the drama of his brief life, the Italian painter and sculptor Amedeo Modigliani was one of the most significant figures in the international artistic milieu that existed in Paris in the first decades of the 20th century and that is known as the School of Paris. His work consists of a small number of stone sculptures, all executed between 1909 and 1913, about 350 paintings, and many drawings. The subjects are almost exclusively portraits and female nudes. The style has easily recognizable and relatively consistent characteristics: the use of broad expanses of colour for the plastic construction of the image, rhythmic modulation of line, reduction of the third dimension, asymmetry of composition, and elongation of the figure.

Modigliani was born in Leghorn (Livorno), Italy, on July 12, 1884, into a Jewish family of small merchants. After suffering from pleurisy and typhus in 1895 and 1898, he was forced to give up a conventional education, and it was then that he began to study painting. Because of his poor health, he spent the winter of 1901 at Naples and Capri; his letters to the painter Oscar Ghiglia, in which he writes of his artistic vocation and expounds his idea on art, began during this period. After a brief stay in Florence in 1902, he continued his artistic studies in Venice, remaining there until the winter of 1906, when he left for Paris.

In Paris, he was overwhelmed by the painting of Paul Cézanne, which exerted a decisive influence on the earliest phase of his work. His initial important contacts were with the poets André Salmon and Max Jacob, with Pablo Picasso, and—in 1907—with Dr. Paul Alexandre, a friend of the avant-garde artists and the first to become interested in Modigliani and to buy his works. In 1908 he exhibited six works at the Salon des Indépendants. For a time his interests turned toward sculpture. After the summer of 1909, which he spent with his family in Leghorn, he returned in the fall to Paris. There, through Dr. Alexandre, he met the Romanian sculptor Constantin Brancusi, by whose work he was impressed and on whose advice he made a serious study of Negro sculpture. To prepare himself for sculpture, he intensified his graphic experiments. He detested what he considered the false Impressionism of Auguste Rodin, with its pictorial modelling and susceptibility to the play of light. In his drawings he tried to give to his contours the function of limiting or enclosing the volume; in his sculpture, he carved the stone directly in an attempt to preserve in the form the plastic unity of the block. In 1912 he exhibited a "decorative ensemble" of eight stone heads at the Salon d'Automne.

He soon returned entirely to painting, but his experience as a sculptor had fundamental consequences for his style, both in the simplification and essentiality of the image and in the use of colour, which is employed as the con-

"Self-Portrait," oil on canvas by Modigliani, 1919. In the Museu de Arte Contemporânea da Universidade de São Paulo, Brazil.

structive material of the painting in the same way that stone is the constructive material of sculpture. By reducing and almost eliminating chiaroscuro—that is, the illusory third dimension—he achieved, by the strength of his contours and juxtaposed colours, a solidity in the flat image that is similar to that of sculpture.

Influence of Cézanne

The outbreak of war in 1914 increased the difficulties of Modigliani's life. Alexandre and other friends were at the front; his pictures did not sell; his already delicate health was deteriorating because of his poverty, feverish work, and the abuse of alcohol and drugs. He was in the midst of a troubled affair with the English poetess Beatrice Hastings, with whom he lived for two years, from 1914 to 1916. He was assisted, however, by the art dealer Paul Guillaume and especially by the devoted friendship of the Polish poet Leopold Zborowski, who bought or helped him to place a few paintings and drawings.

Modigliani was not a professional portraitist; for him the portrait was only an occasion to isolate a figure in an absolute unity of space and colour. He painted his friends, personalities of the Parisian artistic and literary world, but also unimportant people: models, servants, girls from the neighbourhood. In 1917 he began a series of large female nudes that are among his best works. In December, Berthe Weill organized a one-man show for him in her gallery, but the police judged the nudes indecent and had them removed.

His last, touching love affair began in the same year, 1917, with the young painter Jeanne Hébuterne, with whom he went to live on the Côte d'Azur. Their daughter Jeanne was born in November 1918. This was also a happy period for his painting, which became increasingly refined in line and delicate in colour. A more tranquil life and the climate of the Mediterranean, however, did not restore the artist's undermined health. After returning to Paris in May 1919, he became ill in January 1920 and ten days later, on the 24th, died of tubercular meningitis. Next day, Jeanne Hébuterne killed herself by jumping from a window.

Little known outside avant-garde Parisian circles, Modigliani seldom participated in official exhibitions, and his single one-man show was the one held in 1917 at Berthe Weill's. Fame came after his death with the 1922 exhibition at the Galerie Bernheim-Jeune and, later, with a monograph by the poet André Salmon.

Posthumous fame

His original sculptures, mostly in sandstone, are 25 in number; the number of drawings cannot be determined. Except for some 30 large female nudes (1916–19) and four landscapes (1919), his paintings are almost always portraits of relatives, artists, writers, musicians, actors, dealers, and collectors, along with many of unidentified persons. The names of the individuals portrayed may give an idea of the Montparnasse milieu frequented by the artist: Constantin Brancusi, Diego Rivera, Henri Laurens, Pablo Picasso, Chaim Soutine, Juan Gris, Max Jacob, Jean Cocteau, Jacques Lipchitz. Some, such as Paul Guillaume, Hanka and Leopold Zborowski, Beatrice Hastings, and Jeanne Hébuterne, were painted several times. Of Modigliani himself, there is only a single self-portrait, painted in 1919, shortly before his death.

MAJOR WORKS

"Head of a Young Woman" (1908; Jean Masurel Collection, Mouvaux, France); "La Juive" (1908; private collection, Paris); "Paul Alexandre" (1909; private collection, Paris); "Cariatide in piedi" (*c.* 1912; R.D. Judah Collection, London); "Seated Nude" (*c.* 1912–13; Courtauld Institute Galleries, London); "Diego Rivera" (1914; Museu de Arte, São Paulo, Brazil); "Bride and Groom" (1915; Museum of Modern Art, New York); "Paul Guillaume" (1916; Galleria d'Arte Moderna, Milan); "Beatrice Hastings con cappello" (1916; Barnes Foundation, Merion, Pennsylvania); "Jacques Lipchitz and His Wife" (1916–17; Art Institute of Chicago); "Léon Bakst" (1917; National Gallery of Art, Washington, D.C.); "Girl with Braids" (1917; E. Kahn Collection, Cambridge, Massachusetts); "Chaim Soutine" (1917; National Gallery of Art, Washington, D.C.); "Nude with Necklace" (1917; Ralph Colin Collection, New York); "Nudo sdraiato" (1917; Gianni Mattioli Collection, Milan); Hanka Zborowska seduta su un divano (1917; Museum of Modern Art, New York); "Madame Amédée (Woman with Cigarette)" (1918; National Gallery of Art, Washington, D.C.); "Anna (Hanka Zborowski)" (1918; Galleria Nazionale d'Arte Moderna, Rome); "Little Girl in Blue" (1918; private collection, Paris); "Leopold Zborowski" (*c.* 1918; Museu de Arte, São Paulo, Brazil); "Nudo in piedi (Elvira)" (1918; Walter Hadorn Collection, Bern); "Ritratto di Baranowski" (1918; Mr. and Mrs. R.J. Sainsbury Collection, London); "La giovane Lattaia" (1918; Mr. and Mrs. George Friedland Collection, Merion, Pennsylvania); "Jeanne Hebuterne in camicia" (1918; Nate B. and Frances Spingold Collection, New York); "Gypsy Woman with Baby" (1919; National Gallery of Art, Washington, D.C.); "Reclining Nude" ("Le Grand Nu," *c.* 1919; Museum of Modern Art, New York); "Yellow Sweater" *c.* 1919; Solomon R. Guggenheim Museum, New York); "The Servant Girl" (1919; Albright-Knox Art Gallery, Buffalo, N.Y.); "Self-Portrait" (1919; Museu de Arte Contemporânea da Universidade de São Paulo, Brazil).

BIBLIOGRAPHY. ANDRE SALMON, *Modigliani, sa vie et son oeuvre* (1926), the first biography of the artist, is important because it was written shortly after Modigliani's death by a poet and writer who was close to him. Salmon's *Vie passionnée de Modigliani* (1957; Eng. trans., *Modigliani: A Memoir*, 1961), is a biography in the form of a novel. ARTHUR PFANNSTIEL, *Modigliani* (1929), is a fundamental critical-biographical study with an annotated catalog of 289 works; his *Modigliani et son oeuvre, étude critique et catalogue raisonné* (1956), amplifies his earlier work, particularly in the catalog additions; Pfannstiel's *Modigliani: dessins* (1958), is a short text on the drawings, with reproductions and an annotated catalog. AMBROGIO CERONI, *Amedeo Modigliani, peintre suivi des "souvenirs" de Lunia Czechowska* (1958), is important for Modigliani's letters to his friend Czechowska and for her memoirs; *Amedeo Modigliani: dessins et sculptures avec suite du catalogue illustré des peintures* (1965), contains an important catalog and a bibliography focussing on the drawings and sculpture; Ceroni's *I dipinti di Modigliani* (1970), with an introduction by LEONE PICCIONI, is a very important critical work, with essential bibliography up to 1969, documentary photographs of the artist and of his exhibitions, chronology, an annotated catalog of his works, and biographical data on the people painted. JEANE MODIGLIANI, *Modigliani senza leggenda* (1958; Eng. trans., *Modigliani: Man and Myth*, 1958), written by Modigliani's daughter, is the most reliable and exhaustive biography and includes

letters and unedited documents. JAMES T. SOBY, *Modigliani* (1954), is one of the few noteworthy publications on the artist written in English. LAMBERTO VITALLI, *Disegni di Modigliani* (1929), is dedicated exclusively to the designs that are particularly numerous and important in the range of Modigliani's work. JEAN COCTEAU, *Modigliani* (1950), is another interesting volume written as a testimonial by a poet who was a friend and of whom Modigliani did one of his most famous portraits; JACQUES LIPCHITZ, *Amedeo Modigliani* (1953), is a small book, also written as a testimonial, by a friend who was a sculptor, whose "Man with His Wife" is one of Modigliani's most famous works. CLAUDE ROY, *Modigliani* (Eng. trans. 1958), includes biographical data, bibliography, and a list of exhibitions. ALFRED WERNER, *Modigliani the Sculptor* (1962), is the most important study of his sculpture.

(P.Bu.)

Mohammed I Askia of Songhai

Mohammed I Askia, one of the greatest rulers of the Songhai Empire in the western Sudan of West Africa, introduced important political and administrative reforms that brought security and prosperity to his people.

Both Mohammed's place and date of birth are unknown. For a long time, he was thought to be a Silla (a Tukulor clan of Senegal) or a Touré of Sarakole (Soninke) origin, but it now seems that his name, as spelled in Arabic by 18th-century Timbuktu chroniclers, was Mohammed Towri, or Mohammed of the Toro (Fouta Toro of Senegal). So he was probably of Tukulor origin, from a Senegalese family that had settled in Gao. The name of his clan was probably Kan, or Dyallo. Oral tradition, however, which is still very much alive, makes Mamar (Mohammed's popular name) out to be Sonni ʿAlī's nephew, his sister Kasey's son by a *jinnī*.

After the death of Sonni ʿAlī Ber, the ruler who had solidified the Songhai empire from 1464 to 1492, Mohammed tried, as early as February 1493, to wrest power from Sonni ʿAlī's son Sonni Baru, who had been elected by acclamation on January 21. In the Battle of Anfao on April 12, 1493, Mohammed's forces, though inferior in number, were victorious. Paganism tinged with the esoteric Songhai Islām of the Sonnis gave way to an Islāmic state whose civil code was the Qur'ān and whose official writing was Arabic. After conquering the enemy, Mohammed assumed the title of Askia in order to ridicule, it is said, the daughters of the fallen Sonnis who said of him *a si tya*, or "he will not be."

While Sonni ʿAlī had been a warrior, Askia Mohammed was above all a statesman. He set up an efficient administration of the regions conquered by his predecessor. He began by dividing Songhai into provinces and placed each under a governor. A standing army and a fleet of war canoes were organized under the command of a general and an admiral. Moreover, Askia Mohammed created the positions of director of finance, justice, interior, protocol, agriculture, waters and forests, and of "tribes of the white race" (Moors and Tuaregs who at that time were vassals of the Songhai and furnished them with squadrons of dromedary-mounted troops). All these officials were for the most part chosen from among the nobles and were brothers, sons, or cousins of Askia.

Organization of the Songhai Empire

This exemplary organization of an African state was completed by a religious organization. Although a faithful believer, Mohammed was not very well informed in matters of religious orthodoxy and therefore took as an adviser the Moroccan reformer, el-Mehrili, persecutor of the Jews of Touat, to help him put his realm in order, in particular to recover the possessions belonging to the descendants of the defeated Sonnis and to "servile tribes" not converted to Islām. Establishing Islām as the official religion of the nobles was without doubt the only error of this statesman. From then on, it was no longer a popular religion but an imported one that later was to justify the conquest of the Songhai by Moroccan Muslims.

And yet it was to receive the necessary counsel directly from "God's House" that in 1495, two years before his accession to power, Askia Mohammed undertook a pilgrimage to Mecca. This pilgrimage, from 1495–97, has remained famous as much for the pomp with which it was carried out as for the marvelous tales to which it gave rise. The chronicler Mahmud Kati, who accompanied Askia, wrote in *Tarīkh al-fattāsh* that the *jinnī* of Mecca had had Askia Mohammed named caliph and had told him what his rights were over the former vassal tribes of the Sonnis. By the time he returned in 1497, he was a leader deeply converted to Islām. Next he would proceed to consolidate and enlarge Songhai.

Militarily he met with uneven success. Although between 1498 and 1502 he was victorious over the Mossi of Yatenga and the inhabitants of the Aïr (Niger), a few years later (1505–06) he undertook an unsuccessful campaign against Borgu (the present boundary region of Niger and Nigeria). And similarly, although between 1507 and 1514 he reduced the insurgent Fulani factions in Senegal and the Bornu factions near Agadez, one of his lieutenants, the Karta of Kabi, revolted against him in turn and, despite his efforts between 1516 and 1517, remained independent. As an organizer of an effective administrative system he was more successful.

During the course of his lengthy sojourns in the capital, Gao (1502–04 and 1506–07), he set up with rare talent the system of tithes and taxes, the regulation of agriculture and fishing, and the recruitment and training of his administrators and governors.

The extent of the Songhai Empire of this period remains conjectural. Sadi, the Timbuktu chronicler, has said that the territory that Askia Mohammed conquered "by fire and sword" extended west as far as the Atlantic Ocean, northwest to the salt mines of Teghaza (on the northern border of present-day Mali), southwest as far as Bendugu (Segu), southeast to Bussa, and northeast to Agadez. It is certain that the influence of Songhai during Askia Mohammed's time was considerable and extended even beyond these boundaries. All the surrounding states, whether allies or enemies, experienced its civilizing ferment.

This influence was reinforced by an indirect, though nonetheless profound, Islāmic propaganda. Muslim scholars went into areas they would not have been able to penetrate without the Gao ruler's support. And for several centuries to come, the small African states and the neighbouring leaders would take as their model the Islāmic empire of Songhai and its prestigious leader, Askia Mohammed. Even today, according to oral tradition, Askia Mohammed appears as a supernatural being, a *jinnī*, who either took after his father or after those with whom, by a special gift, he was able to consult during his pilgrimage to Mecca.

Fall from power and death

The end of his reign was, however, tragic. Little by little his dream of an Islāmized Sudan, whose emir he would be, evaporated. Even during his lifetime, his children were quarrelling over the spoils. After the death of his commander in chief, Kanfari Omar, one of his brothers, in 1519, Askia Mohammed was no longer safe even in Gao, and the Songhai people seemed to him "as crooked as the course of the Niger River . . ." Embittered, half blind, the old man had no one left but his friend and adviser, his servant Ali Folen. The almost religious fear that he inspired gave way to contempt. Musa, his eldest son, plotted against him and in 1528 killed his new general in chief, Yaya, another of Askia's brothers, who had remained faithful to him. Musa then dispossessed his father, taking the name Askia Musa. He kept this title for three years before being assassinated himself by one of his brothers. Now deposed, the old Askia Mohammed was banished to an island in the river, a place "infested with mosquitos and toads." There, from 1528 to 1537, he was a blind and despairing witness to the murderous quarrels of his children over the territory of Songhai.

In 1537 his third successor, his son Askia Ismaïl, recalled his father to Gao. To reward him, Mohammed bequeathed to him his green turban and his caliph's sabre. On March 2, 1538, during a period of temporary calm, this founder of a dynasty died. He was buried in Gao, under a pyramid of earth surmounted by wooden spikes. His tomb is still standing and has become one of the most venerated mosques in all of West Africa.

BIBLIOGRAPHY. A detailed bibliography of the history of Songhai may be found in JEAN ROUCH, *Contribution à l'histoire des Songhay* (1953). ABD AL-RAHMAN IBN ʿABD ALLAH,

AL-SA'DI, *Tarikh-es-Soudan* (written *c.* 1655; published in 2 vol., 1898–1900), is the classic source on the history of Songhai to 1655. See also HEINRICH BARTH, *Travels and Discoveries in North and Central Africa*, 5 vol. (1857–58; reprinted in 3 vol., 1965), based on the Sa'di chronicle. E.W. BOVILL, "The Niger and the Songhai Empire," *Journal of the African Society*, 25:138–146 (1925), is a good account by one of the few historians to emphasize the essential role of the Niger River in Songhai history.

(J.P.R.)

Moldavian Soviet Socialist Republic

The hilly land of Moldavia (formally the Moldavian Soviet Socialist Republic) lies in the extreme southwest of the European portion of the Soviet Union, surrounded by the Ukraine on the north, east, and south and bordered on the west by the Prut River, forming the Soviet frontier with Romania. Occupying an area of 13,000 square miles (33,700 square kilometres), it is the second smallest of the 15 constituent union republics, with a population of more than 3,800,000. The capital is at Kishinyov.

The greater part of the republic lies between the great, meandering rivers Prut and Dnestr (Dniester), as they flow to their Black Sea estuaries. This region was formerly known as Bessarabia. It was an integral part of the Romanian principality of Moldavia until 1812, when it was ceded to Russia by the suzerain Ottoman Empire. It remained a province of the Russian Empire until 1918, except for the southern districts along the Danube River, which were joined to Romania after the Crimean War in 1856, only to be retroceded to Russia in 1878. In 1918 Bessarabia became part of Greater Romania, and in the interwar period it was gradually integrated into the political and economic structure of that country. The Soviet Union did not recognize this cession of territory, and in 1924 it established the Moldavian Autonomous Soviet Socialist Republic, a small strip of territory on the left bank of the Dnestr. In June 1940 the Soviet Union obliged Romania to cede Bessarabia, and in August it established the Moldavian S.S.R. Between 1941 and 1944, while Romania and the Soviet Union were at war, Bessarabia again became part of Romania. In 1944 Soviet troops retook the territory, and the Moldavian S.S.R. was re-established. The territory has been fully incorporated into the Soviet political and economic system, but since the 1960s Bessarabia has again become a subject of controversy between Romania and the Soviet Union.

For related information, see DNESTR RIVER; BALKANS, HISTORY OF THE; RUSSIA AND THE SOVIET UNION, HISTORY OF.

THE LANDSCAPE

Topography. Moldavia lies beyond the great arc of the Carpathian Mountains, mostly on deep sedimentary rocks covering the southwest portion of the ancient structural block known as the Russian Platform. Harder crystalline rocks outcrop only in the north. Its surface is a hilly plain, with an average elevation of 482 feet (147 metres), cut by a deep network of river valleys, ravines, and gullies.

Kodry Hills

The uplands of the centre of the republic, the Kodry Hills, lie at an average elevation of about 1,150–1,300 feet (350–400 metres), and the highest point, Mt. Balaneshty in the west, reaches 1,409 feet (430 metres). These uplands are interlaced by deep, flat valleys, ravines, and landslide-scoured depressions, separated by sharp ridges, and steep, forest-clad slopes account for much of the terrain. The Dnestr uplands, their eastern slopes forming the high right bank of the Dnestr River, border the central uplands on the east and northeast.

The northern Moldavian landscape is characterized by the level plain of the Beltsy steppe (500 to 650 feet, or 150 to 200 metres, in elevation) and also by uplands averaging twice this height, culminating in the 1,053-foot (321-metre) Vysokaya Hill. The northern uplands include the strikingly eroded Medobory-Toltry limestone ridges, which border the Prut River.

In the south, the extensive Budzhak Plain is broken by numerous ravines and gullies, while in the east, left-bank Moldavia includes spurs of the Volyn-Podolsk Upland, cut into by tributaries of the Dnestr.

Climate. Moldavia's climate, warm and moderately continental, is characterized by a lengthy frost-free period, a comparatively mild winter, considerable temperature fluctuations, and, in the south, long dry periods.

Average annual temperature reaches 45.9° F (7.7° C) in the north and 49.8° F (9.9° C) in the south, but the July averages rise to 67° and 73° F (19.5° and 23° C), respectively, and the mercury drops to as low as 23° and 27° F (−5° and −3° C) in January. Absolute temperatures recorded range from a record low of −31° F (−35° C) and a high of 106° F (41° C). Moldavia experiences a very variable rainfall, with the average figures of 18 to 22 inches (450 to 550 millimetres; the figure is a little lower in the south) concealing variations that may double the figure in some years and result in prolonged dry spells in others. Most rainfall occurs in the warmer months, and heavy summer showers, coupled with the irregular terrain, cause erosion problems and river silting. Winter snow cover is thin. Winds tend to come from either the northwest or the southeast.

Drainage. Moldavia has a well-developed network of about 3,000 rivers, all draining south to the Black Sea, but only 246 of these exceed six miles (10 kilometres) in length, and only eight exceed 60 miles. The Dnestr, the rapidly flowing main artery, is navigable almost throughout the republic and has an average discharge of about 10,000 cubic feet (300 cubic metres) per second, swollen by spring snowmelt from the Carpathians and by heavy summer rains. In the warmer winters, it is not frozen. The other, smaller, main artery, the Prut, is a tributary of the Danube, which it joins at the extreme southern tip of the country. The Yalpukh, Kogilnik, and other small southern rivers drain largely into the Danubian estuary in the nearby Ukraine.

Underground water, extensively used for the republic's water supply, includes about 2,200 natural springs. The terrain favours construction of reservoirs.

Soils. Moldavian soils are varied and very fertile, with chernozem—rich, black soils—covering three-quarters of the republic. The best developed chernozem, fostering the growth of grain, tobacco, and sugar beets, is found in the north, in the low-lying parts of the central Moldavian and Dnestr uplands, as well as in the left-bank regions. Chernozem quality diminishes southward, but grapes and sunflowers can still be grown. Woodland soils characterize the uplands: 40 percent are covered by forests, the rest by orchards, vineyards, and fields of grain. Floodplain soils characterize the riverside areas, while the lower reaches of the Prut and southern river valleys have saline and marshland soils.

Chernozem soils

Plant and animal life. Northern and central Moldavia is a forest zone, while a steppe belt crosses the south. There are more than 1,500 species of plants in the republic, with scenic expanses of forests, covering about 1,150 square miles (3,000 square kilometres), of particular importance, especially in the central Kodry Hills region. The commonest trees are hornbeam and oak, followed by a rich variety including linden, maple, wild pear, and wild cherry. There are beech forests at the sources of the Ikel and Byk rivers. Large-scale reforestation projects have been carried out in the republic.

Moldavia's steppes were originally grass covered, but most of them are now cultivated. Lush meadows and reed growths occur in the floodlands of the Dnestr and portions of the Prut, while salt-marsh grasslands flourish in the saline valleys of the Kogilnik, Yalpukh, Botna, and lower Prut.

Moldavian animal life is rich, despite the republic's small size. Mammals include boar, roe deer, hare, wolf, fox, badger, wildcat, ermine, and polecat. Siberian stag, fallow deer, spotted deer, and muskrat have been successively introduced and are firmly established. Roe deer, hares, foxes, and muskrats are of commercial importance.

There are many species of birds, both resident and migratory. The marshy lower reaches of Moldavia's rivers provide sanctuary for wild geese, migratory ducks, and herons, while white-tailed sea eagles are to be found in

the floodland forests. The wood lark, jay, song thrush, blackbird, hawk, and long-eared owl frequent the republic's forests. Plentiful fish supplies include carp (raised in artificial reservoirs), perch, bream, ruff, and pike.

THE PEOPLE

By the mid-1970s, Moldavia was the home of more than 3,800,000 people, an increase of 32 percent since 1959 and of some 54 percent since 1940. The annual population increase is about 1.2 percent, and Moldavia has a higher average population density than any other Soviet Union republic.

Ethnic composition

Of the total population, according to the 1970 census, 2,304,000 (64.6 percent) were Moldavian, 507,000 (14.2 percent) Ukrainian, 414,000 (11.6 percent) Russian, 125,000 (3.5 percent) Gagauzi (a Turkic people), 98,000 (2.7 percent) Jewish, and 74,000 (2.1 percent) Bulgarian. Between 1959 and 1970 the Moldavians and Ukrainians in the total population declined by 0.8 and 0.4 percent, respectively, while the Russians increased by 1.4 percent.

The urban population has increased as a result of industrialization: by 1974 about 35 percent of the people lived in towns, compared with 13 percent in 1940. Most of the towns are small; in 1974 Kishinyov had an estimated 432,000 inhabitants, Tiraspol and Beltsy each had a little over 100,000, and Bendery had 89,000, with other towns below 50,000.

Moldavian villages are large, most of them having a thousand and more inhabitants; all are supplied with electricity, and the gas network is being extended.

THE ECONOMY

A diversified industry has been established in Moldavia, agriculture has been modernized, and transport and the building industry have been overhauled. Investment programs had borne fruit by the mid-1970s, when gross industrial output was more than 35 times the level of 1940. The same period witnessed a more rational distribution of productive forces over Moldavian territory, equalizing the economic development of various regions. By 1973 the specialized labour force approached 1,150,000, or 11 times the total in 1940. Moldavian industrial and agricultural products are supplied to all the union republics and are exported to some 50 foreign countries.

Industry. The leading branch of the Moldavian economy, industry concentrates in the main on food processing, with the machine-building, power-engineering, consumer-goods, and building-materials industries undergoing development as well.

The food industry

The food industry has numerous branches: wine making, canning, sugar refining, and oil pressing, as well as production of essential oils, are of all-union significance. In particular, Moldavia is an important supplier of wine, including champagne and brandy, and is responsible for one-fifth of the Soviet output.

The canning industry processes mainly vegetables and fruits, and Moldavia is responsible for 9 percent of Soviet production of these and for a full third of Soviet fruit juice output. Southeastern Moldavia alone produces about 1,000,000,000 cans annually.

Moldavia holds the third place in Soviet sugar production, the sugar-refining industry being located in the north.

The republic produces more than 5 percent of Soviet vegetable oil and one-third of Soviet tobacco. For local needs the republic has flour and other mills and well-developed meat, dairy, and confectionary industries.

Machine building, established in the mid-1950s and centred on Kishinyov, Beltsy, Tiraspol, and Bendery, is acquiring increasing importance. Tractors made in Moldavia, specially equipped for use in orchards and vineyards, are supplied to other Soviet republics.

Light industry includes the production of furs at Beltsy, garments and knitwear at Kishinyov and Tiraspol, footwear at Kishinyov, and silk fabrics at Bendery.

Building materials produced in Moldavia include bricks, limestone, tiles, cement, slate, and concrete blocks. Rybnitsa is the leading centre of this industry.

The power industry of the republic is expanding; thermoelectric power plants are located in Kishinyov, Beltsy, and Tiraspol, and there is a hydroelectric station in Dubossary on the Dnestr. A Moldavian hydroelectric station in the town of Dnestrovsk was completed in 1971 (and enlarged during 1973–74), with a final installed capacity of 2,000,000 kilowatts. Some 12,200,000,000 kilowatt-hours of electricity are generated annually, compared with a total of 17,200,000 in 1940. The republic provides electricity to the southern regions of the Ukraine and since 1972 has supplied power to Bulgaria through a transmission line. The republic's power system is connected to the unified southern power system of the Soviet Union.

Agriculture. There are about 480 collective and 240 state farms, and the total sown area is 4,650,000 acres (1,900,000 hectares). There is no large-scale private farming, but collective farmers do have small plots for their own use. Collective farms cultivate four-fifths of the area under grain crops and are generally engaged in mixed farming. On an average a collective farm has 7,000 acres (2,800 hectares) under crops and more than 1,200 acres (500 hectares) of vineyards and orchards. The state farms usually specialize in cultivating and processing a particular crop, some of them producing grapes and wines, others growing aromatic plants and producing essential oils.

Agriculture is highly mechanized, 98 percent of agricultural jobs being carried out by machines. All collective and state farms are provided with electricity, and use is made of chemical means of pest control and mineral fertilizers. The irrigation system is being expanded.

Arable farming

Arable farming is responsible for slightly more than 70 percent of the gross agricultural output, while the share of animal husbandry is not quite 30 percent. Arable farming accounts for up to 72–73 percent of the cash income of the collective farms.

The structure of arable farming has undergone radical changes in the Soviet period: the share of grain crops is about 45 percent, compared with 80 percent in 1940, while the share of industrial crops has increased, accounting for more than 20 percent by the 1970s. In order to consolidate animal farming, the share of fodder has also been raised and amounts to 30 percent. Since 1940 the area under vegetables, orchards, berries, and vineyards has undergone significant expansion. Viticulture, fruit and vegetable growing, and other specialized farming are particularly important, comprising 90 percent of the commodity output of arable farming. The largest vineyards are to be found in the southern and central regions, and most of the orchards are situated in northern and southeastern Moldavia. Walnuts are also significant.

Sunflower seed is the most important industrial crop, and, though it is grown all over Moldavia, the southeastern regions have the largest plantations. Sugar beets, a relatively new crop in Moldavia, are cultivated in the north. Moldavia is also the major Soviet tobacco grower. Vegetables are grown mainly in the southeast.

The chief grain crops are winter wheat and maize (corn). Wheat is used for the republic's own needs, and maize is supplied as seed to other republics. While the areas under wheat have decreased considerably, its gross output, aided by measures to increase productivity, has gone up. Moldavia holds first place in cereal crop capacity in the Soviet Union. Most of the grain is grown in the north.

Dairying and cattle breeding account for almost 30 percent of agricultural output, followed by pig farming. The sturdy Karakul and *tsigayk* breeds constitute a large portion of the sheep, raising of which is particularly important in southern Moldavia.

Economic subregions. The Moldavian S.S.R. is divided into four subregions: Northern, Central, Southern, and Southeastern. Each of the subregions has distinct natural and economic features, possessing unique problems of development.

The Northern subregion. This stretches from the northern border to the central Moldavian upland. It covers 13 districts, and its area constitutes about a third of the total area of the republic and the same proportion

of the total population. Urban and rural populations constitute, respectively, 21 and 79 percent. Agriculture dominates the economy: the subregion produces about 40 percent of the republic's grain, 95 percent of sugar beets, half the tobacco, 30 percent of fruit, 40 percent of sunflower, and 45 percent of animal-husbandry products. A diversified industry has been established. The subregion is responsible for 27 percent of the total industrial output, including all the cement and sugar production, and more than 80 percent of processed tobacco. Instrument making and electrical engineering are important industries. Beltsy is a prominent industrial centre, and Soroki and Rybnitsa are also developing industrial towns.

The Central subregion. This lies in the middle of Moldavia, between the Dnestr and the Prut. It occupies about a quarter of the republic's territory and is the home of a third of the population. Engineering and light industry are of great importance, alongside the food industry. The subregion also has a developed agriculture, concentrating on viticulture, fruit, and dairy and poultry farming.

Kishinyov

Kishinyov, the Moldavian capital, is the largest industrial centre of the subregion and of the republic. The urban complex produces more than one-third of the republic's engineering industry output, more than two-fifths of the light industry commodities, more than 25 percent of the building materials, and about 20 percent of the food industry products.

The Southern subregion. Occupying 20 percent of the republic's territory, and the home of only 14 percent of its people, the Southern region is predominantly agricultural. There are no large cities, and the most important town is Kagul, on the Prut River, which has wine-making and building-materials industries.

The Southeastern subregion. This occupies about 18 percent of the republic's territory and has about the same proportion of the population. It is noteworthy for its highly developed intensive agriculture and industry, specializing in the production of vegetables, fruits, grapes, and sunflower seeds and in animal husbandry. It also has silk-manufacturing, canning, oil-pressing, meat-packing, and heavy industrial plants, with Tiraspol and Bendery the main industrial centres.

Transport. Railway and motor transport are the basis of the Moldavian transport system. The railway network contains two lines—one linking Tiraspol, Kishinyov, and Ungeny and the other linking Tiraspol and Reni—that are of importance in the Soviet Union as a whole.

By 1972 the railways were carrying nearly 13 times as much outgoing freight as they had in 1940, while incoming freight, a good gauge of economic development, had increased more than 30-fold. Incoming goods include coal, petroleum products, iron and nonferrous metals, timber, mineral fertilizers, and machines and equipment. Agricultural goods and products of the food industry prevail among the outgoing commodities, although a growing quantity of machines and light industrial goods is sent to other parts of the Soviet Union. In addition, Moldavian railways carry 10,000,000 passengers annually.

Motor transport generally carries freight inside the republic, over a road network of which somewhat less than half is asphalt covered. By 1973 road transport was responsible for hauling 224,100,000 metric tons of freight, 150 times the 1940 figure, while buses carried more than 240,000,000 passengers.

River transport is of local importance, and air transport links Moldavia with other parts of the Soviet Union, Kishinyov being the site of the main airport.

POLITICAL AND SOCIAL STRUCTURE

The constitutional framework. According to the constitution of the Soviet Union and the constitution of the Moldavian Soviet Socialist Republic (adopted in February 1941), Moldavia is a sovereign socialist state of workers and peasants. Its political foundation is the Soviets of Working People's Deputies, and its economic foundation is the socialist ownership of the means of production. It has a coat of arms, flag, and national anthem.

A one-chamber Supreme Soviet, elected for a four-year period, is the highest organ of state power, supplemented, between sessions, by the Presidium of the Supreme Soviet, which it elects. The Supreme Soviet appoints the government—namely, the Council of Ministers, which is the highest executive and administrative organ.

The organs of state power in districts, cities, and rural localities are the Soviets of Working People's Deputies, which are elected for two-year periods. The Supreme Soviet also appoints, for a five-year period, the Supreme Court, which is the highest judicial establishment of the republic. The general procurator of the Soviet Union appoints for a five-year period the chief procurator of Moldavia, who is responsible to him.

The Communist Party

The Communist Party of Moldavia, part of the Communist Party of the Soviet Union (CPSU), is the only political party allowed to function. There is no organized political opposition. So-called nonparty candidates may run for election to the Supreme Soviet and other bodies, but only on a single list with Communist candidates approved by the Communist Party. Nonparty deputies do not pursue policies distinct from those of the Communist Party. As in the other union republics, the party employs the various state organs mentioned above to carry out its policies in all spheres of activity. The primary purpose of elections and the various public bodies is, consequently, to rally mass support for party policies. The party had about 125,000 members and candidates to membership by the mid-1970s. The Young Communist League (Komsomol) of Moldavia, with a membership of about 450,000 young people, is in close collaboration with, and under the leadership of, the Communist Party of Moldavia.

The trade unions of the republic have a membership of 1,220,000. As in other socialist countries, they concern themselves with the recreational and working conditions of their members, the stimulation of fulfillment of various economic goals, and the organization of the emulation process known as socialist competition. The trade unions have little independence or power of initiative. No strikes in Moldavian industry have been recorded since the end of World War II.

Education and social services. Significant changes have occurred in Moldavian society during the years of Soviet power. Illiteracy was eradicated, and, as in other union republics, a general eight-year education scheme—changing over to a general 10-year program by the early 1970s—was introduced. Emphasis has been placed upon technical education in order to satisfy the steadily growing needs of agriculture and industry for specialists and a highly skilled work force. In 1975 there were nearly 700,000 school children; 92 percent of those who finished the eight-year program continued their education. Before 1940 Moldavia had only one institution of higher education, a teacher-training college. In 1973–74 there were 42,400 students in higher educational institutions and 52,500 in specialized middle schools.

Academy of Sciences

At the highest level, the Moldavian S.S.R. Academy of Sciences, established in Kishinyov in 1961, coordinates the activities of some 20 scientific institutions. An additional 50 or so research centres in the fields of viticulture, horticulture, beet growing, grain cultivation, and wine making have been set up, and Moldavian scientists have won international acclaim in these fields.

The rising standards of living in the republic are closely connected with the development of an economy utilizing scientific methods to improve techniques and overall productivity. The monthly income of the average Moldavian is enhanced by a third or so by the provision of social services from the republic's national income. In addition to free education in elementary, secondary, and high schools, this "social consumption fund" is used for medical help, for pensions and stipends to students, for free stays in sanatoriums and the like, for kindergartens and nurseries, and for Pioneer camps for younger children. Social insurance funds created for agricultural workers are used to provide medical assistance during sickness and temporary disability. All payments for education and social services come out of the state budget.

By the early 1970s the annual rate of completion for new apartments and houses in both town and country was around 36,000 annually. This figure nevertheless re-

mained inadequate to meet all needs, particularly in the light of the movement to the cities, and the need for further improvement in housing continued to occupy the attention of Moldavian planners.

Medical facilities

Moldavia has about 360 hospitals, with about 40,000 beds, in addition to some 230 clinics and consulting medical stations for women and children. There are 24 doctors and 82 medical professionals for every 10,000 people; all kinds of medical aid are free.

CULTURAL LIFE AND INSTITUTIONS

Because of the historical ties between Bessarabia and Romania and the ethnic identity of Moldavians and Romanians, the culture of the Moldavian S.S.R. to a considerable extent still reflects these primordial sources. Although the Moldavian language, as it is officially called, employs the Cyrillic alphabet, the differences between it and literary Romanian are of little significance and are confined to phonetics and vocabulary. Soviet scholars, mainly for political reasons, have insisted since the 1920s that Moldavian is an independent Romance language distinct from Romanian, a view rejected in the West.

Since World War II the development of Moldavian culture and literature has followed the prevailing pattern of the Soviet Union as a whole. Moldavian literature experienced the vicissitudes of Soviet literature generally during the Zhdanov era of the late 1940s and early '50s. Nonetheless, some notable work was done by the poets Emilian Bucov and Andrei Lupan, among the older generation, and by the dramatist and prose writer Ion Druţa, whose novel *Frunze de dor* (1957; "Leaves of Yearning") marks the coming of age of literature in Romanian in the Moldavian republic.

Particular attention has been given to the expansion of cultural opportunities for the general population. There are numerous amateur theatres and musical and art groups. The Doina choir and the Zhok popular ballet company have won international reputations.

Publishing has grown with the expansion of education. In 1973, 1,627 books (548 in Moldavian) in 12,700,000 copies (7,300,000 in Moldavian), 129 newspapers (58 in Moldavian), and 63 magazines and journals (18 in Moldavian) were published.

PROSPECTS

Plans for the further development of Moldavian society and economy will continue to emphasize the expansion of industry, especially in the areas of power, machinery and instruments, food processing, and light industry. Some attention will also be given to an increase in consumer goods, particularly wines. In agriculture, efforts are to be made to increase the amount of land under cultivation and to improve crop yields, especially through the expansion of irrigation projects.

(F.N.S./K.A.H.)

Molecular and Atomic Beams

Molecular beams are streams or rays of molecules moving in the same general direction, usually in a vacuum; *i.e.*, inside an evacuated chamber. In this context the word molecule includes atoms as a special case. Most commonly, the molecules comprising the beam are at a low density; that is, they are far enough apart to move independently of each other. Because of the one-directional motion of the atoms or molecules, their properties can be studied in experiments that involve deflecting the beam in electric and magnetic fields or directing the beam onto a target. The target may be a solid, a gas, or a second beam of atoms or molecules.

Deflections of beams in electric and magnetic fields can give information about the structure and properties (such as rotation and spin) of the molecules, or atoms, in the beam. In more sophisticated experiments, two beams are allowed to intersect, producing scattering interactions or collisions between molecules in pairs, one from each beam. Scattering can demonstrate such properties of these pairs as the potential energy of their interaction as it varies with the distance of separation, their chemical reactivity, and the probability that they will exchange internal energy on collision. Reactivity and internal energy will be treated in detail below.

First experiment

The first experiment with molecular beams, in 1911, confirmed a postulate of kinetic theory that molecules of a gas at a very low pressure travel in straight lines until they hit the walls of their container. At higher pressures, molecules have a shorter free path because they collide with each other before arriving at the wall. The first extensive experiments with molecular beams were made in Germany between 1920 and 1933. The use of beams to study chemical reactions and the transfer of energy between colliding molecules increased rapidly after 1955.

PRODUCTION, CONTROL, AND DETECTION

A molecular beam is produced by allowing gas to enter a vacuum chamber through a small hole or slit in a box containing vapour of the molecules that are to make up the beam (see Figure 1). The vapour often comes from

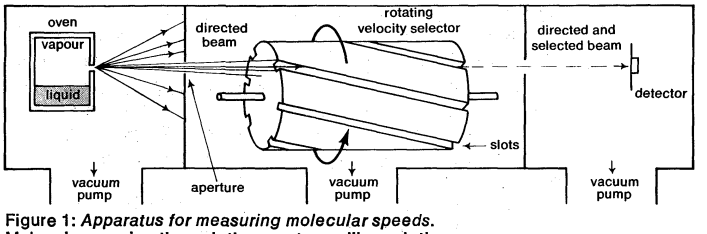

Figure 1: *Apparatus for measuring molecular speeds.* Molecules passing through the aperture will reach the detector only if the cylinder is rotating with such speed that the molecules have clear passage through the cylinder slots (see text).

evaporation of a liquid sample in the box, called an oven, that can be heated to a suitable temperature. At low pressures of vapour in the box, when the free path of the molecules is greater than the width of the exit hole, the molecules will effuse (as will be discussed later) through the hole; at higher pressures they will flow through the hole as fluids do under pressure, forming a jet. The molecules in the jet are at first close enough together to interact with each other, but the jet rapidly expands in the vacuum until the molecules move independently. Only those molecules from the oven that happen to be moving in just the proper direction to pass through a second hole become part of the beam that is used for the experiment. The others are pumped away.

Controlling speed with a velocity filter

Molecules in the beam move at various speeds. If molecules of nearly uniform speed are needed for a particular experiment, the beam can be put through a filter (called a velocity selector) that permits only molecules within a small range of speeds to pass through. These selectors are often made of slotted disks or cylinders spinning rapidly on an axis parallel to the beam. The molecules that emerge from the selector are those with the right speed to stay in a given slot as they move along the cylinder. Molecules of other speeds are removed as they stick to or reflect from the sides of the slots. Changing the speed of rotation of the cylinder changes the speed at which the molecules are transmitted.

To be useful in experiments the deflection or scattering of a beam must be detected. This detection may be difficult because there are relatively few molecules in a typical beam and their velocities, and hence kinetic energies, are low. A detector should have high sensitivity, and there must be little interference from molecules coming from other sources, such as the residual gas in the vacuum chamber. When an experiment is performed with beams consisting of atoms of metals such as the alkalis, which are easily ionized (*i.e.*, given a net positive charge) by the loss of one electron, an efficient detector can be made with a tungsten wire heated to redness. Because of the relatively high energy available for the capture of an electron by a hot tungsten surface, almost all alkali atoms hitting the wire give up one of their electrons to the wire, passing on as ions to be recorded as an electric current at a collecting electrode. A different kind of detector is needed for other kinds of beam molecules. Atoms and molecules can be ionized by bombarding them with a

stream of electrons, and the resulting ions can then be sorted and identified as to mass and charge by directing them into an instrument called a mass spectrometer. Although versatile, this type of detector is much less sensitive for alkali atoms than is the tungsten wire, because the mass spectrometer is generally able to register no more than one-tenth of one percent of all the beam molecules that enter it.

PROPERTIES OF MOLECULAR BEAMS AND THEIR COMPONENTS

The velocity distribution of molecules. According to the kinetic theory, molecules in a gas at thermal equilibrium (*i.e.*, all parts in the system being at the same temperature) in a container at a constant temperature are in rapid, random motion (the average speed of a hydrogen molecule at room temperature is over 4,000 miles [6,400 kilometres] per hour), making a large number of collisions with each other and with the walls of the container. Motion is equally probable in any direction, and there is a range of speeds in any volume of gas running all the way down to zero. The use of molecular beams permits a quantitative test of an expression first derived by the British physicist James Clerk Maxwell, who showed that for a large number of molecules in thermal equilibrium at a given temperature, there is a well-defined distribution of speeds in which some molecules are faster and some slower than those that have the most probable speed. If the hole in a box of gas that is the source for the molecular beam, pictured in Figure 1, has a diameter much smaller than the average distance travelled by molecules between collisions, a small fraction of the molecules will leave the box through the hole. This fraction can be made so small that the loss of molecules does not appreciably disturb the distribution of the speeds (numbers per unit of speed) of the molecules remaining in the box. The molecules leaving are said to effuse from the hole. They are then a representative sample of those in the box. If the beam formed from these molecules passes through the velocity selector and produces an electric current at the detector, the magnitude of this signal is directly related to the number of molecules in the gas of the source having the particular speed transmitted by the selector. Repeating the experiment at many different speeds gives an experimental set of values for the numbers of molecules versus speeds, which when plotted as points fit closely to the theoretical distribution curve derived by Maxwell. Such fits provide direct confirmation of the kinetic theory of gases.

Maxwellian distribution

Deflection processes and experiments. Beams of ionized molecules or atoms can be accelerated or deflected with comparative ease because of the strong forces exerted on charged particles by electric and magnetic fields. Beams of electrically neutral molecules, on the other hand, are not influenced when they move through uniform fields. If the charge distribution in a molecule or atom is asymmetric, if, that is, one part of the molecule is positively charged compared to another part, it has what is called an electric dipole moment and will be subjected to a force when it is in a nonuniform, or inhomogeneous, field, one that varies from point to point. Although this force is small, it can produce measurable deflections of a molecular beam.

Stern–Gerlach experiment

A famous experiment involving the deflection of an atomic beam was performed in 1922 by Otto Stern and his colleague, Walther Gerlach. They prepared a beam of silver atoms (in an apparatus like that of Figure 1, but without the velocity selector) and then let the neutral beam pass between the poles of a magnet shaped so that the field was much stronger near one pole than the other. After leaving the magnetic field, the beam hit a cold surface, where the atoms condensed. The shape of the deposit showed that the beam was deflected away from its initial direction to form two spots, one corresponding to deflection toward a higher value and one toward a lower value of the magnetic field, and equally spaced from the position of the undeflected beam. This result, as will be seen below, is exactly the one required by the quantum theory. Certain species of atoms have magnetic moments (or magnetic dipole moments); that is, they behave like tiny magnets because of the orbital motion or spin of their electrons. For silver atoms, the magnetic moment is caused by the spin of a single electron outside a closed shell of electrons, and, according to quantum mechanics, there are only two orientations of the magnetic moment permitted in an external magnetic field: parallel to or opposed to the direction of the field. The corresponding classical theory permits all orientations. If the classical theory had been applicable, the beam would have produced only a single, widened spot centred at the position of the undeflected beam. In showing dramatically that only definite orientations of the magnetic moment of an atom are permitted in a magnetic field, the experiment provided strong confirmation for the predictions of the quantum theory.

For reasons inherent in the phenomena of the spectra and the structure of atoms, the observation of very closely spaced lines, called hyperfine structure, in optical spectra suggested that atomic nuclei might also act like magnets—*i.e.*, have magnetic moments—although they were expected to be much smaller than those of the unpaired electrons of atoms like silver. (Spins of paired electrons are of opposite direction and thus can cancel one another's magnetic moment.) The magnetic moment of the proton, the positively charged nucleus of the hydrogen atom, which is also caused by its spin, was of particular interest because the proton is the simplest of all nuclei. At low temperatures, hydrogen molecules exist almost entirely in two energy states: in the first of these, the molecule is not rotating and the magnetic moments or spins of the two nuclei (protons) are oriented opposite to each other; in the second, the molecule itself is rotating and the spins of the two nuclei are parallel to each other. In a refinement of the Stern–Gerlach experiment, it was found that molecules in the first energy state were not deflected in the inhomogeneous field (because the nuclear moments cancel each other) and molecules in the second energy state were split into a pattern consistent with quantum theory. The measured value of the magnetic moment of the proton, however, was bigger than had been calculated, suggesting that the proton must have a more complex structure than does an electron.

Magnetic moment of protons

Most molecules in which the atoms are arranged unsymmetrically have electric dipole moments as a result of uneven distribution of their electrons and may be deflected when they move through an inhomogeneous electric field, just as atoms having magnetic dipole moments can be deflected by inhomogeneous magnetic fields. In one experiment, a molecular beam passes through a field that can be switched on or off. A small stop is arranged to block the direct beam to the detector when the field is off. When the field is then switched on, molecules having electric dipole moments greater than some small value are deflected around the stop and reach the detector. In this way, molecules such as those of barium chloride were shown to have electric dipole moments and thus to have an unsymmetrical structure of the form $\left(\mathrm{Ba}\begin{smallmatrix}\diagup\mathrm{Cl}\\ \diagdown\mathrm{Cl}\end{smallmatrix}\right)$. This structure indicates that the barium atom (symbolized by Ba) is bonded to two chlorine atoms (symbolized by Cl) that are not balanced against one another on either side of the barium. The symmetric, linear form of the molecule can be indicated as (Cl—Ba—Cl), and in this arrangement of atoms, the dipole moment would necessarily be zero. Calcium chloride, unlike barium chloride, is apparently linear and of the form (Cl—Ca—Cl), because it is not deflected. Information about the shapes of these molecules was not known before the deflection experiments.

Spectroscopy with beams. Spectroscopy is the study of the interaction of electromagnetic radiation, including visible light and radio waves, with matter.

The internal energy of a molecule is due, in part, to the fact that it can rotate about an axis and its atoms can vibrate with respect to one another. These motions are quantized—that is, only certain frequencies of rotation

and vibration are allowed, depending on quantum numbers arising from quantum theory. Each set of quantum numbers specifies a distinct energy level or state. Rotational levels are separated by energies corresponding to ultra-high-frequency radio waves and far infrared radiation. Different vibrational levels are separated by energies corresponding to the near infrared. Thus, the absorption of a quantum of energy in the infrared may be sufficient to raise the energy of a molecule by increasing the vibration rate from that associated with a particular level to that of another, higher level. Or, the emission of a quantum of energy may be caused by the molecule, changing from one rotational state to another one, of lower energy.

The frequency of the radiation absorbed when a molecule is excited, or raised, from an initial state of internal energy to a final state of energy is equal to the difference of the two energies divided by Planck's constant and is given by the equation $\nu = (E_f - E_i)/h$, in which ν is the frequency, E_f is the final energy, E_i is the initial energy, and h is Planck's constant. This frequency varies somewhat with the speed of the molecule with respect to the source of the energy, just as the pitch of sound waves varies when the source moves away or toward the listener. For a gas, in which molecules are moving at different speeds and directions, there is a range of frequencies in which the spectroscopic line is no longer sharp but is widened, in what is known as Doppler broadening. This variation of the frequency absorbed with the molecular speed often limits the accuracy with which the energy difference can be measured in ordinary optical spectroscopy and thus conceals fine differences in the energy states. Molecular beam measurements are advantageous in that the method reduces the Doppler broadening of spectral lines because the beams can be observed at an angle of 90 degrees from the direction in which the molecules are moving so that their speed away from or toward the observer becomes zero.

Doppler broadening

The most notable contributions of molecular beams to spectroscopy come from the possibility they offer of observing in a sensitive way the absorption of small amounts of energy by molecules that are electrically asymmetric; *e.g.*, those having spin or dipole moments. The trajectories that such molecules in a beam follow through a nonuniform magnetic field depends on the energy state of the molecules; if the state can be changed by the absorption of radiation, the molecules follow changed trajectories that can be designed to make them miss a detector they would otherwise hit. In this arrangement, a drop in the beam current at the detector indicates that the molecules in the beam are absorbing the radiation. The frequencies absorbed can be measured accurately, and the measurements in turn yield information about the molecules.

Resonance phenomena. The internal energies of atoms and molecules, the energy, for example, with which a molecule rotates, are not distributed continuously over a range. Instead, each molecule is able to exist only in certain discrete energy states. When a molecule is in an electric or magnetic field, however, the energy of a particular state varies as the strength of the field varies. Transitions between these states, which may occur on the absorption or emission of a quantum of energy, occur at frequencies that also vary with the strength of the field. Resonance occurs for a molecule when the irradiating frequency just corresponds to the energy difference existing between two states for that molecule.

Although in the past measurements of the deflections of molecular beams in inhomogeneous fields provided new information of fundamental importance for physics, they were difficult to render quantitative both because of the need of measuring accurately the values of the inhomogeneous fields and because of the large range of speeds of the molecules in the beam. A remarkable improvement in accuracy was provided by a resonance method introduced in 1938.

Resonance experiment

A schematic view of the apparatus used in this method is shown in Figure 2. At the left is a source from which the beam moves into a steady, nonuniform field (labelled A)

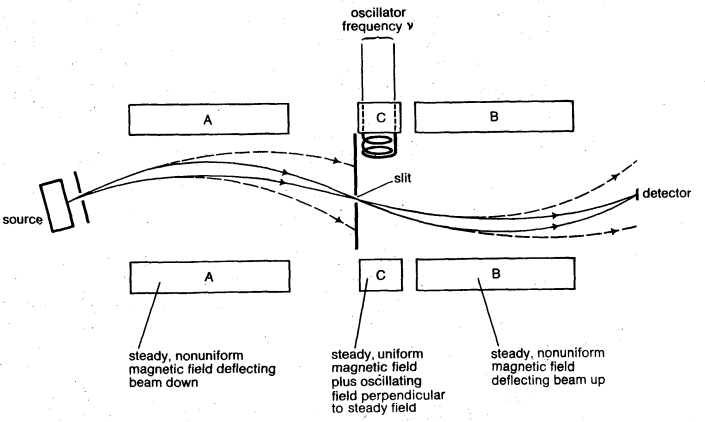

Figure 2: Molecular beam apparatus for magnetic resonance experiments (see text).

like that used for the Stern–Gerlach experiment. The solid lines show two trajectories for molecules, of the particular energy state for which they are deflected just enough to pass through the slit. Molecules in other states follow trajectories, such as those shown as dashed lines, that miss the slit. Beyond the slit the molecules enter a region (labelled C) in which the main magnetic field is uniform but where there is also a second field, perpendicular to the first and oscillating at a given frequency. There some molecules may absorb radiation from the oscillating electromagnetic field and be raised to a higher energy state. From C, the beam enters the field marked B, which is like the field at A except that it causes deflection in the opposite direction. Molecules that have not absorbed radiation from the oscillating field reach the detector (solid lines), but those that have undergone transitions follow new trajectories (dashed lines), which miss the detector. An essential feature of the apparatus is that the inhomogeneous fields serve solely to take molecules in particular energy states to the region C and then on to the detector. The only quantities that must be determined accurately are the strength of the uniform field at C and the oscillator frequency. The technique has been so effective that since its development most studies of molecular and atomic structure employing molecular beams have used it.

An important advance in the technique of making accurate time measurements is the use of an atomic beam of cesium in a resonance experiment to provide a standard frequency. Although there are many transitions between energy states of isolated cesium atoms, which can be caused by the absorption of radiation, for example, in the visible region, there is one transition that is almost independent of the strength of the homogeneous magnetic field in the C region (Figure 2). Thus, the frequency absorbed in this transition is essentially a property of the cesium atom alone and independent of the apparatus. When the signal at the detector is used to control and stabilize the radio frequency used in the C region, this frequency becomes one of the most accurately measured physical quantities known. It is stable to one part in 10^{11}. In 1967 its value, 9,192.631770 megahertz (or units of 10^6 cycles per second), was adopted as a new standard for the definition of the second as a unit of time. The cesium beam can be used as part of an extremely stable clock if a counter is set up to keep track of the number of oscillations.

Cesium clock time standard

In the development of physics, measurements of the properties of the simplest particles of matter have been of especial importance. The electron is one of these particles, and a significant application of molecular beams was to obtain a value for the magnetic moment of a free electron (that is, an electron not bound to a nucleus in an atom) relative to its intrinsic angular momentum or spin. This ratio, called the gyromagnetic ratio (g), originally was given the value of exactly two according to the electron theory of an English physicist, P.A.M. Dirac. The uncertainty principle (*i.e.*, it is impossible to specify or determine simultaneously both the position and mo-

mentum of a particle with full accuracy), prevents a direct measurement of the gyromagnetic ratio for a free electron in a typical resonance experiment. This restriction, however, does not prevent measurements of electrons bound in atoms; so the value of the gyromagnetic ratio can be deduced from experiments conducted with beams of heavy, neutral atoms, such as the alkali metals, each of which has a single electron in its outer shell, in resonance apparatus like that shown schematically in Figure 2. For these alkali-like atoms there is no net magnetic moment due to the orbital motion of the electrons about the nucleus, and so the total magnetic moment may be expected to be the same as that of a free electron. The value of the gyromagnetic ratio found, and confirmed later by other, more precise experiments not involving molecular beams, was larger than two by 0.119 percent. This small difference helped to lead to significant corrections to the theory of the electron.

The energy of a state can be expressed as a wave number, reciprocal (1 divided by the value) of the wavelength, that is, $1/\lambda$ (in which λ is the radiation wavelength), given in units of reciprocal centimetres, cm^{-1}. The two lowest excited states of the hydrogen atom are the ones labelled in spectroscopic notation $2^2S_{1/2}$ and $2^2P_{1/2}$, which lie about 82260 cm^{-1} above the ground state (state of lowest energy). According to Dirac's theory of the electron, these states should have the same energy and be about 0.365 cm^{-1} below the $2^2P_{3/2}$ state. In an experiment in 1947, two U.S. physicists, Willis Eugene Lamb and R.C. Retherford, showed that the $^2S_{1/2}$ state is higher in energy than the $^2P_{1/2}$ state by about 1,060 megahertz (0.035 cm^{-1}). This difference, which is called the Lamb shift, established that the Dirac theory required modification.

Lamb shift

In the experiment, a beam of hydrogen atoms was first formed by heating hydrogen molecules to a temperature of 2,500° K. Bombardment of the hydrogen atoms by electrons produced some atoms in the $^2S_{1/2}$ state, which survive for a lifetime of about 0.1 second before returning spontaneously to the ground state with the emission of a photon. This time was enough for most of them to reach the detector, a tungsten surface, where they produced a current by ejecting electrons from the surface. Between the source and the detector, however, the atoms were in a uniform magnetic field where they were irradiated (as in the C-labelled field of Figure 2) at the right microwave frequency to excite the $^2S_{1/2}$ state to the $^2P_{3/2}$ state. The latter state has a lifetime of only about 10^{-9} second, decaying to the ground state before reaching the detector and thus being unable to eject electrons at the detector. Thus a dip in the detector current showed when a resonance frequency had been reached. The resonance frequency, of course, gave the energy separation between the $^2S_{1/2}$ and the $^2P_{3/2}$ levels, which turned out to be higher than the Dirac theory predicted, higher by the amount called the Lamb shift.

Electric resonance

Apparatus of the general type shown in Figure 2 can be used for resonance experiments when the fields labelled A, B, and C are electric instead of magnetic. The molecules in one particular energy state are deflected in the A field, irradiated in the C field, where they may make transitions to other states, and then directed by the B field toward the detector. Because the resonance frequencies that cause diatomic molecules such as lithium fluoride to make transitions between different rotational states vary slightly from one vibrational state to another, the dipole moments for several of the lower vibrational states can be measured. The accuracy with which these measured differences are predicted serves as a sensitive test for theories of the electronic structures of molecules.

COLLISION PROCESSES

Crossed beam studies. Molecules that collide with each other are said to be scattered, and this scattering usually produces a change in the direction of relative motion of the molecules. If there is no change in speed as a result of the collision, the scattering is elastic; whereas if the speed changes, kinetic energy has been lost and the scattering is inelastic. If the atoms in the colliding molecules are rearranged as a result of inelastic collisions, the scattering is called reactive.

Scattering experiments with molecular beams provide a particularly direct way of studying the collisions between molecules because changes in direction and speed of the relative motion can both be observed. The apparatus required is similar to that shown in Figure 1 with the addition of a second beam intersecting the first in a small region of space called the scattering volume (Figure 3).

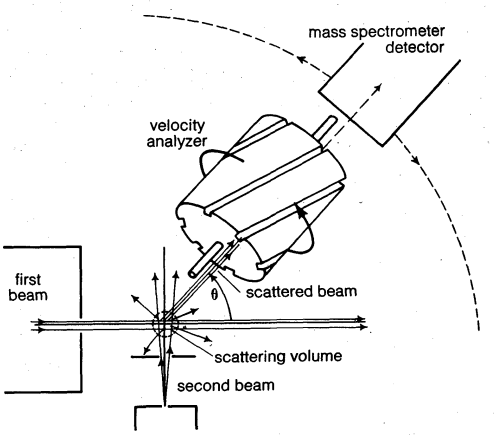

Figure 3: *Arrangement for a scattering experiment with molecular beams.*
A mass spectrometer used in tandem with a velocity analyzer measures the angular distribution, θ, of molecules scattered from intersecting beams (see text).

As the detector is moved around this centre, it can record the relative numbers of molecules scattered for different angles. Furthermore, if another rotor, like that used to select the speed for the beam in Figure 1, is inserted between the scattering centre and the detector, the distribution of speeds of the scattered molecules can be analyzed.

When molecules of one kind are scattered by molecules of another kind, the number of the first kind arriving in unit time at a detector placed at an angle from the original direction of the first beam is equal to a proportionality constant times the densities of the two kinds of molecules, the relative speed of the two kinds of molecules with respect to one another, the volume of the scattering region, and the solid angle subtended by (included by) the detector at the scattering volume. The constant of proportionality is called the differential cross section for that angle. The total cross section, which has units of area, is the integral or summation of the differential cross section over all angles; giving the cross section is a convenient way of describing a particular type of scattering.

The elastic scattering of one atom or molecule by another has been studied thoroughly. Most of the scattering produces deflections of small angles because the molecules pass each other at such relatively large distances that the forces between them are small. For some collisions, however, the molecules approach more nearly head-on so that they interact relatively strongly and scatter to large angles. The differential cross sections show a complex structure that often has a series of many maxima as the scattering angle is changed. The closely spaced maxima cannot be explained on the basis of classical mechanics; they show directly that even particles as large as heavy atoms behave like waves. Interpretation of scattering results like these indicates how the potential energy of interaction between molecules varies with their distance of separation.

Similar experiments, in which a second, analyzing rotor is used to measure the change in speed occurring as a result of inelastic collisions, show the likelihood for the transfer of varying amounts of kinetic energy of relative motion of the molecular pair to rotational or vibrational energy of one or both of the individual molecules. Inelastic collisions play an important part in the sequence of individual collisions that together make up the overall change called a chemical reaction.

Reactive collisions

Molecular beams have been of special use in the study of reactive collisions, but, of course, in this application the detector normally must be able to distinguish the reactants from the products. Mass spectrometers are frequently used as detectors for this purpose. In some experiments the amount of product formed is measured for a range of speeds of relative motion to see if there is a minimum speed below which reaction cannot take place. If there is one, this is the threshold below which the total cross section for reaction is zero. The amount of product, its angular distribution around the scattering volume, and the extent to which the molecules produced are rotating or vibrating can also be determined. Some reactions, like that of potassium atoms with bromine molecules, occur on almost every collision for which the molecules come within ten angstroms (10^{-7} centimetre) of each other, an unusually large distance compared to the maximum for most other chemical reactions. The threshold energy seems to be zero for this reaction, and most of the chemical energy released is converted to rotational and vibrational energy of the product, potassium bromide. For another reaction, that of methyl iodide with potassium atoms, measurements of the differential cross section for nonreactive scattering can be interpreted to show how the probability of reaction varies with the potential energy of interaction or the distance of separation. For this same reaction the methyl iodide can be oriented in space by the use of electric fields similar to those needed for the A field in an electric resonance experiment. The products, potassium iodide and methyl, are formed with a substantially greater probability when the beam of potassium atoms approaches the methyl iodide from the side of the iodine atom rather than from the side of the methyl group.

Beam experiments can also show if molecules react abruptly, so that the products are formed and separate directly after the first approach, or if the two reactants stay together as one aggregate at least long enough to make several revolutions about each other. In the latter case, the products are scattered symmetrically forward and backward along the original direction of approach.

Merging beam studies. One of the difficulties of experiments with beams is that of detecting slowly moving molecules. In most experiments with faster particles, which are easier to detect, the relative velocities, and hence energies, of beams intersecting at right angles are so large that they greatly exceed the relatively smaller energies of chemical reactions. A way of overcoming this problem is by the use of merging beams. In this experiment two beams of different molecules or atoms are separately ionized and accelerated in an electric field along the same path and in the same direction to similar but slightly different high speeds. Either or both beams may be neutralized by being passed through a dilute gas in which the fast particles of the beam transfer their charge to the slow molecules of the gas. In the merged beam the two species move at low speeds relative to each other, and so reactions between the molecules can be studied at low energies. The kinetic energy relative to the stationary detector remains large, however, and thus the result of reaction in the merged beam can be more easily detected than it can in the usual arrangement. This technique gives total but not differential cross sections.

INTERACTIONS OF BEAMS WITH CRYSTALS

When beams are used to study the interaction of individual atoms or molecules with the surfaces of solids, the results vary greatly as the energy of the beam varies. When an atom in the beam is moving rapidly, the relatively weak attractive forces existing between atoms have little effect on its trajectory. Only the much stronger repulsive forces that it encounters on approaching close to the nucleus of another atom are significant. Because of the extremely short range over which these forces are appreciable, the incoming atom interacts essentially with only one atom of the solid at a time. At each impact this atom from the beam loses some of its energy, but its large initial energy permits it to penetrate deeply into the structure of the solid. At lower energies the atom from the beam interacts at any given time with a larger number of atoms because of the longer range of the relatively weak attractive forces between atoms. At the lowest energies the incident atom may be trapped on the surface or be reflected from it, but the atom does not penetrate appreciably into the bulk of the solid.

Channelling. When a fast incoming atom hits a target that is an amorphous (noncrystalline) solid, the atom collides with successive atoms of the target much as it would in passing through a dense gas. The atom's trajectory is a random, zigzag one. When the target is a crystalline solid, however, the regular arrangement of its atoms makes penetration by the incoming atom relatively easy or difficult depending on the angle of its approach. When it enters a crystal in a direction that takes it through the more densely packed planes of atoms, the incoming atom moves less freely than it does when its direction is parallel to these planes of atoms. The spaces between these planes form channels. Moving in a channel the incoming atom makes glancing collisions with the atoms forming the walls of the channel, using up relatively little energy per impact. Thus it penetrates farther into the crystal than it would have if it had entered the crystal at a different angle. The idea of channelling offers possibilities for new interpretations of damage to crystals that have been exposed to radiation.

Crystal channels

Sputtering. When a fast atom from a beam hits a solid target such as a crystalline surface, the atom transfers some of its kinetic energy and momentum to the atoms of the solid. As a result, these target atoms may even receive enough momentum to leave the surface of the solid. This process is called sputtering of the target by the beam. It has been theorized that the atoms of the target recoil after being hit by the incoming atom and in turn hit other atoms of the crystal. These chains of successive impacts may be focussed along crystal directions in which the atoms are densely packed and ultimately cause the ejection of atoms when chains reach the surface of the crystal.

Diffraction. It was suggested in 1924 that beams of heavy particles such as atoms would behave like waves in which the wavelength could be given by Planck's constant divided by the momentum. This suggestion led to an experiment involving scattering a beam of helium atoms from a clean surface of a crystal of lithium fluoride. By the use of a sensitive pressure gauge, specially developed to detect the scattered helium, it was found that when the intensity of the scattered helium atoms was plotted, a strong scattered peak appeared at the angle corresponding to mirror-like reflection from the surface of the crystal. On both sides of this peak, however, there were smaller peaks exactly where they should have been if the atoms were behaving like waves. The helium had been diffracted by the crystal. This was an important confirmation of the wave nature of matter.

Gas-surface interactions. In spite of the successful observation of the diffraction of a beam of helium atoms from a crystal of lithium fluoride, further studies of the scattering of atoms of low energies from surfaces often led to confusing results. One of the main difficulties is that even in a good vacuum enough gas molecules are present so that any freshly prepared clean surface is quickly covered by unwanted impurities, such as water or carbon monoxide molecules, which often stick firmly and change the nature of the surface in an unknown way. The effects of these impurities are reduced substantially if a fresh surface is continuously created in the vacuum. One way to do this is to let a stream of atoms, such as those of silver vapour, condense steadily on the surface. The impurities are then buried beneath the much larger number of incoming silver atoms even though the latter are still few enough not to interfere with another beam, which is being reflected from the slowly growing surface. If the silver crystal grows on an underlying crystal, such as a piece of mica, chosen to have an appropriate spacing of its atoms, the mica directs the deposition of the silver, which is said to grow epitaxially; *i.e.*, in a pattern established by the underlying crystal. If a beam of helium atoms hits a silver surface of this kind, the helium atoms leave the surface as a directed beam, gen-

erally at the angle expected if the silver surface were to be considered a mirror. Diffracted peaks—that is, angular variations in intensity caused by different energies and crystal spacing—are not seen. A beam of ammonia molecules, on the other hand, which interacts much more strongly with the silver crystal, is scattered diffusely with no direction being preferred over another. Although the scattering of molecular beams from single crystals is one of the least ambiguous experiments that can be done with surfaces, the results are not well understood theoretically.

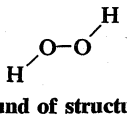
Molecular Structure

Atoms and molecules are the chief intellectual abstractions of chemistry. Atoms are the fundamental building blocks from which molecules are constructed, and molecules the smallest particles of a pure compound that retain its characteristic properties. Although there are only about one hundred different kinds of atoms (see ATOMIC STRUCTURE), they combine in tens of millions of different molecules (see CHEMICAL COMPOUNDS, INORGANIC; CHEMICAL COMPOUNDS, ORGANIC), and chemists add new kinds of molecules at a rate of more than 100,000 per year. Atoms and molecules undergo physical change without change in number or kind; atoms participate in chemical reaction without change in number or kind, but they can be transformed in nuclear reactions; molecules can be transformed in chemical reactions. It is a fundamental problem of chemistry to determine the arrangement of atoms in molecules and to elucidate the manner in which atoms are reorganized in the course of chemical reactions.

GENERAL CONSIDERATIONS

The simplest molecule is that of hydrogen, H_2, in which two hydrogen atoms are joined together. The minute size of these particles is suggested by the fact that one gram of hydrogen contains more than 10^{23} hydrogen molecules. Molecules range in size and complexity from hydrogen to molecules within living organisms that may contain many millions of atoms. In the case of two-atom, diatomic, molecules, such as those of hydrogen, nitrogen (N_2), oxygen (O_2), or hydrogen chloride (HCl), the only question about the molecular structure would be the distance between the two joined atoms. Adding an oxygen atom to the hydrogen molecule to make water (H_2O) raises several other questions. Water molecules could consist of chains with a terminal or a central oxygen atom, H—H—O or H—O—H; the chain could be straight or bent. If it is not straight, the angle of bend as well as the distances between the centres of the atoms must be known in order to specify the molecular structure. For molecules with larger numbers of atoms, three-dimensional shapes must be considered. While water, for example, has two hydrogen atoms attached at an angle of 104.5° to a central oxygen atom, hydrogen peroxide (H_2O_2) has two hydrogen and two oxygen atoms joined in a structure known to have the shape:

Structural possibilities with water



Historical background of structural concepts. Early in the 19th century an English chemist, John Dalton, proposed his atomic theory, and the precise distinction between atoms and molecules was first drawn in 1811 by an Italian physicist, Amedeo Avogadro. It was not until 1858, however, that his countryman Stanislao Cannizzaro, a chemist, showed that all physical and chemical facts confirmed the validity of Avogadro's conclusions and that the distinction reconciled many contradictory experimental results accumulated since the beginning of chemistry as a science. It was then recognized that molecules can possess three-dimensional shapes formed by connected (bonded) atoms. The contributions of another generation of chemists and a great deal of controversy were required, however, to ready the problem of molecular structure for solution, but the final steps in discarding the earlier, flat-molecule theory were taken by chemists Jacobus Henricus van't Hoff of The Netherlands and Joseph-Achille Le Bel of France. Van't Hoff's ideas, summarized in his book *Chemistry in Space*, were ferociously attacked by one of the leading chemists of the day. Thanks to this controversy the idea of geometrical relations within molecules became widely known and accepted.

During the same period, the concept that matter is in continual motion (kinetic-molecular theory) prevailed over the concept that matter is in a state of static equilibrium. Thus, the geometrical relationships of atoms within molecules cannot be considered as fixed. In addition to the movements of the molecules themselves through the gases and liquids that they constitute (translation), the various parts of the molecular structure itself are in continuous motion. This internal motion may take the form of vibrations in which atoms and groups of atoms move back and forth, increasing and decreasing the distances between them (stretching) and opening and closing the angles made by their bonds (bending). In complex molecules, groups may rotate about portions of the structure. These motions are fast and frequent, typical vibrations taking place on a timescale of 10,000,000,000,000 (10^{13}) per second; rotations are somewhat slower (typically 100,000,000,000 [10^{11}] per second). Because of this flexibility, molecular dimensions are taken as time-averaged values of the positions of the atoms. At higher temperatures, the atoms take longer and more violent excursions from their equilibrium positions, and new patterns of motion sometimes become possible. Molecular structure thus depends upon temperature.

Internal motions of atoms

In addition, the exact dimensions of molecules vary according to the situation in which they are studied. Thus, somewhat different measurements are obtained for molecules in the three phases, solid, liquid, and gas, or dissolved in solution or adsorbed on a surface. Drastic changes from the normal form have been found in determining structures of molecules carrying excess charges (called ions or radicals) and those possessing excess energy (excited-state species).

Structural theories. *Quantum mechanical approach.* No truly adequate theory of molecular structure is yet available. The detailed structure of complex molecules cannot be predicted but must be obtained from experiment. Recent studies, however, have been specifically directed toward the development of theories that could yield structural information.

One approach is through quantum mechanics (see MECHANICS, QUANTUM), in which an orbiting electron is considered to have the characteristics of a wave; treating the electron standing waves (atomic orbitals) mathematically allows determination of how pairs and groups of atoms come together to form joint orbitals (bonds). Such an approach relies on data from experiment in conjunction with approximate mathematical methods utilizing high-speed computers, but only the simplest systems can be calculated exactly. To achieve a strong bond, the electron orbitals of the atoms involved must overlap in space as much as possible (see CHEMICAL BONDING); and since atomic orbitals are themselves directed in space, the resulting bonds must conform to their arrangements. The quantum-mechanical approach leads to correct predictions concerning the shape of only simple molecules; for example, the bent shape of the water molecule.

Electrostatic approach. An alternative approach is to consider the molecule as a system in electrostatic balance

—the attraction between electrons and their nuceli (because they have opposite charges) tending to be maximum and the repulsion between electrons (because they carry the same charge) tending to be minimum. The attraction between each nucleus and the electrons of an adjacent nucleus is also of primary importance in bonding atoms. In this view, the most likely shape of the molecule will be the one that best meets these electrostatic requirements. Those pairs of electrons farthest from the nucleus of a central atom of a group are considered to be important in determining the molecular structure of the group. To minimize the repulsion between centres of negative charges, the system adopts the most balanced arrangement possible; when there is more than one pair, each takes up a position as far as possible from the others, while remaining as close as possible to the nucleus. Two electron pairs thus place themselves on opposite sides of the nucleus to give a linear (180°) relationship; three pairs lead to a trigonal planar arrangement, with bond angles of 120°; four to a tetrahedral arrangement, with angles of 109°28′; six to an octahedron, with 90° angles; etc. The electron pairs can be either shared with a second atom (bonding) or lone pairs (nonbonded). Shared pairs are drawn out between two positive centres and lie farther from other pairs of electrons on the same atom, and their repulsive effect is thus somewhat reduced. Unshared pairs, on the other hand, are under the influence of only one positive centre and, because of their proximity, create the most severe repulsions. The relative repulsive power is thus, in descending order, lone pair–lone pair, lone pair–bonding pair, bonding pair–bonding pair; this is also the order in which distortion (opening) of bonding angles has been found experimentally for molecules taking the regular geometric shapes listed above.

Shared and unshared pairs

No perfectly regular solid figures exist with five or seven points (or vertices); the electron pairs are, however, well separated in the semiregular trigonal and pentagonal bipyramidal shapes, and there are many molecules of those kinds.

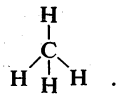
The structure adopted by a molecule must also meet the spatial requirements of its constituent atoms and groups of atoms. The exact dimensions of atoms are not known, but the volumes occupied by given numbers of atoms are largely incompressible. No amount of force generated in one part of a structure can bring about interpenetration of atomic volumes in another. These spatial requirements are a controlling factor in molecular geometry.

MOLECULAR BONDS AND SHAPES

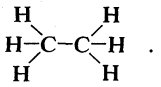
Spatial arrangement of atoms. The basic laws of chemistry give the number of attachments, usually variable, that each atom is capable of making with other atoms. The restriction against atoms occupying the same volume guides their packing together to fill space. Distances and angles between atoms are adjusted to maximize attractive (bonding) interactions and to minimize electrostatic repulsions. On these principles a bewildering variety of molecular shapes and sizes are constructed. The range of structural possibilities is difficult to comprehend and impossible to represent adequately on the printed page, first because most molecules have three-dimensional shapes and, second, because all are in rapid, dynamic motion. Static, two-dimensional figures in which atomic symbols are placed at equilibrium positions in the structure are nevertheless the most useful way of representing molecular structures.

Chains. The chemistry of carbon, the archetypal participant in shared-electron-pair (covalent) bonds, is the basis of organic chemistry. Carbon and hydrogen together form a fantastic number of compounds; those containing only the two elements are called hydrocarbons. These have derivatives that contain other elements as well. All are called organic compounds, because it was thought at one time they could be made only by living organisms. The simplest hydrocarbon is methane, with the formula CH_4, in which carbon directs four equivalent bonds toward the vertices of a tetrahedron, so that methane can be represented structurally as:

Organic compounds

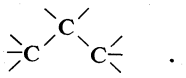


Ethane, with an empirical formula of C_2H_6, can be considered to be constructed by replacing one of the hydrogen atoms of methane by a CH_3 group, thus

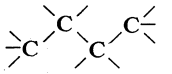


This arrangement can also be written without showing the hydrogens:

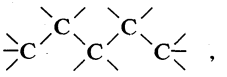
Repeating the same operation and replacing a hydrogen atom of ethane by another CH_3 group leads to propane, C_3H_8:



A hydrogen atom on a terminal, or end, carbon can again be replaced with a CH_3 group, to produce butane, C_4H_{10}:

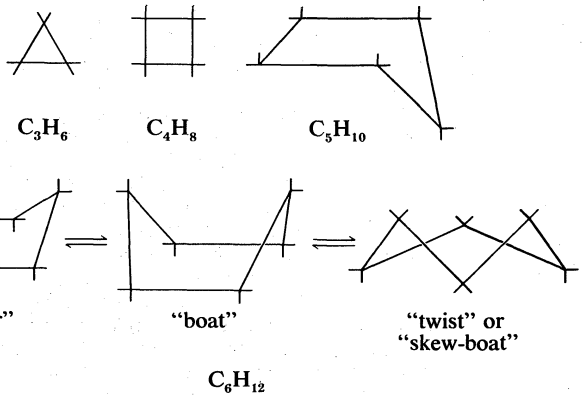


from which the same process produces pentane, C_5H_{12}:



etc. This series of hydrocarbon compounds in which the carbon atoms always form a straight chain can be extended indefinitely. In actuality, the light, shorter chain hydrocarbons are derived from natural gas, which is a mixture of straight-chain hydrocarbons having one to four carbon atoms (in abbreviated form, C_1 to C_4); bottled fuel gas is usually C_3 or C_4; gasoline C_6–C_{10}, kerosene C_{10}–C_{18}, paraffin waxes $C_{>20}$; and polyethylene consists of chains of 5,000 or more of the same CH_2 units that first occur in propane (see HYDROCARBONS).

Rings. Compounds that consist of ring structures of various sizes can be formed by connecting the ends of chains, as in C_3 to C_6 hydrocarbons represented diagrammatically below:



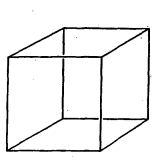
The names of ring compounds are made up of their straight-chain names combined with the prefix cyclo-. Cyclopropane, C_3H_6, is highly reactive, because the interior 60° angles of the three corners bring electrons that are mutually repulsive into close proximity. The cyclobutane (C_4H_8) molecule, with interior angles of 90°, is also easily decomposed. A pentagon has interior angles of 108°, close to the tetrahedral angles of 109°28′, which are the normal bonding angles of carbon, and, therefore, cyclopentane (C_5H_{10}) is quite stable. The puckered form that it adopts minimizes hydrogen contact. It might be thought that, as larger numbers of carbon atoms join rings, the molecules would become less stable again, since

Puckered rings

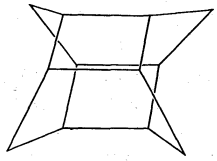
the interior angles of the planar figures become larger than 109°28′; for example, 120° in the hexagon. The problem does not arise, however, because of the possibility of reducing the angles by puckering the structure and eliminating a flat configuration. The C_6 cyclohexane molecule (C_6H_{12}) can exist in a "chair," a "boat," or a "twist," or "skew-boat," form, all involving tetrahedral angles at the carbon atoms while minimizing hydrogen-atom repulsions. The molecules flip rapidly from one form to another at room temperature. Stable hydrocarbon rings with more than 30 carbon atoms are known.

More complex ring types are represented by bicyclobutane and bicyclooctane and the fused-ring systems such as those found in steroids.

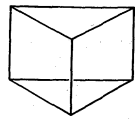
In recent years, chemists have synthesized a spectacular number of hydrocarbons with unusual polyhedral structures. Some examples, with their highly descriptive, nontechnical names, are given below:



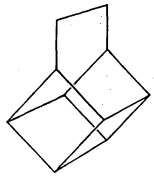
cubane



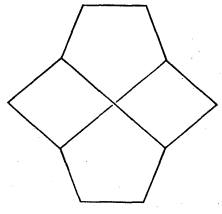
asterane



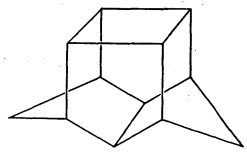
prismane



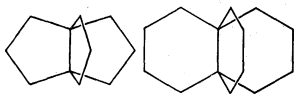
basketane



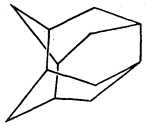
twistane



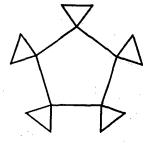
birdcage



propellanes

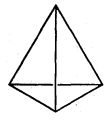


iceane

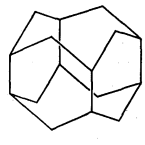


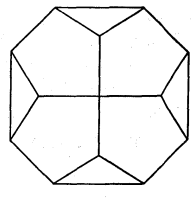
paddlewheelane

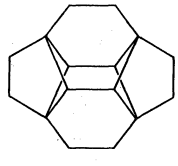
Efforts are under way to add the following:

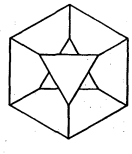


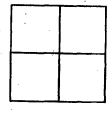
tetrahedrane





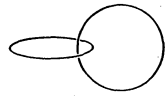






windowpane

The idea of what constitutes a molecule has itself been modified by the synthesis of linked rings:



Silicon and oxygen in minerals

As carbon and hydrogen form the basis of the organic world, so are silicon (Si) and oxygen (O) the basic elements of the mineral world, and the linkages represented by $-\overset{|}{\underset{|}{Si}}-O-$ form the backbone of molecular structures. Small numbers of these individual oxygen–silicon units are found in the soft rocks, such as talc; long chains of them give rise to fibrous minerals such as asbestos; planar sheets form the two-dimensional structure of mica, while quartz contains the same $-\overset{|}{\underset{|}{Si}}-O-$ units cross-linked into three-dimensional network arrays. Lately, materials have been synthesized that can be viewed as the organic derivatives of these rock forms. In one example, CH_3 groups are bonded to silicon atoms, which are linked through oxygen into long chains. These materials, called silicones, combine the advantages of the strong oxygen–silicon backbone with the tractable nature of organic compounds.

Chelates. Hydrocarbons can be modified by the substitution of other atoms for carbon. When a carbon atom in a ring is replaced by another kind of atom, the compound produced is called heterocyclic, and it adopts conformations that accommodate the particular spatial, or steric, requirements of the heteroatom, the noncarbon atom in the ring. Incorporation of heteroatoms and groups into hydrocarbon molecules often confers special properties, including the ability to form additional bonds, typically to a charged metal atom (ion), in what are called coordination compounds (*q.v.*). Important examples are provided by molecules with two or more heteroatom sites juxtaposed spatially in such a way as to enable them to attach simultaneously to a single metal ion. Such compounds, called chelates, after the Greek for "crab's claw," can be synthesized in bidentate (two active sites), tridentate, etc., varieties. If the spacing between the heteroatoms is just appropriate to hold a metal ion of a certain size, the chelating action will be selective. The hexadentate compound ethylenediaminetetraacetic acid (EDTA), for example, has its six points of attachment so arranged that it can wrap itself around a lead atom and remove that element from the body in cases of lead poisoning. Other complexing agents of biological importance include heterocycles fused into large, flat rings, leaving a central hole into which the heteroatoms protrude. The porphyrins are such a class, with four nitrogen atoms in a central opening just large enough to fit a metal ion. The biologically essential molecules hemoglobin and chlorophyll consist of porphyrin rings in which iron and magnesium are held, respectively. Recently, chelating agents have been synthesized that mimic the natural materials but differ from them in potentially important ways.

Heteroatoms

Novel shapes. Other novel molecular shapes are found in compounds in which metal atoms are sandwiched between the planar faces of hydrocarbon rings; for example, ferrocene, $(C_5H_5)_2Fe$, and dibenzenechromium, $(C_6H_6)_2Cr$, in which the ring planes are parallel, and stannocene, $(C_5H_5)_2Sn$, with an angular sandwich structure. These and other synthetic organometallic compounds are the fruits of attempts to break elements out of intractable, inorganic compounds such as salts and oxides or tough metallic forms and to incorporate them into molecules with useful and interesting properties. The operation involves the replacement of the inorganic or metallic lattice bonds with bonds to hydrogen or organic groups. The element boron, for example, forms an icosahedral structure (having 20 faces), and a hydrogen derivative of this structure has been prepared, with the formula $B_{12}H_{12}^{2-}$, along with several smaller borane molecules, which can be viewed as derivatives of icosahedral boron fragments. Carboranes, with formulas such as $B_{10}H_{10}C_2H_2$, have two icosahedral vertices substituted by carbon. In a similar way, there have been syntheses of organic derivatives of a large number of the familiar metals that preserve the clusters of atoms found in the metals themselves.

Polymers. When a simple molecule is bonded to itself or to a few other simple molecules to form long chains, the result is a polymer, or macromolecule. Polymers constitute a special class of molecular structure because of their giant size and because any given sample is always a mixture of molecules of various sizes. It is possible to distinguish one-dimensional, chain, or linear, struc-

Spatial structures

tures, such as the natural polymers in unvulcanized rubber, silk, and asbestos and the artificial polyethylene and silicone fluids; two-dimensional macrostructures such as those formed by mica and graphite; and three-dimensional structures such as quartz or diamond. In fact, a perfect crystal of diamond (one of the forms of carbon) could be considered to be a single, giant molecule, owing its extraordinary hardness to the four strong electron-pair bonds radiating from each carbon atom to four other carbon atoms. Some of the polyhedral hydrocarbon compounds mentioned above can be considered to be fragments of the diamond structure. The constituent units of a linear polymer may be arranged at random, as was the case of all artificially produced polymers made before 1954, or in some highly ordered manner, as is the case of materials such as natural rubber and the artificial materials produced after the discovery (1954) of a special type of polymerization, called stereospecific.

Protein structures

Special problems in molecular structure arise with proteins. The basic constituents of proteins are molecules with two different group properties (bifunctional molecules). These properties are provided by two functional groups attached to the molecule, in this case an acid group and a base group, in compounds called α- (alpha-) amino acids. The acid (carboxyl) end of one such molecule can act on the base (amino) end of another to form a molecule of water, which is released, and a bond called the peptide link between the remaining parts of each molecule. Using R— to represent the body of an α-amino acid, the formula is $H_2N{-}CHR{-}COOH$, H_2N being the amino group and COOH the acid group. The reaction between any two amino acids (R_1 and R_2) is:

$$H_2N{-}CHR_1{-}COOH + H_2N{-}CHR_2{-}COOH$$

$$\longrightarrow H_2N{-}CHR_1{-}CONH{-}CHR_2{-}COOH + H_2O.$$

Repeating this process over and over, each time eliminating a molecule of water, produces a polypeptide chain. The various amino acids are distinguished by the nature of the R groups; because 23 amino acids have been recognized as constituents of proteins, the selective order in which they polymerize is, practically speaking, infinite in number.

The order of the amino acids in the polypeptide chains is called the primary structure, and the first such sequence was determined in 1952 by an English chemist, Frederick Sanger, for the protein insulin. The regular way in which the polypeptide chains are arranged in space to form a protein molecule is called the secondary structure. The principal type of secondary structure is called the alpha helix. The polypeptide chain can be folded into the spiral form with about four amino acid units per turn. Many fibrous proteins, including hair and muscle, consist of these polypeptide helices twisted about one another to form cables. In 1960 investigation of the protein myoglobin revealed that its single polypeptide chain coils into eight short, helical segments separated by nonhelical sections. This arrangement of the three-dimensional structures of the polypeptide chain in space is the tertiary structure, while the combination of two or more polypeptide chains constitutes the quaternary structure.

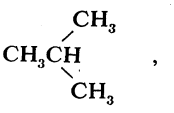
Isomerism. The possibilities for variety in molecular structure are enormously expanded by the freedom to arrange the same group of atoms in more than one way to form different structures, a phenomenon called isomerism. The properties of a compound are determined not only by its chemical composition but also by the arrangement of its constituent atoms in space. Two substances are said to be isomers if they have identical chemical composition and molecular weight but differ in molecular structure (see ISOMERISM).

Early studies of the structure of cyanates

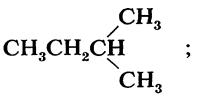
The first such sets of compounds identified were the explosive fulminates (salts of fulminic acid) prepared in 1824 by the German chemist Justus von Liebig and the inactive cyanates (salts of cyanic acid) prepared in the following year by another German chemist, Friedrich Wöhler. At first, each man thought the other wrong, since the formulas for the two salts proved to be the same, but they soon met and in a common series of experiments showed that both parent acid compounds possessed the same atoms, of carbon, hydrogen, oxygen, and nitrogen. The French scientist Joseph-Louis Gay-Lussac correctly concluded that the spatial arrangement of atoms in the two compounds must be different. Cyanic acid has the formula HOCN, while fulminic is HONC. It remained for Jöns Jacob Berzelius in Sweden to formulate a precise definition of the concept of isomerism.

The subject is best illuminated by listing briefly some of the many types of isomerism.

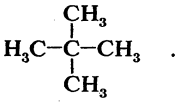
Branching. In building up the straight-chain hydrocarbons from methane as shown above, a CH_3 group was substituted for a terminal hydrogen atom in each step. Substitution at an interior atom would produce a hydrocarbon of the same formula but with a branched structure, as in isobutane, C_4H_{10}:



compared with *n*-(normal) butane: $CH_3CH_2CH_2CH_3$, also C_4H_{10}. Pentane, C_5H_{12}, has three isomeric forms: *n*, $CH_3CH_2CH_2CH_2CH_3$; iso,



and neo,

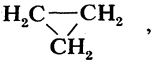


Even relatively simple molecular formulas permit enormous numbers of differently branched structures; for example, it can be calculated that $C_{20}H_{42}$ can exist in 366,319 isomeric forms and that $C_{40}H_{82}$ has 62,491,178,805,831 isomers. No chemist has been sufficiently interested to attempt to isolate the complete set beyond C_9H_{20}, for which all 35 different structures are known.

Positional. A noncarbon atom or group, symbolized as X, can be substituted for hydrogen that is attached to any carbon. The *n*-butane formula, for example, is C_4H_{10}, and C_4H_9X is the empirical formula for any substitution compound. The X may be attached to any carbon atom, and, thus, the substitution compounds derived may be $CH_3CH_2CH_2CH_2X$ and $CH_3CH_2CHXCH_3$; because X occupies different positions, each of these compounds differs from the other.

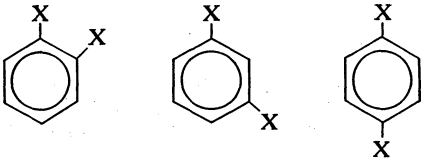
Functional. Ethyl alcohol has the same formula as methyl ether, C_2H_6O, but their structures are quite different, being CH_3CH_2OH and CH_3OCH_3, respectively.

Ring versus unsaturated. The formula C_3H_6 can belong to the cyclopropane ring,



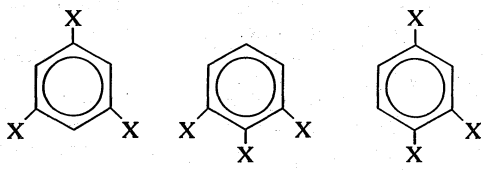
or to the unsaturated (containing one or more double or triple bonds between carbon atoms) propylene, $CH_3CH{=}CH_2$, which contains a double bond. A hydrocarbon containing a triple bond is isomeric with members of three other classes of compounds: those containing two double bonds, those containing two rings, or those containing one ring and one double bond.

Ring. The derivatives of benzene, C_6H_6, which is planar, with two hydrogens substituted (disubstituted), with the formula $C_6H_4X_2$, give three isomers:



ortho- *meta-* *para-*

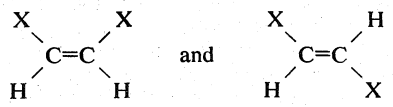
The trisubstituted $C_6H_3X_3$ can also take three forms:



sym- *vic-* *asym-*

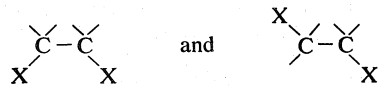
Geometrical. The double bond also holds its substituents in a flat plane. The substituted ethylene, $C_2H_2X_2$, in which each X is attached to a different carbon atom, can exist in two isomeric forms; in one the X groups are on the same side of the double bond (*cis-*) and in the other on the opposite sides (*trans-*), thus:

Cis- and *trans-* forms



cis- *trans-*

The two forms are distinct because rotation of the two halves around the double bond is restricted, unlike the case of the single bond, about which there is a possibility of free rotation. A similar geometric relationship can exist in substituted ring compounds:



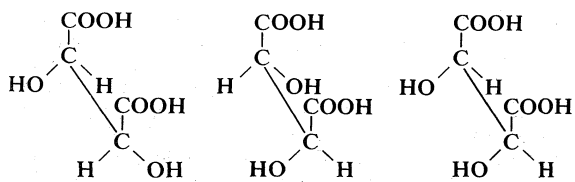
cis- *trans-*

Positional isomers are available for the above examples in which each X is located on the same carbon atom.

Iso-, syndio-, atactic. The pendant, side-chain groups attached to a linear-chain carbon polymer backbone can all be oriented in one direction (iso-); alternately, in each of two directions (syndio-); or randomly (atactic).

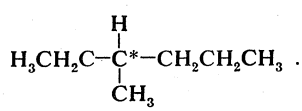
Optical. Optical isomerism occurs when two molecules differ only in that one is a mirror image of the other; *i.e.*, when they are enantiomorphs and exhibit what is called right- and left-handedness. The structures of enantiomorphs cannot be superimposed as a consequence of their asymmetry. The two forms of tartaric acid, first investigated by the French scientist Louis Pasteur, constitute a molecular example, while a third form is symmetrical and, therefore, not optically active. The structural formulas for these are:

Right- and left-handedness in chemical compounds

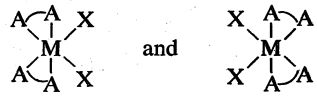


(i) (ii) (iii)

Pasteur was able to identify right- and left-handed crystals of sodium ammonium tartrate under the microscope and to pick the types apart. Most properties of enantiomorphic pairs are identical, but they always differ in that one turns the plane of polarized light clockwise (dextrorotatory), while the other turns it counterclockwise (levorotatory). Pasteur was able to correlate the optical activity of the tartrates with the asymmetry of the crystals. Only a very few examples of the spontaneous separation of optical isomers on crystallization have been discovered to date. The asymmetry that gives rise to optical activity, however, is present in every compound containing a carbon atom with four different groups attached, the simplest such hydrocarbon being hexane with a methyl group attached to the third carbon,



The starred carbon atom is said to be the asymmetric centre. Among inorganic compounds, octahedral *cis-* $M(A{-}A)_2X_2$ exists in two optical isomers: (see ISOMERISM).



An extraordinary fact is that only the left-handed enantiomorphic amino acids in which the α-carbon is in general an asymmetric centre have been found to occur in plant and animal proteins. A man constructed of right-handed proteins could make use of the optically inactive oxygen and water but would not be capable of digesting ordinary food or begetting children with an ordinary wife. No one knows why proteins are constructed of left-handed amino acids.

TIME-DEPENDENT PROPERTIES

Motions preserving molecular integrity. The rather static world of experience is, at the molecular level, only the blur of ceaseless, dynamic motion. Gas molecules in a room atmosphere have speeds of 10^4–10^5 centimetres per second (200–2,000 miles per hour) and collide with each other about 10^{10} times per second. Since a typical frequency of rotation is 10^{11} times per second, such a molecule completes ten rotations between collisions. Molecular bonds typically vibrate with a frequency of about 10^{13} per second, and, therefore, bonds vibrate about 100 times during each molecular rotation and about 1,000 times between collisions in the gases in a room atmosphere.

Molecular motion in liquids

Molecular motion in the liquid phase is more difficult. Translation is impeded because the molecules are tightly packed. Even rotations will be relatively rare unless the molecules are almost spherical or are nearly cylindrical about one axis. Rotations tend to be transformed into oscillations or twisting motions and the translations into a rapid back and forth bouncing off nearest neighbours. The frequency of collision is great, about 10^{12} per second, because the molecules are so close; the bond vibration frequencies, however, will still be higher by almost tenfold.

Translation ceases on solidification; molecules oscillate and, where space permits, rotate about fixed equilibrium positions.

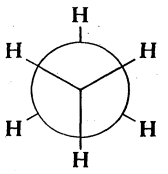
Flexibility is, then, a chief characteristic of molecules, and it is restrained only by powerful forces. The various types of molecular motions that contribute to this flexibility are summarized below.

Vibration. A diatomic (of two atoms) molecule can vibrate in only one way. This vibration consists of an in-phase motion of the two atoms toward and away from their centre of mass along the internuclear axis (comparable to the motions of a pair of weights connected by a spring). By in-phase is meant that the atoms pass through their mean positions and reach their turning points simultaneously. Such vibrations along bond axes are called stretching motions. The amplitude (magnitude or extent) of such motion is typically about 10 percent of the bond length.

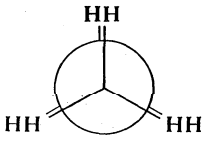
A bent, triatomic (of three atoms) molecule, such as water, HOH, can execute three fundamental modes of motion: a concerted compression and stretching of the two O—H bonds: an asymmetrical motion by which one O—H stretches while the other compresses; and a bending motion in which the angle opens and closes. If such a triatomic unit is held by its centre atom in a more complex system, this last scissoring motion will be accompanied by various twisting, wagging, and rocking torsions as well. Planar (in one plane) molecules undergo out-of-plane deformations of terminal atoms; cyclic molecules undergo simultaneous stretching apart of the ring atoms (called breathing). Bending requires less energy than stretching.

Rotation. Detailed consideration of the rotational motions of groups within molecules led in 1937 to the recognition of several new possibilities. Viewing the ethane molecule, C_2H_6, for example, down its central C–C axis,

reveals two extreme positions for the hydrogen atoms:



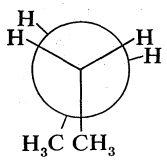
staggered, and



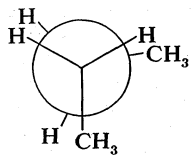
eclipsed. The onset of repulsions when the hydrogens pass each other creates slight barriers to completely free rotation about the C–C bond. The exact cause of the restricted rotation is not known, but the repulsions are lowest in the staggered form. Rotation from one staggered configuration (called rotamer) to another is extremely rapid at room temperature.

Rotamers

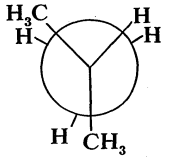
The barrier to free rotation is raised when one hydrogen on each ethane carbon is replaced by a CH_3 group to give *n*-butane. Six rotameric forms can now be drawn, with the barrier decreasing from the form in which the two CH_3 groups are eclipsed to the most favourable staggered form with the two groups farthest apart. In the structural forms below, rotamers (ii) and (iii) and (iv) and (v) constitute enantiomorphic pairs:



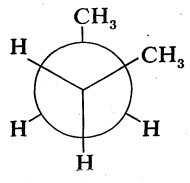
(i)



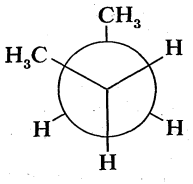
(ii) eclipsed



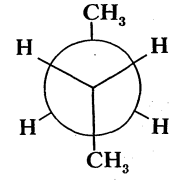
(iii)



(iv)



(v) staggered



(vi)

Rotation at room temperature is too rapid to permit isolation of the individual rotamers.

Another form of motion, called pseudorotation, was postulated in 1960 to explain the rapid interchange of the positions of atoms in trigonal bipyramidal molecules. A similar twisting of CH_2 units is now thought to be responsible for the easy interconversion of conformation in cyclic hydrocarbons; *e.g.*, in cyclohexane (see above). Such pseudorotations have very low energy requirements and take place easily and rapidly at room temperature. The individual conformers of cyclohexane (boat, chair, and twist, or skew-boat) cannot be isolated.

Inversion. Ammonia, NH_3, and its substituted derivatives, called amines, are pyramidal molecules. If the three groups attached to nitrogen are different, two forms with nonsuperimposable mirror images should exist. No such optical isomer has ever been isolated, however, because pyramidal molecules of this type undergo a rapid motion by which the pyramid becomes inverted. In this vibration the nitrogen atom oscillates through the plane of the three attached groups, much as an umbrella can turn inside out. The inversion frequency of ammonia is over 10^{10} times per second. Substitution of bulky groups for hydrogen slows the inversion rate somewhat.

Fluxional molecules. Several organometallic molecules are now known in which a metal atom rapidly changes its point of attachment from one to another of the carbon atoms of a hydrocarbon ring or chain. In the first recognized example, mercury (Hg) in $(C_5H_5)_2Hg$ was shown in 1954 to exchange its bonding position about the five carbons of the C_5H_5 ring. The bromine–magnesium (BrMg) unit in $CH_2{=}CHCH_2MgBr$ appears bonded to one, then another of the terminal carbon atoms. Such nonrigid structures have been described as "ring whizzers" or "chain swingers" or, more simply, as fluxional.

Nonrigid structures

It should be recognized that, despite the possibility of more complex flexible torsions, some types of which can occur simultaneously, molecular vibrations involving each bond and group of bonds are always in progress. Each of the motions described above occurs with a characteristic frequency, energy, and rate.

Motion in which molecular integrity is disrupted. *Dissociation.* Stretching movements of sufficient energy will disrupt the bond between two vibrating atoms, with several possible results, depending upon the final disposition of the electrons in the broken bond.

In heterolytic fission (breaking into differing parts) of a bond, both electrons remain with one fragment, making it an ion with one excess negative charge, while the other fragment, lacking an electron, becomes an ion with one positive charge. In water, hydrogen is a typical positive ion (H^+); molecules releasing H^+ are called acids. Hydroxide ion (OH^-) is a typical negative ion in water; molecules releasing OH^- are called bases. In water these ion products of heterolytic fission are separated and stabilized by oppositely charged centres in the medium, the ionic molecules, like other charged particles, obeying the physical law of being attracted by opposite and repelled by similar charge.

Homolytic fission (separation into two neutral atoms or groups) of bonds leaves each fragment with a balance of charges, but each possesses an odd number of electrons. Such fragments, called radicals, are usually reactive since they can readily form new electron pair bonds with other odd-electron species. Homolytic fission of bonds occurs when molecules are subjected to heat or radiation.

Addition or coordination compounds are made up of constituent molecules that can exist independently and that return to their independent state upon dissociation of the complex. One example is the complex formed reversibly with oxygen by hemoglobin, which transports oxygen through the bloodstream. Dissociation of the complex in the tissues releases oxygen molecules for oxidation of foodstuffs and frees hemoglobin for return to the lungs and repetition of the cycle.

Exchange reactions. Change in position among easily displaced atoms or groups in gases and liquids is common and can be assumed to take place at some rate among most linkages. Readily changed hydrogen linkages represent an extreme case; the exchange of hydrogen between H_2O molecules in liquid water is particularly fast.

Interconversion of isomers. The pure substance acetaldehyde (C_2H_4O) furnishes an example of tautomerism, a condition in which isomers change into each other easily and ordinarily exist together in equilibrium. It has the chemical and physical properties expected for a mixture of two different structures, one with a carbon–carbon double bond ($\diagdown C{=}C \diagup$) and an oxygen–hydrogen (OH) group and the other with a carbon–carbon single bond ($-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-$) and a carbon–oxygen ($\diagdown C{=}O \diagup$) double bond. The two isomers undergo rapid interconversion within the molecule through exchange of hydrogen between carbon and oxygen in the structure to give the keto ($CH_3{-}CH{=}O$) and enol ($CH_2{=}CH{-}OH$) forms. These changes take place too rapidly to permit separation from the mixture under ordinary conditions.

Isomerization. In many cases the interconversion of isomers is so easy that the individual isomers cannot be isolated. Optical isomers capable of fast, reversible transformation into a symmetric arrangement, for example, will always exist as an equal mixture of dextrorotatory and levorotatory forms; *e.g.*, the enantiomorphic rotamers of ethane. Tautomeric exchange of hydrogen is

within the molecule and fast. Just as fast is the migration of metal atoms in the constantly changing fluxional molecules. At the other extreme lie hydrocarbon and oxygen–silicon isomers, which are stable because the rupture of several strong, inert bonds is necessary to rearrange the structure; for example, mirror image (enantiomorphic) crystals of quartz have retained their identity for eons. Between the two extremes are many molecular rearrangements of stable substances that can be brought about under mild conditions by heat or chemicals.

MOLECULAR STRUCTURE AND GENERAL PROPERTIES OF MATTER

The bulk materials of experience are made up of tremendous numbers of atoms or molecules, and the macroscopic properties of materials can usually be generalized from the properties of the constituent units. Behaviour of molecular materials can be understood through knowledge of molecular structure and intermolecular forces. In this way, the nature of known materials is learned and possibilities for new materials realized.

In the following section the physical and chemical properties of molecules as they can be understood from molecular structure are dealt with.

Physical properties. Those characteristics of molecules generally classified as physical are due to molecular size and shape, forces between molecules, and their interaction with electromagnetic radiation and fields.

Size and shape effects. A collection of molecules fits into a regular crystalline arrangement according to the same rules of geometry as the packing of large objects. Molecular crystalline arrangements conform to various shapes known in solid geometry. Bulk crystalline form can also reflect the shape of the molecules making up the crystal, as demonstrated by Pasteur's identification of right- and left-handed crystal shapes composed of enantiomorphic molecules, solutions of which rotate the plane of polarized light in opposite directions. Long-chain molecules often form fibrous crystals, and sheet-like molecules form layer lattices. Other bulk properties are similarly related to molecular characteristics.

Structure of rubber

Rubber, for example, is an aggregate of very long molecules intertwined in a random way. Unvulcanized rubber is sticky because the molecules tend to pull away from each other. Vulcanized rubber has been heated with sulfur, which forms bridges of sulfur-atom chains linking the rubber molecules together; small amounts of sulfur (few cross-links) lead to soft rubber, larger amounts of sulfur to much harder materials. Rubber's elasticity arises from the reversible stretching of the randomly twisted and coiled molecules, under stress, into a more ordered, chainlike arrangement.

Size and shape are important in other respects; for example, in diffusion of molecules through channels in rigid mineral forms or in nonrigid, biological membranes. Only a single dimension may be critical, as in the case of a rodlike molecule passing through an orifice or of a long-chain structure passing through a membrane channel that its branched isomer cannot penetrate.

Intermolecular forces (see following discussion) determine whether a substance will be found in gas, liquid, or solid phase. Strong attractive forces result in solidification, even for the lightweight lithium hydride, while weak attractive forces between the much heavier radon atoms are easily disrupted, and radon exists as a gas at room temperature. When intermolecular forces are relatively constant through a series of molecules, their size and shape can determine the phase. The saturated hydrocarbons are an example: methane, CH_4, is a gas; isooctane, C_8H_{18}, is a liquid; and triacontane, $C_{30}H_{62}$, is a waxy solid. Shape is also important. The chain molecule decane, $C_{10}H_{22}$, is a liquid at room temperature, but the flat, fused-ring naphthalene, $C_{10}H_8$, of similar mass, packs efficiently into a crystal and is solid under the same conditions. Attaching one carbon–hydrogen group (CH_3) to naphthalene can disrupt the layer packing and make the methyl derivative a liquid at room temperature.

Intermolecular forces. At very short distances, all atoms and molecules attract each other. In the absence of other more powerful forces, weak attractions account for liquefaction and, as temperature is lowered, eventual soldification of subtances. At the other extreme are the very powerful forces of electrical attraction between oppositely charged ions. Crystalline lattices are typical of ionic aggregates. Between the two extremes are electrically neutral molecules with, nevertheless, concentrations of negative charge in one part of the molecule and of positive charge in another part; such molecules are electric dipoles (just as bar magnets are magnetic dipoles) and are called polar, as compared with nonpolar molecules, in which the charges are evenly distributed. The oppositely polarized ends of two molecules will attract one another. Molecules consisting of two atoms of the same element, $A-A$, are nonpolar. On the other hand, all heteronuclear (containing different kinds of atoms) diatomic molecules, $A-B$, are polar, since the electrons joining A and B will inevitably lie closer to one atom or the other, thereby distorting the electrical balance of the system. The presence of the electric dipole can be experimentally verified, since in an electric field the molecules, like the magnets, will align themselves with the electron-rich end toward the positive pole. The extent of the imbalance, called the dipole moment, is a vector quantity (*i.e.*, it has both magnitude and direction), and vector addition can be used to relate the measured dipole moment of a complex molecule to the individual contributions of the bonds that make it up. Linear $A-B-A$ molecules made up of polar bonds between oxygen and carbon, O=C=O, for example, have no net polarity because the two equal and oppositely directed dipolar C=O vectors cancel each other. The polarity of the water molecule, on the other hand, was used by a Dutch scientist, Peter Debye, to show that the H—O—H system is bent, since only in that shape could the two dipolar O—H vectors add to give a net dipole moment for the molecule.

Polar molecules

The electron-rich ends of polar molecules attract the electron-poor ends of their neighbours. This attraction, while much weaker than the force between charged ions, imparts important properties to polar water molecules. The dipole vectors in the water (H_2O) molecule produce an attraction called hydrogen bonding in liquid water and ice. These intermolecular hydrogen bonds are only 5 to 10 percent of the strength of the covalent O—H bonds in the water molecules themselves but account for most of water's unique properties, including its liquid state under mild terrestrial conditions, while the combination of hydrogen with the 20 elements most resembling oxygen are all gases under the same conditions, despite the much greater mass of most of them. In freezing, water expands into a structure that permits the most effective hydrogen bonding of its molecules, and as a consequence ice is less dense than liquid water and floats on its surface. Water is one of the very few materials known in which the solid form does not sink in the liquid. The electron-rich end of the water molecule is drawn even more strongly to positively charged ions than is the opposite end to negative ions. Water is thus an excellent solvent for compounds, such as salts, which give ions, as well as for other polar molecules such as alcohol or sugar. Nonpolar molecules, such as those found in oils, do not mix with water. In general, "like dissolves like" as far as molecular polarity is concerned, but oil and water can be made to mix in the presence of soaps or detergents, the molecules of which are constructed with highly polar, water-soluble groups to which are attached long oil-soluble hydrocarbon chains. Washing action combines the two unlike types of materials into an emulsified mixture with the soap molecules.

Soap structure

Resonance with radiation. Each of the different types of molecular flexibility considered under time-dependent phenomena has a characteristic rhythm of oscillation or frequency. That molecules can oscillate only with certain allowed frequencies is the result of quantum-mechanical laws that govern the behaviour of minute particles. Similarly, molecules can absorb energy only

in certain characteristic amounts. The absorption can stimulate more rapid rotations or vibrations or excite bonding electrons to higher energies. Radiation is described by frequencies or energies characteristic of its position in the electromagnetic spectrum (listing of the wavelengths and frequencies of electromagnetic radiation).

Molecular spectroscopy is based upon the absorption of electromagnetic radiation by molecules. Just as dishes in a cupboard can be made to rattle when certain notes are sung, particular types of motions in certain regions of a molecule will resonate with radiation of selected frequencies or energies. In order of decreasing energy, electronic excitation is generated by ultraviolet or visible light, molecular vibrations by infrared radiation, and rotations by far-infrared and microwave radiation.

Chemical properties. In general, the overall chemical behaviour of molecules is determined by the nature of the chemical bonds and the atoms they join. Subtle changes can arise in more complex systems, however, from the way certain portions of the structure are positioned. Reaction rates and whether a given reaction will take place at all are often governed by these spatial, or steric, factors. Chemical reactions in living organisms are almost always controlled by detailed molecular structure. This is evident in the requirement for particular isomers, such as for left-handed amino acids in food, versus the right-handed structure, which cannot be digested. Chemical processes in biology are apparently governed by the ability of sometimes highly complex molecular aggregates to fit together in space. The double helix structure of deoxyribonucleic acid, DNA, is a famous example: the cylindrical form brings complementary portions of the two individual strands together in a hydrogen-bonding interaction between matched base groups. For the interwound strands to be held together by hydrogen bonding, the sequence of the bases on the two strands must be complementary; this sequence is the information used in constructing new strands. The order on one of the strands is used alone in the production of a slightly different polymer, similar to DNA, called ribonucleic acid, RNA, and RNA serves as the pattern upon which amino acids are brought together and incorporated into new linear protein polymers. Viruses carry RNA units, which invade cells and cause destructive changes in their functioning. Changes in the order of the units in DNA, which can be brought about by radiation with enough energy to disrupt chemical bonds or by other molecular agents (mutagens), produce mutations. Biochemists have succeeded in synthesizing a number of biologically active materials in the laboratory, including an exact copy of the DNA in a virus, in 1967, and a yeast gene (an element that transmits hereditary characters), in 1970.

Structure of DNA

Through investigations into the genetic materials of creatures lower on the evolutionary ladder, the molecular background of human life is revealed. Work continues on the possibility of correcting hereditary defects, by supplying missing genes, and even of designing DNA and RNA molecules that could lead to forms of life that are not now known.

STRUCTURE DETERMINATION

Information about molecular structure, once limited to inferences derived from gross physical properties and chemical reactions of compounds, has been greatly expanded through the techniques of spectroscopy and diffraction. Some of these techniques are now used routinely by the practicing chemist and can give, within minutes, data from which the nature of molecular structure can be inferred. Other techniques, especially diffraction, are capable of determining the dimensions of molecules, but long periods of time are required to collect the data and laborious computations to interpret it. Such methods are used by a relatively few expert chemists.

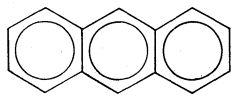
Precise methods. *Microwave.* Rotational characteristics can, in principle, provide information about molecular dimensions, since the frequency of a body's rotation is governed by its moment of inertia (its tendency to continue in motion), which in turn depends upon the masses and the distances between them. With knowledge of the precise masses of atoms, precise distances can be calculated from rotational data. In practice, the microwave technique (a microwave is electromagnetic radiation of between one and 100 centimetres in wavelength) has been limited to relatively simple polar molecules in the gas phase. It has shown, for example, that the two hydrogen atoms in the water molecule are about one angstrom (10^{-10} metre) from the oxygen atom and that the angle formed by the three atoms is 104.5°.

Electron diffraction. Electron beams passing through a sample of molecules are diffracted (scattered). Such radiation cannot penetrate deeply into matter, but the pattern of diffraction of electrons by gaseous samples can be used to obtain molecular dimensions. Molecules of a gas are relatively far apart and so no intermolecular diffraction effects occur; instead, it is the relative dispositions of the atoms in space within each molecule that determine the diffraction pattern. In using this method a molecular structure is assumed, the intensities of the diffracted beams that it would cause are calculated, and the observed values are compared with those predicted to determine the validity of the assumed model. In practice, the technique is used for fairly simple, somewhat symmetrical, gaseous molecules, but different structural arrangements cannot always be distinguished. Electron-diffraction patterns of small molecular fragments boiled off the surfaces of refractory salt crystals, such as sodium chloride (NaCl), have been studied at high temperatures.

X-ray and neutron-beam diffraction. X-rays are scattered far less than electrons and can penetrate deep into crystalline solids. Each atom of the regular arrangement within a crystal can diffract X-rays, and the manner of diffraction within molecular crystals depends upon the shape and size of the molecules and on their positions and orientation in the crystal. The X-ray diffraction patterns are compared with prior calculations based on plausible assumptions, in a trial and error process ideally suited to a computer. This technique has been developed into the most effective method available for the determination of detailed molecular structure. Because hydrogen atoms have far less scattering power than heavier atoms, the positions of hydrogen atoms in complex molecules usually cannot be obtained from X-ray data. Neutrons, on the other hand, are scattered by all atoms to a similar extent, and therefore the positions of hydrogen atoms can be readily established, even when very much larger atoms are present. To obtain neutron beams of the necessary intensity, however, requires an atomic pile, and neutron-diffraction studies can be carried out only in few laboratories. X-ray diffraction requires only that the molecules be in a crystalline, not glassy, solid. Liquids and gases can be studied as crystals at low temperatures.

Limitations of X-ray diffraction

Many special techniques have been devised to reduce the labour of calculating structures from diffraction data. Structures of simple molecules, which once required months of computation, can be solved with great accuracy in a matter of days, using computers. An example is the electron-density-distribution map of the molecule anthracene, $C_{14}H_{10}$, from X-ray data, which verified the chemist's intuitive concept represented in its structural formula



(see Figure 1). The structure of DNA, proposed in 1953 from X-ray data, was a breakthrough toward understanding the fundamental chemistry of life (see Figure 2).

Inferential methods. In recent years there has been rapid growth in experimental methods based on some physically measurable property that varies according to molecular structure. This category includes spectroscopic techniques, in which a beam of radiant energy is dispersed by a sample and its component waves then arranged in order of their wavelengths; these techniques are commonly used to give information that can be re-

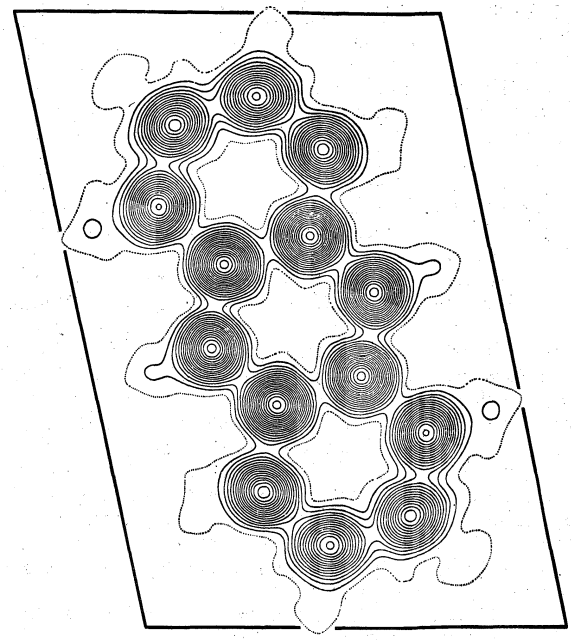


Figure 1: Electron-density map of anthracene, $C_{14}H_{10}$, drawn from X-ray-diffraction data. Contour lines are drawn at density intervals of one-half of an electron per angstrom (see text).

lated to molecular structure. In most cases it is not possible to make theoretical predictions about the relationship between molecular structures and the measured property from established principles. The practicing chemist, therefore, relies upon assumed similarities to measurements on compounds of known structure. The information thus obtained for the solution of new problems is inevitably circumstantial; a choice must often be made between a number of apparently reasonable interpretations. In this respect, especially, additional data from other physical methods can be of great value.

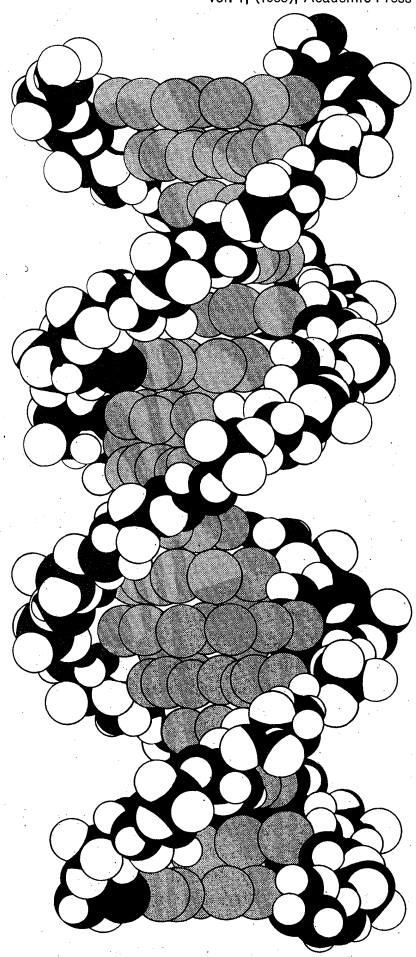

Figure 2: DNA double helix molecule.

Ultraviolet and visible (electronic) spectra. Stable compounds of low molecular weight are electronically excited only by radiation in the higher energy ultraviolet region of the spectrum; and water, carbon dioxide, ethyl alcohol, and other compounds of low weight are thus colourless. Colour in a compound indicates the presence of easily excited electrons, and certain functional groups or types of structure (chromophores) provide colour. In series of compounds with chains of alternating double and single bonds (conjugated), such as 1,3-butadiene, $H_2C{=}CH{-}CH{=}CH_2$, and 1,3,5-hexatriene, $CH_2{=}CH{-}CH{=}CH{-}CH{=}CH_2$, the absorption of radiation, corresponding to electronic excitation, progressively falls in required radiant energy through the ultraviolet into the visible region, with the compound with eight double bonds showing colour. Double bonds isolated in a molecular structure can thus be distinguished from those that are conjugated. Samples are usually studied in dilute solution.

Significance of colour in compounds

Infrared (vibrational) spectra. Absorption of infrared radiation stimulates the vibration of bonded atoms and groups to more violent and longer excursions from their equilibrium positions. By analogy with a pair of weights connected by a spring, strong bonds require more energy to stimulate stretching and bending, while increasing the masses of the bonded atoms lowers the energy required. Because energies and distances between nuclei are relatively constant values for pairs of bonded atoms, despite the great variety of molecular structures into which they are incorporated, it has been possible to assign characteristic infrared group-absorption frequencies to some pairs of atoms. Tabulations of such frequencies are exceedingly useful in the rapid identification of these groups from their infrared spectra, and shifts of frequencies are often used to deduce the nature of adjacent groups in the molecule. The complete infrared spectrum of a complex molecule can be considered to a first approximation as the superposition of the absorptions of the various pairs of atoms and functional groups in the molecule. Such a spectrum will be characteristic of the particular molecular structure; an unknown sample can be identified by comparing its infrared spectrum with that of a known compound. Small changes can be easily detected. Infrared spectroscopy is in general use in all chemical laboratories. Samples can be studied in any phase.

Mass spectrometry. Traditional methods of deducing molecular structure by disrupting it chemically, identifying the fragments, and mentally constructing them into a plausible structure for the original molecule find a counterpart in the study of compounds by fragmenting them under electron bombardment in the mass spectrometer. The masses of the (usually positively) charged fragments so produced are analyzed by electric- and magnetic-field separation, and extremely accurate measurements, which allow the type and number of atoms in each fragment to be specified, can be obtained. The original structure can be reconstructed by trial and error, on a computer. Minute samples can be studied by this technique.

Nuclear magnetic resonance. Except for mass and electric charge, nuclear properties were once of little interest to the chemist. Today it is known that interactions of nuclei with their chemical environment give rise to a broad range of phenomena, and molecular structures are studied with many techniques based upon energy changes in the nucleus. Nuclear-magnetic-resonance spectroscopy, which measures the energy necessary to reorient the magnetic dipole moment of the nucleus in an applied magnetic field, is the most widely used of such methods. The resonance energy required depends upon the particular environment of the atom, typically hydrogen,

in the molecular structure. Thus, the three types of hydrogen atoms in ethyl alcohol, CH_3CH_2OH, can be distinguished, and the signal response is in the ratio 3:2:1, which tells the relative numbers of the structurally distinct hydrogens. Neighbouring hydrogen atoms affect the signal in a way that allows further inferences to be drawn about structure in the surrounding region of the molecule. Nuclear magnetic resonance spectra are measured in solution.

The prodigious progress in molecular-structure analysis since World War II has resulted in large part from the widespread use of combinations of physical techniques; each yields some information about molecular structure and is reinforced by complete and precise determinations of key examples. The foregoing techniques for the identification of the components of molecules can be adapted to micro samples; a complex molecular structure can be solved in a matter of hours by information collected by a battery of methods from a sample barely large enough to see.

In the middle of the 19th century, the gifted British physicist James Clerk Maxwell wrote:

> A molecule is the smallest possible portion of a particular substance. No one has ever seen or handled a single molecule. Molecular science, therefore, is one of those branches of study which deal with things invisible and imperceptible by our senses, and which cannot be subjected to direct experiment.

The basic concepts have not changed. What has changed is that increasingly indirect physical effects have been found to be understandable in terms of molecular structure. The insights obtained from the application of these experimental techniques to problems of molecular structure have provided the major stimulus to mid-20th-century chemistry as a science and are beginning to have similar effect in the world of biology.

Molecular Weight

A molecule is a group of atoms bonded together strongly enough to establish a separate identity and act together as a unit and, consequently, to have a constant mass and atomic composition. Measurements of molecular weight were first made on simple gases of known atomic composition, which at very low densities could be considered to be separable—*i.e.*, discrete—molecules.

Historic development of atomic-molecular theory

Although the idea of molecular weight is accepted today, it evolved only slowly. As modern atomic-molecular theory was developed and the existence of discrete molecules asserted, the Italian physicist Amedeo Avogadro postulated (1811) that equal volumes of different gases would contain the same number of molecules if the temperature and pressure were the same. Therefore, if equal volumes of two gases were weighed under identical conditions of temperature and pressure, the weights would compare exactly as the masses of single molecules. Stanislao Cannizzarro, an Italian chemist, revived Avogadro's concept in 1858 and showed its significance by analyzing existing measurements of gas densities. He was able to rationalize the molecular weights and chemical formulas of the well-known gases, and molecular weights came to be accepted as one of the fundamental properties of any chemical compound.

The number of molecules in one millilitre (ml) of gas is about 10^{19} at room temperature and atmospheric pressure. Although gas densities vary, a value of 0.001 gram per millilitre is common. The mass of a single gas molecule would then be about 10^{-22} gram. Because this mass is not directly measurable, other ways of determining molecular weight are required, and a scale of relative values has been built around the concept of a mole (*i.e.*, the amount of a substance in grams that corresponds to the sum of the atomic weights of all the atoms that make up the molecule; the atomic weight of the atom of an element is defined as its mass as compared with the mass of the atom of carbon-12). A mole of a substance is considered to contain exactly the same number of molecules as there are atoms in 12 grams of the pure carbon isotope carbon-12: $6.02252 \pm 0.00028 \times 10^{23}$ atoms of carbon. This number is called Avogadro's number or, in some literature, Loschmidt's number.

The molecular weight of a substance is defined as the weight in grams of one mole of the substance; that is, the actual weight in grams of 6.02×10^{23} molecules. Molecular weights are expressed in grams per mole (or daltons, a term common in the field of biological chemistry, although it has not been approved by the International Union of Pure and Applied Chemistry). Molecular weights range into the millions, as shown by the Table of representative molecules.

Approximate Molecular Weights

molecule	structure	molecular weight (in grams/mole)
Hydrogen	H_2	2
Sucrose (sugar)	$C_{12}H_{22}O_{11}$	342
Insulin	51 amino-acid residues	5,700
Polyesters	$(O(CH_2)_5CO)_n$	10,000–20,000
Hemoglobin	587 amino-acid residues	65,000
Synthetic rubbers	$(CH_2—CH=CH—CH_2)_n$	100,000
Myosin		600,000
Polystyrene	$(C_6H_5CHCH_2)_n$	50,000,000
Nucleic acids	phage DNA	130,000,000 and greater
Dextrans	polysaccharides	up to 500,000,000

All molcules over this range of molecular weights can be at least conceptually separated from one another for some measurement of molecular weight. For many solids with molecules that cannot be separated into a gaseous state, it is possible to find a solvent that will dissolve the substance and thus separate the molecules so that their weights can be determined.

This simple procedure is subject to two frequent chemical complications: (1) The solution of the dissolved molecules often results in chemical reactions that produce associated or dissociated species rather than a simple, unchanging molecular species. (2) Solids such as sodium chloride (NaCl) have a neat geometrical arrangement of sodium ions and chloride ions in the solid state, but they have a disordered arrangement of ions and no clearly defined molecular species of NaCl in the solution state (in which the ions dissociate and move about in accordance with electrochemical factors). In both these cases the simplest chemical formula that represents the proper chemical composition is assumed, and the molecular weight is assigned to that formula. If alcohol, for example, has a structure for which the simplest formula is C_2H_5OH, its molecular weight is found by multiplying the number of atoms in this formula by their atomic weights as found in the atomic-weight tables: that is, 2 atoms of carbon $\times$ (12.011) + 1 atom of oxygen $\times$ (15.999) + 6 hydrogen atoms $\times$ (1.008) = 46.069. This

weight of alcohol—*i.e.*, 46.069 grams—then constitutes one gram mole. Often when dealing with known simple materials such a calculation is sufficient. For unknown substances or known substances in a totally new environment, one of the methods discussed below is used.

PRINCIPLES OF MOLECULAR-WEIGHT DETERMINATION

The three methods of determining the molecular weight of uncharged molecules are based respectively on thermodynamic theory, on kinetic theory of transport phenomena, and on known spatial arrangements of atoms in the solid state. A fourth method, mass spectrometry, can be used on species that can be ionized; *i.e.*, given an electrical charge either by adding or by removing one or more electrons from the structure.

Thermodynamic methods

The thermodynamic methods of molecular-weight determination rely on the equation of state for gases or the equation of state for solutions. The laws concerning the physical behaviour of gases are among the most useful in science, but they are based upon the concept of an ideal gas in which each molecule is, in effect, a point without volume, without any attraction or repulsion toward other points, and with perfect resilience in collisions. The molecules of a real gas have volume and are attracted to or repelled by one another; they often have electrical charges and magnetic properties, and they have a true mass that makes them react to the gravitational field. They may react chemically under certain conditions, and they spin and tumble about. Their internal structure is such that they can absorb energy or lose it in ways that may or may not affect their motion. In an ideal gas the volume (V), pressure (P), temperature (T), and a constant of proportionality (R) are related in such a way that the volume is directly proportional to the temperature and to the constant and is inversely proportional to the pressure, thus: $V = RT/P$. This relationship is true with R only if one mole of gas is considered. If the gas weighs W_2 and its molecular weight is M, then the number of moles is W_2/M, and the equation may be rewritten pressure times volume is equal to constant times temperature times weight divided by mass, or: $PV = RT(W_2/M)$. Molecules in a solution may be considered to behave somewhat like gases, and an equation of state can be derived for solutions following the same sort of reasoning as with gases, with the additional factors that dominate the liquid state. If π represents osmotic pressure (defined below) as analogous to gas pressure, and C_2 is the concentration of dissolved molecules, analogous to the weight of gas molecules, then the van't Hoff relation for the equation of state for solutions is written $\pi = RT(C_2/M)$. Although ideal gases and ideal solutions are never encountered, the ideal is approached with increasing dilution. Furthermore, if measured quantities are extrapolated to infinite dilution, the use of ideal-gas or ideal-solution laws is usually justified.

Transport and other methods

Transport phenomena include the movement of a variety of properties through a system; *e.g.*, heat. The transport methods of molecular-weight determination depend on the relationship of the size of the molecule to the diffusion, or spreading of concentration, the viscosity (*i.e.*, a liquid's internal resistance to flow), or sedimentation (*i.e.*, the settling of finely divided particles from a liquid) of the molecules, whether in the gaseous or dissolved states. Other transport methods rely on the heat conduction or electrical mobility. If a simple shape can be assumed for the molecule, there is a direct relationship of size, mass, and density. Historically these methods were used for determining Avogadro's number, but today they are seldom used for molecular-weight determinations of small molecules except under special experimental conditions.

The geometrical arrangements of the molecules and their constituent atoms can sometimes be clearly determined in the crystalline state (*e.g.*, when X-rays are passed through a thin slice of a crystal to fall on a photographic plate, the two-dimensional pattern on the plate can be interpreted in terms of the three-dimensional structure of atomic nuclei that deflected the X-rays); in such instances, it is easy to calculate the average volume occupied by the molecule. By multiplying the average molecular volume by the macroscopic crystal density, the average mass of a molecule can be determined. The molecular weight can then be determined quite accurately using Avogadro's number. This method is obviously limited to a few well-studied compounds and is not used for routine molecular-weight determinations.

If the molecule can be ionized (*i.e.*, given an electrical charge by either adding or removing electrons), the ionized sample can be fed into a mass spectrometer, in which the heavier molecules are separated from the lighter. The ratio of mass to charge can be accurately determined (see MASS SPECTROMETRY). Since the ions are frequently of low charge, it is possible to determine ion mass. Using Avogadro's number, the molecular weight can be determined. This method is extremely accurate but is restricted to low molecular weights. Because of its speed, it is used extensively in the petroleum industry.

Application of methods

For an unknown compound the thermodynamic and transport methods discussed above are usually used, unless the molecule is of low molecular weight or the substance is gaseous. In the latter cases the mass spectrograph may be preferred. The thermodynamic and transport types of measurement can be simply and inexpensively performed. From an operational point of view, molecular-weight measurements by the thermodynamic and transport methods generally require that: (1) the substance be used in a solution, (2) the solution be sufficiently dilute that van't Hoff's law is obeyed, and (3) the substance be a pure chemical compound, not a mixture of different molecules.

Frequently, the substance is not a pure chemical compound; petroleum samples, for example, are often mixtures of several hydrocarbons, the boiling points of which are close together. Furthermore, polymer samples, such as plastics, rubbers, or wood, are always mixtures of differing molecular weights (see below *Molecular-weight distributions*). Even pure proteins often occur with small traces of other similar components. The best representation of any mixture is a frequency count of all components, as is routinely done with petroleum samples, using the mass spectrometer. With samples of higher molecular weight, however, such as polymers and proteins, the same techniques are not applicable; average molecular weights must be given. In averaging, the different molecules are counted either by number or by weight. In the first case, the molecular weight is called a number-average molecular weight and, in the second, a weight-average molecular weight.

METHODS OF MOLECULAR-WEIGHT DETERMINATION

Gaseous-state methods. *Density.* The measurement of gas densities to determine the molecular weight of a gas is an application of the ideal-gas law, which can be used with any volatile liquid or solid. Sensitivity of the method is low because large vessels must be weighed to determine the mass and volume of the gas. Real molecules are not simple points in space as the ideal-gas law assumes, and, accordingly, a pressure-dependent term must often be added to the ideal-gas law. At one atmosphere pressure, the correction is less than 1 percent for very simple gases.

Effusion. The general theory of diffusion (the expansion of a gas as a result of its internal pressure, brought about by the incessant motion and collisions of its molecules) indicates that the rate of diffusion will be inversely proportional to the mass of the diffusing particle; *i.e.*, the more massive particle diffuses more slowly. Effusion of a gas through a small hole can be used to measure the ratios of molecular weight of any two gases. The rates of effusion R_1 and R_2, of two species, for example, are related to the square roots of their molecular weights (M_1 and M_2) inversely and therefore can be expressed numerically as $\frac{R_1}{R_2} = \sqrt{\frac{M_2}{M_1}}$, all other variables being constant. In the mass spectrometer, the rate at which molecules enter or leave the ion chamber (a process of effusion) is measured, a technique that allows analysis of mixtures by molecular weights.

Formula for effusion methods

Mass spectrometry. The mass spectrometer is so sensitive that it can distinguish between isotopes (atoms of the same element that differ in atomic mass) in molecules of low molecular weight. Consequently, in many reactions the changes in molecular weight of the molecules involved can be followed through isotope or heavy atom exchange. The amount of material required for analysis is small (less than 0.1 millilitre of gas). Mass spectrometers are tied directly into refinery operations to make automatic molecular-weight determinations of petroleum fractions. The limited range of the mass spectrometer is its only major disadvantage in this application. It is suitable only for a range of molecular weight (for a unit electrical charge) of up to several thousand grams per mole, and the mass spectrometer is generally used for molecular weights no greater than 500 grams per mole. Another disadvantage is that, after the sample is volatilized inside the instrument, only fragments of the original molecule remain to be measured.

Solution methods using colligative-property measurements. Solution methods are in general use because they can be inexpensive, and they cover a very large molecular-weight range, about 100 grams per mole to greater than 100,000,000 grams per mole. They also can vary from simple thermodynamic methods to transport methods that are based on thermal conduction and mass transport. Solution methods usually are separated into those that count numbers of molecules (colligative properties) and those that count weights of molecules.

Osmotic pressure. When molecules of the substance to be measured are placed in a solvent, they affect the energy of the solvent molecules so that the latter no longer have the same chemical potential (or internal pressure) as the pure solvent. If the pure solvent is separated from the solution by a membrane that is impermeable to all but solvent molecules, these will migrate through the membrane from a higher to a lower concentration of solvent; *i.e.*, from the pure solvent side to the solution side. Pressure applied to the solution will inhibit the migration, and the exact pressure that must be applied to bring about equilibrium between solution and solvent is called the osmotic pressure. This is a direct measure of the effect of the substance whose molecular weight is sought upon the chemical potential of the solvent, and experiments show that osmotic pressure (π), as was stated earlier, equals the product of the concentration of dissolved molecules (C_2), the temperature (T), and the gas constant (R) from the ideal-gas law, divided by the molecular weight (M) of the dissolved molecules. Rearranging this, the equation may be written: $M = RTC_2/\pi$. As with the gas equation of state, all of the solution measurements are conducted at low concentrations or are extrapolated to zero concentration, in order to minimize the discrepancy between an ideal state and the actuality, in which molecules affect one another in various other ways as well.

Automatic osmometers

In recent years automatic osmometers have become commercially available. They are not more accurate than simple osmometers, using capillary tubes, but they are faster. With corrections for diffusion through the membrane, osmotic-pressure measurements have accurately measured the molecular weight of sucrose ($M = 342$ grams per mole). Osmometers have been used to measure M as high as 1,000,000 grams per mole.

Vapour pressure. The vapour pressure of a pure solvent is always lowered when the substance to be measured is added to it, because the concentration of solvent molecules at the surface is reduced. The solvent molecules have fewer chances at the surface to exert a pressure. Such small pressure differences, however, are generally so difficult to measure that the technique is not used routinely for molecular-weight determinations.

Vapour-pressure osmometer. Differences in vapour pressure can be measured by thermistors, devices that employ semiconductors to measure minute changes in temperature. If a thermistor has a drop of solution and a drop of solvent, with only a small air gap separating the drops, the different rates at which vapour is transported between the drops cause a temperature difference that the thermistor can sense. This temperature difference can be related to the molecular weight of the solute. The technique needs to be calibrated with known compounds, but the measurement has become common in organic- and polymer-chemistry laboratories. The range is limited to a few thousand grams per mole in molecular weight.

Boiling point and freezing point. When a compound is dissolved in a solvent, the chemical potential of the solvent is reduced, and the freezing point of the resulting solution becomes lower than that of the pure solvent. The difference in temperature is inversely proportional to the molecular weight of the solute. Again, the phenomenon may be explained in terms of the concentration of solvent molecules. A solution also has a higher boiling point than the pure solvent, and the difference in temperature is, as with the freezing point, inversely proportional to the molecular weight (the greater the difference the smaller the molecular weight). The elevation of the boiling point, however, is less sensitive than the lowering of the freezing point because of the higher heat of vaporization. The method is used in teaching because it is inexpensive, using only a thermometer and a water bath. Its range, except in the most experienced hands, is less than 5,000 grams per mole.

Other solution methods. *Equilibrium sedimentation.* If a sample solution is centrifuged (spun in a container shaped like a test tube) at extremely high speed, the dissolved molecules may collect in the region at the bottom of the tube. The process of concentrating the solution near the bottom of the tube, however, sets off an osmotic driving force that tends to make the dissolved molecules diffuse back into now less concentrated solvent. If the experiment is carried out carefully, the two forces are balanced and a very simple determination of molecular weight is possible through the osmotic equation of state (as explained above). The range of molecular weights that can be determined is enormous because the buoyancy of the medium and the speed of the centrifuge rotation can both be altered. In many ways measurement of solutions with the centrifuge, using the product of mass and buoyancy, are analogous to measurement with the mass spectrometer of gas, using a ratio of mass and charge. The method is capable of great accuracy and is fast. Its primary application has been in biological chemistry.

Light scattering. Fluctuations of concentration in a solution were analyzed by Einstein and found to be proportional to the change of osmotic pressure with concentration. To make a concentration fluctuation requires working against the osmotic forces in the solution, *i.e.*, the tendency for the ratio of solute to solvent molecules to become uniform throughout the solution. If a light beam strikes a solution in which there are fluctuations of concentration, it will be scattered. The Dutch chemist Peter Debye during World War II showed how the intensity of scattered light could be measured and applied to the analysis of the molecular weights of synthetic rubber through the osmotic equation of state. There is no limit in range for this method and it can be very precise, but extreme care is necessary to get meaningful results. Most polymer and biological laboratories use this method.

Solid-state measurements. In the technique of X-ray crystallography, extremely thin sections of solid sample are bombarded with X-rays, which are deflected by the pattern of nuclei in the sample to emerge in a pattern that can be photographed. This technique is so complex that it is used only for exceedingly important materials that cannot be dissolved in any useful solvent. In principle, a large molecule that is completely homogeneous could be analyzed by viewing its entire length by high-resolution electron microscopy. In practice, estimates of molecular weight can be made for any dispersed particle thought to be a single molecule if the densities can be guessed from other experiments.

X-ray crystallography

Relative methods using size. *Sedimentation rate and diffusion constant.* The sedimentation velocity and free diffusion methods assume that certain laws are obeyed, and, from this assumption, the molecular weight can be determined. If both diffusion and sedimentation mea-

surements are made, the need for the assumption is eliminated. These methods are seldom used for measuring molecular weight.

Intrinsic viscosity. A molecule turning over as it is moved in the flow of a solution has friction properties; a viscometer is used to make intrinsic viscosity measurements from which the molecular weight can be calculated. Einstein solved the problem very generally for spherical particles. The method is also used extensively for determining the molecular weight of polymers.

Gel permeation chromatography (GPC). The most recent development in routine methods of molecular-weight determination is gel permeation chromatography. Gels are semisolids consisting of two components—a liquid dispersed through a network of solid material. In chromatography, a solution is passed through a medium that has a stronger affinity for one of the dissolved compounds, which settles out first and thus is separated. Gels that have very well defined holes have been made of polystyrene and dextrans; when a solution passes through a column of the gel, the smaller molecules can diffuse into the holes and therefore are retained longer in the gel column. The larger molecules, not able to get into the holes, move through the column faster. Using calibration with known materials, the technique has worked effectively throughout a molecular-weight range of from a few hundred to many million grams per mole. This technique is fast becoming a standard method in the polymer industry because of its speed. Even porous glass with uniform holes has been used successfully.

MOLECULAR-WEIGHT DETERMINATIONS OF MACROMOLECULES

Very large molecules—that is, molecules with molecular weights greater than 20,000 grams per mole and perhaps up to 1,000,000,000 grams per mole—have become extremely important in industry and biochemistry. Plastics, rubbers, thickeners, paints, wood, paper, proteins, nucleic acids, polypeptides, and polysaccharides are of this type. As recently as the 1920s, these molecules were considered to be aggregates of smaller molecules rather than single large molecules, and their molecular-weight determination has been an extremely important development.

Gels. Gels exist as macromolecules, but their molecular weight is immeasurably large. A gel is not really a dissolved molecule but rather a separate continuous phase (a phase is a state of matter such as solid, liquid, gas). From a molecular point of view, a gel is analogous in three dimensions to the coupling of many short segments of threads in a two-dimensional mesh fabric. Such gels can be held together as a mesh by covalent bonds or hydrogen bonds. If the bonding forces are covalent, the gel cannot be handled by any of the above methods, and the molecular weight tends toward infinity, but the gel will have a particle size almost large enough to be observed by the unaided eye. Vulcanized rubber is typical of this type of gel. Gelatin is typical of a protein gel that can be dissolved in special solvents or at higher temperatures and become individual chains that are no longer in a gel structure. These single chains can then be analyzed for their molecular weight.

Effect of bonding in gels

Molecular-weight distributions. Although biological processes tend to produce relatively uniform macromolecules, industrial synthetic polymerization processes produce a rather broad range of groups of molecules. In terms of molecular weights, the proteins are said to be monodisperse in molecular weight, while the polymers are polydisperse.

Petroleum, a natural product, can be treated in a refinery to separate fractions that are more or less uniform, and thus the molecular weights of the components can be determined. A detailed accounting of all of the molecular weights in a truly polydisperse system, however, cannot be obtained. Instead, a statistical description, called the molecular-weight distribution (MWD), may be obtained.

In polymers, the existence of small amounts of other components of lower or higher molecular weight is important. Industrially, optimum processability and strength are related to the type of molecular-weight distribution. The presence of dimers or trimers (molecules consisting of two or three, respectively, identical subunits), or degraded material from a biological macromolecule, gives insight into many kinds of biochemical processes; consequently, the fast elucidation of the MWD has been a goal of macromolecular chemistry. In recent years this goal has been achieved by gel permeation chromatography and less routinely by a process called boundary spreading in the ultracentrifuge (extremely high speed of rotation and, consequently, better separation of particles). Previously, time-consuming separation by fractionation schemes was required. In both these faster techniques, however, the molecular-weight distribution may be reported incorrectly, because the analysis assumes that only linear molecules are present in the sample whereas the sample may also contain branched and complicated ring and other types of molecular structures.

Industrial techniques

Branched molecules. Both natural and synthetic polymers have nonlinear, branched molecules. For the problem of samples that are mixtures of linear and branched polymers, as well as for many other problems, the equilibrium-sedimentation method is useful because it offers the greatest versatility in determining a true molecular-weight distribution.

Insoluble polymers. Commercial polymers may have such high melting points that the operations of solution chemistry are difficult to carry out. One popular product has never had an accurate molecular-weight description because the solutions must be handled at 300° C (about 600° F). New special-purpose polymers are often high melting. To determine their molecular weights, experimenters have used correlations of molecular weight with viscoelastic properties and mechanical strength found in other, lower melting polymer systems. For example, cellulose is difficult to characterize because it must be dissolved in chemically active solvents, and such solvents may alter the cellulose. This is the case with many polymers.

End-group analyses. If the polymer has identical subunits, the ends of the molecule can often be analyzed chemically because they are different from all the other chemical units in the chain and will react with reagents. The molecular weights of food additives, foaming agents, and other intermediate-molecular-weight polymers are determined by chemical analysis of the number of ends. If the ends can be counted, the number of chains is known, and the average mass per chain, or molecular weight, can easily be determined.

Nonideal solutions. All macromolecules, as a result of their size, are affected in many ways and therefore have large additive terms, in addition to the van't Hoff relation, for molecular weight. To avoid such factors as much as possible, macromolecules must be measured in very dilute solutions and the resultant molecular weight extrapolated to infinite dilution. All early work in this field is now of limited value because this effect was not fully understood. Sometimes a poor solvent, which then ensures a more ideal solution, is used to minimize the extrapolation. Biological macromolecular systems and synthetic polyelectrolytes are always nonideal because of the charges on the molecules, and they must be analyzed for their molecular weight with special experimental care.

Biological macromolecular systems

Association of macromolecules occurs in biological macromolecules, such as insulin, and in synthetic polymers such as polyvinyl chloride. Like any other association equilibrium with similar small-molecular-weight systems, the problem can often be avoided by using a more active solvent or by studying the change of molecular weight with dilution or temperature or both.

BIBLIOGRAPHY. J.R. PARTINGTON, *An Advanced Treatise on Physical Chemistry*, vol. 1 (1949), presents original references to early work in molecular weights and basic equations. See also the same author's *A History of Chemistry*, vol. 4 (1964), for a detailed account of the historical development. The development of molecular weight as a concept is carefully woven into the fabric of the whole kinetic-molecular hypothesis in JAMES B. CONANT and LEONARD K. NASH

(eds.), *Harvard Case Histories in Experimental Science*, vol. 1 (1957). Other recommended works include: E.A. MOELWYN-HUGHES, *Physical Chemistry*, 2nd rev. ed. (1961), an excellent general reference book in physical chemistry; F.W. BILLMEYER, *Textbook of Polymer Science* (1971), a readable account of all aspects of polymer science; and C. TANFORD, *Physical Chemistry of Macromolecules* (1961), an excellent physical-chemical introduction to biomacromolecules.

Molière

Although the sacred and secular authorities of 17th-century France often combined against him, the comic genius of Molière emerged finally to win him eventual acclaim as the greatest of all French writers. Comedy had a long history before Molière, who employed most of its traditional forms, but he succeeded in inventing a new style that was based on a double vision of normal and abnormal seen in relation to each other—the comedy of the true opposed to the specious, the intelligent seen alongside the pedantic. An actor himself, Molière seems to have been incapable of visualizing any situation without animating and dramatizing it, often beyond the limits of probability; though living in an age of reason, his own good sense led him not to proselytize but rather to animate the absurd, as in such masterpieces as *Tartuffe*, *L'École des femmes*, *Le Misanthrope*, and many others. It is testimony to the freshness of his vision that the greatest comic artists working centuries later in other media, such as Charlie Chaplin, are still compared to Molière.

Beginnings in theatre. Molière was born (and died) in the heart of Paris. The registers showed that he was baptized on January 15, 1622, as Jean-Baptiste Poquelin. His mother died when he was ten; his father, one of the appointed furnishers of the royal household, gave him a good education at the Collège de Clermont (the school that, as the Lycée Louis-le-Grand, was to train so many brilliant Frenchmen, including Voltaire). Although his father clearly intended him to take over his royal appointment, the young man renounced it in 1643, apparently determined to break with tradition and seek a living on the stage. That year he joined with nine others to produce and play comedy as a company under the name of the Illustre Théâtre. His stage name, Molière, is first found in a document dated June 28, 1644. He was to give himself entirely to the theatre for 30 years and to die exhausted at the age of 51.

A talented actress, Madeleine Béjart, persuaded Molière to establish a theatre, but she could not keep the young company alive and solvent. In 1645 Molière was twice sent to prison for debts on the building and properties. The number of theatregoers in 17th-century Paris was small, and the city already had two established theatres, so that a continued existence must have seemed impossible to a young company. From the end of 1645, for no fewer than 13 years, the troupe sought a living touring the provinces. No history of these years is possible, though municipal registers and church records show the company emerging here and there: in Nantes in 1648, in Toulouse in 1649, and so on. They were in Lyons intermittently from the end of 1652 to the summer of 1655 and again in 1657, at Montpellier in 1654 and 1655, and at Béziers in 1656. Clearly they had their ups as well as downs. These unchronicled years must have been of crucial importance to Molière's career, forming as they did a rigorous apprenticeship to his later work as actor-manager and teaching him how to deal with authors, colleagues, audiences, and authorities. His rapid success and persistence against opposition when he finally got back to Paris is inexplicable without these years of training. His first two known plays date from this time: *L'Étourdi ou les contretemps* (*The Blunderer*, 1762), performed at Lyons in 1655, and *Le Dépit amoureux* (*The Amorous Quarrel*, 1762), performed at Béziers in 1656.

First success

The path to fame opened for him on the afternoon of October 24, 1658, when, in the guardroom of the Louvre and on an improvised stage, the company presented Corneille's *Nicomède* before the king, Louis XIV, and followed it with what Molière described as "one of those little entertainments which had won him some reputation with provincial audiences." This was *Le Docteur amoureux* ("The Amorous Doctor"); whether it was in the form still extant is doubtful. It apparently was a success and secured the favour of the King's brother Philippe, duc d'Orléans. It is difficult to know the extent of the Duc's patronage, which lasted seven years, until the King himself took over the company known as "Troupe du roi." No doubt the company gained a certain celebrity and prestige, invitations to great houses, and subsidies (usually unpaid) to actors, but not much more.

From the time of his return to Paris in 1658, all the reliable facts about Molière's life have to do with his activity as author, actor, and manager. Some French biographers have done their best to read his personal life into his works, but at the cost of misconstruing what might have happened as what did happen. The truth is that there is little information except legend and satire. The fact that authors like Montaigne, Plutarch, Julius Caesar, and Seneca may have been in his library (according to a legal inventory of 1708), for example, does not mean that his plays should be read with the doctrines of such authors in mind.

Although unquestionably a great writer, Molière was not an author in the usual sense: he wrote little that could be called literature or even that was meant to be published—some poems and a translation of the ancient Latin writings of Lucretius, incomplete. His plays were made for the stage, and his early prefaces complain that he had to publish to avoid exploitation. (Two of them were in fact pirated.) He left seven of his plays unpublished, never issued any collected edition, and never (so far as is known) read proofs or took care with his text. Comedies, in his view, were made to be acted. This fact was forgotten in the 19th century. It took such 20th-century actors as Louis Jouvet, Charles Dullin, Jean-Louis Barrault, and Jean Vilar to present a new and exact sense of his dramatic genius.

Nor was he at all a classical author, with leisure to plan and write as he would. Competition, the fight for existence, was the keynote of Molière's whole career. To keep his actors and his audiences was an unremitting struggle against other theatres. He won this contest almost single-handed. He held his company together by his technical competence and force of personality.

Molière's first Paris play, *Les Précieuses ridicules* (*The Affected Young Ladies*), prefigured what was to come. It centres on two provincial girls who are exposed by valets masquerading as masters in scenes that contrast, on the one hand, the girls' desire for elegance coupled with a lack of common sense and, on the other, the valets' plain

speech seasoned with cultural clichés. The girls' fatuities, which they consider the height of wit, suggest their warped view of culture in which material things are of no account. The fun at the expense of these affected people is still refreshing and must have been even more so for the first spectators.

Molière's Paris theatres

Les Précieuses, as well as *Sganarelle* (first performed in October, 1660), probably had its premiere at the Théâtre du Petit-Bourbon, a great house adjacent to the Louvre. The Petit-Bourbon was demolished (apparently without notice), and the company moved early in 1661 to a hall in the Palais-Royal, built as a theatre by Richelieu. Here it was that all Molière's "Paris" plays were staged, starting with *Dom Garcie de Navarre, ou le prince jaloux* in February 1661, a heroic comedy of which much was hoped; it failed on the stage and succeeded only in inspiring Molière to work on *Le Misanthrope*. Such failures were rare and eclipsed by successes greater than the Paris theatre had known.

Scandals and successes. The first night of *L'École des femmes* (*The School for Wives*), December 26, 1662, caused a scandal as if people suspected that here was an emergence of a comic genius that regarded nothing as sacrosanct. Some good judges have thought this to be Molière's masterpiece, as pure comedy as he ever attained. Based on Paul Scarron's version (*La Précaution inutile*, 1655) of a Spanish story, it presents a pedant, Arnolphe, who is so frightened of femininity that he decides to marry a girl entirely unacquainted with the ways of the world. The delicate portrayal in this girl of an awakening temperament, all the stronger for its absence of convention, is a marvel of comedy. Molière crowns his fantasy by showing his pedant falling in love with her, and his elephantine gropings toward lovers' talk are both his punishment and the audience's delight.

From 1662 onward the Palais-Royal theatre was shared by Italian actors, each company taking three playing days in each week. Molière also wrote plays that were privately commissioned and thus first performed elsewhere: *Les Fâcheux* (*The Impertinents*, 1732) at Vaux in August 1661; the first version of *Tartuffe* at Versailles in 1664; *Le Bourgeois Gentilhomme* at Chambord in 1670; and *Psyché* in the Tuileries Palace in 1671.

Marriage to Armande Béjart

On February 20, 1662, Molière married Armande Béjart. It is not certain whether she was Madeleine's sister, as the documents state, or her daughter, as some contemporaries suggest. There were three children of the marriage; only a daughter survived to maturity. It was not a happy marriage; flirtations of Armande are indicated in hostile pamphlets, but there is almost no reliable information.

Molière cleverly turned the outcry produced by *L'École des femmes* to the credit of the company by replying to his critics on the stage. *La Critique de L'École des femmes* in June 1663 and *L'Impromptu de Versailles* in October were both single-act discussion plays. In *La Critique* Molière allowed himself to express some principles of his new style of comedy, and in the other play he made theatre history by reproducing with astonishing realism the actual greenroom, or actors' lounge, of the company and the backchat involved in rehearsal.

The quarrel of *L'École des femmes* was itself outrun in violence and scandal by the presentation of the first version of *Tartuffe* in May 1664. The history of this great play sheds much light on the conditions in which Molière had to work and bears a quite remarkable testimony to his persistence and capacity to show fight. He had to wait five years and risk the livelihood of his actors before his reward, which proved to be the greatest success of his career. Most men would surely have given up the struggle: from the time of the first performance of what was probably the first three acts of the play as it is now known, many must have feared that the Roman Catholic Church would never allow its public performance.

Undeterred, Molière made matters worse by staging a version of *Dom Juan, ou le festin de Pierre* with a spectacular ending in which an atheist is committed to hell—but only after he had amused and scandalized the audience. *Dom Juan* was meant to be a quick money raiser, but it was a costly failure, mysteriously removed after 15 performances and never performed again or published by Molière. It is a priceless example of his art. The central character, Dom Juan, carries the aristocratic principle to its extreme by disclaiming all types of obligation, either to parents or doctors or tradesmen or God. Yet he assumes that others will fulfill their obligations to him. His servant, Sganarelle, is imagined as his opposite in every point, earthy, timorous, superstitious. These two form the perfect French counterpart to Don Quixote and Sancho.

Setbacks and harassment by the authorities

While engaged in his battles against the authorities, Molière continued to hold his company together single-handedly. He made up for lack of authors by writing more plays himself. He could never be sure either of actors or authors. In 1664 he put on the first play of Jean Racine, *La Thébaïde*, but the next year Racine transferred his second play, *Alexandre le Grand*, to a longer established theatre while Molière's actors were actually performing it. He was constantly harassed by the authorities. These setbacks may have been offset in part by the royal favour conferred upon Molière, but royal favour was capricious. Pensions were often promised and not paid. The court wanted more light plays than great works. The receipts of his theatre were uncertain and fluctuating. In his 14 years in Paris, Molière wrote 31 of the 95 plays that were presented on his stage. To meet the cumulative misfortunes of his own illness, the closing of the theatre for seven weeks upon the death of the Queen Mother, and the proscription of *Tartuffe* and *Dom Juan*, he wrote five plays in one season (1666–67). Of the five, only one, *Le Médecin malgré lui* (*The Doctor in Spite of Himself*, 1914), was a success.

In the preceding season, however, *Le Misanthrope*, almost from the start, was treated as a masterpiece by discerning playgoers, if not by the entire public. It is a drawing-room comedy, without known sources, constructed from the elements of Molière's own company. Molière himself played the role of Alceste, a fool of a new kind, with high principles and rigid standards, yet by nature a blind critic of everybody else. Alceste is in love with Célimène (played by Molière's wife, Armande), a superb comic creation, equal to any and every occasion, the incarnate spirit of society. The structure of the play is as simple as it is poetic. Alceste storms moodily through the play, finding no "honest" men to agree with him, always ready to see the mote in another's eye, blind to the beam in his own, as ignorant of his real nature as a Tartuffe.

The church nearly won its battle against Molière: it prevented public performance, both of *Tartuffe* for five years and of *Dom Juan* for the whole of Molière's life. A five-act version of *Tartuffe* was played in 1667, but once only: it was banned by the President of Police and by the Archbishop on pain of excommunication. Molière's reply was to lobby the King repeatedly, even in a military camp, and to publish a defense of his play called *Lettre sur la comédie de l'Imposteur*. He kept his company together through 1668 with *Amphitryon* (January 13), *George Dandin* (Versailles, July 18), and *L'Avare* (September 9). Sooner or later so original an author of comedy as Molière was bound to attempt a modern sketch of the ancient comic figure of the miser. The last of his three 1668 plays, *L'Avare*, is composed in prose that reads like verse; the stock situations are all recast, but the spirit is different from Molière's other works and not to everyone's taste. His miser is a living paradox, inhuman in his worship of money, all too human in his need of respect and affection. In breathtaking scenes his mania is made to suggest cruelty, pathological loneliness, even insanity. The play is too stark for those who expect laughter from comedy; Goethe started the dubious fashion of calling it tragic. Yet, as before, forces of mind and will are made to serve inhuman ends and are opposed by instinct and a very "human" nature. The basic comic suggestion is one of absurdity and incongruity rather than of gaiety.

His second play of 1668, *George Dandin*, often dismissed as a farce, may be one of Molière's greatest creations. It centres on a fool, who admits his folly while suggesting that wisdom would not help him because, if

things in fact go against us, it is pointless to be wise. As it happens he is in the right, but he can never prove it. The subject of the play is trivial, the suggestion is limitless; it sketches a new range of comedy altogether. In 1669, permission was somehow obtained, and the long run of *Tartuffe* at last began. More than 60 performances were given that year alone. The theme for this play, which brought him more trouble than any other, may have come to him when a local hypocrite seduced his landlady. Of the three versions of the play, only the last has survived; the first (presented in three acts played before the King in 1664) probably portrayed a pious crook so firmly established in a bourgeois household that the master promises him his daughter and disinherits his son. At the time it was common for lay directors of conscience to be placed in families to reprove and reform conduct. When this "holy" man is caught making love to his employer's wife, he recovers by masterly self-reproach and persuades the master not only to pardon him but also to urge him to see as much of his wife as possible. Molière must have seen even greater comic possibilities in this theme, for he made five acts out of it. The final version contains two seduction scenes and a shift of interest to the comic paradox in Tartuffe himself, posing as an inhuman ascetic while by nature he is an all-too-human lecher. It is difficult to think of a theme more likely to offend pious minds. Like Arnolphe in *L'École des femmes*, Tartuffe seems to have come to grief because he trusted in wit and forgot instinct.

The long run of *Tartuffe*

Last plays. The struggle over *Tartuffe* probably exhausted Molière to the point that he was unable to stave off repeated illness and supply new plays; he had, in fact, just four years more to live. Yet he produced in 1669 *Monsieur de Pourceaugnac* for the King at Chambord and in 1670 *Le Bourgeois Gentilhomme*.

Le Bourgeois Gentilhomme treated a contemporary theme—social climbing among the bourgeois, or upper middle class—but it is perhaps the least dated of all his comedies. The protagonist Jourdain, rather than being an unpleasant sycophant, is as delightful as he is fatuous, as genuine as he is naïve; his folly is embedded in a bountiful disposition, which he of course despises. This is comedy in Molière's happiest vein: the fatuity of the masculine master is offset by the common sense of wife and servant.

Continuing to write despite his illness, he produced *Psyché* and *Les Fourberies de Scapin* (*The Cheats of Scapin*, 1677) in 1671. *Les Femmes savantes* (*The Blue-Stockings*, 1927) followed in 1672; in rougher hands this subject would have been (as some have thought it) a satire on bluestockings, but Molière has imagined a sensible bourgeois who goes in fear of his masterful and learned wife. *Le Malade imaginaire* (first performed 1673; Eng. trans., *The Imaginary Invalid*), about a hypochondriac who fears death and doctors, was Molière's last play. It is a powerful play in its delineation of medical jargon and professionalism, in the fatuity of a would-be doctor with learning and no sense, in the normality of the young and sensible, the young lovers, as opposed to the superstition, greed, and charlatanry of other characters. During the fourth performance of the play, on February 17, 1673, Molière collapsed on stage and was carried back to his house in the rue de Richelieu to die. As he had not been given the sacraments or the opportunity of formally renouncing the actor's profession, he was buried without ceremony and after sunset on February 21.

Molière's collapse on stage and death

Molière as actor and as playwright. Molière's acting had been both his disappointment and his glory. He aspired to be a tragic actor, but contemporary taste was against him. His public seemed to favour a tragic style that was pompous, with ranting and roaring, strutting and chanting. Molière had the build, the elasticity, the india-rubber face, as it has been called, of the born comedian. Offstage he was neither a great talker nor particularly merry, but he would mime and copy speech to the life. He had the tireless energy of the actor. He was always ready to make a scene out of an incident, to put himself on a stage. He gave one of his characters his own cough and another his own moods, and he made a play out of actual rehearsals. The characters of his greatest plays are like the members of his company. It was quite appropriate that he should die while playing the part of the sick man that he really was.

The actor in him influenced his writing, since he wrote (at speed) what he could most naturally act. He gave himself choleric parts, servants' parts, a henpecked husband, a foolish bourgeois, and a superstitious old man who cursed "that fellow Molière." (The comparison with Charlie Chaplin recurs constantly.) Something more than animal energy and a talent for mime was at work in him, a quality that can only be called intensity of dramatic vision. Here again actors have helped to recover an aspect of his genius that the scholars had missed, his stage violence. To take his plays as arguments in favour of reason is to miss their vitality. His sense of reason leads him to animate the absurd. His characters are imagined as excitable and excited to the point of incoherence. He sacrifices plot to drama, vivacity, a sense of life. He is a classical writer, yet he is ready to defy all rules of writing.

To think of Molière as a cool apostle of reason, sharing the views of the more rational men of his plays, is a heresy that dies hard; but careful scrutiny of the milieu in which Molière had to work makes it impossible to believe. The comedies are not sermons; such doctrine as may be extracted from them is incidental and at the opposite pole from didacticism. Ideas are expressed to please a public, not to propagate the author's view. If asked what he thought of hypocrisy or atheism, he would have marvelled at the question and evaded it with the observation that the theatre is not the place for "views." There is no documentary evidence that Molière ever tried to convey his own opinions on marriage, on the church, on hell, or on class distinctions. Strictly speaking, his views of these things are unknown. All that is known is that he worked for and in the theatre and used his amazing power of dramatic suggestion to vivify any imagined scene. If he has left a sympathetic picture of an atheist, it was not to recommend free thought: his picture of the earthy serving man is no less vivid, no less sympathetic. Scholars who have tried to make his plays prove things or to convey lessons have made little sense of his work and have been blind to its inherent fantasy and imaginative power.

The heresy of Molière as a propagandist

Since the power of Molière's writing seems to lie in its creative vigour of language, the traditional divisions of his works into comedies of manners, comedies of character, and farce are not helpful: he does not appear to have set out in any instance to write a certain kind of play. He starts from an occasion in *Le Mariage forcé* (1664; *The Forced Marriage*, 1762) from doubts about marriage expressed by Rabelais's character Panurge, and in *Le Médecin malgré lui* he starts from a medieval fable, or *fabliau*, of a woodcutter who, to avoid a beating, pretends he is a doctor. On such skeleton themes Molière animates figures or arranges discussion in which one character exposes another or the roles are first expressed and then reversed. It is intellectual rhythm rather than what happens, the discussion more than the story, that conveys the charm, so that to recount the plot may be to omit the essential.

His unique sense of the comic. The attacks on Molière gave him the chance in his responses to state some aesthetic home truths. Thus, in *La Critique de L'École des femmes*, he states that tragedy might be heroic, but comedy must hold the mirror up to nature: "You haven't achieved anything in comedy unless your portraits can be seen to be living types . . . making decent people laugh is a strange business." And as for the rules that some were anxious to impose on writers: "I wonder if the golden rule is not to give pleasure and if a successful play is not on the right track."

The attacks on *L'École des femmes* were child's play in comparison with the storm raised by *Tartuffe* and *Dom Juan*. The attacks on them also drew from the poet a valuable statement of artistic principle. On *Dom Juan* he made no public reply since it was never officially condemned. The documents in defense of *Tartuffe* are two placets, or petitions, to the King, the preface to the first

Concept of comedy

edition of 1669 (all these published over Molière's own name), and the *Lettre sur la comedie de l'Imposteur* of 1667. The placets and preface are aesthetically disappointing, since Molière was forced to fight on ground chosen by his opponents and to admit that comedy must be didactic. (There is no other evidence that Molière thought this, so it is not unfair to assume that he used the argument only when forced.) The *Lettre* is much more important. It expresses in a few pregnant lines the aesthetic basis not only of *Tartuffe* but of Molière's new concept of comedy:

> The comic is the outward and visible form that nature's bounty has attached to everything unreasonable, so that we should see, and avoid, it. To know the comic we must know the rational, of which it denotes the absence and we must see wherein the rational consists. . .incongruity is the heart of the comic. . .it follows that all lying, disguise, cheating, dissimulation, all outward show different from the reality, all contradiction in fact between actions that proceed from a single source, all this is in essence comic.

Molière seems here to put his finger on what was new in his notion of what is comic: a comedy, only incidentally funny, that is based on a constant double vision of wise and foolish, right and wrong seen together, side by side. This is his invention and his glory.

A main feature of Molière's technique is a mixing of registers, or of contexts. Characters are made to play a part, then forget it, speak out of turn, overplay their role, so that those who watch this byplay constantly have the suggestion of mixed registers. The starting point of *Le Médecin malgré lui*, the idea of beating a man to make him pretend he is a doctor, is certainly not subtle, but Molière plays with the idea, makes his woodcutter enjoy his new experience, master the jargon, and then not know what to do with it. He utters inanities about Hippocrates, is overjoyed to find a patient ignorant of Latin, so that he need not bother about meaning. He looks for the heart on the wrong side and, undeterred by having his error recognized, sweeps aside the protest with the immortal: "We have changed all that." The miser robbed of his money is pathetic, but he does not arouse emotions because his language leads him to the absurd ". . . it's all over . . . I'm dying, I'm dead, I'm buried." He demands justice with such intemperance that his language exceeds all reason and he threatens to put the courts in the court. Molière's *Misanthrope* is even more suggestive in his confusion of justice as an ideal and as a social institution: "I have justice on my side and I lose my case!" What to him is a scandal of world order is to others just proof that he is wrongheaded. Such concision does Molière's dramatic speech achieve.

A French genius. When Voltaire described Molière as "the painter of France," he suggested the range of French attitudes found in the plays, and this may explain why the French have developed a proprietary interest in a writer whom they seem to regard in a special sense as their own. They stress aspects of his work that others tend to overlook. Three of these are noteworthy.

First, formality permeates all his works. He never gives realism—life as it is—alone, but always within a pattern and a form that fuse light and movement, music and dance and speech. Modern productions that omit the interludes in his plays stray far from the original effect. Characters are grouped, scenes and even speeches are arranged, comic repartee is rounded off in defiance of realism.

Second, the French stress the poetry where foreigners see psychology. They take the plays not as studies of social mania but as patterns of fantasy that take up ideas, only to drop them when a point has been made. *Le Misanthrope* is not considered as a case study or a French *Hamlet* but as a subtly arranged chorus of voices and attitudes that convey a critique of individualism. The play charms by its successive evocations of its central theme. The tendency to speak one's mind is seen to be many things: idealistic or backbiting or rude or spiteful or just fatuous. It is in this fantasy playing on the mystery of self-centredness in society that Molière is in the eyes of his own people unsurpassed.

A third quality admired in France is his intellectual penetration in distinguishing the parts of a man from the whole man. Montaigne, the 16th-century essayist who deeply influenced Molière, divided qualities that are acquired, such as learning or politeness or skills, from those that are natural, such as humanity or animality, what might be called "human nature" without other attributes. Molière delighted in opposing his characters in this way; often in his plays a social veneer peels off, revealing a real man. Many of his dialogues start with politeness and end in open insults.

Molière opposed wit to nature in many forms. His comedy embraces things within the mind and beyond it; reason and fact seldom meet. As the beaten servant in *Amphitryon* observes: "That conflicts with common sense. But it is so, for all that."

MAJOR WORKS

Les Précieuses ridicules (first performed 1659, published 1660; trans. by B.H. Clark, *The Affected Young Ladies*, 1915); *L'École des femmes* (1663; trans. by the Earl of Longford, *The School for Wives*, 1948; and by M. Malleson, 1954); *Le Tartuffe, ou l'imposteur* (first version 1664, present version 1669; trans. by M. Malleson, *The Imposter*, 1950); *Dom Juan, ou le festin de pierre* (1665; trans. by J. Ozell as *Don John; or, The Libertine*, 1665 and rev. and augmented by O. Mandell, 1963); *Le Misanthrope* (first performed 1666, 1667; adapted by W. Wycherly, *The Plain-Dealer*, 1677; trans. by M. Malleson, 1955); *L'Avare* (1669; trans. by H. Fielding as *The Miser*, 1733; by M. Malleson, 1950; and by K. Cartledge, 1962, with the same title); *Le Bourgeois gentilhomme* (1670; trans. by M. Malleson, *The Prodigious Snob*, 1952); *Les Femmes savantes* (1672; trans. by V. Beringer and M. Down, *The Blue-Stockings*, 1927); *Le Malade imaginaire* (1674; trans. as *The Imaginary Invalid* by B.H. Clark, 1925; by M. Malleson, 1959; and B. Briscoe, 1967; and as *The Hypochondriac* by H. Baker and J. Miller, 1961).

BIBLIOGRAPHY

Editions: Collected editions of Molière's works include those by C. VARLET DE LA GRANGE, 8 vol. (1682); by M.A. JOLY, 6 vol. (1734); by E. DESPOIS and P. MESNARD in the "Grands Écrivains de la France Series," 13 vol. (1873–1900); by RENE BRAY in the "Belles Lettres Series," 8 vol. (1935–52); by GUSTAVE MICHAUT, 11 vol. (1949); by ROBERT JOUANNY in the "Garnier Series," 2 vol. (1960); and by GEORGES COUTON in the "Pléiade Series," 2 vol. (1971). Among editions of particular plays those of *L'Avare* by CHARLES DULLIN (1946), of *Le Malade imaginaire* by PIERRE VALDE (1946), of *Tartuffe* by F. LEDOUX (1953), and of *Le Misanthrope* by GUSTAVE RUDLER (1947) deserve special mention.

Biography: Earlier literature is superseded by GUSTAVE MICHAUT, *La Jeunesse de Molière* (1922), *Les Debuts de Molière à Paris* (1923), and *Les Luttes de Molière* (1925). See also JOHN PALMER, *Molière: His Life and Works* (1930, reprinted 1968); GUSTAVE MICHAUT (ed.), *Molière raconté par ceux qui l'ont vu* (1932); GEORGES MONGREDIEN, *La Vie privée de Molière* (1950); and RENE BRAY, *Molière, homme de théâtre*, new ed. (1963). Official documents have been collected in MADELEINE JURGENS and ELIZABETH MAXFIELD-MILLER, *Cent Ans de recherches sur Molière, sur sa famille et sur les comédiens de sa troupe* (1963).

Mollusca

The mollusks are the most numerous, varied, and widely distributed of animal groups after the insects and verte-

brates. The phylum Mollusca includes an immense variety of forms, including the snails and slugs (class Gastropoda), clams and oysters (Bivalvia), and octopuses and squids (Cephalopoda). There are also four smaller classes: Aplacophora (the worm-like solenogasters), Monoplacophora (represented by only a single living genus), Amphineura (chitons), and Scaphopoda (tusk shells). Despite the variety of body plans in the phylum, mollusks have in common a soft body without an internal skeleton, a slippery, mucus-secreting skin, and in most, but not all, an external calcareous shell.

In this article the biology and classification of mollusks are considered in general terms. For more detailed information on the three major classes, see GASTROPODA; BIVALVIA; CEPHALOPODA.

General characteristics of mollusks

The largest mollusks are giant squids of 12-metre (40-foot) arm span; the smallest are snails a millimetre long. Large gastropods are numerous, and the clams *Tridacna* are the giants among the bivalves. Mollusks live on rocky, sandy, and muddy bottoms. They can burrow into soft or calcareous rock or into wood, or can become free-swimming (pelagic). Both snails and bivalves have spread in some numbers to freshwaters, and pulmonate gastropods —the most numerous of all in species—live chiefly upon land, particularly in forests, but also in dry areas. Some gastropods are internal parasites of other animals. Mollusks, in short, are worldwide in distribution and have penetrated to most habitats that will support animals. They go back to the earliest ages as fossils in the rocks.

Mankind has a strong interest in the mollusks for economic, as well as scientific, reasons. Many gastropods and even more of the bivalves serve as choice protein foods. The cephalopods (squid, cuttlefish, and octopus) are famous culinary items in many countries. Bivalve shells are used for many ornamental purposes, and a few species produce valuable pearls. Highly coloured or sculptured gastropod shells and the iridescent mother-of-pearl of bivalve shells, are used as ornaments, for buttons, or as primitive currency. Some freshwater snails are medically important as carriers of the intermediate larval stages of parasitic worms.

NATURAL HISTORY

Habitat and feeding habits. Most gastropods of the subclass Prosobranchia are marine, but a few live on land or in freshwater. All opisthobranchs are marine, many being residents of the littoral zone, a few on the bottom to depths of over 2,000 metres. Others, including both nudibranchs and shelled forms, are pelagic. The pulmonates include several families of freshwater snails, but the large majority are land snails, widely distributed through every sort of terrestrial habitat. Gastropods feed by a variety of methods: some scraping algae from the substrate with the tonguelike radula, others browsing on attached (sessile) or free-floating seaweeds, still others feeding on detritus or carrion. A number of gastropods are predatory, feeding on a variety of animals from sponges and coelenterates to other mollusks and live fish.

Bivalves inhabit marine and freshwater from the coastal (littoral) high tide line to about 6,000-metre depths. The largest number of species and individuals is found in shallower waters. Nearly all bivalves are filter feeders; that is, they extract microplankton from water pumped across the gills. Some bottom-dwelling bivalves apparently feed primarily on plant and animal macrodetritus, dead material that sinks from nearer the surface.

Among cephalopods, the octopuses are littoral in distribution, inhabiting rocky areas, where they feed on crustaceans, fishes, and bivalves. Squid are pelagic swimmers or bottom dwellers (often to great depths) also predatory on crustaceans and fishes, and even on other squid.

The smaller molluscan classes have been less studied than the three better known classes. The Aplacophora are found in bottom mud at depths of 18–4,000 metres or closely associated with other marine animals such as corals, anemones, and polychaete worms. It is inferred from the gut contents of preserved specimens that the burrowing species feed by filtering micro-organisms from the mud and those living on other animals feed on their hosts.

The chitons are most numerous on rocks of the intertidal zone, but one family is found commonly to depths of 4,000 metres. Most chitons feed by scraping algae and other organisms from the rock surfaces with the radula.

Little is known about the ecology of *Neopilina*, the only living monoplacophoran, all of which have been taken by bottom dredges from depths of 2,700–5,700 metres. The animals apparently feed on microscopic animals gleaned from the ooze of the ocean floor.

Tusk shells (Scaphopoda) are bottom dwellers on sand or mud to depths of 5,000 metres. They feed on small organisms, from diatoms to minute crustaceans and mollusks, captured by filamentous tentacles (captacula).

Locomotion. Few mollusks except the cephalopods are fast-moving, and some (such as boring bivalves) are virtually stationary as adults. Gastropods move by wave action of the broadly spread sole. The rear edge is moved forward first and an undulatory wave moves along the sole, carrying the animal forward. Most bivalves burrow by thrusting the large, bladelike foot into mud or sand to form an anchor, toward which the body is drawn by the foot retractor muscles. Many bivalves, including pearl oysters, mussels, and some scallops, do not burrow but remain attached to firm surfaces by byssus threads. The byssus is a bundle of tanned protein fibres secreted at the base of the foot. The nonsessile scallops (*Pecten*) and file shells (*Lima*) can perform spasmodic swimming motions by clapping the valves to expel water.

Most cephalopods alternate between walking and swimming. Slow movements are accomplished by drawing the body along on the arms. Swimming is accomplished, especially in the beautifully streamlined pelagic squids, by expelling a jet of water from the mantle cavity.

The chitons (Polyplacophora) cling to rocks or other hard substrates by a broad flat foot, on which they move for feeding. The closely related solenogasters (Aplaco-

phora) burrow in mud, thrusting the anterior end forward by alternate expansions and contractions. Other solenogasters move slowly among colonies of hydroids and corals in a manner similar to that of terrestrial snakes. The monoplacophorans have never been observed alive but apparently creep across soft bottom ooze on the broad foot, in a manner like that of chitons. The fourth small class of mollusks, the tusk shells, burrow into mud or sand using the foot as do the burrowing bivalves.

Reproduction. Reproduction in mollusks is primitively by separate sexes, eggs and sperm being released into the water and fertilized externally. This still prevails in Aplacophora, Polyplacophora, Monoplacophora, Scaphopoda, and primitive Gastropoda and Bivalvia. In the Gastropoda the first larva is called a trochophore, succeeded after torsion (see below) by a veliger with the strongly ciliated swimming lobes known as a velum. Bivalves have a larva with comparable wheel-like swimming lobes, often called a rotiger. Amphineura, Scaphopoda, and bivalves of the superfamily Nuculoidea have yolky larvae called vitellariae, of shorter free-swimming existence. Most prosobranch gastropods practice internal fertilization between separate sexes and produce capsulate spawn, from which swimming larvae may or may not be released. The opisthobranchs and pulmonates have complexly hermaphroditic reproductive systems, and fertilization is most often reciprocal. Two individuals, each with both male and female organs, join and exchange sperm.

The hallmark of all the Gastropoda is the developmental modification of torsion. During early life, in the free-swimming larva (when present), the visceral mass is rotated through 180° with respect to the head. The result is to bring the mantle cavity from its ventral, back-facing position to a dorsal forward-facing aspect. The right and left paired (mantle) pallial and pericardial organs are transposed. The visceral nerve loop is twisted to a figure eight. The illustrations of larvae before and after torsion (Figure 2) show the facility offered after torsion for withdrawing the vulnerable head and velum (the ciliated flap that provides locomotion) into the mantle cavity, followed by the foot bearing the horny covering (operculum).

From J.E. Morton, *Mulluscs*, 4th ed. (1967); Hutchinson Publishing Group Ltd.

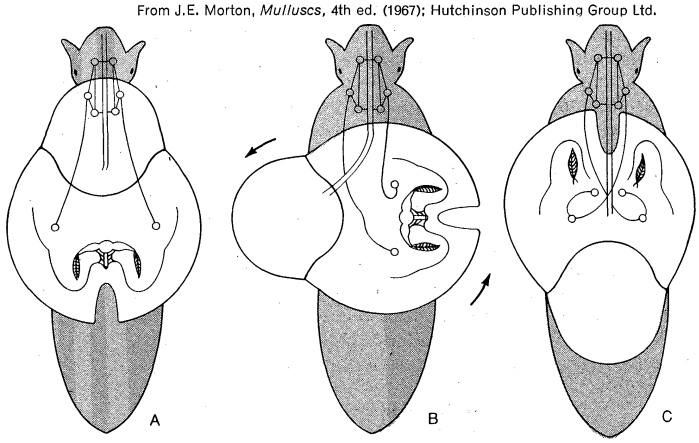

Figure 2: *Torsion.*
(A) Before torsion. (B) 90° of torsion. (C) Torsion completed (180°).

In addition to those with separate sexes, some bivalves exhibit various forms of simultaneous or successive hermaphroditism. A few, such as oysters, incubate the larvae between the gills of the mother. The Cephalopoda copulate by the male transferring spermatophore packets to the female by a modified "hectocotylus" arm; the eggs are allowed to float freely in the ocean or are attached to the bottom. In octopuses they are guarded by the mother and in the paper nautilus (*Argonauta*) are carried in a special "shell," secreted by an arm of the female.

FORM AND FUNCTION

Body plan. Mollusks are highly diverse as to body plans, and there is no standard molluscan shape or life form. Each of the seven classes has a different and rather characteristic pattern.

The majority of gastropods have the familiar snail shape. The mantle cavity and visceral mass are enclosed in a single helicoid shell piece, almost always coiled to the right. Marine gastropods generally close this by the operculum, a hard plate at the back of the foot. The shell spire is reduced to a shallow cone in many families, such as the limpets. In the more advanced gastropods the shell has become progressively reduced or lost. The whole subclass of opisthobranchs has evolved toward the naked slug form, culminating in the nudibranchs, which have unparalleled beauty of colour, often with graceful gill appendages.

Body plan of bivalves

The bivalves show an entirely different pattern, with a two-piece shell hinged dorsally by a ligament and closed or relaxed by adductor muscles. The whole body is withdrawn between the flaps of the mantle, which line the shell. The head is lost as such, and feeding is by ciliary means, with the large gills responsible for drawing in a water current and filtering food particles from it. The foot is large and laterally compressed. In burrowing bivalves, such as cockles, wedge-shells, venus shells, and clams, the edges of the mantle are fused, leaving only a gape for the foot and posterior openings that are drawn out into inhalant and exhalant siphons. Many surface-dwelling bivalves have brightly coloured shells with a lavish development of nacre or mother-of-pearl over the inner surface. The oyster family have lost the byssus and the foot and are cemented by one shell valve to the substratum. The cephalopods are the largest, most mobile and most metabolically active of the mollusks. The long lineages of shelled fossil forms are represented by only one surviving genus, *Nautilus*, in many ways more primitive than any other living cephalopods. In the other modern forms the body is naked, with a chambered internal shell plate in cuttlefish or a horny bar or rod (pen) in squids. These decapod (ten-armed) forms have a circlet of eight short arms, equipped with suckers, and two long, retractile tentacles with suckers at the expanded tips. A spiral, chambered internal shell is found in *Spirula*. The squids are streamlined for fast swimming. Giant squids of the genus *Architeuthis* may reach 12 metres (40 feet) in length. The octopods have no internal skeleton, and the body is soft and spherical, with eight tentacular arms of equal length.

Of the four small classes of mollusks, three, the Aplacophora, Polyplacophora and Monoplacophora, are undoubtedly primitive. All are marine. In the chitons (Polyplacophora) the shell is not of one piece, like a limpet's, but of eight, movably articulating and surrounded by a fleshy or scaly girdle that holds the animal close to the ground. This can be lifted up at any point, to take in a water current to the numerous gills lying in a shallow mantle cavity at the sides of the foot. The mouth is in front and the anus, renal, and genital pores at the back. The exposed shell surface is studded by numerous light-sensitive and tactile organs. Different from chitons, but evidently related to them, are the deep-water, wormlike Aplacophora, aberrant in structure, with the shell entirely lost.

Body plan of Monoplacophora

The Monoplacophora have a one-piece limpet-like shell. They are regarded as the most archaic mollusks and were long believed extinct. Consequently, the discovery of a living member of the family Tryblidiidae, *Neopilina galatheae*, at 5,000 metres depth off the Pacific Coast of Mexico by Henning Lemche of the Galathea Expedition (1950–53) was one of the greatest events in the history of malacology. This "living fossil" has a shell up to four centimetres long, and a broad flat foot. The mouth lies in front, the anus behind, a condition considered primitive. The mantle cavity forms shallow lateral grooves, as in chitons, but has five digitately branched gills. Figure 4 shows the internal structure of *Neopilina*. There are six pairs of renal organs and two pairs of gonads, with eight shell muscles on each side.

The class Scaphopoda contains the small elephant's tusk shells (*Dentalium*) and relatives. They are specialized in structure, with a tapered shell, open at both ends, a cylindrical foot, and fine tentacular filaments called captacula, attached in a cluster at each side of the mouth. These

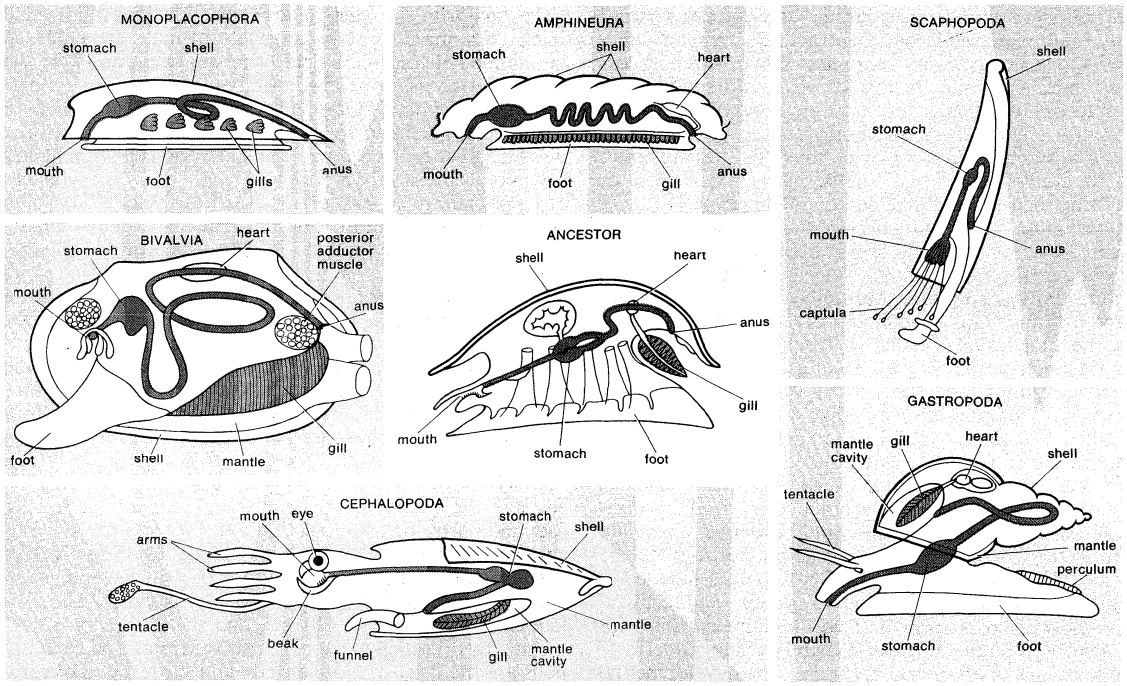

Figure 3: Body diagrams of the six classes of mollusks and a hypothetical generalized ancestor. Dark gray indicates the digestive tract; lighter gray represents the respiratory system. Scaphopoda, which have no specialized respiratory system, respire directly through the fleshy mantle.

emerge from the aperture of the broad end of the shell when the foot is retracted and are used to capture prey and carry it to the mouth for swallowing. The narrow end of the shell projects from the sand and through it the animal passes inhalant and exhalant water currents.

Internal structure. With the great diversity of the mollusks, an account of the internal structure can best be given from an idealized mollusk, combining the general features of the phylum (Figure 3).

Plan of the generalized mollusk

Early mollusks must have had two components, both of them variously surviving in all modern forms: (1) the head-foot, with a flat muscular crawling surface and snout held close to the ground, and (2) the viscero-pallium, consisting of visceral mass, the mantle or pallium (the fleshy outer fold of the integument) and mantle cavity. Attachment to the ground was by mucus, and locomotion by cilia, or a backward muscular wave. Muscles from the broad pedal base extended up to insertion on the shell, to withdraw the animal or pull the shell firmly against the ground. In the idealized mollusk the mouth leads to a muscular buccal mass containing the odontophore, or "tongue," bearing a radula, a chitinous sheet studded with microscopic teeth. This is rolled forward over the ground, abrading and sweeping up particles of food. The glands of the alimentary canal include salivary glands, esophageal pouches (in different ways modified among higher forms), and a bulky digestive gland forming most of the visceral mass. The brown lobes of this gland have several functions, to take up particulate food by engulfing, to complete digestion intracellularly, or (in most higher and carnivorous mollusks) to secrete extracellular enzymes, as well as to store protein, fats, glycogen, and calcium salts. The stomach is primitively a flasklike sac, with its neck continued toward the intestine. Here it contains a mucous or fecal rod, rotated by cilia, which in bivalves and a few gastropods becomes the muco-protein crystalline style. Its functions are to serve as a capstan winding in food and as a store of starch-digesting enzymes.

The mantle cavity forms the commanding structural feature of almost all mollusks. Lying within the muscular fold of the pallium, which adds to the growing shell edge, the mantle cavity is posterior in primitive mollusks or extends as shallow grooves along the sides of the foot. Originally a cloacal space into which the anus and excretory organs discharged, it appears to have taken on a respiratory function by folds of its vascular wall, which have now become complex gills. Cilia upon the gills pump a continuous water current through the cavity and between the gill filaments. This serves for respiration and also—in the bivalves and a few of the gastropods—to bring microscopic particulate food.

A sense organ called the osphradium is set strategically to sample the entering water current at the threshold of the mantle cavity before it reaches the gill and provide chemical information. Into the exhalant current pass the feces, the renal and genital products, and sometimes secretions such as mucus and coloured protective substances (purple or brown). The hypobranchial gland secretes an abundance of mucus, binding and consolidating waste particles.

The gills or ctenidia have a characteristic structure in the majority of mollusks. They are almost always two in number, as in bivalves and gastropods. Some primitive forms have them multiplied as in chitons (up to 70 pairs) and the primitive cephalopod *Nautilus* (2 pairs). *Neopilina* has five pairs, but their truly ctenidial nature is doubtful. The ctenidial filaments have well-developed ciliary tracts. As well as maintaining the water current, they serve in bivalves for filtering and retaining food particles, for conveying them to the mouth, and sometimes for sorting particles by size.

Much of the body space is a hemocoele; *i.e.*, an expanded series of venous sinuses, virtually restricting the true coelom (body cavity) to the pericardium. Venous blood is returned to the two gills and thence by way of the two auricles to the ventricle, from which anterior and posterior aortas distribute it to the tissues. The blood has only sparse stellate or amoeboid corpuscles. In gastropods and cephalopods the plasma contains the pigment hemocyanin; some muscular parts such as the buccal mass locally have myoglobin. Hemocoelic blood has an important role as a fluid skeleton, giving to the body turgidity without loss of flexibility. It massively fills the foot, providing a firm base for the action of the complex muscles. Tentacles, siphons, and other appendages are erected by blood flow.

Excretion from the blood takes place by hydrostatic pressure, passing into the pericardium a filtrate (minus proteins) from the blood in the heart. The renal organ walls are themselves glandular and special excretory glands may develop upon the auricle walls. Marine mollusks excrete ammonia or urea; terrestrial gastropods frequently produce uric acid.

In the early mollusks the reproductive system was simple, a single sac, possibly producing both eggs and sperm, opening into the pericardium and using the renal organs as gonoducts. Chitons, primitive gastropods, scaphopods, and most bivalves and cephalopods have the sexes separate. Some prosobranch and all opisthobranch and pulmonate gastropods are hermaphroditic. In these gastropods and in cephalopods fertilization is internal. The female genital ducts have a glandular role, investing the eggs with albumin, and protective capsules, or jelly mass. They also store outgoing and incoming sperm. Even in hermaphrodite species, the vast majority practice cross-fertilization, copulating and exchanging sperm.

The nervous system shows an enormous range of elaboration between chitons and primitive gastropods and advanced cephalopods with their complex behaviour and powers of learning.

Primitively, there was evidently a nerve ring around the esophagus, with dorsal cerebral centres linked at the sides to centres in the viscera and foot. The former gave rise to the visceral loop, supplying the pallial organs and visceral mass, and carrying visceral ganglia; the latter produced the nerves of the foot, primitively a ladderlike system of ganglionic cords. The sense organs include, in addition to the cerebral tentacles, paired sacs called otocysts or statocysts, in or close to the foot, and paired eyes. The otocysts apparently function in the perception of balance and motion. The eyes range from simple pigmented cups without image formation to the complex eyes of the cephalopods, virtually as intricate as those of higher vertebrates. For further information on these organs, see MECHANORECEPTION and PHOTORECEPTION.

EVOLUTION AND PALEONTOLOGY

Paleontology. The distribution of the molluscan classes in time may be briefly summarized. Chitons make an early appearance in the Ordovician, 500,000,000–430,000,000 years ago. The Monoplacophora extend from the Cambrian, about 500,000,000 years ago, while among the Gastropoda the true limpets Pleurotomariidae and Bellerophontidae with one or two other families go back to Cambrian times, 550,000,000–500,000,000 years ago. The scaphopods begin in the Ordovician, as do the bivalves of the Nuculidae, Arcidae, and some of the Pteriacea. The anisomyarian lamellibranchs were on the whole predominant in the Mesozoic (220,000,000–65,000,000 years ago), being superseded by siphonate and burrowing eulamellibranchs in the Tertiary (65,000,000–25,000,000 years ago). The oldest cephalopods, the Nautiloidea, were initiated in the Upper Cambrian (500,000,000 years ago), reaching a maximum in the Silurian and declining through Devonian to the Triassic, about 200,000,000 years ago. The ammonoids came in with the Devonian and persisted until complete extinction in the Cretaceous, about 100,000,000 years ago. The earliest of the coleoid cephalopods were the shelled belemnoids, from Triassic to Eocene; the squids and octopods were evidently delayed in maximum development until Tertiary and recent times.

Evolutionary trends. The fossil record gives little clue as to how the six classes diverged from the molluscan base. Useful as it may be as a concept, the structure of the presumed "archi-mollusk" must still be largely inferred from comparative morphology. In the present picture, the phylum shows three hugely successful stocks: the Gastropoda, Bivalvia, and—less diverse but in most ways the zenith of molluscan evolution—the Cephalopoda. There is as well a primitive pool of smaller classes, of which only the Scaphopoda shows any distinctive line of advance. The Polyplacophora and Aplacophora are so different from each other as probably to deserve separate classes. It is chiefly from the Polyplacophora and Monoplacophora (*Neopilina*), along with the earliest Gastropoda, that something can be gleaned about the archaic condition.

Significance of *Neopilina*

Neopilina is of inestimable value as a living fossil. Its undoubtedly primitive features include the restricted pallial cavity, the gut structure (especially the stomach), the larger extent of coelom, the relations between gonads and renal organs, and the ladderlike nervous system. The claims for segmental character, however, with implications of annelid origins, must be taken cautiously. Five pairs of gills, two pairs of gonads, two pairs of auricles, six pairs of renal organs, with variable multiplication of shell muscles, give a strange segmental arithmetic. They would appear to represent not true metamerism (segmentation), but an example of the widespread tendency for repetition of many organ systems in archaic mollusks. *Nautilus*, for example (and perhaps other primitive cephalopods), has two pairs of pallio-pericardial organs, ex-

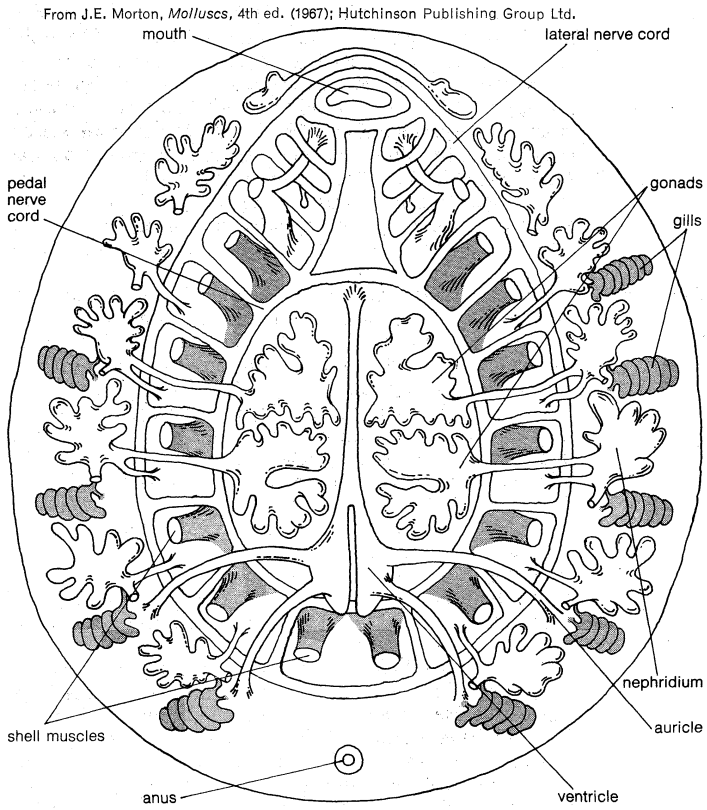

Figure 4: Monoplacophora, internal anatomy of *Neopilina*.

plicable on functional grounds. Chitons have up to 70 gill pairs, eight shell plates, and a varying number of shell muscles.

The relation of mollusks to other phyla is still obscure. In spite of the similar spiral cleavage and trochophore larva, the connection with annelids is not strong. The segmented worms have a fixed metamerism, with a locomotor wave very different from that of the mollusks. The backwardly directed wave of the molluscan foot suggests stronger ties with Turbellaria, a class of flatworms. Several workers have reviewed the evidence for a distant turbellarian relationship. They conclude that the rhythmic contractility of a flatworm presumably became confined to the molluscan ventral surface, and the dorsal parts became visceralized, covered by a mantle shell, and acquired a radial growth pattern.

Evolution of gastropods

It is, on the whole, the Gastropoda that keep closest to the basic molluscan pattern. They have, however, evolved a multifarious diversity of shapes and forms with different habitats.

The most characteristic feature of gastropods is torsion; moreover, all have a spiral coiling of the visceral mass. The early *Bellerophon*, of the extinct order Amphigastropoda, had a paired pallial complex and a bilaterally symmetrical flat spiral. Most living gastropods present an asymmetry of the pallio-pericardial organs, with the suppression of the right members after torsion. Early patterns remain in the prosobranch order Archaeogastropoda, in which *Pleurotomaria, Haliotis*, and the keyhole limpets have paired gills and pallial complex.

The full evolutionary potential of the gastropods was

realized in the order Pectinibranchia. In this group glandular genital ducts, a penis, and internal fertilization made possible early colonizations of the land and freshwater. Most other prosobranchs remained marine and the orders Mesogastropoda and Neogastropoda radiated into large and diverse groups, each evolving toward carnivorous life.

The prosobranchs are outstripped in adaptive novelty only by the Opisthobranchia. Here, as shown in several parallel lines, there is an evolutionary tendency toward early reversal of torsion, loss of the shell, and then loss of the mantle cavity. The plan typified by the slugs is typical of this large group, with the body variously and beautifully coloured or ornamented with appendages. The opisthobranchs have evolved two successful pelagic offshoots in the swimming pteropods, Thecosomata and Gymnosomata, parallel but not closely related. The land Pulmonata are the largest subclass of mollusks, but by comparison with the opisthobranchs, their structural evolution has been conservative. Their impressive achievements are physiological: adaptations for terrestrial life and associated water economy; adaptations for dormancy to avoid cold and desiccation; and specialization of reproductive and courtship behaviour.

Evolution of bivalves

By contrast with the gastropods, the Bivalvia are specialized in a restrictive manner. The mantle cavity has been converted to ciliary feeding by ctenidia and there is an efficient system of adductor muscles for rhythmically controlled opening and closing of the shell. The Protobranchia, undoubtedly primitive, but perhaps polyphyletic, constitute an archaic stock with the gills still relatively small and posterior in position, showing links with the original molluskan condition. The foot is broad and plug-like with a flattened distal expanse, comparable to a sole. The protobranchs have relatively huge labial palps, the tentacles of which are used by some species for food gathering. This may well have been the original bivalve habit, the mouth being withdrawn from the ground, then the head and buccal mass, leading to feeding on micro-organisms.

Subsequent evolution of bivalves is marked by great emphasis on pallial feeding and sorting mechanisms. A large group, the Heterodonta, most of which appeared in the Tertiary, have become adapted for burrowing deeply into a soft substrate, the mantle edges becoming fused and extended into siphons. Another large assemblage, the Anisomyaria (pearl oysters, wing shells, scallops, true oysters, and file shells) either live attached at the surface, by the byssus threads or by firmly cementing the shell to the substratum. The scallops have become free-living and "swim" by clapping the shell valves.

Evolution of cephalopods

The Cephalopoda must have arisen from a very early molluscan stock, and primitively were distinguished by pointed, caplike external shells. The first advance must have been the lightening of the shell, by withdrawal of the viscera from the apex and enclosure of air in the chambers of the shell. In modern nautiloids these chambers are not sealed-off buoyancy tanks but are under control like a fish's swim bladder. It has recently been shown that living *Nautilus* varies its specific gravity by admitting or expelling small quantities of water under active osmotic control. Along with shell buoyancy, new agility was acquired in cephalopods with muscular expulsion of water from the mantle cavity. In the shelled forms, such as the modern *Nautilus*, this is controlled largely by the funnel. In naked modern forms the muscular mantle is itself strongly contractile. The foot early lost its original functions and developed into tentacular processes, later taking the form of ten or eight suckered arms. Of the huge assemblage of ammonoid species none is living, and of nautiloids only one genus. Nautiloids, ammonoids, and the early shelled coleoids provide one of the most detailed evolutionary sequences of the past, but the cuttlefish, squids, and octopus, with their behavioral specializations, are a success story of relatively modern date.

CLASSIFICATION

Distinguishing taxonomic features. The six classes of Mollusca are defined primarily on the basis of overall body plan (symmetry and the presence of torsion in the adult or larva), the type of shell, and modifications of the internal organs.

Annotated classification. This classification is a consensus of recent views, especially those of L.H. Hyman, C.M. Young, K.M. Wilbur, and J.E. Morton.

PHYLUM MOLLUSCA

Unsegmented metazoans with body originally divisible into head-foot and viscero-pallium, the latter covered with a mantle or pallium that secretes a calcareous shell. No true endoskeleton, body cavity a hemocoele, with true coelom generally reduced to gonocoele and pericardium. External body surface frequently ciliated and mucous. A fine-toothed radula, lying in the buccal mass, is characteristic of most mollusks.

Class Monoplacophora

Extinct forms from Lower Cambrian through Devonian; one living genus, *Neopilina*, with four species. Bilaterally symmetrical, with ventral foot and posterior anus; one-piece oval shell; mantle cavity with five pairs of lobate branchiae. Dorsal and ventral coelomic cavities well developed. Two pairs of auricles; 2 pairs of gonads, discharging through 2 of the 6 pairs of renal organs. Primitive nervous system, with long pallial and pedal cords. Deep ocean bottom; known only from eastern Pacific.

Class Polyplacophora or Amphineura (chitons)

Elongated, flattened, bilaterally symmetrical, with posterior anus; mantle extensive, covering dorsum and sides; broad foot for adhesion to substrate; eight articulating dorsal shell plates, bordered by spiculose or scaly band; numerous pairs of gills (ctenidia). Dorsal posterior heart, with ventricle and lateral auricles; primitive nervous system, with longitudinal ganglionic cords. Marine littoral; length 1–33 cm (0.5–13 in.).

Class Aplacophora (solenogasters)

Wormlike; mantle surrounding body, except (in some) for ventral groove of foot; naked, except for minute calcified spicules; mantle cavity small and posterior. Marine; in deep water ooze or on sessile coelenterates. Length 2.5 cm (1 in.).

Class Gastropoda (snails and slugs)

Asymmetrical, with well-developed head and—at least primitively—a broad foot. Shell in one piece, coiled in a helical spiral; sometimes absent in adults. Viscero-pallium showing torsion of 180°; pallio-pericardial complex reduced and one-sided. Marine, freshwater, and terrestrial (see GASTROPODA).

Subclass Prosobranchia

Mostly marine snails. Generally aquatic; torsion pronounced and retained; visceral nerve loop crossed in figure 8. Head with paired tentacles and eyes at base. Spiral shell closed by an operculum. Mantle cavity primitively with two ctenidia, usually reduced to one (post-torsionally on the left). Heart posterior to mantle cavity. Solitary gonad opens primitively through right kidney, but later forms develop a glandular genital duct. Usually, where marine, a free-swiming veliger larva. Adult length from less than 1 to 60 cm.

Subclass Opisthobranchia (sea slugs)

Hermaphroditic, with shell reduced and becoming internal. Torsion usually reversed, with mantle cavity moving back along right side, and visceral loop shortening and uncrossing. Mantle cavity ultimately lost. Various adaptive gills, never ctenidia. Eventual return to bilateral sluglike external symmetry, with great range of form, colour, and locomotion. Usually with a (reduced) free-swimming veliger larva. Marine; length to 43 cm (16 in.).

Subclass Pulmonata (land snails)

Hermaphroditic, generally terrestrial, but some freshwater and primitive members marine. No ctenidium; mantle cavity generally vascularized as a lung. Small contractile pallial aperture. Detorsion seldom complete, but nervous system concentrated so as to lose all trace of crossing of nerves. Shell and visceral mass generally spiral, but some assume naked sluglike form. Length 0.5–20 cm (0.2–8 in.).

Class Scaphopoda (tusk shells)

Bilaterally symmetrical, mantle and shell elongated to a tapered tube open at each end. Foot pointed and cylindrical, used for digging. No ctenidia; heart, or distinct blood vessels. Head without eyes but carrying bunches of slender tentacles (captacula), for taking foraminiferans as food. Radula well-developed. Sexes separate without special genital ducts. Fertilization external. Marine, worldwide; length 2–15 cm (0.8–6 in.).

Class Bivalvia (clams, oysters and relatives)

Bilaterally symmetrical with head rudimentary, lacking radula, buccal mass or head sense organs. Ciliary feeders, collecting particles with enlarged and highly specialized

ctenidia. Large labial palps used for particle sorting. Mantle lobes completely enclose laterally compressed body; shell consists of two separately calcified valves and dorsal ligament. Foot strongly muscular, compressed and adapted for burrowing. Sexes separate or united (hermaphroditic). Genital ducts simple, paired, with fertilization external. Usually long larval life. Marine and freshwater; worldwide; length 0.5–170 cm (0.2–52 in.). See BIVALVIA.

Subclass Protobranchia

Small and primitive; ctenidia with flat, nonreflected filaments, foot with flat ventral surface; body organization primitive. Feeding chiefly by tentacular prolongations of labial palps.

Subclass Lamellibranchia

The majority of bivalves, including mussels, oysters, clams and scallops. Ctenidia much larger in relation to palps and form feeding organs; filaments elongated and narrow, reflected to form two-sided lamellae. Attached by a byssus; or burrowing, with siphons.

Class Cephalopoda (octopuses, squids, cuttlefishes)

Bilaterally symmetrical mollusks with a circle of tentacles around the head. Foot modified as a funnel, from which a propulsive water jet is produced. Nervous system and sense organs, especially eyes, highly developed. Marine, worldwide (see CEPHALOPODA).

Subclasses Nautiloidea and Ammonoidea

Shelled cephalopods of vast number and diversity. All extinct, except living *Nautilus*, with chambered shell, numerous nonsuckered retractile arms, two pairs of gills.

Subclass Coleoidea

Cuttlefish, squids, octopus, and extinct belemnoids. Modern cephalopods, with mantle naked, shell internal or lacking. Head with eight sucker-bearing arms and in squids and cuttlefish (Decapoda) a pair of long tentaculate arms in addition. In Octopoda, eight long tentaculate arms of equal length.

Critical appraisal. The above classification shows certain changes from the traditional division of the mollusks. With the discovery of the primitive class Monoplacophora, there is much to be said for raising also to the level of a class the small aberrant Aplacophora, which, except in a basic archaism of structure, are very remote from the chitons (Polyplacophora). In the Gastropoda, the older practice of separating Streptoneura (Prosobranchia) from Euthyneura (Opisthobranchia and Pulmonata) has been discontinued. It is better to regard the pulmonates and opisthobranchs as separate assemblages coequal in rank and diverging widely from an early point where they seem to have arisen close together from prosobranchs. With the use of the continental class name "Bivalvia," the old term Lamellibranchia has been lowered to a subclass name. It expresses admirably the type of gill structure of the vast majority of bivalves, as contrasted with the diversity of archaic forms gathered into the Protobranchia. Some would raise the septibranch bivalves (Cuspidariidae and Poromyidae) to a separate subclass; but they appear to follow neatly upon certain families of the higher Lamellibranchia. The old division of Cephalopoda into Tetrabranchia and Dibranchia has long disappeared. There is as yet no information on the gill number of any ancient shelled cephalopod, save for the possibly atypical genus *Nautilus*.

Moltke, Helmuth von

Chief of the Prussian and German general staffs, Helmuth von Moltke was the military architect of the victories over Denmark (1864), Austria (1866), and France (1870–71) that enabled Otto von Bismarck to transform a loose league of German states into an empire dominated by Prussia.

Early career. Helmuth Karl Bernhard von Moltke was born on October 26, 1800, at Parchim, in Mecklenburg (since 1952 in the German Democratic Republic's district of Schwerin). His father, a man of unstable character, belonged to the nobility of Mecklenburg, his mother to an old family of the free city of Lübeck. The Moltkes were impoverished; and the young Moltke, whose health was not too good, had an unhappy start to life. Since his father had emigrated to Holstein (then a Danish possession) in 1805 and had taken Danish nationality, the boy completed his education with the Royal Cadet Corps in Copenhagen and joined a Danish infantry regiment. After a visit to Berlin in 1821, however, he decided to transfer to the Prussian Army, and in 1822 he obtained a commission as a second lieutenant in the Prussian Life Guards, being posted to Frankfurt an der Oder.

In October 1823 Moltke was sent to the General War College for a three-year course; but, since his health was deteriorating, he went in the summer of 1825 to Bad Salzbrunn for convalescence, during which he studied modern languages. On his return to Frankfurt in the summer of 1826 he took up writing, largely to improve his financial position, and published a novel, *Die beiden Freunde* (1827; new ed., 1957). In May 1828 he was transferred to the General Staff's Topographical Bureau in Berlin.

Continuing his literary work, Moltke published his *Darstellung der innern Verhältnisse und des gesellschaftlichen Zustandes in Polen* (1832; Eng. trans., *Poland: an Historical Sketch*, 1885) and also accepted a publisher's offer for a translation of Edward Gibbon's *Decline and Fall of the Roman Empire*; although he completed most of it, it was never published.

Moltke was attached to the Prussian General Staff in March 1832 and promoted to the rank of first lieutenant a year later. Toward the end of 1835 he was sent to Turkey to advise Sultan Mahmud II on the modernization of the Turkish Army; and in 1836 he was authorized by Berlin to enter the Turkish service. After some work in Istanbul and travels in the Balkans, he went in 1838 to Armenia, where Turkish forces were preparing an offensive against the Egyptian invaders of Syria. The failure of the offensive, in 1839, was due largely to the Turkish commander's disregard of Moltke's advice.

Mission in Turkey

Returning to Germany at the end of 1839, Moltke re-entered the Prussian service. He published a selection of his letters from Turkey, *Briefe über Zustände und Begebenheiten in der Türkei,* in 1841. In April 1842 he married an English girl, Marie Burt (1825–68), stepdaughter of his sister Augusta. An essay on the considerations that should govern the choice of routes for new railways (1843) is more significant of his future than his next book, *Der russisch-türkische Feldzug in der europäischen Türkei 1828–1829* (1845; Eng. trans., *The Russians in Bulgaria and Rumelia,* 1854).

Late in 1845 Moltke was appointed personal aide-de-camp to the invalid Prince Henry of Prussia (1781–1846), who was living privately in Rome. Though this appointment ended with Prince Henry's death, it gave Moltke the opportunity to begin work on a splendid topographical map of Rome and its vicinity (published in 1852) and to write his "Wanderungen um Rom" (published in his *Wanderbuch,* 1879; Eng. trans., *Notes of Travel,* 1880). Moreover, when the warship bringing Prince Henry's body back to Germany reached Gibraltar, Moltke left it and made his own way home across Spain, recording his impressions in his "Tagebuchblätter aus Spanien" (also published in the *Wanderbuch*).

Working again for the Prussian General Staff, Moltke started thinking about the major problems confronting Prussia: the unification of Germany and the security of a country surrounded by potential enemies yet lacking natural frontiers. He was convinced that only the army could provide a satisfactory solution to these problems; and he expressed his delight at the suppression of the revolution of 1848–49 by writing to his brother that the curtain had come down on Prussia's worst enemy—democracy.

A colonel from 1851, Moltke was in 1855 appointed personal aide-de-camp to Prince Frederick William, the future king of Prussia and German emperor (Frederick III). This post involved more travels: to Scotland and thence to England; to Russia (*Briefe aus Russland,* published 1877; Eng. trans., *Letters from Russia,* 1878), and to France. Even so, apart from the period of his Turkish service and his brief stay in Rome, Moltke's career up to 1856 had been mostly dull routine or concerned with the affairs of his princely masters rather than the profession of arms. Only in Turkey had he commanded troops.

Career as chief of the General Staff. Moltke was selected as chief of the Prussian General Staff in 1857 and confirmed in that office in September 1858. Thus began the era of the great triumvirate—Otto von Bismarck (chancellor), Moltke, and Albrecht von Roon (1803–79; minister of war from 1859)—that within 13 years was to change the map of Europe.

Moltke entered upon his new official duties at a time when a technical revolution was changing the whole conception of war. The rearmament of the German infantry with the breech-loading needle gun had been proceeding since 1848 and was almost complete. Breech-loading guns for the artillery were on the way but were not finally introduced until 1861. Much more significant, however, was the rapid development of railways.

Military use of railways

Moltke was the first military man to appreciate the important role that railways could play in the deployment, movement, and supply of armies on a great scale. Hitherto, the movement of troops had been restricted by the paucity and seasonal unreliability of road communications, and the aim of strategy of every great commander had been to bring the strongest possible force in the best possible condition onto a small battlefield where he could survey the entire army and almost every soldier could hear him. Moltke saw that the advent of railways had changed this. Many more men and much more equipment could now be deployed much faster on vastly wider fronts. In place of battlefields of a few square miles, there would be long battlefronts of perhaps hundreds of miles. The limited flank attack by a few battalions would give place to wide turning movements by many divisions. Supplied by railways, troops would be able to keep the field in all weather throughout the year.

At the same time, Moltke appreciated that a new technique and a much more highly trained body of staff officers would be required to realize his new conception of warfare. The mounted staff officer with his necessarily confined outlook would give way to one with a much wider view, capable of compiling intricate railway-movement tables for vast numbers of men, animals, and equipment and of arranging for daily trainloads of supplies. He saw, too, that changes were necessary in another direction. Whereas, previously, commanders had kept a very tight hold on their subordinates and had been able always to give short and explicit orders, it was clear to Moltke that this system would not work in an army of perhaps millions locked in battle along a front that might extend for hundreds of miles. He therefore instituted the system of "general directives" in place of rigid "operation orders." In these directives the recipient was given a long-term task in general terms but was allowed considerable latitude and was expected to use his discretion and initiative in carrying it out. When Moltke joined the General Staff, its "chairborne" officers were held in little esteem by the "real" soldiers. He built up the new system of the Prussian General Staff, which later became the model for all armies organized on modern lines.

The Seven Weeks' War (1866). Some of Moltke's theories and methods were tested in practice by the Prussian forces in the short German–Danish War over Schleswig-Holstein in 1864; but a far more instructive opportunity of testing them came with the Seven Weeks' War, which Prussia, under Bismarck's guidance, launched against Austria and certain other German states in the summer of 1866. This war, for which initially Prussia deployed some 256,000 men in three armies on a front of 260 miles (nearly 420 kilometres), culminated in Prussia's overwhelming victory at Königgrätz (Sadowa). Moltke's contribution to victory was rewarded by Prussia with a donation of money that enabled him to buy an estate at Kreisau in Silesia (since World War II in the Wrocław Province of Poland); and the military result vindicated his system in the eyes of some older and hitherto recalcitrant generals. The war also served to expose deficiencies in the functioning of the system, among them ill-trained staff officers and an inadequate intelligence service. With the newly secured cooperation of his subordinates, he remedied these shortcomings before the final proving of his notions in 1870–71. He was also responsible for the official Prussian history of the Seven Weeks' War, *Der Feldzug von 1866 in Deutschland* (1867; Eng. trans., *The Campaign of 1866 in Germany,* 1872).

The Battle of Königgrätz

The Franco-German War (1870–71). Prussia's triumph of 1866 excited the envy of France, whose emperor Napoleon III was tempted to seek an increase in prestige at Prussia's expense or through intervention in German affairs. To eliminate this challenge, Bismarck envisaged war against France; and Moltke and Roon, having profited from the lessons of 1866, were able to tell him, at the end of 1869, that in their judgment the Prussian Army was capable of defeating the French and that the time seemed ripe. Consequently, Bismarck, in the next few months, provoked Napoleon III into hostilities: the Franco-German War began in July 1870, Moltke deploying some 384,000 men in three armies.

The Battle of Sedan

The Germans' great victory at Sedan on September 2, 1870, brought the fall of the Second Empire in France and was soon followed by the proclamation, at Versailles on January 18, 1871, of a new German Empire. France sued for peace in February and accepted Bismarck's terms in May 1871. Moltke, whose military machine had been far more efficient than France's, was created Graf (count) in October 1870, after Sedan, and appointed field marshal in June 1871, after the peace treaty.

The last years of office. Moltke was chief of the General Staff for 17 more years from 1871. For part of this time he was occupied with planning for the eventuality of Germany's having to fight a war on two fronts—against Russia in the east as well as against France again in the west. In August 1888, however, the old man at last resigned his post, not least because of his lack of sympathy with the manners and ideas of his new sovereign, the emperor William II. He had, however, already chosen his own immediate successor, Alfred von Waldersee.

Personality. On resigning office in 1888, Moltke retired to Kreisau. He died, during a visit to Berlin, on April 24, 1891. A tall, spare figure, he had a tanned face that usually wore an expression of grave austerity. His acute intelligence was obvious to all who met him; but, though he was a considerable linguist, he was habitually so taciturn that he was described as being "silent in seven languages" (he knew at least German, Danish, French, English, Italian, and Turkish, besides any Slavic or Iberian languages that he might have picked up). No indiscreet or unkind word is recorded as having passed his lips, and to his military colleagues he became "the Golden Man," without enemies or detractors. His married life was affectionate and happy but childless. As a writer, he is sometimes reckoned among the masters of 19th-century German prose.

BIBLIOGRAPHY. There are editions of MOLTKE'S *Gesammelte Schriften und Denkwürdigkeiten*, 8 vol. (1891–93); of his *Militärische Werke*, 4 vol. (1892–1912); and of his *Briefe an seine Braut und Frau und an andere Anverwandte*, 2 vol. (1894; Eng. trans., *Letters to His Wife and Other Relatives*, 2 vol., 1896). Important selections from the two former collections can be read in English: *The Franco German War of 1870–71*, 2 vol. (1891; rev. ed., 1893); *Projects for the Campaign of 1866 Against Austria* (1907); and *Military Correspondence, 1870–71* (1922–23). The fullest modern study is by E. KESSEL, *Moltke* (1957). For a shorter biography, see E. VON NASO, *Moltke, Mensch und Feldherr* (1963). For the English reader there is still F.E. WHITTON, *Moltke* (1921). W. GORLITZ, *Der deutsche Generalstab: Geschichte und Gestalt, 1657–1945* (1950; Eng. trans., *History of the German General Staff, 1657–1945*, 1953), provides a rather good background, explaining Moltke's part in both the development and the implementation in war, of the general staff system.

(C.N.B.)

Mommsen, Theodor

A scholarly masterpiece as well as a great work of literature, Theodor Mommsen's *Römische Geschichte* (*The History of Rome*) made him the most popular of all German scholars of his time and spread his fame throughout the world. It earned him the Nobel Prize for Literature for 1902. Mommsen believed that the historian is perhaps more of an artist than a scholar. Yet anyone attempting to write a history of Rome based on original research obviously must master both the methods and materials of classical philology; he must also have a thorough knowledge of Roman law. Mommsen met these conditions and made a unique contribution to the development of a systematically historical treatment of antiquity covering encyclopaedically every aspect of the Classical period.

Education

Career. He was born on November 30, 1817, the son of a Protestant minister, in Garding, Schleswig-Holstein, and he grew up in Oldesloe (now Bad Oldesloe). Mommsen received his basic classical training in the senior classes of the Gymnasium (secondary school) Christianeum in Altona, then part of the duchy of Holstein. From 1838 to 1843 he studied jurisprudence at the University of Kiel; inasmuch as the study of jurisprudence in Germany at the time was largely a study of Roman law, this had an essential influence on the direction of his future research. He owed his idea of the close interrelationship between law and history not so much to his teachers as to the writings of Friedrich Karl von Savigny, one of the founders of the historical school of jurisprudence. After he had received his master's and his doctor's degrees, a research scholarship granted by his sovereign, the king of Denmark, allowed him to spend three years—from 1844 to 1847—in Italy. During this time Italy became his second home and the Archaeological Institute in Rome one of the headquarters from which he pursued his research. By that time Mommsen had already conceived the plan for the *Corpus Inscriptionum Latinarum*, a comprehensive collection of Latin inscriptions preserved since antiquity on stone, iron, and other enduring materials, arranged according to the basic principles of philological methodology. Having been prepared for this field by the young Kiel professor, Otto Jahn, he soon became a master of epigraphy—the study and interpretation of inscriptions—under the guidance of Bartolomeo Borghesi, the learned statesman of San Marino. Within the next several decades Mommsen made the corpus of Latin inscriptions into a source work that was essential in complementing the one-sidedly literary tradition and that, for the first time, made a comprehensive understanding of life in the ancient world possible.

Career as a politician and journalist

When he returned from Italy, Mommsen found his country in a state of mounting unrest. As a native of Schleswig he was a subject of the Danish king, but he considered himself German, wanted to remain German, and looked forward to German unity. For him freedom meant not only the independence of the German states from foreign influence but also the freedom of the German citizen to adapt himself to any sort of constitution except that of despotism or a police state. A liberal, he considered the republic the ideal state, yet he was quite content with a constitutional monarchy so long as it was not a cover for some sort of pseudo-constitutional autocracy. Mommsen's political activities began with his editorship of the *Schleswig-Holsteinische Zeitung* for the provisional government established during the revolution of 1848. Yet journalism was not much to his taste; he was happy when, at the end of 1848, he was offered a professorship in civil law at the University of Leipzig. Nevertheless, he remained politically minded as long as he lived—as a thoughtful and critical observer as well as an active politician. (He was a deputy in the Prussian Landtag from 1873 to 1879 and in the German Reichstag from 1881 to 1884.) He continued to devote time and energy to politics, but it is doubtful that he thereby served his country's and his own best interests. While he was an acknowledged authority in his field of scholarship, in politics he remained a camp follower, who achieved no more than many others. Moreover, he more than once jeopardized his career by his political activities. Because of his participation in an uprising in Saxony in May 1849, he lost his professorship and almost landed in prison.

After his dismissal from his post in Leipzig, Mommsen in 1852 accepted a professorship in jurisprudence in Zürich. The grief he expressed about being an "exile" showed how deeply he felt himself to be a German. In 1854, however, he was offered a professorship in Prussia at the University of Breslau. It was at this time that he married Marie Reimer, daughter of a bookseller. During a long and happy marriage his wife bore him 16 children.

History of Rome

The historian and his works. During the years he spent at Leipzig, Zürich, and Breslau, Mommsen wrote the first three volumes of the *Römische Geschichte*, up to the Battle of Thapsus, 46 BC. This work embodied the new historical method applied to the history of Rome. Mommsen critically examined hitherto unques-

tioned traditions and rejected the attitude of the Enlightenment, which had idealized the classical age. He readily acknowledged himself to be a disciple of the historian Barthold Georg Niebuhr, who introduced rigorous criticism of sources into historiography, however much their methods of research and presentation differed and despite the fact that he went considerably beyond his great predecessor in demythologizing Roman history. In Mommsen's view it was important that the ancients should come down to earth from the Olympian heights upon which they appeared to the mass of the public. This modern style was not to everyone's taste, for, in bringing the past to life, he used the political and sociological vocabulary of the 19th century. When he speaks of the squirearchy and the cloth exerting their "malignant" influence even in ancient Rome, it is Mommsen the liberal politician speaking. Nevertheless, his *Römische Geschichte* is not a politically tendentious work but a piece of scholarship of the highest rank, which gains from its distinction of style.

The philologist is regarded as the preserver of verbal tradition, but as a philologist Mommsen was more than that: he was an artist, and he proved his artistry in his treatment of language. He disliked any incongruous mixture of prose styles and, in the *Römische Geschichte* and *Romisches Staatsrecht* ("Roman Constitutional Law"), he created two works both of which attain exemplary unity of form and content yet demonstrate two different styles. Without being a creative poet, he used the means of poetry and enjoyed exercising his poetic talent. An excellent testimony to his abilities is the *Liederbuch dreier Freunde* ("Songbook of Three Friends"), which he published in 1843 together with his brother Tycho and the writer and poet Theodor Storm. Throughout his life Goethe was his ideal not only as a poet but also as "the wisest man of the century." His perfect command of English, French, and Italian did much to make his journeys of research successful; he quoted Shakespeare in his letters almost as often as Goethe.

To many critics Mommsen's glorification of the dictator Caesar and his disparagement of Caesar's opponents, Pompey and Cicero, seem strangely inconsistent with his political liberalism. He tried to make his critics understand that he had praised Caesar only as a saviour of the decaying state; yet Mommsen's admiration for the autocrat reveals something of his own character. He himself was an autocrat in his own branch of scholarship, adopting a manner that his opponents labelled "caesarism." At the same time, however, he had an unusual need for the fellowship of like-minded men. He held personal contacts to be one of the most important elements of life; indeed, it might be said that he had a genius for friendship. Yet it was mostly a friendship with men who looked up to him. With anyone who considered himself Mommsen's equal, a friendly relationship was not likely to last long.

It was only as a member of the Prussian Academy of Sciences that Mommsen could pursue his project of publishing his collection of Latin inscriptions, and for this reason in 1858 he was offered a post in Berlin. In 1861 he also became a professor in the philosophy faculty at the university; because of his philological and historical interests he chose that faculty rather than that of law. As a teacher of Roman history and epigraphy—especially in his seminars—he trained many students who were later to make their mark in these fields. The main part of his scholarly work was taken up with the continuation of the *Corpus Inscriptionum Latinarum*. He also acted as adviser on many other great scholarly enterprises, such as the *Monumenta Germaniae Historica*, the exploration of the *limes* (Roman border fortifications in southwest Germany), the numismatic work of the Prussian Academy, and the *Thesaurus Linguae Latinae*. Even in old age his mind was open to the new demands of scholarship, as shown by his interest in the new study of papyrology.

Mommsen's historical work was interrupted by his work on inscriptions; thus, the *Römische Geschichte* was never completed. When, several decades later, in Berlin, he set out to complete his history, he abandoned the idea of writing the fourth volume, which was to contain the history of the emperors, because he felt that he would not be capable of writing it in the same brilliant style as his history of the republic. The fifth volume (1885) deals with the history of the Roman provinces in the first three centuries of the empire. No one but Mommsen could have depicted this period in so authoritative a manner, for no one else knew the nonliterary sources—the inscriptions and coins—as did he.

The greatest monument to Mommsen's scholarship, the work which is of even greater significance for scholars than the *Römische Geschichte*, is *Römisches Staatsrecht* ("Roman Constitutional Law"), published between 1871 and 1888. He himself said that if he were to be remembered by anything, it would be by this work. The Romans themselves never codified their constitutional law; Mommsen was the first to do it. His historical approach to classical scholarship led him to systematize the innumerable legal details upon which the Roman constitution was based and to explain this complex body of law through an understanding of its historical development. Only a man who, like Mommsen, was grounded both in law and in the classics would be in a position to investigate the public law of the Romans, and only a man trained to think in historical concepts could understand it.

"Roman Constitutional Law"

In public law, criminal law stands side by side with constitutional law, and Mommsen's last great work, published in 1899, is *Römisches Strafrecht* ("Roman Criminal Law").

When Mommsen, who had already become a mythical figure for his contemporaries, died in Berlin on November 1, 1903, just four weeks before his 86th birthday, he had attained what he had always wanted. The task which he had set himself to fulfill, according to his own almost superhuman standards, he had completed.

MAJOR WORKS

ROMAN STUDIES: *Römische Geschichte*, vol. 1–3 (1854–56; *The History of Rome*, 1862–75), vol. 5 (vol. 4 never written; 1885; *The Provinces of the Roman Empire*, 2 vol., 1909); *Geschichte des römischen Münzwesens* (1860); *Corpus Inscriptionum Latinarum* (1863 and after); *Römische Forschungen*, 2 vol. (1864–79); *Römisches Staatsrecht*, 3 vol. (1871–88); *Römisches Strafrecht* (1899).

OTHER WORKS: *Unteritalische Dialekte* (1850); *Inscriptiones regni Neapolitani Latinae* (1852).

The *Römische Geschichte* has been either completely or partially translated into Danish, English, French, Hungarian, Polish, Russian, and Spanish. English translations include *The History of Rome* by W.P. Dickson, 4 vol. (1862–75) with vol. 5 as *The Provinces of the Roman Empire* (1909); another translation in the Everyman series (1911); and abridgments by C. Bryans and F.J.R. Hendy (1888, new ed. 1959) and by D.A. Saunders and J.H. Collins (1958). There is a French translation of the *Geschichte des römischen Münzwesens* by le Duc de Blacas: *Histoire de la monnaie romaine*, 4 vol. (1865–73); and of the *Römisches Strafrecht* by J. Duqesne: *Le Droit pénal romain* (1907).

BIBLIOGRAPHY. KARL ZANGEMEISTER, *Theodor Mommsen als Schriftsteller: Ein Verzeichnis seiner Schriften*, revised and continued by EMIL JACOBS (1905); *Gesammelte Schriften*, 8 vol. (1905–13). Correspondence: with Ulrich von Wilamowitz-Moellendorff, ed. by FRIEDRICH and DOROTHEA HILLER VON GAERTRINGEN (1935); with Otto Jahn, ed. by LOTHAR WICKERT (1962); with Theodor Storm, ed. by HANS-ERICH TEITGE (1966). LOTHAR WICKERT, *Theodor Mommsen: Eine Biographie*, 3 vol. (1959–69, vol. 4 in prep.), an exhaustive biography.

Shorter studies: CARL BARDT, *Theodor Mommsen* (1903); OTTO HIRSCHFELD, "Gedächtnisrede auf Theodor Mommsen" (1904), in *Kleine Schriften*, pp. 931–965 (1913); LUDO MORITZ HARTMANN, *Theodor Mommsen: Eine biographische Skizze*, including an appendix "Ausgewählte politische Aufsätze Mommsens" (1908); W. WARDE FOWLER, *Theodor Mommsen: His Life and Work* (1909); ALFRED HEUSS, *Theodor Mommsen und das 19. Jahrhundert* (1956); HANS LIEBESCHÜTZ, "Treitschke and Mommsen on Jewry and Judaism," in *Year Book VII of the Leo Baeck Institute of Jews from Germany*, pp. 153–182 (1962); BERTHOLD SUTTER, "Theodor Mommsens Brief 'An die Deutschen in Österreich' (1897)," in *Ostdeutsche Wissenschaft*, 10:152–225 (1963); ALBERT WUCHER, *Theodor Mommsen: Geschichtschreibung und Politik*, 2nd ed. (1968); LOTHAR WICKERT, *Drei Vorträge über Theodor Mommsen* (1970).

Monaco

A sovereign principality whose densely clustered hills and headland look southward over the Mediterranean Sea, Monaco (officially Principauté de Monaco) has an area of only about 0.73 square mile (1.9 square kilometres). Many unusual features, however, have made the principality among the most luxurious tourist resorts in the world and have given it a reputation far exceeding its size. Situated astride the resort area of the Cote d'Azur (French Riviera)—the city of Nice lies nine miles to the west, the Italian border five miles to the east—it has a mild Mediterranean climate with annual temperatures averaging 61° F (16° C) and with only about 60 days of rainfall. Monthly average temperatures range from 50° F (10° C) in January to 75° F (24° C) in August. Many of the visitors alternate their hours between the glistening beaches and boating facilities, the international sportscar races, and the world-famous Place du Casino, the gambling centre in the Monte Carlo section that made Monte Carlo an international byword for the extravagant display and reckless dispersal of wealth.

History of the principality. Evidences of Stone Age settlements in Monaco are preserved in its Museum of Prehistoric Anthropology. In ancient times the headland was known to the Phoenicians, Greeks, Carthaginians, and Romans. In 1191 the Genoese took possession of it, and in 1297 the long reign of the Grimaldi family began. The Grimaldis allied themselves with France except for the period from 1524 to 1641, when they were under the protection of Spain. In 1793 they were dispossessed by the French Revolutionary regime, and Monaco was annexed to France. With the fall of Napoleon I, however, they returned; the Congress of Vienna (1815) put Monaco under the protection of Sardinia. The principality was reduced in size in 1848 by the loss of territory to France. The Franco-Monegasque treaty of 1861 restored Monaco's independence, and in 1865 a customs union was established between the two countries. Another treaty with France in 1918 contained a clause providing that, in the event that the Grimaldi dynasty should become extinct, Monaco would become an autonomous state under French protection.

Beginning of Grimaldi rule

Contemporary Monaco. The four sections, or *quartiers,* of Monaco are the town of Monaco, or "the Rock," a headland jutting into the sea on which the old town is located; La Condamine on the west of the bay, with its natural harbour; Monte Carlo, including the casino and numerous hotels; and the newer zone of Fontvieille, in which various light industries have developed.

In Monaco are the Roman Catholic cathedral, which houses a Louis Bréa painting of St. Nicholas and which was built in 1875 on the site of an ancient church; the prince's Genoese and Renaissance palace; and the Oceanographic Museum of Monaco built in 1910.

On the Monte Carlo coast a 1,600-foot (500-metre) beach has been constructed, adding 22 acres to Monaco's territory. In the early 1970s, another strip of ground was being added in the Fontvieille district, upon which a new town was to be built overlooking the sea.

Monaco's population in 1971 was slightly over 23,000. More than half of the people were French citizens, some 4,000 were Italian, and only about 3,500 could claim Monegasque descent. Monaco's refusal to impose income taxes on its residents and on international businesses that have established headquarters there led to a severe crisis with France in 1962. A compromise was reached and French citizens with less than five years residence were taxed at French rates and by which taxes were imposed on Monegasque companies doing more than 25 percent of their business outside the principality.

Monaco has had a constitution since 1911, but, in 1959, Prince Rainier III suspended part of the constitution and dissolved the National Council; in 1961 he appointed instead a national assembly. The crisis of 1962 with France led him to restore the National Council and to grant a new, liberal constitution. The council comprises 18 members, elected by universal sufferage for a term of five years. Government is carried on by a minister of state (who must be a French citizen) and three state councillors acting under the authority of the prince. Legislative power is shared by the prince and the National Council. Since 1819 the judicial system has been based on that of France, and two Parisian judges form a Court of Appeal. There is also a Municipal Council (15 members elected for four years) that administers municipal affairs.

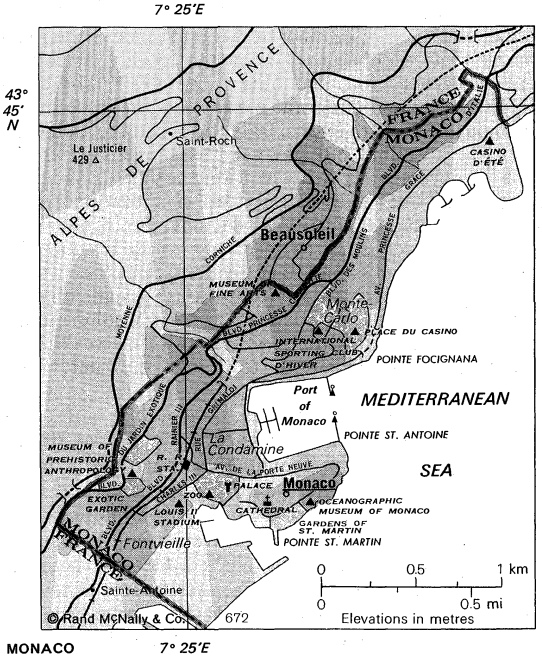
Administration of the principality

In the early 1970s, more than one-half of the government's revenues came from taxes on commercial transactions; the remainder was drawn from franchises on radio, television, and the casino, from state-operated monopolies on tobacco and stamps, from sales taxes, and from the taxes imposed since 1962.

In recent times, Monaco's chief industry has been tourism, and its facilities make it one of Europe's most luxurious resorts. Once a winter attraction, it now draws summer visitors as well to its beaches and expanded mooring facilities. The social life of Monte Carlo centres about the Place du Casino, with its picturesque gardens, and the nearby International Sporting Club d'Hiver, which houses a theatre. The casino was built in 1861, and in 1967 its operations were taken over by the principality. Characteristic of the principality's orientation toward tourism, the minority Monegasque portion of the population is prohibited from gambling activity—but it is also free from taxation.

Tourist attractions

The casino itself contains the home of l'Opéra de Monte Carlo as well as the Foyer de la Dance, which saw the premiers of most of the works by the famous Ballet Russe de Monte Carlo of Sergey Diaghilev. There is also a Monte Carlo national orchestra. The best known of the automobile events are the Monte Carlo Rally and the Grand Prix de Monaco. Radio Monte Carlo broadcasts in 23 languages to Europe and the Middle East, and Télé Monte Carlo's programs are commercially sponsored.



MONACO 7° 25'E

BIBLIOGRAPHY. A standard history of Monaco is L.H. LABANDE, *Histoire de la Principauté de Monaco* (1934); an older one is GUSTAVE SAIGE, *Le Protectorat espagnol à Monaco* (1885). GEORGES REYMOND, *Monaco antique* (1970), is a study of ancient texts and epigraphs.

Monasticism

The word monasticism is derived from the Greek *monachos* "living alone"; but the etymology indicates only one of the elements of monasticism as a force in history and society. The etymological method of arriving at an understanding of monasticism is, at any rate, misleading because a large section of the world's monastics live in cenobite (common life) communities. The term monasticism does, however, indicate what later became a socially

and historically highly significant feature; *i.e.*, living alone in the sense of being unmarried or celibate, though this feature is not directly related to its etymology.

Still, even this aspect of monasticism does not extend beyond the cultures and languages within which was formulated the religious terminology that originated in the eastern Mediterranean; *i.e.*, the Judeo-Christian and Islāmic religions. In the Islāmic world, terms that can be translated by "monk," "monastic," and similar words do not mean "single" in the Arabic and Persian terminologies as in the Greek. Other aspects (*e.g.*, *zuhd*, "asceticism") of the monastic life in Islām provided the etymological and definitional sets denoting "monasticism." None of the many Indic (Sanskrit, Pāli, Apabhraṃśa, Prākrit) terms for monk means "single" or "living alone" in these languages, although monastics within those traditions—Brahmin-Hindu, Buddhist, and Jaina—do indeed live alone or in groupings set off from the rest of their societies, analogously to Jewish, Christian, and Islāmic monastics. The etymologies of the Indian as well as of some of the Arabic and Persian terms connote poverty, certain ecstatic states of mind, dress conventions, and some (by historical rather than semantic connection) imply single, celibate living.

NATURE AND SIGNIFICANCE

Within a cross-cultural perspective, monastics can be seen to have been instrumental in creating, preserving, and augmenting institutions of learning, religious as well as secular, and in transmitting cultural goods, artifacts, and intellectual skills through the generations. Monastic institutions have also had medical, political, and military-related functions, though the latter two have all but disappeared in most societies.

Definition and characteristics

A definition of monasticism that would cover all of its forms, Eastern and Western, must necessarily be wide; particulars must be relegated to the analysis of specific monastic systems. A universal definition might thus be: "monasticism" is a term covering religious institutions, ritual, and belief systems whose agents, members, or participants attempt to practice religious works that are above and beyond those required by the religious teachings of their society or of exceptional individual religious and spiritual leaders in their society; *i.e.*, those who have interpreted radically the tenets that apply to all believers or to the whole society. Beyond such a statement, one can speak only of the major characteristics of the monastic life and its institutions, since none of them is universal. Celibacy is fundamental to the majority of the world's religious orders, but it is by no means universal; asceticism is universal, provided the term is defined widely enough so as to include all supererogatory religious practices. The truly universal characteristic of monasticism follows from its definition: the monastic separates himself from his society, either to be by himself as a hermit or an anchorite (religious recluse) or to join a society of others who have separated themselves from their surroundings with similar intentions; *i.e.*, the full-time pursuit of the religious life in its most radical and usually its most fundamentalistic interpretation.

There is no monasticism in societies that do not have a written and transmitted lore. Nonliterate societies do not have monastic institutions, since the monastic takes his departure from an established corpus, or written body, of religious doctrine, which has undergone criticism and has generated countercriticism as well as a dialectic that presupposes a literate, codified manipulation of the doctrine. The monk and the monastic founders may either support or oppose the official religious tradition, but the presence of such a tradition is essential as the matrix of all monastic endeavour.

PURPOSES OF MONASTICISM

Discovery of the true self. *Overcoming imperfections.* All monasticism has its mainstay in theologically based convictions that the present state of things leaves much to be desired—that life in society cannot generate the spiritual consummation stipulated by the religious world view that was or is recommended overtly or covertly by its founder. In some traditions, especially in those of South Asian provenance, the true "self" is clogged and covered by imperfections—by sin, ignorance, or other theologically suggested impediments. The ego with which the layman and the seeking neophyte identifies is not his true self—it is the latter that has to be discovered, uncovered. The sundry barriers—differently conceived as matter, individuated mind, or as a soul–mind aggregate defiled by sin, ignorance, and perversion—must be broken through, or a veil lifted, so that the true self, the primordial spirit, may shine forth. In most traditions, this breakthrough is held to be unattainable through the ordinarily acceptable good social life. A new, hardened, and disillusioned approach must be sought. The body and the mind, which are part or the whole of the impediment, have to be controlled, disciplined, and chastised—hence either asceticism or a set of psychophysical experimentations that differ radically from the normal acts of life is espoused.

Spiritual perfection. The quest for spiritual perfection is elitistic, even when, as within Christian monastic orders, humility is essential. Withdrawal from society is necessary, since the instrumentalities of perfection cannot normally be acquired and augmented in the surroundings of everyday life. The operational basis is meditation on a set of spiritual concepts that either represent the supreme value or provide crutches to support the body and the mind on their tedious journey toward whatever their supreme consummation may be. Processes of intense contemplation, often accompanied by physical exercise, constitute the mystical practice—*i.e.*, prayer, worship, incantation, propitiation, and various forms of self-abasement or self-inflation. All these are pursued in enormously variegated forms and degrees.

Forms of mystical practice

Emancipation of the self. *Salvation.* Seen cross-culturally, the ultimate purpose of the monastic endeavour is the attainment of a state free from bondage, both bondage and freedom in such endeavours being defined in theological terms. Most languages of cultures with monastic traditions have special terms to denote bondage and freedom; others use terms of common parlance that are then understood by members of society as referring to theologically adumbrated types of bondage and freedom. Thus, the term salvation in the Christian context means deliverance from the powers of evil besetting the person's body, mind, and soul. Varying concepts of salvation, liberation, and emancipation are generated by, or closely related to, the society's identification of an individual, the extensions of his body, mind, soul, and spirit, and his status within a larger universe. The idea of salvation, like other such concepts, presupposes a specific cosmological view against which to frame the answers to the question—formulated or unformulated—"What is it that is bound and that can, should, or must be freed to achieve the most desirable state within or vis-à-vis the totality of things; *e.g.*, the cosmos, God, and other absolutes?" The question has spatial and temporal parameters; in some of the indigenous Indian religions, salvation can be achieved during one's lifetime, but whether this happens or whether the achievement is delayed into another existence is actually accidental to Indian notions of liberation. In the Judeo-Christian and Muslim world, salvation proper cannot be achieved as long as the body continues to exist. "Salvation" and its semantic equivalents, in other words, refer to the present *or* future in the South Asian religions but refer only to the future in the eastern Mediterranean creeds. The life of the monastic is a full-time seeking of salvation, in contradistinction to that of the "part-time" general believer.

Redemption. Redemption as deliverance from the spiritual effect of past transgressions may or may not be identical with salvation, though the terms are in many cases synonymous. In any event, as part of his monastic ambition, the monk seeks redemption from his sins or he intercedes, takes upon himself and works out the redemption of others. This is accomplished through personal sacrifice or many forms of self-mortification. The processes of mortification augment or stabilize the austerities required of the monastic and are part of the picture in all

monastic traditions. The emphasis on the autocentric or the vicarious aspect of the quest for redemption depends entirely on the doctrinal framework with which the monastic identifies. In either case, the dialectic of autocentric and vicarious emphases cuts both ways—in mortifying his own body and mind for the benefit of others, the monk also helps his own advancement along the spiritual path. When a Jaina monk (a follower of a 6th-century-BC Indian religious reformer, Mahāvīra) volunteers to lie upon a bed infested with vermin that suck his blood, he may do so for a client or a patron with a view to diminishing that person's karmic load (involving the doctrine that every deed, good or bad, receives due retribution), but at the same time he practices the monastic virtues prescribed for him as a monk. When a Franciscan monk (a follower of Francis of Assisi, the 12th-13th century Christian monastic leader) serves the poor and the sick, he also improves his own virtues of service and humility, all of which are instruments for his own redemption.

Social and vicarious acts as means of spiritual advancement

Liberation. When liberation from cycles of birth and death constitutes the foundation of a belief system, as in the basic pattern of *saṃsāra* (*i.e.*, an inevitable metempsychotic chain that can be broken only through supererogatory efforts of the meditational order) in the Indian traditions, the monks are the harbingers of the methods of liberation. In India and Tibet as well as in Southeast Asia, the monk has always been the centre of attention of the religious life far more than in the Christian world, in which he was and is marginal to the main ritualistic and ideological thrust. The importance of the monastic life in a religious system is related to its ideological content. Thus, if the state of life after salvation is transformed, but is yet basically a continuous type with the present life, then the monastic has less importance than he does in belief systems in which salvation means a totally different state, one that cancels finitude and eradicates all traces of separate individual existence.

Limited personal goals—*e.g.*, power or wealth—are aimed at by some Hindu monastics, but these are infrequent and atypical for the total monastic situation.

Social and institutional purposes. *Conquest of the spiritual forces of evil.* Social goals are interwoven with those of salvation in most monastic traditions, and there is a vacillating emphasis on one or the other depending on the founders' interpretation of the theological framework. The first Christian hermits of the Egyptian desert (*c.* AD 250–500), Anthony of Egypt, Paul of Thebes, Pachomius of the Thebaid and others, were referred to as the "Desert Fathers." They presaged later monastic institutions and were the inceptors of cenobitism—literally "lying [*i.e.*, eating, sleeping, and living] together"—which was to be fundamental to all later Christian monastic institutions. Though the early hermits, mostly native Egyptian (Coptic) peasants, were inspired by the example of famous recluses, their rigorous monastic asceticism soon projected an orientation toward communal life that was related to paramilitary models encountered at one time or another in virtually all monastic traditions—the community that was viewed as composed of soldiers of the spirit. The Desert Fathers believed that they were to combat the forces of the devil tempting them in the desert. Much of this might have been antedated by the Jewish Qumrān community, which was located near the Dead Sea and is often identified with the Essenes, a religious group that flourished in the Judaean desert between 150 BC and AD 70. The Qumrān ascetics considered themselves to be the true, unpolluted priests of orthodox Judaism, decrying the Jerusalem priesthood that they characterized as defiled, spurious, and unclean, sullied by Hellenism and potentially heretical. This may have been the first instance of a monastic elite versus an urban sacerdotal establishment in which the interpretation of the canonical teachings was under dispute. Rigorous asceticism, communal prayer, and common work were the rule, though celibacy might not as yet have been part of that community (see also CHRISTIANITY BEFORE THE SCHISM OF 1054; BIBLICAL LITERATURE).

The Qumrān community

Improvement of society. By and large, monastic institutions may have aided the progress of civilization, even though they are often, and perhaps rightly, blamed for obstructing and retarding it.

Monasticism as an instrument for the creation, preservation, and transmission of secular and religious traditions was pervasive in all those cultures that gave a special status to the cenobite institution. Its function as a propagating or proselytizing agent of the religious tradition, however, is by no means universal, nor even regionally determined. In the Mediterranean religions, as well as in those that originated in South Asia, there are discrete, uninterrupted, ordered sequences from the totally contemplative, hence nonproselytizing, to the teaching and preaching orders with virtually no scope for contemplation. The role of monks and their orders in the arts, sciences, letters, as well as in the pedagogical and the therapeutic social services, is thus discussed under the headings of the diverse monastic systems (see below).

Institutional centres for religious leadership. In some religions, monasteries become training centres for institutional religious leaders. There is, however, a clear dichotomy between training centres for ecclesiastical and for monastic leaders. Even though the distinction may seem to be blurred in the Roman Catholic and Eastern Orthodox traditions, the fact that monastic training could also be priestly should be viewed in a cross-cultural survey as accidental. In all Indian religions, by contrast, there is a radical and exclusive division between the priestly and the monastic careers and their concomitant institutions. The common denominator lies in the supererogatory status of the monastic life—if churches and seminaries prepare ecclesiastical leaders, teachers, and intellectuals, monasteries may train people to whom the same epithets apply, but with a difference: the monk is usually said to be more radical and less compromising, modally speaking, than the ecclesiastic.

Priestly and monastic training

Other purposes. Apart from the ubiquitous redemptory, spiritual, and social goals of monastic systems, most of them condone peripheral goals of more or less mundane types. Thus, a Tibetan lamasery (monastic religious centre) is not only a centre of spiritual counsel but also a bank, a judicial court, a school, and a gossip centre for the laity. Some of the most specialized operations are found in monasteries, including coaching in wrestling, in some Hindu orders, and the preparation of perfumes by the Muslim Sanūsīyah (a conservative, rational, and missionary order established in the 19th century).

TYPES OF MONASTICISM

Organizational or institutional types. *Eremitic.* A taxonomy of institutional types includes several varieties: first, historically and in terms of simplicity, is the eremitic (religious recluse) type, including the early Christian hermits or anchorites; the actual or legendary *ṛṣis* ("seers") of Vedic India (pre-800 BC); some of the earliest Jaina *śramaṇas* ("ascetics"), particularly the semihistorical founders of Jainism (Mahāvīra and Pārśvanātha); the Taoist recluses of early southwestern China; and, down even to today, sporadic hermits in the various religious areas of the world—such as Gauribala in Ceylon (now Sri Lanka), La Mêre in Pondicherry, India and other Western converts to Asian belief systems without organized monastic trappings. Some of the European and American neomystics should also be included in this class.

Common to all true hermits and eremitic institutions is an emphasis on living alone, on a highly regularized contemplative life (with individually generated, often experimental spiritual disciplines), and on frequently idiosyncratic and even heretical interpretations of underlying scriptural or disciplinary codes. Incipient self-mortification and individual austerities can be traced, but these are incidental to the eremitic style.

Quasi-eremitic. The lauras (communities of anchorites) of early Christianity in Greece and Cyrenaica (exemplified by the Mt. Athos tradition that exists even today), the small-scale *āśrams* ("religious retreats") of monastic Hinduism from at least 300 BC to this day, and perhaps the semiformal congregations of the early Buddhist monks and nuns, preceding the establishment of

the *saṅgha* ("monastic order," or "community"), are best called "quasi-eremitic." Common elements in this type of monastic assembly are loose organizational structures with no administrative links to mother institutions and no external hierarchies. The category forms a transition between the eremitic and the cenobitic; in many cases, such as that of the medieval Indian *panthā* organizations (sectarian), groups may display eremitic and cenobitic features consecutively, either during different annual seasons or on the occasion of special conventions. In the 20th century, some Nepalese followers of Gorakhnāth (8th century AD) live as recluses during most of the time but form themselves into a quasi-military association on certain occasions, such as during the all-Indian monastic assemblies (*kumbhamelā*) every sixth year at certain centres of pilgrimage. During these periods they become organizationally indistinguishable from the most highly structured cenobitic units present at the conventions.

Cenobitic. It is probably not wrong to identify proper "monasticism" with cenobitism. There seems to be a correlation between a formulated rule, or set of rules (*regula* in the Christian orders, *vinaya* and *śīla* as part of the Buddhist canon), and cenobitic institutions; eremitic and quasi-eremitic settings lack formulated rules and give more scope to the individual's self-imposed disciplines. A Christian ascetic, Pachomius of the Thebaid (*c.* AD 290–346), was reputedly the founder of organized cenobitism in the Western world and is said to have built nine monasteries for men and two for women. These monasteries may have been the model for the monasteries founded by the Greek theologian St. Basil the Great (*c.* 330–379), who set down what was the first monastic rule. The basis for all subsequent Eastern Christian (Greek) monastic institutions, it was simple and primitive compared to the *regulae* ("rules") of the orders founded in later centuries in Europe. Avoiding the extreme austerities of the Desert Fathers, St. Basil's rule was strict but not severe. Its asceticism was an instrument in the consummate service of God; it was to be pursued in community life and in obedience. Liturgical prayer and manual and mental work were obligatory. Germinally, the Rule of St. Basil enjoined or implied chastity and poverty, though these were far less explicit than in the later *regulae*. What Basil's rule was for Eastern monachism, St. Benedict's was for early Western monasticism. Benedict of Nursia (*c.* 480–543/547) was a practical Roman, and his *regulae* (enjoining poverty, chastity, obedience, and stability), which was used—for the most part—by most of the paramilitary aristocratic orders, such as the Knights Templars, until the 13th century, and which is the rule of the Benedictine Order today, incorporates instructions on institutionally held property. It also set the model for all subsequent Roman Catholic monastic orders; *i.e.*, the requirement that the individual monk does not own property, but that it is held by the order through its appointed trustees.

Rules of St. Basil and St. Benedict

One-third of the Theravāda (southern, or so-called Way of the Elders) Buddhist canonical literature is *vinaya* ("comportment"), the Buddha's own statement of more than 200 rules for his monks. Compared to these, the later Brahmanic (Hindu) orders, such as the *Saṃnyāsin* order founded by the Hindu reformer Saṅkarācārya (8th century AD), contain hardly any "rules" except an implicit renunciation of worldly desires, a detachment from society, and an indifference toward the "opposites" such as pleasure and pain. The 6th-century-BC founder of Jainism, Mahāvīra, about 80 years senior to the Buddha, formulated the nucleus of the Jaina doctrine and also established the core Jaina order, giving it a very elaborate rule that goes into minute regulations for monastic residence: restricting the itinerant monk's sojourn to one week at a time in a village and one month in a town; requiring that the monk must not sleep more than three hours and that he must spend the day and the rest of the night in expiation, meditation, studying Jaina scripture, and begging for alms. Some scholars believe that the Jaina rule provided the model for all monastic rules in India and thus for the monastic traditions in all the Asian countries that came under India's religious tutelage.

Indian and other monastic orders and groups

The Essenes of Judaism, regardless of whether or not they were identical with the Qumrān settlement, probably had a written rule; certainly, they were highly formalistic, emphasizing ritualistic purity, with ablutions prescribed for the members, and with a fundamentalistic adherence to the letter of the Jewish ritualistic and legal books Leviticus and the Deuteronomy written into their discipline. In modern times, the so-called hippie communes, insofar as they seek religious experience, should be included in a historical list of cenobitic organizations; growing food, preparing and consuming it jointly, and sharing common dormitory facilities are essential elements of the cenobitic structure.

Quasi-monastic. Paramilitary, or quasi-monastic, associations are another type of monastic group. Most Christian orders of this type also had medical or healing commitments; non-Christian monastic orders of this type did not cater to the sick. The Knights Templars, whose order was founded in the 12th century during the Crusades—the most prestigious and most thoroughly defamed aristocratic organization—styled themselves "poor fellow soldiers of Christ and the Temple of Solomon"; their foundational commitment was the protection and the guidance of pilgrims en route to and in the Holy Land. Though the Templars, following the rules of St. Basil and St. Benedict, took vows of poverty, chastity, and obedience, their corporate wealth and the secrecy of their initiation and of all their internal affairs helped bring about their extermination under the French king Philip IV the Fair in the early 14th century. The military model was evident in their hierarchical structure—there were chaplains, knights, and sergeants under a grand master of the temple.

Christian military orders

The Templars were inspired by the Knights Hospitallers (or Order of the Hospital of St. John of Jerusalem), founded in the 11th century. The Hospitallers were probably the first to generate genuine medical and hospital services, at first for pilgrims to Jerusalem. They were the classical nursing order, and their first foundation was the Hospital Saint-Antoine-de-Viennois (*c.* 1100). There were other houses in Spain, Italy, and Germany. Their chief officers were ordained priests, but the majority of the members were nonsacerdotal "hospitallers," or lay brothers and sisters. They adopted the Benedictine rule until 1231, meeting under an elected master, and an annually rotating chapter-general assembling the "commanders"; the order switched to the "modern" rule of St. Augustine in 1247.

The Teutonic Knights (Deutscher Ritterorden), founded in Jerusalem in 1189, had a feudally independent relationship to Rome and the papal administrative bureaucracy (Curia) specially defined by over 100 papal bulls; their grand master, who had the same rights as a prince of the Holy Roman Empire, was assisted by five "grand commanders." The organization was composed of knights (usually noblemen), middle-class priests, and sisters (mostly noblewomen), well trained in hospital services. After the fall of Acre to the Muslims in 1291, the order moved its headquarters to various places in Europe. But in the 13th century and after, the order revived its erstwhile function, when European rulers called upon it to war against the Altaic and the Prussian pagan peoples.

The popular, and wrong, identification of Tibetan monks as "lamas" has obscured the highly segmented institution of the Tibetan Buddhist clergy. Among the Khamba (*khams pa*) in eastern Tibet, men with minimal monastic initiation (*lung*) organized themselves as a military or police force to protect the unarmed higher initiated clergy as well as the monastic territory. These were not defenders of, or fighters for, Buddhism, but were a type of monastic police force, sartorially indistinguishable from the actual clerics. They were very evident in Tibet's confrontation with the Chinese Communists (1959–65).

Buddhist, Muslim, and Sikh military orders

In the Islāmic world, the mystical orders (Ṣūfī) and the partially overlapping dervish (*darvīsh*) assemblies constituted a living critique, as it were, of the formalistic, fundamentalist, and Qur'ān-oriented (scriptural) orthodoxy controlled by the *'ulamā'* ("teachers") from Cairo,

the assemblage of Muslim learned ones who set standards for orthodox faith and practice. The Ṣūfīs' direct approach to divinity through such meditative or ecstatic practices as the *dhikr* (the chanting of the names of Allāh, or God)—that was accompanied by variegated physical expressions such as dances and songs and by the ingesting of drugs, usually of the genus *Cannabis* (such as hashish)—became symbolic representations of the criticism of officially sanctioned behaviour. The Turkish Bektaşi (Bektashi) excelled in poetry and in humorous repartee, which even now is recalled in references to the art of the Bektaşi. The Sanūsīyah (Senussi) order of Ṣūfīs, in Libya and other northeast African countries, not only antagonized the Wahhābīyah (a generic name for fundamentalistic orthodoxy in Islām rather than a term denoting any specific group) but also achieved impressive political and military corporate stature in very recent times, opposing the Italian colonialist forces in Libya with some measure of success. These orders sought communion with Allāh through mystical practices rather than salvation by righteousness. "Not I and God but only God" was one of their mottoes.

Though the religion of Sikhism is historically Hindu, the early "pure" (khālsā) did not encourage monasticism; Gurū Nānak, the founder of Sikhism (1469–1539), was a married man, and so were most of the other nine Gurūs ("teachers"). In the late 17th century, however, the Nirmal-akhāḍā was created in complete analogy to the celibate monastic orders of Hinduism and organized on the same principles. Underlying this development is a universal Hindu tendency to create monastic corollaries to lay teachings; the process has been repeated in India much more recently. The Arya Samaj (a Hindu reform society), founded by Swami Dayananda Sarasvati in 1875, is a good case in point. Although Sarasvati was a monk in the Daśanāmī *sannyāsin* order (Holy Men of the Ten Names), he discouraged monasticism—yet, bending to an all-Hindu cultural pressure, monks have been ordained in his organization since the early decades of this century. An older quasi-monastic organization among the Sikhs is the Nihaṅg Sāhibs, a basically military organization within Sikhism. Created to fight Muslim incursions into the Sikh communities of the Punjab, the Nihaṅg Sāhibs wear robes that are blue and yellow military uniforms that have been unchanged since the 17th century. The Nihaṅg Sāhibs are married, but during their temporary active service as *nihaṅgs* they abstain from sexual intercourse and live in a cenobitic manner.

Mendicant monks and orders. By a strict definition, mendicancy (living by begging) would preclude cenobitism. In actual fact, however, there are many orders that are mendicant and cenobitic at different times. The Hindu and Buddhist official orders are really both. During his training, the neophyte lives in a strictly cenobitic setting; on subsequent peregrinations, he eats the food he obtains by begging, which is part of his advanced discipline, and he eats alone. The Burmese, Thai, and Sinhalese Buddhist clergy could be termed mendicant stationary—the monks wander out in the early morning to collect food in their alms bowls, but they consume it jointly at the house in a cenobitic fashion.

The Christian mendicant orders

In the Christian world, the Franciscans, founded by St. Francis of Assisi (1181/82–1226), with their numerous subsections, and the Dominicans, founded by Domingo de Guzmán (1170–1221), were and are the most powerful statutory mendicant orders. The synthesis of contemplation and the apostolic ministry is strong in these orders; the Dominican motto "to contemplate and to give the fruits of contemplation to others" is significant. The Sanskrit term *parivrājaka* ("walking around") quite literally connotes mendicant status and as a title is carried by a large number of Hindu monastic organizations. It has canonical sanction—the Hindu scriptural definition of a monk is "[one who] having renounced the desire for sons, for wealth, the fear of social opprobrium and the craving for social approval, he sallies forth, begging for food." Here also there is a blend between the contemplative and the preaching life; the various Hindu orders place varying emphases on the one or the other, a distribution that seems quite parallel to that of the Christian orders. The vow of chastity is spelled out for the Hindu mendicants, but poverty and obedience are implied rather than enjoined. The Hindu monastic organization is much looser than either the Buddhist or the Christian, and in this sense it resembles the earliest eremitic and quasi-eremitic types in Judaism and Christianity.

Other organizational or institutional types. Permanent versus temporary membership correlates with different monastic institutional types, though it does not seem to have any bearing on organizational structure. In the Theravāda Buddhist order (*saṅgha*) of Thailand, Burma, and Sri Lanka, men join a monastery for an unspecified period of time, with minimum periods (three months to a year) prescribed in the *Dhammayut*, the smaller and more highly ascetic of the two sections of the Siamese *saṅgha*; the Mahāssaṅghikas, who form the monastic majority, do not specify any such duration. Lifelong monastic views are, in those regions, a matter of individual choice. The order itself does not take any official stance on them. This differs radically from all full-fledged Catholic orders as well as from those Hindu organizations that initiate members by the *virajā-homa* (*i.e.*, the Vedic rite of renunciation); since the initiate is declared dead by this ceremony, he cannot return to the world of the living (*i.e.*, to society). Dispensations, on the other hand, were given, though reluctantly, to Roman and Greek Christian monks and nuns who wanted to leave their orders. In the Hindu monastic code, there can be no such dispensation—monks who leave and return to social life are highly stigmatized.

Hierarchical and status types. *Sacerdotal.* In addition to organizational and institutional forms, a typological survey must also include aspects of monastic status and hierarchy. The first and most important division here is between sacerdotal and nonsacerdotal full-time supererogatory specialists. Most of the canon-based (scriptural) religions of the world distinguish between priests and nonpriestly practitioners. In the case of Greek and Roman Catholic Christianity, the distinction is crucial on the sacerdotal but incidental on the monastic end. Monks who have priestly ordination are full priests and full monks; monks and nuns who do not have it are full monastic members nevertheless, sharing the same vows and the same discipline. Islām does not officially recognize monastic status, nor does it have priests—the *imām* is the leader in prayer, but he has no special vows or ordinations. The dichotomy does not apply in Judaism either.

Separations of sacerdotal and monastic functions in Hinduism

In the case of the religions originating in India, the situation is markedly different: in Hinduism, only a male person born into a Brahmin (highest) caste is entitled to perform sacerdotal, Vedic (scriptural) ritual; this requires no further initiation than that given to all high-caste boys. A Hindu priest (*purohita*) must be married. Celibacy is not incumbent on all Hindu monastic orders, though it is in those of high prestige. But the monk cannot perform any sacerdotal service, even if he was born into a Brahmin family. The fact of monastic ordination cancels his sacerdotal status. Monastic organizations ordain monks in various ways, and the types of ordination are numerous; but monastic and priestly ordinations are totally different and distinctive in type, scope, and intent. The Brahmin priest supports and enhances the mundane well-being of his client and the worldly estate of his society through Vedic and other rituals. The monk, on the other hand, withdraws from the mundane in a radical sense by rejecting sacerdotal commitments, and he recommends such withdrawal to his clients in a long-range perspective.

Secondary and tertiary orders. The notion of secondary and tertiary orders was generated in the Roman Catholic world, though by analogy it could be extended to non-Christian cultures. The triple division of the Franciscans and the Dominicans epitomizes this hierarchical and status type: the first order consists of ordained priests and lay brothers, the second of contemplative nuns; the third order incorporates laymen and laywomen, "tertiaries," who live under abridged, or "minor," vows

that do not always include celibacy. In the Theravāda Buddhist world, these tertiaries have parallels in the *saṅgha*, which can be viewed as the Buddhist analogue to the first orders of Dominicans and Franciscans. Whereas the full-fledged Buddhist monk has over 200 vows, part-time monks (*śramaṇa*s) have less than one-third that number. In Burma, quasi-monastic, but unordained practitioners (*upāsaka*s) may stay at monasteries and participate in the meditative and congregational activities of the monks, for a limited period and with payment of a nominal fee to the bursar of the cloister.

Status of nuns

In all monastic traditions of the world, the status of nuns is considerably lower than that of monks. The only conceivable exception is that of certain famous saintly women in Hindu India, today and in the past; some of them, known for their extreme piety or, more importantly, for their physical-mental (yogic) and mesmeric (hypnotic) powers, have gained high charismatic (spiritually influential) status that may place them, as individuals, above male monastics. Yet there is no truly hierarchical superiority wherein an ever so exalted nun could have disciplinary powers over a monk or even over a male novice. Though the Roman Catholic tradition has refused equal status to nuns, because women cannot obtain sacerdotal ordination, the Indian attitude rests on notions of ritualistic impurity—women, being polluted through the menstrual cycle, never have access to the ritual complex due to their innate defilement, hence their status is much lower—even though some noncanonical texts (*e.g.*, the *Bhagavadgītā*) assert spiritual, though not ritualistic, equality of women and men.

When women postulants approached the Buddha for admission into the order, he was reluctant; finally, when his disciples and sponsors had succeeded in establishing nunneries, the Buddha said that this step augured the decline of the order. This did not discourage women either then or later. Buddhist nunneries are not numerous, and their ratio to male convents does not exceed 1:20 in any of the Buddhist countries. The modal Buddhist monastic attitude toward the nuns is one of embarrassed silence except in Japan, where the general loosening of monastic rules has worked in their favour.

Tertiary orders

Tertiary orders in the Christian world were established by noblewomen who combined piety with pioneering medical knowledge and strong motivation to gear the latter to religious pursuits approaching the monastic in degree of dedication. Though the term tertiary did not originally contain reference to the sex of the membership, its selective denotation was well established by the 13th century, usually referring to women, often of aristocratic background, who led a saintly life in a cenobitic setting but were inspired by humanitarian ideals rather than by that of sheer contemplation. In a very real sense, women belonging to such groups were the first nurses; their tradition has been continued in all the Christian nursing orders extant today and is being emulated by some new non-Christian orders, such as the Hindu Ramakrishna Mission. Where there are male tertiaries, as in some segments of the Dominican and Carmelite orders, the humanitarian connotation dominates.

Though the hierarchical types in the Christian West must be viewed from an organizational or managerial vantage point, there is much variation in Eastern orders. In the religious world derived from the teachings of India, a true hierarchy comparable to the Christian orders is found only in the Tibetan ecclesiastic setting. Contrary to the popular notion, the lamas are not simply high-ranking monks but are viewed as incarnations of a particular aspect of the Buddha or of a teacher who in turn was such an incarnation. Though Tibetan monasteries prided themselves on the presence of one or more lamas, they really stood above and outside the operational hierarchy, and their function was and is advisory rather than executive.

VARIETIES OF MONASTICISM IN THE RELIGIONS OF THE WORLD

Since monastic systems developed mainly in the Mediterranean monotheistic, and in South Asia's theologically more complex situation, their diffusion into other parts of the Western and Eastern world can generally be viewed as a modification of the two historical core areas that were located in two relatively small regions; *i.e.*, the Judeo-Christian-Islāmic and Hindu-Buddhist-Jaina areas.

Religions of the East. *Hinduism.* With some reservations, the religion of the majority of the population of the Indian subcontinent after the decline and exit of Buddhism can be called "Hinduism," to supplant the erstwhile "Brahmanism" or the Vedic religion of pre-Buddhist days. Buddhism, like Christianity, is an export religion in the sense that it did not survive in an ecclesiastically organized fashion in its homeland. Hinduism—on the other hand—has absorbed so many Buddhist traits that it is virtually impossible to isolate the latter in medieval and later Hinduism. The most important Buddhist-inspired element in Hinduism is no doubt its monastic tradition. Where there were hermitages in ancient, pre-Buddhist India (such as the abodes of the Vedic "seers" [*ṛṣi*s] and the *gurukula* [teacher's family]—which was a germinal cenobitic setting comprising the *ṛṣi*s and their disciples), typically monastic features such as vows of chastity and an unequivocal rule of monastic comportment were not operative before the time of the Buddhist *saṅgha* ("monastic order") in the 6th century BC and its little-known early contemporary movements, such as the Ājīvikas, which are viewed as proto-Jaina, and other incipiently monastic institutions.

The most outstanding Hindu monastic founders and thinkers, comparable in many ways to the Christian St. Benedict of Nursia or the great theologian Thomas Aquinas (1225/26–1274) with regard to their importance in their respective areas, were Śaṅkarā (8th century AD) and Rāmānuja (11th century AD). Both of these teachers propounded the Vedānta theology (a religio-philosophical system concerned with the nature of ultimate reality), albeit in very different, mutually incompatible interpretations. Śaṅkarā's order of Dasanāmī *sannyāsin* (Holy Men of Ten Names) was and has remained the monastic order that set the monastic standards for the rest of Hindu India. Based on a scholastic, nondualistic reading of the four "great dicta" (*mahāvākya*) of the canonical *Upaniṣads* (one of the Hindu scriptures), the monk, following the example given by the founder, meditates constantly on the numerical identity of his individual soul (*Ātman*) with the cosmic soul (Brahman). All his other observances—such as group incantation of canonical liturgy, participation in the monastic assemblies with other orders (*kumbhamelā*) at various places and at astrologically computed time intervals, alms begging, teaching religious topics to the laity, and conducting scriptural discourse with lay and monastic scholars (*śāstrārtha*)—are ancillary to his main purpose; *i.e.*, meditation. He does no social work, and there is nothing to parallel the humanitarian deeds of some other orders in the Indian and most orders in the Judeo-Christian world. He cannot conduct ritual and he has no obligation whatever toward society; but society has its obligation toward him—it feeds and clothes him. For this, he instructs those who wish to be instructed in the methods of meditation leading to emancipation from rebirth, which is believed to be caused by one's good or evil thoughts, words, and deeds in one's previous existence. In a more formal manner, he may or may not initiate lay seekers and monastic postulants (potential monks) into meditation by imparting to them a *mantra*, a sacred secret formula aiding the emancipatory process. Since the monk's initiation entails the symbolic cremation of his body, he is not cremated at his death as is done in the case of lay Hindus, but is interred or immersed in the river.

Śaṅkarā and Rāmānuja

Most of the prestigious Hindu monastic orders follow this pattern, though their disciplinary codes are often radically different. Thus, the followers of Rāmānuja, referred to as Śrīvaiṣṇavas (worshipers of Viṣṇu [Vishnu] and his spouse), are largely lay, high-caste Hindus. The monastic order relating to this tradition emphasizes ritual and worship of the personally conceived deity; its rules of celibacy, compared with the strict and unexceptional

rules in the Daśanāmī *sannyāsin* order, are somewhat vague and flexible—so that, in theory at least, a person who claims the title of a monk could be a married man.

Celibacy in Hindu monasticism

Of the approximately 90 monastic orders in Hinduism, some 70 impose celibacy and a cenobitic rule on their ordained members. Others—such as the Dādū-panthīs (created by Dādū, an important Indian saint of the 16th century) and a number of other orders whose designation ends in *-panthīs* ("path-goers") of relatively recent origin (14th century and later)—follow specific theistic doctrines of medieval Hinduism. Unlike the Daśanāmī, who accept only Brahmins (highest caste Hindus) into their order, the *panthīs* do not discriminate on grounds of caste in their recruitment. In fact, most of these orders can be viewed as anti-Brahmanic revival, or even rebellion, movements.

Jainism. Jainism, founded in the 6th century BC by Mahāvīra in reaction to Brahmanic Hinduism, has fewer than 12,000,000 followers today; but due to its mercantile predilection, it is a wealthy community that has given traditional and substantial support to its monastic organizations. The two main lay divisions of the Jainas derive their primary designation from the monastic setting, which is unique, in India and the West. The Śvetāmbara ("white-clad") sect is so called because its monks wear a white robe and a white piece of cloth to cover the mouth, thereby preventing the inhaling and annihilation of microbes and insects, and carry a broom with which they sweep the ground in front of them as they walk so as to clear away insects and other living beings that would be hurt or killed by being stepped on. The Digambara ("heaven-clad"; *i.e.*, nude) sect is so called because its monks used to go naked, to signify their complete detachment from worldly things and social trappings. Under Muslim rule, this custom was interdicted and since then (15th century) the Digambara monks have been wearing the white robe, thus becoming sartorially indistinguishable from the Śvetāmbaras. The Jaina monk stresses mendicancy, extreme austerity, and detachment. Both Jainism and Buddhism were purely monastic religions—in fact the only ones in a cross-cultural perspective; the rules for the laity are derived from monastic rules. The founders of Jainism (Mahāvīra, the semi-legendary Pārśvanātha), as well as the Buddha, directed their instructions to monks and postulants exclusively—the vows of the monks are more numerous and more intensive, but the way of life enjoined on the laity is simply an abridged monastic rule with more dispensations and compromise.

The *saṅgha* of Buddhism

Buddhism. The generic term for the Buddhist monastic order is the *saṅgha* ("community"); the terms connoting the order in all Buddhist countries are literal translations of the Indian word. Far more than in other monastic traditions of the world—with the possible exception of Jainism—the Buddhist doctrine attaches central importance to the order. The recitation of the "threefold refuge" formula that makes a person a Buddhist, either lay or monastic, imparts a pledge of allegiance to the Buddha, the *dharma* ("teaching"), and the *saṅgha*; most commentaries imply that each of these three constituents is equally important. In northern Buddhism (*i.e.*, Mahāyāna, or the Greater Vehicle) the role of the historical Buddha has been and is negligible, and the order has acquired an even more exalted position. Since the Buddha began every single one of his sermons with the address *bhikkhave* ("O ye begging monks"), fundamentalistic Buddhism is tantamount to monastic Buddhism. The monastic discipline of the Buddhist clergy varies widely in the different parts of the Buddhist world. Ideally, the rules are laid down in the *vinaya* ("monastic rules") portion of the Buddha's sermons, but monastic traditions and regulations have been influenced by the ecological and cultural conditions of Buddhist areas. Rules of vicinity or distance from lay settlements had to be differently interpreted and implemented depending on whether tropical, moderate, or (as in the case of Tibet and Outer Mongolia) sub-Arctic climatic situations are involved. Although celibacy is postulated for the Buddhist clergy everywhere, there have been and are liberal exceptions. The married monks of pre-20th-century Ceylon and those of some of the Japanese Buddhist clergies were highly evident exceptions. Since the vows of the Buddhist monk in principle are not permanent, the theoretical emphasis on celibacy became academic in many parts of Asia. In the Theravāda (Way of the Elders) countries of South and Southeast Asia, the monks were and still are teachers to the people—not only of religious matters, but of basic education—particularly in Burma. There appears to be a correlation between the regional stress on educational and other forms of monastic involvement with the lay society and the provision of special amenities for monks who prefer a strictly contemplative life, as in Sri Lanka and Thailand; conversely, where the involvement is not spelled out, as in Japan, no such special division is apparent. The differences in living style between the northern (Mahāyāna, or the Greater Vehicle) and the southern (Theravāda, wrongly called "Hīnayāna," or the Lesser Vehicle) monastic institutions are quite radical. The fundamental feature, however, is meditation (Sanskrit *dhyāna*, Pāli *jhāna*, from which is derived the Chinese Ch'an and Japanese Zen). The path of meditation leads positively toward the intuitive understanding of momentariness—the condition of existence—or negatively toward the total rejection of all notions of permanence. The negation of existence is described by the term Nirvāṇa, "fading away"—Pāli Nibbāna; Tibetan Thar Pa, or "crossing over"—which is identical with the Zen term Satori, a translation of the Sanskrit *bodhi*, "enlightenment," which was the discovery of the Buddha. All these terms are operational synonyms.

Functions of Buddhist monks

Sikhism. Sikhism, founded by the Punjabi reformer Nānak, was and is a martial version of Hinduism. Of all the indigenous Indian religions, it was the least sympathetic to monastic inspirations. The aforementioned Sikh monastic Nirmal-akhāḍā and the quasi-monastic Nihaṅg are patently compromises with the overall Indian trend to establish monastic traditions to express full-time involvement with redemptive practice. During the last two centuries only, the monastic Udāsīn order (founded by Nānak's elder son Śri Chand) has achieved a most successful rapprochement with Hindu elements. Its disciplinary, sartorial, cenobitic settings are identical with those of the Hindu *sannyāsin* ("holy man"). They refer to the *Granth Sahib*, the sacred book of the Sikhs, as their basic text, in spite of the fact that their intramonastic and intermonastic discourse proceeds on Sanskritic, Vedāntic (religio-philosophical) lines similar to those of the orthodox Hindu orders. This accounts for the fact that the Udāsīns are now respected as equal to the most prestigious and ancient Hindu orders.

Taoism. Taoism, a Chinese religion based on folk religion with Buddhist influences, with some very weak emulation in Japan, holds a middling position with respect to monastic ventures, lying somewhere between the powerfully antimonastic Confucian schools that always represented the official culture and mainstream of sophisticated Chinese opinion and the radically monastic Buddhists. Some scholars believe that since Taoism originated in the southwestern parts of China, Indian influences are conceivable. The chief object of Taoism, however, is not the redemptive, salvational purpose evinced in other scripturally based religions, Eastern and Western. The ultimate aim of the Taoist sage was longevity or ultimate physical immortality rather than salvation from this world or the self. The Taoist quest after the elixir of life, and its expression in cryptic and enigmatic poetry that is well known to, and generally misunderstood by, European and American seekers of the mysterious East in the 20th century, is in no way comparable to the supererogatory search of the monastics thus far discussed. The Taoist settlements of sages, in forests and mountain glades as well as in the cities, are, at best, analogous to the eremitic type of proto-monasticism. When Taoist settlements were cenobitic or celibate, these features were indeed incidental to Taoism, which defies and rejects rules of any corporate kind.

Aim of the Taoist sage

Other Eastern varieties. Monastic orders are thus either of Mediterranean or of Indian origin. The connections between the monasticisms of the two regions are

immensely complicated, since the Indian subcontinent has absorbed or generated traditions that, though abhorrent to the orthodox Islām of the Arabic *'ulamā'* are nevertheless Muslim rather than Hindu in origin. North Indian Hindus have felt a strong attraction to Ṣūfī (Islāmic mystical) poetry, and dozens of Ṣūfī saints are worshipped by Muslims and Hindus alike. With India as one of the centres of monastic diffusion, new quasi-monastic types can be expected to spring up in the present or near future. In a strictly descriptive account, leaving aside historical development, the Ṣūfī orders must be seen as separate from both the Indian and the Mediterranean backgrounds.

South Asian quasi-monastic groups

Of the slightly less than 100 monastic and quasi-monastic orders in South Asia, well over half are local and regional growths. They usually lack even a body of rules and conventions that would be recognized or accepted by a wider Hindu-Buddhist-Jaina consensus. About a dozen orders are rejected and feared as heretical, outside the pale of the acceptable, and charged with using religious pretexts to indulge in antisocial behaviour. The Hindu and Buddhist Tantric sects (practicing occult, esoteric, meditative techniques) represent esoteric countermonasticism in India, though they have been accepted fully in certain Tibetan Buddhist hierarchies.

Of the not numerous but clearly evident monastic or quasimonastic organizations of recent origin in other parts of Asia, the Vietnamese Cao Dai achieved some recognition. They had a military organization and their own army "regulars" up to the mid-1950s; an eclectic theology with such heterogeneous patron saints as the 19th-century French novelist Victor Hugo, the World War II British prime minister Winston Churchill, and the Buddha; and a monastery-fortress in south central Vietnam. The members were bound by vows that did not include celibacy or poverty but stressed obedience to the hierarchy.

Religions of the West. *Judaism.* Judaism and Islām, the two Western religions that assume a father-oriented, social hierarchy as the supreme secular value, did not generate monastic traditions as part of their official institutions. The Essenes of the Qumrān community were, in their own vision, inimical to the ecclesiastic centre and marginal to the official Judaic complex. The weak eschatology (doctrine of the last times) of Jewish theology might account for the lack of a lasting monastic quest, which is typically inspired by individual salvational expectations.

Islām. In a somewhat milder fashion, this holds for Islāmic orders as well. Whereas some Jewish prophets might have had celibate leanings, the Prophet Muḥammad discouraged celibacy. Non-Arabic Islām, nevertheless, generated monastic orders, "Ṣūfīsm" being the generic name for a monastic attitude rather than for monastic institutions. The Bektaşi (see above) and the Sanūsīyah (conservative order founded in the 19th century) are typical for the marginal status of monastic settings in Islām; vestigial rules and formalized vows are discernible, but the main thrust of these monastics was of an interpersonal type, centring on the relation between the individual teacher of esoteric wisdom (*murshid*) and his disciple (*murīd*) and on the practices of chanting and meditation on the secret or known names of God (*dhikr*) and of other ecstasy-producing methods. The "way" (*ṭarīqah*) meant something that, by implication, was not accessible to the pious, orthodox Muslim alone. The Naqshbandīyah order, which originated in Turkic-speaking areas of southwestern Central Asia, became widespread in the Islāmic Middle Ages, rediffusing from India into the western reaches of the Ottoman Empire (14th–20th centuries). The actual or alleged ingestion of *Cannabis* drugs (such as hashish) and the nonconformist, antilegalistic doctrines of the order make it attractive on the popular level. The ritualization of the esoteric, contrasted with that of the social and the civil in the official Muslim prayer, seemed to provide an outlet and an alternative for a large number of devout but nonconformist Muslims, much as the modern cultic movements (such as spiritualist, "hippie," and similar groups) do for the religiously alienated in the West. Nonconformity to the official doctrine was often enhanced by unexpected or deviant behaviour; thus, the Sanūsīyah brethren prepared and used a variety of perfumes for their personal toilets. The element of rebellion, frequently manifested in eccentric behaviour, is typical for a setting where the official religion is antimonastic, as is the case of Islām.

Ṣūfī orders

Christianity. Since the terms monk and monastic are historically and etymologically Christian terms, the ideal-type monasticism is the Christian type by a semantic fiat —thus, the denotation of monastic terms has been extended to religions other than Christianity, the lexical donor for monastic terminology.

An overall view of Christian monastic history reveals a shift of emphasis from the contemplative to the socially active; this shift, if observed in a geographical dimension, moves roughly from East to West. The Eastern Orthodox and other Greek-liturgy-based sections of Christianity generated highly meditative orders, the Mt. Athos (Greece) complex being the most famous among them. The large variety of Roman Catholic orders displays eclectic emphases: the Benedictines, Franciscans, and all the orders designated as "minor" (in the Latin sense of humble or modest, rather than hierarchical or organizational) emphasize meditation; the Dominicans should be called "major"—though they are not—because the areas of preaching, scholastic continuity, and evangelizing rank far above contemplation in their order; and the Society of Jesus, or Jesuits (founded 1534), stands on the other end of the contemplative–social-centred continuum—teaching, social work, and the active life being regarded as the quintessence of supererogatory piety that is so important to this powerful organization.

Viewed from the social-centred end of the continuum, certain institutions in the Protestant tradition should be called monastic. The Taizé (France) communities of the Reformed Protestant tradition, founded in the 1940s, initiated an ecumenical monastic movement. Where emphasis is on faith rather than on works, monasticism would seem to be a viable expression of the Protestant tradition —yet, due to a set of historical accidents whose ideological summation was described in *The Protestant Ethic and the Spirit of Capitalism* by the German sociologist Max Weber (1864–1920), the operational emphasis has been on active engagement in the world rather than on seclusion. This explains why the various kinds of part-time Protestant retreats (linked to places especially designated for recuperation from the Christian involvement in work) are often placed in rural settings, and where they are urban, there is usually an apology at hand. Professional Western monasticism, by contrast, never made much of the rural–urban division, with important monastic centres randomly built in rural and urban settings; it is only the eremitic and some quasi-monastic types that insisted on rural or sylvan environments.

Ecumenical monastic groups and retreats

MONASTICISM TODAY

A discernible trend can be noticed in modern Western monasticism. It appears to be directed towards an enhanced individual liberalism, covertly or overtly condoned and granted to monks who wish to reinterpret fundamental traditions in the light of individualistic experience. If the work of Teilhard de Chardin, the Jesuit paleontologist, and of the Trappist monk Thomas Merton are in any way typical of this trend, it may be a clue for the future of Christian monasticism. Even though the disciplinary bases of the standard religious orders are likely to remain conservative for a very long time, there is much more ideological permissiveness. Individual monks and their disciples have been interpreting the monastic ideal in psychological, anthropological, phenomenological, and existentialist terms. It is perhaps the Christian monks of the future rather than nonmonastic priests and ministers who will seek a trans-Christian ecumenism through religious experimentation. Of significance is the fact that Thomas Merton was killed in an accident while in Bangkok to visit the Dalai Lama (leader of Tibetan Buddhists). Monks had been the religious entrepreneurs of early Christianity—they may well emerge as innova-

tors in an era of infinitely greater inter-religious information and diffusion.

Sponsored largely by college-campus religious organizations (both Protestant and Catholic), a retreat pattern based on ecumenical concerns has been emerging in North America and in Great Britain during the second half of the 20th century, though much less so in other parts of the Western world. There were roughly 1,000 such para-academic, campus-sponsored organizational retreats in North America alone in 1968. Most were Protestant, but with an increasing participation by Catholic and Jewish groups; almost all the participants were of college age. No vows of any sort are enforced or even recommended, but there is emphasis on meditation, discussion, and religious reflection. The projection of ideas about the future of monasticism is easier to discuss than that of the future of religion in general. Since the end of World War II (1945) there has been a highly visible resurgence of monastic ideals and an overall increase of monastic organizations in all parts of the world outside the Communist-dominated countries. The models were admittedly Christian, particularly Jesuit in the case of neo-Hindu orders—such as the Ramakrishna Mission (an eclectic Hindu order founded in the 19th century), which has over a dozen well-established centres in America and Europe. One Hindu monk, a swami—which correctly means an ordained Hindu monk—presides over each of these centres, often assisted by a younger monk; in theory, these centres train monks in the *sannyāsin* tradition, but they actually serve a European and American laity committed in various degrees to the Vedānta theology. On the model of the Ramakrishna Mission, there are some two dozen other India-originated organizations of this quasi-monastic or semimonastic type that have spread over the Western world, some of them with considerable wealth and popularity. Among such groups are the Self-Realization Fellowship, founded by the late Swami Yogananda Paramahamsa, with its headquarters in San Diego, California; and the Hare Ram Hare Krishna with chapters all over North America and western Europe. Founded by Swami A.C. Bhaktivedanta, it attracts and assembles young men and women who temporarily dress in the monastic ochre robe of Hindu monks and chant the names of the Lord as incarnated in Rāma and Kṛṣṇa (Krishna), accompanied by simple, arcane dance movements. Zen Buddhism has been established in North America and Europe, with Zen churches and centres in many major cities. Again, it is usually only the leader and the teacher who is a Japanese Buddhist monk, instructing a variously interested laity.

Infusion of Oriental groups in the West

Since the 1960s much attention has been given to the monastic potential of the communes, the "hippie" and kindred congregations in various parts of the Western world, some of whom have already established settings that have many genuine monastic traits—though with none of the foundational vows of traditional monasticism, Eastern or Western. The growing concern with mystical experience since the mid-20th century, with or without the use of psychedelic ("mind-expanding") drugs, and the general alienation from the official religions parallel many, if not most, of the monastic creations of the last 2,000 years or more.

In the countries of non-Christian monastic traditions (*i.e.*, India, Sri Lanka, Burma, Thailand, Laos, Vietnam, and Japan), monasticism is, in varying degrees, on the decline. If the monastic distribution of the future could be assessed, an intelligent appraisal might be that monastic commitments and organizations will increase in the West and decline in Asia, perhaps in direct proportion to the changing religious concerns of the societies involved —the West, often believed to have had a surfeit of material progress, might seek the spiritual; the East, tired of contemplation, might turn to the pursuit of material progress on the former Western model.

ELDER (ed.), *Chapters in Indian Civilization* (1970), an excellent short survey of the Jaina monastic tradition juxtaposed with the Hindu and Buddhist orders; DAVID KNOWLES, *Christian Monasticism* (1969), a good survey of the history of monasticism and religious orders; NORBERT MCMAHON, *The Story of the Hospitallers of St. John of God* (1959), a history of monastic knightdom in the Crusade and post-Crusade eras; R.J. MILLER, *Monasteries and Culture Change in Inner Mongolia* (1959), an anthropological account of Buddhist monachism in Mongolia (the only study in English to date); J.A.N. MULDER, *Monks, Merit and Motivation* (1969), a report on monastic behaviour in contemporary South and Southeast Asian Buddhism; WALTER NIGG, *Warriors of God: The Great Religious Orders and Their Founders* (1959), an excellent account of the inceptors of monastic traditions, with special reference to the paramilitary trends in early monastic attitudes; J.C. OMAN, *Mystics, Ascetics, and the Saints of India* (1903), a classic work that is a fair account of the monastic situation in both ancient and contemporary India; *Palladius: The Lausiac History*, trans. and annot. by R.T. MEYER (1965), a translation of one of the original classics on early Christian monasticism; J. PRIP-MØLLER, *Chinese Buddhist Monasteries*, 2nd ed. (1967), a good account of the monastic ecology and discipline of the Chinese orders; D.T. SUZUKI, *The Training of the Zen Buddhist Monk* (1934), a classic by a famous Zen scholar; L.A. WADDELL, *The Buddhism of Tibet*, 2nd ed. (1934), the classic by way of an overall view of Lamaism; J.B. WILLIAMSON, *The History of the Temple* (1924), an erudite historical account of the Templars; A.W. WISHART, *A Short History of Monks and Monasteries* (1902), a classical introduction to Christian monachism; NUR YALMAN, "Islamic Reform and the Mystic Tradition in Eastern Turkey," *Archives of European Sociology*, 10:41–60 (1969), an excellent sociological account of Ṣūfism in action; ERIK ZURCHER, *The Buddhist Conquest of China*, 2 vol. (1959), an excellent, learned study of Chinese monastic and lay Buddhism and its conflicts with the official Chinese culture.

(A.Bh.)

Mondrian, Piet

Piet Mondrian, Dutch painter and leading member of the abstract art movement de Stijl, developed a distinctive style of nonobjective painting based on the reduction of pictorial elements to vertical and horizontal lines, using the three primary colours and noncolours. His work has exerted a powerful influence on 20th-century art, including architecture, advertising art, and typography.

He was born Pieter Cornelis Mondriaan on March 7, 1872, in Amersfoort, The Netherlands, the second child of Pieter Cornelis Mondriaan, Sr., who was headmaster of a Calvinist primary school there. Mondrian (who dropped the second *a* in his name when he moved to France in 1912) grew up in a stable yet creative environment; his father was part of the Protestant orthodox circle that formed around the conservative Calvinist politician Abraham Kuyper, and his uncle Frits Mondriaan belonged to The Hague school of landscape painters. Both he and Mondrian's father, an amateur draftsman, gave him guidance at the age of 14, when he began to study drawing on his own.

Mondrian was determined to become a painter, but at the insistence of his family he first obtained a degree in education; by 1892 he was qualified to teach drawing in secondary schools. That same year, instead of looking for a teaching position, he took painting lessons from a painter in a small town not far from Winterswijk, where his family now resided, and moved to Amsterdam to register at the Rijksacademie. He became a member of the art society Kunstliefde in Utrecht, where his first paintings were exhibited in 1893, and in 1894 joined the two local

artist societies in Amsterdam, Arti et Amicitiae and St. Lucas; during this period he still attended the evening courses at the academy for drawing, impressing his professors with his self-discipline and effort. In 1897 he exhibited a second time, at Arti et Amicitiae.

Up to the turn of the century, his paintings followed the prevailing trend of art in The Netherlands: landscape and still lifes painted in subdued hues with picturesque lighting effects, and subjects chosen from the meadows and polders around Amsterdam. In 1899 he was commissioned to paint a ceiling in a large private house in Amsterdam, where, in homage to the youngest son, he painted an allegory of the seasons, somewhat reminiscent of the Dutch painter Matthijs Maris, the uncle of his close friend Simon Maris. In 1901, he competed for the Prix de Rome, was successful in the initial contest, but did not reach the final competition. During the same year, he made a short trip to Spain with Simon Maris, but the country left no lasting impression on him. Mondrian achieved artistic reputation and a certain notoriety in 1903, when he won the Willink van Collem Prize of Arti et Amicitiae for a still life. That same year he visited a friend in Brabant; the calm beauty of the landscape he discovered in the province proved to be an important influence on him. He stayed on in Brabant, and the following year became a period of self-discovery and intense concentration on his artistic gifts: and by the time he returned to Amsterdam in 1905, his art had visibly changed. The landscapes he painted of the surroundings of Amsterdam, mainly on the River Gein, show a pronounced rhythmic framework and lean more toward compositional structure than toward the usual picturesque values of light and shade; windmills, farmhouses, and series of trees were his preferred subjects at this stage of his art. But his painting still remained within the traditional boundaries of contemporary Dutch art.

Influence of Postimpressionists and Luminists. In 1907 the Quadrennial Exhibition was held in Amsterdam, featuring such painters as Kees van Dongen, Otto van Rees, and Jan Sluijters, Postimpressionists who used pure colours boldly. Their preference for colour must have impressed Mondrian considerably, for in the same year he painted "The Red Cloud," a rapidly executed sketch dominated by colour, which initiated a series of works in which Mondrian experimented with his newly discovered values of colourism. "The Red Cloud" was done at Oele, where Mondrian stayed at the invitation of a friend. There, as well, Mondrian's monumental work "Woods Near Oele" was conceived, the final version being executed in his studio in 1908. In this painting new values appear: a new linear movement, somewhat reminiscent of the Norwegian painter Edvard Munch, and a new colour scheme, based on hues of yellow, orange, blue, violet, and red, suggestive of Expressionist paintings. With this vigorous painting of considerable size (50⅜ × 62¼ inches), Mondrian broke away from the national tradition of Dutch painting and took his place in the ranks of European art.

In 1908 his new style was reinforced by his acquaintance with the Dutch artist Jan Toorop, whom he met during a summer trip to Domburg, a seaside resort where artists and art patrons spent their holidays. Toorop, at that time, led the Luminist movement in The Netherlands, which endeavoured to render light by a series of dots or short lines of primary colours (*e.g.*, blue and yellow), not completely mixed, so that the secondary colour (green) is formed in the viewer's eye as he stands away from the picture. This technique, known as Divisionism, produces brighter secondary colours than if they were mixed on the palette. In these years Mondrian concentrated on this use of colour and limited his palette to the primary hues: a painting such as "Windmill in Sunlight," executed mainly in yellow, red, and blue, proved his mastery in this evocation of strong, radiant sunshine. But in a painting such as "The Red Tree," also dated from the same year, 1908, Mondrian expressed his own vision of nature by creating a balance between the contrasting hues of red and blue, between the violent movement of the tree and the blue sky, thus producing a sense of equilibrium, which is his prevailing aim in his representation of nature. In 1909 Mondrian's Luminist works were exhibited in a large show at the Stedelijk Museum in Amsterdam, together with works of his more prominent contemporaries. Thus, Mondrian firmly established himself among Dutch avant-garde painters.

Luminist period

The year 1909 was important for Mondrian's career from another point of view: in May he joined the Theosophical Society, which espoused the mystical belief that all that exists in the universe emanates from one source, that spirit and matter are inseparably united. In the following years Mondrian's new philosophy was reflected in his painting: he concentrated on large forms in nature, such as the lighthouse in Westcapelle, which he had painted before in a Divisionist technique, but which he rendered now—in 1909–10—with a renewed interest in form. Subjects such as the church at Domburg and an impressive Zeeland windmill express a similar striving for monumental forms; "Evolution," his triptych of three standing human figures, painted in 1910–11, shows a surprising similarity between the human figure and architectural subjects, thus stressing the symbolic identity between man and the inanimate structures he creates. His change toward monumental forms is apparent in his paintings of dunes, first painted in 1909 in a Divisionist technique; but more versions of the same motif in 1910 show the concentration on large planes of colour, which were to be a characteristic of his later work. In 1910 Mondrian's Luminist works attracted considerable attention at the St. Lucas Exhibition in Amsterdam; and in 1911 he submitted one of the dune paintings, in which he expressed the infinitude of nature, to the Salon des Indépendants in Paris, his first bid for international recognition.

Cubist period in Paris. That same year, in Amsterdam, Mondrian saw for the first time the early Cubist works of Picasso and Braque. Mondrian was profoundly im-

pressed, so much so that early in 1912 he moved to Paris, where he took lodgings in the Montparnasse district; from this time, in order to make it easier to pronounce his name in French, he spelled his last name with only one *a*. Almost immediately he began to adapt the precepts of Cubism to his own use, and two versions of "Still Life with Gingerpot," done during the winter months of 1911–12, make this apparent. In the first version, the objects are rendered as recognizable forms from everyday life, a table, cloth, jars, etc., united into a rigid composition around the central object, a ginger pot; in the second version the same objects have lost their daily-life identity and have been transformed into compositional structures: what was a knife in the first version is now a diagonal accent in the pictorial score.

The second version of his "Still Life with Gingerpot" stands at the beginning of Mondrian's Cubist period, which lasted from 1912 to 1917. His Cubist development is characterized by an increasing interest in the painting's composition and by the constant subordination of the factual reality of objects to their role in the structural entity of the picture. His compositions of trees, of facades of Parisian houses, and of scaffoldings during this period are proof of this urge to reduce individual forms to a general formula; Mondrian went beyond the trend of analytical Cubism and its tendency to break forms up into their component parts by striving for a vision of reality that surpasses the individual object. His Cubist style, from 1913 onward, showed the first steps toward abstraction—abstraction being understood as the attempt to strip objects of their factual connotations. On the other hand, Mondrian still kept within the boundaries of Cubism by limiting his colours to ochre, brown, and gray so as not to distract from form and by observing the Cubist scheme of composition, in which the painting gravitates toward a central focus, thus stressing the central part of the composition and leaving the corners almost untouched; the result of this scheme is his oval compositions from 1913 to 1917. In an attempt to reduce the elements of his composition even further, Mondrian avoided curved lines and diagonal accents and increasingly used only vertical and horizontal lines. The course of his development can be followed in his sketchbooks (edited by R.P. Welsh and J.M. Joosten, Amsterdam, 1969) in the transformation of the theme of trees and of the Domburg church into Cubist compositions.

First steps toward abstraction

In the summer of 1914 Mondrian returned to The Netherlands to visit his father, who was seriously ill; much to his dismay, the outbreak of World War I prevented him from returning to Paris. In 1915 he settled at Laren, where he became acquainted with Dr. M.H.J. Schoenmaekers, a Theosophical philosopher whose works on the symbolical meaning of lines and on the mathematical construction of the universe had a decisive influence on his vision of reality. In Laren he made friends as well with S.B. Slijper, who supported him both as a patron and a friend, and with the painter Bart van der Leck, who had developed a monumental style derived from the principles of mural painting. Through van der Leck he met Theo van Doesburg, one of the avant-garde artists of this time. During these years he developed his Cubist style to its extreme limits, mainly in his painting of the church at Domburg and in a new theme, "Pier and Ocean." The ultimate version of this theme, completed in 1917 and shown at the Rijksmuseum Kröller-Müller, marks the final stage of his Cubist style: a composition of vertical and horizontal line fragments in black on a white background, concentrated into an oval shape.

De Stijl. After this painting a new and fundamental change occurred in Mondrian's work: the reduction of existing forms into a pictorial formula is now replaced by a complete rejection of external subject matter. This step was taken not only by Mondrian but by the four painters who together founded the art periodical and the movement of de Stijl ("the Style"): Theo van Doesburg, the initiator of the group, Mondrian, van der Leck, and Vilmos Huszar. The principles of the group were the complete rejection of visually perceived reality as subject matter, and the restriction of the pictorial language to its most basic elements—the straight line and the right angle (hence the use of the vertical and the horizontal line), the three primary colours—yellow, red, and blue—and the three primary noncolours—white, gray, and black. The scope of this new style, for which Mondrian coined the term neoplasticism, was to free the work of art from the momentary visual perception and from the personal temperament of the artist. The objectivity that Mondrian had sought for so long now seemed to be within reach: he could now render "a true vision of reality" in his painting.

Neoplasticism

Mondrian's first neoplastic paintings, which did not derive their composition from a fragment of reality but from an overall view of the harmony of the universe, date from the summer months of 1917: rectangles in soft hues of primary colours painted on a white background. His compositions, in opposition to his Cubist style, were now based on colour and appear to expand over the borders of the canvas into space beyond the picture. In 1918 he reintroduced lines into his painting, linking the colour planes to one another and to the background by a series of black vertical and horizontal strips, thus creating rectangles of colour or of noncolour; the "Composition: Colour Planes with Gray Contours" of 1918 initiates this phase. In 1918 and 1919 he executed a series of rhomboid compositions, subdivided into a pattern of regular squares differentiated by thick black lines and by soft hues of ochre, gray, and rose. In 1919 as well, he created two versions of a checkerboard composition, one in dark and one in light colours, in which the difference of the hues transforms this common pattern into a rhythmic sequence of squares. But only in 1920 and the following years did his neoplastic style reach its full maturity.

This definitive phase in his search for an objective vision of reality was reached in Paris; Mondrian returned there in 1919. In spite of his move, he retained his close collaboration with de Stijl. Mondrian had already published "The New Plastic Art in Painting," in the first issue of *De Stijl* in 1917, and was one of the signers in 1918 of the first manifesto of de Stijl, which stressed a universal, rather than an individualistic, view of the world. And in 1920, coinciding with his mature style, his important essay "Le Néo-plasticisme," published in France, further articulated his theories on abstract art previously published in *De Stijl*.

Mature style. In 1921 his mature style emerged clearly: Mondrian now limited his palette to the primary colours of yellow, red, and blue. In 1922 an exhibition of his works, organized at the Stedelijk Museum in Amsterdam by friends on the occasion of his 50th birthday, was a retrospective progression of his paintings; it traced the path from his beginnings in the Dutch traditional style to his abstract paintings depicting a universal harmony through the use of horizontal and vertical lines and primary colours and noncolours. He had now reached his goal: the creation of what he considered the true image of reality. But he did not stand still: from 1922 to 1938 he concentrated on achieving an ever increasing clarity and purity in his paintings. In 1925 he broke with de Stijl on account of Theo van Doesburg's use of diagonal elements in his work: he considered this an aberration from the strict universality of the neoplastic principles. As an answer to van Doesburg, he resumed his rhomboid compositions without the use of diagonals: the vertical-horizontal opposition was maintained, and only cut by the diagonals of the frame, which presented the rhomboid theme.

Stedelijk retrospective expedition

Mondrian did not exhibit frequently: from 1922 to his arrival in the United States, he never held a one-man show. In 1930 he exhibited with the Cercle et Carré group, and in 1931 with Abstraction-Création, the group that stood next to Cercle et Carré. In the years after 1933 his works became more austere and severe. During this period, in 1934, he met the young American artist Harry Holtzman and the English painter Ben Nicholson, both of whom were soon to become helpful to him. Nicholson urged him to publish his essay "Plastic Art and Pure Plastic Art" in the international publication *Circle*, of

which he was coeditor; and when Mondrian decided to leave Paris in 1938, under the shadow of the invasion of Czechoslovakia by Hitler, he was welcomed in London by members of the *Circle* group. For two years he worked and lived in a London suburb, but the bombardment of the city forced him to flee to New York in 1940, where he was welcomed by Harry Holtzman, the art collector Peggy Guggenheim, James Johnson Sweeney, the art critic and museum director, and other members of the American artistic vanguard.

American phase. There, the last change in Mondrian's work occurred. Inspired by his regained freedom, New York's pulsating life, and the new rhythms of American music, he broke away first from the austere patterns of black lines, replacing them with coloured bands, and then substituted for the continuous flow of these bands a series of small rectangles that coalesced into a rhythmic flow of colourful vertical and horizontal lines. His late masterpieces, "New York City" and "Broadway Boogie Woogie," exhibited in 1943 and 1944, in the first personal exhibition Mondrian had after 1922, express this new vivacity. Buoyed by his hope for a better future, Mondrian started his "Victory Boogie Woogie" in 1943; it remained, however, unfinished: Mondrian died from pneumonia on February 1, 1944, in New York, at the age of almost 72.

Objectives in art. Mondrian's work—the most important collection of which is found in The Hague Gemeentemuseum—should not be considered merely as an artistic innovation. Certainly, the consistent development of his neoplasticism was an outstanding feat in the history of modern art, and Mondrian's work foreshadowed what was later called "geometric abstraction." He must have been conscious of his revolutionary innovation and of its implications: in a self-portrait of 1918, he painted himself against a background of one of his new, and at that time strange, pictures, thus stressing the historical importance of the new de Stijl principles.

Ethical significance of his work

But Mondrian's work goes beyond merely aesthetical considerations: his search for harmony through his painting has an ethical significance. Rooted in a strict puritan tradition of the Dutch Calvinism of his paternal home, he continually strove for purity during his long career as an artist. This purity is most clearly explained by the double meaning of the Dutch word *schoon*, which means both "clean" and "beautiful." The beauty of Mondrian's work consists in its purity, a purity that points beyond a painting to show humanity the way toward a life of health and clarity. When, in 1920, Mondrian dedicated his booklet "Le Néo-plasticisme" to "future men," he tried to indicate that art can be a guide to humanity, that it can work toward eliminating casual facts of appearance and the arbitrary outlook of the individual, and thereby substitute a new harmonious view of life for the conventional tragic conception of existence. To this purpose Mondrian chose the strict and rigid language of geometry to produce first of all an extreme purity, and on another level, a Utopia of superb clarity and force. Mondrian is a pioneer in modern art, but he is champion for humanity as well: he described the goal he set out to meet through his paintings in his 1937 essay in *Circle*: "One serves mankind by enlightening it."

MAJOR WORKS

"The Red Cloud" (1907; Haags Gemeentemuseum, The Hague); "Woods near Oele" (1908; Haags Gemeentemuseum, The Hague); "Windmill in Sunlight" (1908; Haags Gemeentemuseum, The Hague); "The Red Tree" (1908; Haags Gemeentemuseum, The Hague); "Still Life with Gingerpot" (1911–12; Haags Gemeentemuseum, The Hague); "The Gray Tree" (1912; Haags Gemeentemuseum, The Hague); "Oval Composition (Trees)" (1913; Stedelijk Museum, Amsterdam); "Blue Facade" (1914; Museum of Modern Art, New York); "Composition" (1916; Solomon R. Guggenheim Museum, New York); "Composition in Black and White" (1917; Rijksmuseum Kröller-Müller, Otterlo, the Netherlands); "Composition in Colour A" (1917; Rijksmuseum Kröller-Müller, Otterlo); "Composition III with Colour Planes" (1917; Haags Gemeentemuseum, The Hague); "Composition: Colour Planes with Gray Contours" (1918; Max Bill Collection, Zürich); "Composition in Diamond Shape" (1919; Rijksmuseum Kröller-Müller, Otterlo); "Composition Checkerboard" (1919; Haags Gemeentemuseum, The Hague); "Composition with Red, Blue and Yellow Green" (1920; Wilhelm Hack Collection, Cologne); "Composition with Red, Yellow, and Blue" (1921; Haags Gemeentemuseum, The Hague); "Composition 2" (1922; Solomon R. Guggenheim Museum, New York); "Composition 1 with Blue and Yellow" (1925; Kunsthaus, Zürich); "Composition with Yellow and Blue" (1929; Boymans-van Beuningen Museum, Rotterdam); "Fox Trot A" (1927; Yale University Art Gallery, New Haven); "Composition with Red, Blue and Yellow" (1930; Mr. and Mrs. Armand P. Bartos Collection, New York); "Composition with Yellow Lines" (1933; Haags Gemeentemuseum, The Hague); "Vertical Composition with Blue and White" (1936; Kunstsammlung Nordrhein-Westfalen, Düsseldorf, West Germany); "Composition with Blue" (1937; Haags Gemeentemuseum, The Hague); "Composition London" (1940–42; Albright-Knox Art Gallery, Buffalo); "New York City I" (1941–42; Sidney Janis Gallery, New York); "Broadway Boogie Woogie" (1942–43; Museum of Modern Art, New York); "Victory Boogie Woogie" (1943–44; Burton Tremaine Collection, Meriden, Connecticut, on loan to Museum of Modern Art, New York).

BIBLIOGRAPHY. PIET MONDRIAN has written a series of essays on art and on the task of art in daily life. The first, "De Nieuwe Beelding in de Schilderkunst" (on the new plastic art in painting) was published in *De Stijl*, vol. 1 (1917), a supplement to it in vol. 2 (1918). The "Dialog over de Nieuwe Beelding" (dialogue about the new plastic art) also appears in vol. 2. Volume 3 contains a trialogue Naturlijke en Abstracte Realiteit, published in English translation ("Natural Reality") in M. SEUPHOR, *Piet Mondrian: Life and Work* (1956). In 1920 Mondrian published "Le Néo-plasticisme: principe général de l'équivalence plastique," reprinted in The Hague *Catalogue of Mondrian Exhibition* (1955). A German adaptation of this essay, with four other texts, was published as a Bauhausbuch, *Die neue Gestaltung* (1925). In 1931 Mondrian wrote "Kunst en Leven" (art and life), published in English translation in H.L.C. JAFFE, *De Stijl, 1917–1931* (1956). His later writings are collected in *Plastic Art and Pure Plastic Art, and Other Essays*, ed. by R. MOTHERWELL in 1945, after Mondrian's death.

The first comprehensive monograph on Mondrian was M. SEUPHOR, *Piet Mondrian: Life and Work* (1956), with a catalogue raisonné of all Mondrian's paintings and an extensive bibliography. This important publication was followed by a series of other monographs: O. MORISANI, *L'Astrattismo di Piet Mondrian* (1956), dealing with the theoretical background of Mondrian's art; D. LEWIS, *Mondrian* (1957); and S. HUNTER, *Mondrian* (1958), two works that give a selection of his most characteristic phases; and C.L. RAGGHIANTI, *Mondrian e l'arte del XX secolo* (1962), a brilliant survey, but proposing some extravagant hypotheses. Further monographs on Mondrian are: F. MENNA, *Mondrian, cultura e poesia* (1962); F. ELGAR, *Mondrian* (Eng. trans. 1968); A. BUSIGNANI, *Mondrian* (Eng. trans. 1968); I. TOMASSONI, *Piet Mondrian* (1969), in Italian; L.J.F. WIJSENBEEK, *Piet Mondrian* (Eng. trans. 1969), written by the director of the Hague Municipal Museum, where the largest collection of Mondrian's work can be seen; and H.L.C. JAFFE, *Mondrian* (1970).

Various exhibition catalogs give important information on Mondrian's work and contain valuable introductions: *Zürich*, Kunsthaus (1955), with introduction by M. BILL; *Basel*, Galerie Beyeler (1964–65); with introduction by G. SCHMIDT ("Mondrian Today"); *Toronto, Philadelphia, The Hague*, ed. by R.P. WELSH (1966); *The Hague* (1968), catalog of the Mondrian collection in the Municipal Museum, ed. by C. BLOK, with an introductory essay; *Paris*, Orangerie des Tuileries (1969), with introduction by M. SEUPHOR; and *New York*, Solomon R. Guggenheim Museum (1971).

A range of articles deal with various aspects of Mondrian's art and with its implications: the series starts with Mondrian's pupil, C. VON WIEGAND, "The Meaning of Mondrian," *Journal of Aesthetics*, 2:62–70 (1943); and continues soon after Mondrian's death with two articles by J.J. SWEENEY: "Mondrian," in *Eleven Europeans in America*, MMA *Bulletin*, no. 13, pp. 35–36 (1946), and *Piet Mondrian* (MMA, 1948); G.C. ARGAN published a fundamental article on Mondrian in his *Studi e Note*, pp. 155–183 (1955). See also MARTIN S. JAMES, "The Realism Behind Mondrian's Geometry," *Art News*, 56: 34–37 (1957), and "Mondrian and the Dutch Symbolists," *Art Journal*, 23:103–111 (1963–64), dealing mainly with Mondrian's early period. M. SEUPHOR, "L'humanisme de Mondrian," *Aujourd'hui*, no. 2, pp. 5–9 (1955), deals with the sense of Mondrian's art, as experienced by a close friend. R.P. WELSH and J.J. JOOSTEN published *Two Mondrian Sketchbooks, 1912–1914* (1969), thereby casting light on the working process of Mondrian in his transitory phase.

(H.L.C.J.)

Monet, Claude

The art movement known as Impressionism began to take form about 1864, but it was not so identified until ten years later, when Claude Monet exhibited an oil sketch of the harbour at Le Havre under the title "Impression: Sunrise." This small, unpretentious study was sarcastically criticized by a journalist, who headed his article "Exhibition of the Impressionists," thus christening the movement that was to succeed Realism, led by the painters Gustave Courbet and Édouard Manet. Other great artists, among them Pissarro, Renoir, and Sisley, contributed much to the Impressionist style, but it was Monet who was its initiator, leader, and most undeviating advocate. As the critic Félix Fénéon wrote in 1888, "the word 'impressionism' was created for him, and it fits him better than it does anyone else."

Monet standing in front of one of his water-lily paintings in his studio, 1920.

Childhood and early works. Claude Monet, the eldest son of Adolphe Monet, a grocer, was born in Paris on November 14, 1840. In 1845 the family moved to Sainte-Adresse, near Le Havre, where Monet's father took over the management of his family's thriving ship-chandlering and grocery business. This event has more than biographical significance, for it was Monet's childhood, spent along the beaches, and his intimate knowledge of the sea and the rapidly shifting Norman weather from which his fresh vision of nature arose. Monet's first success as an artist came when he was 15, with the sale of caricatures that were carefully observed and well drawn. Also preserved from these early years is a page of pencil sketches of sailing ships, almost technical in their clear descriptiveness. His aunt, Mme Lecadre, was an amateur painter, and, perhaps at her suggestion, Claude was sent to study drawing with a local artist. But his life as a painter did not begin until he was befriended by Eugène Boudin, who introduced the somewhat arrogant student to the practice—then uncommon—of painting in the open air. A single day working with Boudin focussed his familiarity with outdoor light and his talent as an artist. The experience was a revelation that set the direction for more than 60 years of concentration on visible phenomena and on the innovation of effective methods to transform perception into pigment.

Influence of Boudin

Although oil landscapes have been painted at least since the 16th century, they were produced in the studio—ideas of nature rather than direct perceptual records. The English painters John Constable and J.W.M. Turner made small oil sketches outdoors before 1810, but it is unlikely that Monet knew these studies. He first visited Paris in 1859–60, where he was impressed by the work of the Barbizon school painters Charles Daubigny and Constant Troyon. To his family's annoyance, he refused to enroll in the École des Beaux-Arts. Instead, he frequented the haunts of advanced artists and worked at the Académie Suisse, where he met Camille Pissarro. This informal training was interrupted by a call to military service, which he began in Algeria, where he was excited by the African light and colour. In 1862 he returned to Sainte-Adresse, perhaps because of illness, again painted the sea with Boudin, and met the Dutch marine painter Johan Barthold Jongkind. Later that year he continued to study in Paris, this time with the academician Charles Gleyre, in whose atelier he met Frédéric Bazille, Alfred Sisley, and Pierre-Auguste Renoir. After disagreements with their master, the group departed for the village of Chailly-en-Bière, near Barbizon in the forest of Fontainebleau. It was also during this period—or at least before 1872—that Monet discovered Japanese prints, the decorativeness and flatness of which were to have a strong influence on the development of modern painting in France. Perhaps also, Monet's choice of Algeria for service was a result of his admiration for the Romantic painter Eugène Delacroix, whose colouristic work he had seen in Paris and who had visited Morocco in 1832.

The exceptional achievements of Monet's prolific youthful period can be measured in works completed between 1865 and 1870, before he had begun to fragment his brushstrokes into the characteristic broken touches that were to become the hallmark of Impressionist style. One of the most ambitious of these early works (which was never finished, supposedly because of negative comments by Courbet) was "The Picnic" (1865–66), named after Édouard Manet's notorious painting of the same name ("Déjeuner sur l'herbe") shown in the Salon des Refusés in 1863. But, quite differently from Manet's masterpiece, which was a parody of a Renaissance painting in a contemporary setting, Monet's painting, about 15 feet high by 20 feet wide, was a direct, unprovocative representation of a group of fashionably dressed picnickers in the forest of Fontainebleau. For a young painter attempting plein-air style, the size of his composition was absurd—far too large to complete in the open. Only a fragment of the original canvas, now in the Louvre, has been preserved, but the entire composition can be seen in a superb smaller version in the Pushkin Museum, Moscow, and its early Impressionist style in a large study of Bazille and Camille Doncieux, Monet's mistress, in the National Gallery of Art, Washington, D.C. Monet shared with Manet, however, the new concern for actual scenes of modern life rather than contrived historical, romantic, or fanciful subjects. Thus, Monet's "Picnic" was an extension, by virtue of a more immediate empiricism, of the Realism of Courbet. Camille wore the same fashionable clothes for the famous "Women in the Garden" (1866–67), also in the Louvre. In the garden of his rented house at Ville-d'Avray, near Versailles, Monet fashioned a device to lower the eight-foot-high canvas into a trench, so he could paint a life-size composition entirely in the open. Another major figure composition of this period, "The Terrace at Sainte-Adresse," was purchased by the Metropolitan Museum of Art in 1967 for $1,411,200. Unique among Monet's early works, it represents his family regarding the sea from their flower-covered terrace. Monet's letters and documents from this period speak plaintively of the critical state of his finances, the difficulties of his life, trouble with his eyes, and the problems attending the birth of his first child, Jean, in 1867. Indeed, until the 1890s, when he was a revered and prosperous master, Monet was continually in dire financial straits. These complaints are not verified, however, by his paintings of the same period, which reflect a comfortable and middle class home life: "The Luncheon" (1868; Stadelsches Kunstinstitut, Frankfurt, West Germany) represents Camille, fastidiously dressed, seated with young Jean at the table. An equally well dressed friend leans, watching, against the window sill, and a uniformed maid appears at an open door. The food, dishes, napery, and glassware are superbly and almost impressionistically rendered.

"The Picnic"

To paint *la vie moderne* ("modern life") was not to be the primary aim of Monet's art, although Impressionism, broadly viewed, was a celebration of the pleasures of middle class life. Of more significance in Monet's case was his ceaseless search for painterly means to implement his radical view of nature. "The River" (1868) or "The

Beach at Sainte-Adresse" (1867), both in the Art Institute of Chicago, give a better accounting than do the ambitious figure paintings of his advance toward the Impressionist style. Of all types and periods of Monet's painting, moreover, the beach and sea pictures of 1865–67—more powerfully painted than those of Boudin—seem closest to "normal" (*i.e.*, casual) vision. Monet was plainly trying not to copy the scene before him as examined in detail but to record on the spot the impression that relaxed, momentary vision might receive—what is seen rather than what is known, with all its vitality and movement. Boats, buildings, incidental figures, and the pebble beach are swiftly brushed in as flat colour patterns, with little attention to their weight or solidity.

Advance toward Impressionism

First Impressionist paintings. Monet's life during the '60s was precarious and itinerant, and he sold almost nothing; but several works were accepted for exhibition in the yearly salons, most notably, and with great success, a fine but not yet Impressionist portrait of Camille. In 1868 he won a medal in Le Havre. Despite difficulties, moreover, he was able to paint in Paris, Le Havre, Chailly, Honfleur, Trouville, Fécamp, and at other stations between Paris and the sea. The '60s came to an auspicious close at the Seine River resort known as La Grenouillère, at Bougival, where he and Renoir worked together for the first time. In canvases almost identical in style, they made rapid notations of pleasure-seekers and bathers, rowboats bobbing in the foreground, and the scintillating reflections in the lapping water. Regarded by Monet as "bad sketches," they were already Impressionist. Both artists' Bougival studies interpret the light and movement of outdoor life in strong, abbreviating strokes, improvised at the moment of perception, that together serve as equivalents for visual experiences never before so truthfully committed to canvas. In 1870 at Trouville, in broad, assured gestures, Monet painted a study of Camille on the beach (Tate Gallery, London). It is as animated an example of visual realism as had ever been painted: grains of sand remain embedded in the pigment.

As the '70s began, Monet continued his pursuit of natural phenomena. In order to avoid the Franco-Prussian War, he left his son and Camille, whom he had just married, and travelled to London. Here, with Pissarro, he must have seen work by English masters—perhaps even Constable and Turner—and was introduced by Daubigny to Paul Durand-Ruel, who was to become his dealer. In 1871 and 1872 he painted canals, boats, and windmills in Holland and worked again at Le Havre; "Impression: Sunrise" was a product of this stop. On his return, Monet rented a house at Argenteuil, on the Seine near Paris. The years he lived there mark the height of the group Impressionist movement. Sometimes joined by Renoir or another friend, he painted his home and family, the town, the river, and the pleasures of life on it and along its banks. In 1874 even Manet visited Monet and painted him working in the "floating studio" he had constructed the year before. Indeed, it was the younger artist who introduced the elder to the practice of painting in the open—not the other way around, as the historical sequence of the Realist and the Impressionist movements suggest. The radiant, luminous paintings of this period (1872–75) by Monet, Renoir, Sisley, Pissarro, and others remain today the most coveted and characteristic works of Impressionism as a collaborative venture.

Work at Argenteuil

Later Impressionism. Monet's celebrated method of producing works in series, each representing the same motif under different light and weather conditions, was not fully implemented until the '90s, but what is usually regarded as the first series was executed in or around the Gare Saint-Lazare in Paris during the winter of 1876–77. A total break with the customary Impressionist subjects, the engines belching smoke and steam in the great shed recall Turner's "Rain, Steam, and Speed—The Great Western Railway" of 1844 and prefigure the mechanical subjects painted by Italian Futurists after 1909. The summer of 1877, moreover, was the end of the idyllic art of Argenteuil. Monet's life was less happy after he moved to Vétheuil, farther from Paris. In 1876 a liaison had begun between Monet and Alice Hoschedé, the wife of a department-store owner and collector. Monet had incurred a burden of debts in Argenteuil, and Camille was pregnant and ill. At Vétheuil they were joined by Mme Hoschedé, who had left her husband, and at least five of her children. From her dowry she assumed Monet's debts and cared for Camille, who died in September 1879. Many of the paintings done in the new locale radiate the same joy in nature as those of Argenteuil, but one group, done after Camille's death, is surely the most melancholy of Monet's career. It represents the Seine in flood during the winter, blocks of ice heaped above its surface, and trees crushed by the flow. Rendered in broad jabs of grayed greens, blues, and browns, these are scenes of profound sadness and desolation. The "Break-up of the Ice" series also demonstrates, as do paintings from every period, that Impressionism was not a theoretical art devoted merely to simulating sunlight by juxtaposing bright hues, as it once was assumed. From the beginning, Monet's palette always responded to the unique appearances before him; if the day was overcast, his tones were muted and gray. For Monet, winter was as valued a subject as summer, despite the discomforts it entailed. And, though Impressionist colour was surely of a higher key than previous landscape painting had been and more roughly brushed, it was an art not of formula but of poetic response and innovation. Once a motif was selected, Monet composed as a photographer does on his ground glass, accepting the pattern of the elements before him but framing them with great care. Later he emphasized those elements—vertical masts, tall trees, the horizontals of riverbanks, boats, or rooftops—that provide pictorial structure.

By 1881 the original Impressionist group began to disintegrate, although it was still to hold two more exhibitions—the eighth and last (in which Monet did not show) in 1886, after the advent of Neoimpressionism. Only Monet continued with the same fervour to carry on the scrutiny of nature. If one regards science as empirical rather than deductive, his intense application can be seen as "scientific." Yet Monet's landscapes were always immediate, poetic, and continually changing in treatment from motif to motif. Among the sites he chose during the '80s were Pourville, Étretat, Fécamp, and Varangéville in Normandy, the rugged and isolated Breton island of Belle-Île, the wild Creuse River Valley, Menton and Antibes in the Midi, and Bordighera in Italy. In 1886, he made a second visit to Holland to paint the tulip fields, before important sojourns at Étretat and Belle-Île.

Continuing scrutiny of nature

In 1883 Monet, Mme Hoschedé, her children, and Monet's sons Jean and Michel settled at Giverny, a hamlet near Vernon, 52 miles from Paris, on the tiny Epte River but still close to the Seine. Here Monet purchased a farmhouse surrounded by an orchard, which was to be his home until his death and is now a French national monument. After the travels of the '80s, the '90s were spent at or near Giverny in concentrated application to one series after another, but were interrupted from January to April in 1895 by a bold painting trip to Norway to paint the Arctic winter and a rest cure that June in the Pyrennees. The series were usually dated and often exhibited in groups: "Poplars" (1890–91), "Haystacks" (1889–93), "Rouen Cathedrals" (1892–94), "Mornings on the Seine" (1896–97), etc. The most radical, perhaps, was the "Haystacks," of which 15 were shown at the Galeries Durand-Ruel in 1891. By comparison with earlier Impressionist subjects, they provided a neutral motif, devoid of the lyricism of the '70s. The mute heaps of hay served simply as modulators of light—for light, season, moment of the day, weather, and the psychological and technical process of envisioning and transmitting impressions to canvas and pigment were all that seemed to interest Monet at that time. Surely these unprecedented canvases were as radical for their time as the abstract paintings of Wassily Kandinsky in 1912 or the poured and dripped paintings of Jackson Pollock in 1947. The "Cathedrals," 20 of which were shown together in 1895, were the most systematic and theoretical of all Monet's works. Begun in Rouen, they were completed at Giverny but represented the facade of Rouen Cathedral at dawn, at various times during

The "Cathedrals"

the day, at sunset, in bright and gray weather, in sun and mist. They were no more religious in content than the "Haystacks" were rustic. The architectural screen of the worn facade served, like the spongy fabric of the stacks, as an armature, pulverized by sun or drowned in mist, on which to hang an iridescent curtain of light.

Last years. After 1900, two ambitious projects, both far from Giverny, concluded Monet's search for new motifs. The first (for which he made at least three trips to London between 1899 and 1904) was the extensive, multiple series representing the Thames River, the Waterloo and Charing Cross bridges, and the House of Parliament. Recalling, in their exotic coloration and mysterious, romantic mood, the Thames paintings of Turner and Whistler, it is atmosphere, more than structures, that is the subject; buildings and bridges are less tangible than the pulsating brush strokes that give volume to the light-filled fog and mist. The second and last of the architectural motifs was the canals and palaces of Venice. They were begun in 1908 and continued in 1909, although Monet worked on the series at Giverny until 1912. Venice was a perfect Impressionist subject, but the light, water, movement, architecture, and reflections in the water are more generalized than the specific weather effects of the systemic "Haystacks" and "Cathedrals."

In 1890 Monet had bought a strip of marshland across the road from his house and flower garden, through which flowed a tributary of the Epte. By diverting this stream, he began to construct his now world-renowned water-lily garden. Soon weeping willows, iris, and bamboo grew around a free-form pool, clusters of lily pads and blossoms floated on the quiet water, and a Japanese bridge closed the composition at one end. By 1900 this unique product of Monet's imagination (for his Impressionism had become more subjective) was in itself a major work of environmental art—an exotic lotus land within which he was to meditate and paint for over 20 years. The first canvases of lilies, water, and the Japanese bridge were only about one yard square, but their unprecedented open composition, with the large blossoms and pads suspended as if in space, and the azure water in which clouds were reflected, implied an encompassing environment beyond the frame. This concept of embracing spatiality, new to the history of painting and only implicit in the first water-lily paintings, was expanded by 1925 into a cycle of huge murals to be installed in Paris in two 80-foot oval rooms in the Orangerie of the Tuileries. These were described in 1952 by the painter André Masson as "the Sistine Chapel of Impressionism." This crowning achievement of Monet's long, probing study of nature—his striving to render his impressions, as he said, "in the face of the most fugitive effects"—was not dedicated until 1927, more than a year after his death. The many large studies for the Orangerie murals, as well as other unprecedented and unique works painted in the water garden between 1916 and 1925, were almost unknown until the 1950s but are now distributed throughout the major private collections and museums of the world. Among these is a bequest made to the Musée Marmottan, Paris, by Monet's son Michel and opened to the public in 1971. Despite failing eyesight, Monet continued to paint almost until his death in Giverny, on December 5, 1926.

The Orangerie murals

MAJOR WORKS

"Still Life" (*c.* 1859; Leigh B. Block collection, Chicago); "Farm in Normandy" (*c.* 1864; Louvre, Paris); "View of the Coast at Le Havre" (1865; Minneapolis Institute of Arts, Minnesota); "Camille (The Green Dress)" (1866; Kunsthalle, Bremen, West Germany); "Garden of the Princess, Paris" (1866; Oberlin College, Ohio); "The Terrace at Sainte-Adresse" (1866; Metropolitan Museum of Art, New York); "Women in the Garden" (1866–67; Louvre, Paris); "The River" (1868; Art Institute of Chicago); "La Grenouillere" (1869; Metropolitan Museum of Art, New York); "The Beach at Trouville" (1870; Tate Gallery, London); "Hyde Park, London" (1871; Philadelphia Museum of Art); "The Thames and the Houses of Parliament" (1871; Lord Astor of Hever collection, London); "Impression: Fog" (1872; Musée Marmottan, Paris); "Impression: Sunrise" (1872; Musée Marmottan, Paris); "Wild Poppies" (1873; Louvre, Paris); "The Railroad Bridge at Argenteuil" (1875; Philadelphia Museum of Art); "La Japonaise" (1876; Museum of Fine Arts, Boston); "Gare Saint-Lazare, Paris" (1877; Fogg Museum of Art, Harvard University); "Rue Montorquiel Bedecked with Flags" (1878; Musée des Beaux-Arts, Rouen); "Vétheuil in Summer" (1880; Metropolitan Museum of Art, New York); "Haystacks at Giverny" (1884; Josef Rosensaft collection, New York); "Antibes" (1888; Toledo Museum of Art, Ohio); "Two Haystacks" (1891; Art Institute of Chicago); "Rouen Cathedral, Sunset" (1894; Museum of Fine Arts, Boston); "Water-Lily Pool" (1899–1906; Louvre, Paris); "Les Nymphéas" series (1906–26; Jeu de Paume, Paris).

BIBLIOGRAPHY. No *oeuvre* catalog or definitive biography of Monet exists. A volume purporting to fill the latter need, by CHARLES MERRILL MOUNT, *Monet: A Biography*, appeared in 1967. Its account of Monet's life is distorted and prejudiced. The author, however, presents some new and important documentation of Monet's early life and especially of his relationship with his mistress and first wife, Camille Doncieux. Indispensible for the study of Monet, as for other Impressionist painters, is JOHN REWALD, *History of Impressionism*, rev. ed. (1962). It includes copious notes, with references to publications, problems, and documents, and an exhaustive annotated bibliography. WILLIAM C. SEITZ, *Claude Monet* (1960), is a most useful recent book, including colour reproductions and an extensive outline biography. Among the books published during Monet's lifetime, perhaps that by Monet's friend GUSTAVE GEFFROY, *Claude Monet, sa vie, son temps, son oeuvre* (1922), is the most rewarding. See also GEORGE HEARD HAMILTON, *Claude Monet's Paintings of Rouen Cathedral* (1960), and for an account of the water garden, including photographs, STEPHEN GWYNN, *Claude Monet and His Garden* (1934).

(W.C.Se.)

Money

The subject of money has fascinated wise men from the time of Aristotle to the present day because it is so full of mystery and paradox. The piece of paper labelled one dollar or 100 francs or 10 kroner or 1,000 yen is little different, as paper, from a piece of the same size torn from a newspaper or magazine, yet it will enable its bearer to command some measure of food, drink, clothing, and the remaining goods of life while the other is fit only to light the fire. Whence the difference? Why should these particular pieces of paper be accepted in transactions for goods and services?

The basic function of money

The easy answer, and the right one, is that people accept money as such because they know that others will. The pieces of paper are valuable because everyone thinks they are, and everyone thinks they are because in his experience they always have been. At bottom money is, then, a social convention, but a convention of uncommon strength that people will abide by even under extreme provocation. The strength of the convention is, of course, what enables governments to profit by inflating the currency. But it is not indestructible. When great variations occur in the quantity of these pieces of paper —as they have during and after wars—they may be seen to be, after all, no more than pieces of paper. People will then seek substitutes—like the cigarettes and cognac, which for a time became the medium of exchange in Germany after World War II. As John Stuart Mill wrote:

> There cannot, in short, be intrinsically a more insignificant thing, in the economy of society, than money; except in the character of a contrivance for sparing time and labour. It is a machinery for doing quickly and commodiously, what would be done, though less quickly and commodiously, without it: and like many other kinds of machinery, it only exerts a distinct and independent influence of its own when it gets out of order. (*Principles of Political Economy*, W.J. Ashley [ed.], 1909, p. 488.)

Mill was perfectly correct although one must add that there is hardly a contrivance man possesses that can do more damage to a society when it goes wrong.

The basic function that money performs is to enable buying to be separated from selling, thus permitting trade to take place without the so-called double coincidence of barter. If a person has something to sell and wants something else in return, he does not have to search for someone able and willing to make the desired exchange of items. He can sell what he has for general purchasing

power—that is, "money"—to anyone who wants to buy it; he can then use the proceeds to buy what he wants from anyone who wants to sell it.

The importance of this function of money is dramatically illustrated by the experience of Germany just after World War II, when paper money was rendered largely useless because, despite inflationary conditions, price controls were effectively enforced by the American, French, and British armies of occupation. People had to resort to barter or to inefficient money substitutes. The result was to cut total output of the economy in half. The German "economic miracle" just after 1948 reflected partly a currency reform by the occupation authorities, but some economists hold that it stemmed primarily from the German government's elimination of all price controls, thereby permitting a money economy to replace a barter economy.

Separation of the act of sale from the act of purchase requires the existence of something that will be generally accepted in payment—this is the "medium of exchange" function of money. But also, there must be something that can serve as a temporary abode of purchasing power, in which the seller holds the proceeds in the interim between his sale and his subsequent purchase, or from which the buyer can extract the general purchasing power with which he pays for what he buys. This is the "asset" function of money.

VARIETIES OF MONEY

Anything can serve as money that habit or social convention and successful experience endow with the quality of general acceptability, and a very wide range of items have so served—from the wampum (beads made from shells) of American Indians to cowries (brightly coloured shells) in India, to whales' teeth among the Fijians, to tobacco among early colonists in North America, to large stone disks on the Pacific island of Yap, and to cigarettes and liquor in post-World War II Germany. The wide use of cattle as money in primitive times survives in the word pecuniary, which comes from the Latin word *pecus*, meaning cattle.

Metallic money. The use of metals as money has occurred throughout history. As Aristotle observed,

> The various necessities of life are not easily carried about, and hence man agreed to employ in their dealings with each other something which was intrinsically useful and easily applicable to the purposes of life, for example, iron, silver, and the like. Of this the value was at first measured by size and weight, but in process of time they put a stamp upon it, to save the trouble of weighing and to mark the value.

The use of metal for money can be traced back to over 2,000 years before the birth of Christ. But standardization and certification in the form of coinage, as referred to by Aristotle, did not occur except perhaps in isolated instances until the beginning of the 7th century BC. Historians generally assign to Lydia, a Greek state in Asia Minor, priority in using coined money. The first coins were made of electrum, a natural mixture of gold and silver, and were crude, bean-shaped ingots bearing a primitive punchmark certifying to either weight or fineness, or perhaps both.

Debasing the currency

The use of coins enabled payment to be by "tale" or count rather than weight, greatly facilitating commerce. But this in turn encouraged clipping (shaving off tiny slivers from the sides or edges of coins) and sweating (shaking a bunch of coins together in a leather bag and collecting the dust that was thereby knocked off) in the hope of passing on the lighter coin at its face value. Gresham's law (that "bad money drives out good" when there is a fixed rate of exchange between them) came into operation, and heavy, good coins were held for their metallic value, while light coins were passed on. The coins became lighter and lighter, and prices higher and higher. Then payment by weight would be resumed for large transactions, and there would be pressure for recoinage. These particular defects were largely ended by the "milling" of coins (making serrations around the circumference of a coin), which began in the late 17th century.

A more serious matter was the attempt by the sovereign to benefit from his monopoly of coinage. In this respect, Greek and Roman experience offers an interesting contrast. Though Solon, on taking office in Athens in 594 BC, did institute a partial debasement of the currency, for the next four centuries, until the absorption of Greece into the Roman Empire, the Athenian *drachma* had an almost constant silver content (67 grains of fine silver until Alexander, 65 grains thereafter) and became the standard coin of trade in Greece and in much of Asia and Europe as well. Even after the Roman conquest, the *drachma* continued to be minted and widely used.

The Roman experience was very different. Not long after the silver *denarius* patterned after the Greek *drachma* was introduced (in 269 BC), the prior copper coinage (*aes* or *libra*) began to be debased until by the time the Empire began its weight had been reduced from one pound to half an ounce. The silver *denarius* and the gold *aureus* (introduced about 87 BC) suffered only minor debasement until the time of Nero (54 AD), when almost continuous tampering with the coinage began. The metal content of the gold and silver coins was reduced, and the proportion of alloy was increased to three-fourths or more of its weight. Debasement in Rome (as ever since) was a reflection of the state's inability or unwillingness to finance its expenditures "through explicit taxes." But the debasement in turn worsened Rome's economic situation and undoubtedly contributed to the collapse of the empire.

Paper money. In the late 18th and early 19th centuries, paper money and bank notes spread widely. The bulk of the money in use came to consist not of actual gold or silver but of fiduciary money—promises to pay specified amounts of gold and silver. These promises were initially issued by private individuals or companies as bank notes or transferrable book entries that have come to be called deposits. But gradually the state assumed an increasing role.

From fiduciary paper money promising to pay gold or silver, it is a short step to fiat paper money—that is, notes that are issued on the "fiat" of the sovereign, are specified to be so many dollars or francs or yen and are legal tender but are not promises to pay something else. The first large-scale issue in Western countries occurred in France in the early 18th century (though there are reports of paper money in China many centuries earlier). Later, the French revolutionary government issued paper money in the form of *assignats* from 1789 to 1796. The American colonies and later the Continental Congress issued bills of credit that could be used in making payments. These early experiments gave fiat money a deservedly bad name. The money was overissued, and prices rose drastically until the money became worthless or was redeemed in metallic money (or promises to pay metallic money) at a small fraction of its initial value.

Subsequent issues of fiat money in the major countries during the 19th century were temporary departures from a metallic standard. In Britain, for example, payment of gold for the outstanding bank notes was "suspended" during the Napoleonic Wars (1797–1816). As a result, gold coin and bullion became more expensive in terms of paper. Similarly, in the U.S. during the Civil War, convertibility of Union currency (greenbacks) into specie was suspended and resumption did not occur until 1879. At its peak, in 1864, the greenback price of gold, nominally equivalent to $100, reached over $250.

In the Middle Ages, when money consisted primarily of coins, silver and gold coins circulated simultaneously. As governments came increasingly to take over the coinage, and especially as fiduciary money was introduced, they tended to specify their nominal monetary units in terms of fixed weights of both silver and gold—to adopt a national bimetallic standard. Gresham's law, however, usually assured that the bimetallic standard degenerated into a monometallic standard: if the quantity of silver designated as the monetary equivalent of one ounce of gold was less than the quantity that could be purchased in the market for one ounce of gold; *i.e.*, if the mint overvalued silver, no one would bring gold to be coined. If he had gold, it was better to buy silver and bring it to be coined.

Silver, the cheaper metal, "drove out" gold and became the standard. This happened in most of the countries of Europe, so that by the early 19th century all were effectively on a silver standard. In Britain, on the other hand, the ratio established in the 18th century at the advice of Sir Isaac Newton, then serving as master of the mint, overvalued gold and therefore led to an effective gold standard. In the United States, a ratio of 15 ounces of silver to 1 ounce of gold was set in 1792. This ratio overvalued silver, so silver became the standard. In 1834, the ratio was altered to 16 to 1, which overvalued gold, so gold became the standard.

Gold. The great gold discoveries in California and Australia in the 1840s and 1850s produced a temporary decline in the value of gold in terms of silver. This price change plus the dominance of Britain in international finance led to a widespread shift from a silver standard to a gold standard. Germany adopted gold in 1871–73; the Latin Monetary Union (France, Italy, Belgium, Switzerland) in 1873–74; the Scandinavian Union (Denmark, Norway, and Sweden) and the Netherlands in 1875–76. By the final decades of the century, silver remained dominant only in the Far East (China, in particular). Elsewhere the gold standard reigned.

The international gold standard

The early 20th century was the great era of the international gold standard. Gold coins circulated in most of the world; paper money, whether issued by private banks or by government, was convertible on demand into gold coins or gold bullion at an official price (with perhaps the addition of a small fee); and bank deposits were convertible into either gold coin or paper currency that was itself convertible into gold. In a few countries, a minor variant prevailed—the so-called gold-exchange standard, under which the currency was converted at a fixed price into the currency of another country (usually the British pound sterling) that was itself convertible into gold.

There was, in effect, a single world money called by different names in different countries. A U.S. dollar, for example, was defined as 23.22 grains of pure gold (25.8 grains of gold 0.9000 fineness). A British pound sterling was defined as 113.00 grains of pure gold 123.274 grains of gold 11/12th fine). Accordingly, one British pound equalled 4.8665 U.S. dollars (113.00/23.22) at the official parity. The actual exchange rate could deviate from this only by an amount that corresponded to the cost of shipping gold. If the price of the pound sterling in terms of dollars rose to a considerably higher value than this in the foreign exchange market, someone in New York who had a debt to pay in London might find that, rather than buy the pounds he needed on the market, it was cheaper to get gold for his dollars at his bank or at the U.S. subtreasury, ship the gold to London, and get pounds for his gold from the Bank of England. This set an upper limit to the exchange rate. Similarly, the cost of shipping gold from Britain to the U.S. set a lower limit. These limits were known as the gold points.

Under such an international gold standard, the quantity of money in each country is determined by the specie-flow adjustment mechanism analyzed by 19th-century economists. If for whatever reason, the quantity of money in a country rises unduly, this will tend to raise prices in that country relative to prices in other countries, discouraging exports and encouraging imports. The decreased supply of foreign currency from the sale of exports plus the increased demand for foreign currency to pay for imports will tend to raise the price of foreign currency in terms of domestic currency. As soon as this price hits the upper gold point, gold will be shipped out of the country to other countries. The decline in the amount of gold will produce in turn a reduction in the total amount of money—because banks and government institutions, seeing their gold reserves decline, will want to protect themselves against further demands by reducing the claims against gold that are outstanding. This will tend to lower prices at home. The influx of gold abroad will have the opposite effect, increasing the quantity of money there and raising prices. These adjustments will continue until the gold flow ceases or is reversed.

This is precisely the mechanism that operates within a unified currency area; the mechanism that determines how much money there is in Illinois compared to how much there is in other states or how much there is in Wales compared to how much there is in other parts of the United Kingdom. In the early 20th century, most of the world was a unified currency area so the gold standard functioned throughout the world. Its great advantage, which accounts for the widespread support that still exists for a real gold standard, is that—if permitted to operate—it greatly limits the power of any national government and prevents it from engaging in irresponsible monetary expansion. This is also its great disadvantage. In an era of big government and of full employment policies, a real gold standard would tie the hands of national governments in one of the most important areas of policy.

The decline of gold. World War I ended the real international gold standard. Most belligerents suspended the free convertibility of gold. The U.S., even after its entry into the war, maintained convertibility but embargoed gold exports. For a few years after the end of World War I, most nations had inconvertible national paper standards—inconvertible in the sense that paper money was not convertible into gold or silver, rather than in the more recent sense of its not being convertible into other currencies. The exchange rate between any two currencies was a market rate that fluctuated from time to time. During this period this was regarded as a temporary phenomenon, like the British suspension of gold payments during the Napoleonic era, and the U.S. suspension during the Civil War greenback period. The great aim was a restoration of the prewar gold standard.

Managed gold-exchange standard

This aim dominated monetary developments during the 1920s. Britain, still a major financial power, returned to gold in 1925. Winston Churchill, then Chancellor of the Exchequer, decided to follow prevailing financial opinion and adopt the prewar parity (*i.e.*, to define a pound sterling once again as equal to 123.274 grains of gold 11/12th fine). This produced exchange rates that, at the existing prices in sterling, overvalued the pound and so tended to produce gold outflows, especially after France returned to gold in 1928 at a parity that undervalued the franc. By 1929 the important currencies of the world, and most of the less important ones, were again linked to gold.

The gold standard that was restored, however, was a far cry from the prewar gold standard. The establishment of the Federal Reserve System in the United States introduced an additional link in the international specie flow mechanism. That mechanism no longer operated automatically. It operated only if the Federal Reserve chose to let it do so, and the Federal Reserve did not so choose; it took certain measures that prevented gold inflows from producing a corresponding expansion in the money supply. The United Kingdom had recurring difficulties in retaining its gold. It followed a restrictive monetary policy, but, because of rigidities in prices and particularly in wages, the result was unemployment rather than a lowering of prices. The unemployment reduced imports and stimulated exports, thus preventing gold losses. But this was not a tenable long-term position, as a lower level of prices might have been. Most other countries adopted a gold-exchange standard. Everywhere national central banks took scattered measures to loosen the connection between changes in the money supply and inflows or outflows of gold.

If the Great Depression had not occurred, this system might have grown and matured and improved. But the Great Depression brought the managed gold standards to a quick end. It originated in the United States, spread to all the countries linked to the U.S. by the gold exchange standard, and then reverberated back to the U.S. Britain was the first major country to cut the link, leaving the gold standard in 1931. The United States followed in March 1933.

The best simple description of the world's monetary system today is perhaps that the world is on a dollar standard. The dollar is widely used in international trade, even in trade between countries other than the U.S. It is the unit in terms of which the exchange rates of other currencies are expressed. Other countries maintain their

"official" exchange rates by buying and selling U.S. dollars and hold dollars as their primary reserve currency for this purpose. The existence of a dollar standard does not mean that other countries may not change their exchange rates from time to time—as Germany and France did in 1969—just as the gold standard did not mean that countries could not "devalue" or "appreciate" in terms of gold. What it does mean is that the U.S. cannot determine its own exchange rate or its balance of payments position. It also means that U.S. monetary policy has a major effect on the world economy.

MODERN MONETARY SYSTEMS

Monetary systems are today very much alike in all the major countries of the world. They consist of three levels: (1) the holders of money (the "public")—individuals, businesses, governmental units; (2) commercial banks (privately or governmentally owned), which borrow from the public and make loans to individuals, firms, or governments; and (3) central banks, which have a monopoly on the issue of certain types of money, serve as the bankers for the central government and the commercial banks, and have the power to determine the quantity of money.

The money holdings of the public

The public holds its money in two forms: (1) currency (including coin) and (2) bank deposits.

In most countries the bulk of the currency consists of notes issued by the central bank. In the United Kingdom these are Bank of England Notes, in the United States Federal Reserve Notes, and so on. It is hard to say precisely what "issued by the central bank" means. In the U.S., for example, the currency bears the words "Federal Reserve Note," but these notes are not obligations of the Federal Reserve Banks in any meaningful sense. The holder who presents them to a Federal Reserve Bank has no right to anything except other pieces of paper adding up to the same face value. The situation is much the same in most other countries.

The other major item of currency held by the public is coin. In almost all countries this is token coin, worth as metal much less than its face value.

Bank deposits. Bank deposits are also counted as part of the money holdings of the public. In the 19th century most economists regarded only currency and coin as "money," treating deposits only as claims to money. As deposits became more and more widely held, and as a larger fraction of transactions came to be effected by check, economists started to include, not the checks but the deposits they transferred, as money on a par with currency and coin.

The definition of money has been the subject of much dispute. The chief point at issue is which categories of bank deposits to call money and which to regard as near money. Many economists include as money only deposits transferrable by check (demand deposits). Others include nonchecking deposits such as "time deposits" or "current deposits" in commercial banks. Still others include deposits in other financial institutions such as savings banks, saving and loan associations, and so on.

The term deposits is highly misleading. It connotes something deposited for safekeeping, like currency in a safe-deposit box. Bank deposits are not like that. When one brings currency to a bank for "deposit," the bank does not put the currency in a vault and keep it there. It may put a small fraction of the currency in the vaults as "reserves," but it will lend most of it to someone else or buy an investment—that is, a bond or some other security. As part of the inducement to depositors to lend it money, it provides facilities for transferring demand deposits from one person to another by check.

The deposits of commercial banks are assets of their holders but liabilities of the banks. The assets of the banks consist of "reserves"—currency plus deposits at other banks—and "earning assets"—loans plus investments in the form of bonds and other securities. The reserves are only a small fraction of the aggregate deposits. Initially, in the history of banking, the amount of reserves held was determined by each bank separately in terms of its judgment of the likely demands on it. The growth of deposits enabled the total quantity of money (including deposits) to be larger than the total sum available to be held as reserves. A bank that received, say, $100 in gold might add $25 to its reserves and lend out $75. But the recipient of the $75 loan would himself spend it. Some of those who received gold this way would hold it as gold but others would deposit it in this bank or in other banks. If, for example, two-thirds was redeposited, some bank or banks would find $50 added to deposits and to reserves and would repeat the process, adding $12½ to its reserves and lending out $37½. When this multiple expansion process worked itself out fully, total deposits would have increased by $200, bank reserves by $50, and $50 of the initial $100 deposited would have been retained as "currency outside banks." There would be $150 more money in total than before (deposits up by $200, currency outside banks down by $50). Although no individual bank "created" money, the banking system as a whole did. This is the well-known multiple expansion process that lies at the heart of the modern monetary system.

Central banking. An important part of the monetary system is the central bank. The Bank of England was the first modern central bank, serving as the model for many others. It was established as a private bank in 1694 but quickly came to be largely an agency of the government. The Bank of France was established as a governmental institution by Napoleon in 1800. In the U.S., the 12 Federal Reserve Banks, which together with the Board of Governors in Washington constitute the Federal Reserve System, are technically owned by their member commercial banks, but this is a pure formality. Member banks get only a fixed annual percentage dividend on their stock and have essentially no formal power. To all intents and purposes, the system is a governmental agency and is best treated as such.

High-powered money

The notes issued by a central bank (or another governmental agency) plus deposits at the central bank are often called high-powered money, because when held as bank reserves each dollar or pound or franc may correspond to several dollars or pounds or francs of commercial bank deposits. Generally speaking, there is now no formal limit to the amount of notes and deposits that a central bank may have as liabilities.

The way in which a central bank increases or decreases the total amount of high-powered money is, typically, by making loans (discounting) or by buying and selling government securities (open-market operations). If, for example, the Federal Reserve System purchases $1,000,000 of government securities, it will pay for these securities by a check on itself, adding $1,000,000 to its assets and $1,000,000 to its liabilities. The seller of the security can take the check to a Federal Reserve Bank, which will give him $1,000,000 in Federal Reserve Notes. Or the seller may deposit the check at his bank, and the bank will in turn present it for payment to a Federal Reserve Bank which will "pay" the check by making a book entry increasing that bank's deposits with it by $1,000,000. The bank may, in turn, transfer this sum to a borrower who again will either convert it into Federal Reserve Notes or deposit it.

The important point is that these bookkeeeping operations simply record a process whereby the central bank has created, out of thin air as it were, additional high-powered money—the direct counterpart of printing Federal Reserve Notes. Similarly, if the central bank sells government securities, it destroys high-powered money.

In addition to the high-powered money of the central bank, the total quantity of money at any given time depends on the preferences of the public as to the relative amounts of money it wishes to hold as currency and as deposits and on the preferences of the banks as to the ratio they wish to maintain between their reserves and their deposits. (The reserve ratio is of course dominated by legal reserve requirements, where they exist, but may vary somewhat as banks think it prudent to keep a larger or smaller cushion in excess of required reserves.)

It follows that, by controlling the quantity of high-powered money and by other less important means, a central

bank can vary the total quantity of money as it wishes within broad limits. The major problem of modern monetary policy is how the central bank should use this power.

THE QUANTITY THEORY OF MONEY

The relation between money and what it will buy has always been a central issue of monetary theory. Economists have generally held that the level of prices is determined by the quantity of money. But precisely how the quantity of money affects the level of prices, and what the effects are of changes in the quantity of money, have been conceptualized in different ways at different times. For an interval of two or three decades from the mid-1930s to the mid-1960s there was a widespread rejection of the quantity theory by professional economists. More recently, there has been something of a counterrevolution involving a partial return to and modification of earlier views. The following discussion of monetary theory will therefore deal first with the quantity theory of money, as it developed before the 1930s, then with the Keynesian revolution, and finally with the recent counterrevolution.

The basic principles of the quantity theory

In whatever way it has been formulated, the quantity theory of money has involved a distinction between the *nominal* quantity of money and the *real* quantity of money. The nominal quantity of money is that expressed in whatever units are used to designate money—talents, shekels, pounds, francs, lire, drachmas, dollars, yen, and so on. The real quantity of money is that expressed in terms of the volume of goods and services that the money will purchase. The quantity theory assumes that what ultimately matters to holders of money is the real quantity rather than the nominal quantity. If this is so, then whatever factors may determine the nominal quantity of money, it is the holders of money who determine the real quantity and, in the process, the price level.

The following may be considered a hypothetical example. In a certain community the quantity of money in existence is $1,000,000, and the total income of the community is $10,000,000 a year. On the average, each member of the community holds an amount of money equal in value to one-tenth of a years' income, or to 5.2 weeks' income. Put differently, the income velocity of circulation is equal to ten per year; that is, each $1 on the average is paid out ten times a year. For the sake of simplicity there are no business enterprises; the members of the community buy and sell services from and to one another.

The quantity of money is somehow then doubled, but in such a way that no one expects the quantity to change again. Each member of the community will regard himself as better off. He now has 10.4 weeks' income in the form of cash, where as before he had only 5.2 weeks'. If everyone were to hold onto the extra cash, nothing further would happen. But people will try to spend it. One man's spending, however, is another man's receipts. All the people together cannot spend more than all the people receive. The attempt of each to do so is bound to be frustrated. In the attempt to spend more than they receive, people will simultaneously try to buy more of various services from each other and to sell less. To induce others to sell, they will offer higher prices; to induce others not to buy, they will ask higher prices. Whether the quantity sold goes up or down depends on whether the attempt to buy more is stronger or weaker than the attempt to sell less. But in either case total spending is sure to go up and so are total income and prices paid. When income has doubled, to $20,000,000, the amount of money in existence will again be equal in value to 5.2 weeks' income. The community will have succeeded in reducing its real cash balances to their former level, not by reducing nominal balances but by raising incomes and prices. The process of adjustment may not be smooth; spending may go too far and leave people with real balances that are too small, requiring a subsequent fall in the price level; but the final position will tend toward a doubling of prices, and the previous real flows of services will be resumed with no one any better off than before the new money was distributed.

This simple example embodies most of the basic principle of monetary theory: (1) the central distinction between the *nominal* and the *real* quantity of money; (2) the equally crucial contrast between the alternatives open to the individual and to the community as a whole. To each individual separately (in the hypothetical example and in the real world) it looks as if his income is outside his control, but he can determine how much cash he holds. To the community as a whole, the total amount of cash is fixed but it is able to determine the size of its income in dollars; (3) the importance of attempts. The *attempt* of people as a whole to spend more than they receive, even though doomed to frustration, has the effect of raising total nominal expenditures and receipts.

The quantity equations. A useful device for clarifying the variables stressed in the quantity theory is the so-called quantity equation. The quantity equation has taken different forms according as quantity theorists have stressed different variables. The most famous is the so-called transactions version:

$$MV = PT \qquad (1)$$

This version starts with the identity that any transaction has two sides: an amount of money paid and a corresponding quantity transferred at a certain price—for example, $10 paid for two books at $5 each. The left side of the equation sums up the amount of money paid out; the right side, the value of the transaction. Generalized to the whole economy, the left side of the equation becomes the amount of money in existence (M) multiplied by the average number of times per year (or other unit of time) that each dollar is used in effecting a transaction—the transaction velocity of circulation (V). The right side of the equation then becomes the product of an average price (P) times an *aggregate* quantity of goods (T).

In this version, all transactions of whatever kind are included—purchases of securities along with purchases of restaurant meals, purchases of the food ingredients by the restaurant as well as of the final restaurant meals. The inclusion of capital as well as current transactions, and of intermediate as well as final goods, makes the concepts of total transactions (T) and the "general price level" (P) highly ambiguous and difficult to handle statistically. The emergence of national income accounting in recent decades has led to the substitution of an income version of the quantity equation:

$$MV = Py \qquad (2)$$

In this equation y represents national income in constant prices (the total value at fixed prices of all final goods and services including additions to the stock of capital), P is a price index, and V is the average number of times that the money stock is used for making *income* transactions (that is, payments for final goods and services, or alternately, for final productive services—services of labour, land, and so forth).

In both these equations the two sides are, by definition, precisely equal to one another—that is, each equation is an identity (like the equality of total assets and total liabilities on a double-entry balance sheet). In practice, the data on transactions or on income—the right sides of the equations—come from different statistical sources than do the data on the quantity of money, and only indirect data exist for velocity. As a consequence, when these equations are used to describe the real world, V is usually computed in such a way as to make the two sides equal, thus embodying all the statistical errors of the other terms.

These versions of the quantity equation emphasize the function of money as a medium of exchange—its use in making payments. But money also serves as a temporary store of purchasing power in the interim between sale and purchase. This aspect of money is emphasized in the cash balance approach.

It has generally been supposed that the amount of money people will want to hold for this purpose bears some relation to their income. This leads to the equation

$$M = kPy \qquad (3)$$

in which M, P, and y are defined as in equation (2), and k is the ratio of money stock to income. Although equation (3) is simply a mathematical transformation of equation (2)—k being numerically equal to the reciprocal of V—it brings out the difference between the aspects of money stressed by the transactions approach and those stressed by the cash-balances approach.

In particular, the cash-balances approach fits in better with general economic analysis than does the transactions approach. Equation (3) can be regarded as describing the demand for money, with P and y being two of the variables on which the demand for money depends and with k symbolizing all the other variables. For completeness, the analysis requires another equation showing how the supply of money is determined. This approach provides a better bridge to the later Keynesian and more recent monetarist development than does the transactions approach.

Their uses. The purpose of the quantity equations is mainly to provide an analytical filing system to help sort out the forces at work. Their usefulness derives from the empirical hypothesis that each of the four main labels (M, V, P, and y for the income version) refers to a fairly distinct set of forces subject to influences that are different from those classified under another label.

Interpretation of the quantity equations

In its simplest form, the quantity theory regards output (y) as being determined by the productive opportunities of the community and its tastes and preferences; it regards the quantity of money (M) as being determined by the conditions of production of the monetary metal plus the characteristics of the financial and banking structure (for a commodity standard) or the decisions of the monetary authorities and the financial structure (for a fiat standard); it regards velocity (V) as being determined by payments practices, the financial and economic arrangements for effecting transactions, and the costs and returns from holding money instead of other assets; and, finally, it regards the price level (P) as the variable that adjusts to reconcile the conditions of production determining y with the financial conditions determining M and V.

In the most rigid form of the quantity theory, velocity is seen as very stable. This view regards the level of prices as determined directly by changes in the quantity of money, and as moving in strict proportion to the quantity of money. But the more sophisticated quantity theorists never took this simplistic view. They all recognized that prices could not adjust instantaneously and fully and that, during so-called transition periods, changes in the quantity of money would affect output as well as prices. They also recognized that V was not a constant but itself a function of other variables such as interest rates and that it was subject to substantial random perturbations. As a result, they all recognized that changes in output and prices could be produced in principle by independent changes in either V (that is, the demand for money) or M (that is, the supply of money).

On an analytical level the quantity theory of money is not the tautology of the equation; it is, rather, an analysis of the factors determining the quantity of money that the community wishes to hold. On an empirical level, it does not assume that V is constant; it holds that changes in the demand for money tend to proceed slowly and gradually or to be the result of events set in train by prior changes in supply, whereas, in contrast, substantial changes in the supply of nominal balances can and frequently do occur independently of any changes in demand. The conclusion is that substantial changes in prices or nominal income are almost invariably the result of changes in the nominal supply of money rather than of V.

An implication of the foregoing is that monetary policy —policy as to changes in the quantity of money—is the appropriate means for preventing inflation or deflation and for avoiding wide cyclical fluctuations.

The Keynesian critique. The groundwork for the Keynesian attack on the quantity theory was laid by two historical experiences. One was the British experience after the return of gold in 1925. In order to maintain the parity set for the pound in terms of gold, the Bank of England followed a persistently tight monetary policy. But prices did not move downward sufficiently, and there was persistent unemployment. This raised doubts about the allegedly classical postulate that money was only a veil, that total output was determined by real conditions, and that full employment was the "equilibrium" or normal position. The second, and even more dramatic experience, was the Great Depression. Later study has shown that the severity of the depression, certainly in the U.S., can be attributed to bad monetary policy—a policy that permitted or forced the quantity of money to decline by one-third from 1929 to 1933. This was not known or understood at the time; on the contrary, the Federal Reserve authorities insisted that they were doing everything they could to offset the forces making for depression, and that they were unable to do more.

This stimulated the British economist John Maynard Keynes—who had been a highly sophisticated quantity theorist on strictly classical lines—to develop an alternative interpretation of the debacle after 1929 and an alternative prescription for policy. It also produced a sympathetic climate for his new theory, so that the Keynesian revolution swept the economics profession in a remarkably short time.

Keynes did not, of course, deny the validity of the quantity equation. What he maintained was very different: that the right-hand side—Py or prices times output—was determined by forces largely independent of the left-hand side. P, he argued, was largely an institutional datum, linked to customary nominal rates of wages that were very resistant to change, or at least to decline. Real income or output, y, he argued, was determined by aggregate demand, which depended primarily on the amount of "autonomous spending"—that is, spending not linked directly to current income—and consisted mostly of investment expenditures by enterprises and spending by government. The rest of aggregate demand consisted mostly of consumption, which was linked closely to current income and so determined by autonomous spending. On this view, the key factor determining the level of real income and output, and thereby the level of nominal income, was the strength of investment and of government spending.

How then could the quantity equation hold? Keynes's answer was that V was so pliable that it would adjust to keep the two sides equal. Let autonomous spending increase without a change in the quantity of money and V would simply increase in response; let the quantity of money increase without an increase in autonomous spending, and V would decline to offset the increase in M.

In its extreme form—as much a caricature of Keynes's thinking as the attribution of a constant V is of his predecessors'—the quantity of money simply did not matter at all for the course of prices or real output but only for the movement of V.

How did Keynes explain the plasticity of V? He did so by means of a very special explanation of the demand for money, to which he applied the phrase "liquidity preference." He regarded the quantity of money demanded as divided into two parts, one part M_1, "held to satisfy the transactions and precautionary-motives," the other, M_2, "held to satisfy the speculative-motive." He regarded M_1 as a roughly constant fraction of income, and with respect to this part he accepted a rather rigid form of the quantity theory. He regarded M_2, however, as largely independent of income and as highly sensitive to current interest rates and to the expectations of future interest rates. This explained the plasticity of V.

According to Keynes, if current interest rates are above the level many holders of money expect to prevail in the future, people will prefer to hold their speculative balances in bonds instead of money—because they expect a fall in interest rates, which means a rise in bond prices. Conversely, if current interest rates are below the level expected to prevail in the future, they will prefer to hold money. Over short periods, he argued, these expectations are widely and strongly held at about the same level. In the extreme with everyone holding the same expectations and everyone sensitive, liquidity preference will become, as he termed it, absolute. Under such circumstances, let the monetary authorities try to in-

crease the amount of money by buying bonds. This will tend to raise bond prices and lower interest rates, but even the slightest lowering will lead speculators to absorb the additional money and sell bonds. The result will be a lower V or a higher k for the community as a whole. The converse will hold if the authorities try to reduce the amount of money.

The decline and rise of the quantity theory

Alternatively, if nominal income rises, for whatever reason, without a change in the quantity of money, that will require an increase in M_1, but it can and will come out of M_2 without any further effects. The conclusion is that *under circumstances of absolute liquidity preference* income can change without a change in M or in interest rates, and M can change without a change in income or in interest rates. The holders of money are in metastable equilibrium, like a tumbler on its side on a flat surface; they will be satisfied with whatever the amount of money happens to be.

For the long run, Keynes regarded the size of M_2 as depending on the level of interest rates for a different reason. The interest rate measures the cost of holding money instead of bonds—it is the price, as Keynes put it, that the holder of money pays for parting with liquidity. If the interest rate is low, the cost of liquidity is low; hence people will hold a large fraction of their wealth in the form of money, and the fraction will be sensitive to small changes in the interest rate—liquidity preference being absolute in the long run as well as in the short run. If interest rates were high, and M_2 low—a condition that Keynes expected to hold only at times of full employment—then the quantity theory would "come into its own," in the double sense that velocity would be constant and that prices rather than output would respond to changes in the quantity of money.

Keynes himself regarded absolute liquidity preference as a strictly "limiting case"; while it "might become practically important in future," he knew "of no example . . . hitherto." In practice, however, he treated velocity as if its behaviour frequently approximated this limiting case, and his disciples went much further than he did.

If liquidity preference was not absolute, then in the Keynesian view a change in the quantity of money would first affect interest rates in order to induce the community to hold the changed quantity of money. This change in interest rates might in turn affect autonomous spending—a decline encouraging investment and a rise discouraging investment—and in this way aggregate demand, income and employment. The more sensitive is the quantity of money demanded to interest rates, and the less sensitive is investment to interest rates, the smaller will be the final effect of changes in the quantity of money, and conversely. (For a fuller discussion of the Keynesian view see INCOME AND EMPLOYMENT THEORY.)

The monetarist view. The Keynesian revolution swept the economics profession in the late 1930s and early 1940s; by the 1960s Keynesian ideas had become deeply embedded in the thinking of informed intellectuals. The course of events, however, did not follow the pattern that many had expected. Their analysis had predicted a great postwar depression if war spending was not replaced by other government spending. But government spending fell precipitously in the U.S. and elsewhere without ill effect. The analysis of the Keynesians had called for "cheap money" policies—that is, low interest rates—with a view to stimulating investment and thereby avoiding mass unemployment. Those policies proved in the main to be unnecessary; where they were adopted they were consistently followed by inflation that could be restrained only by abandoning the cheap-money policies. A re-examination of the Great Depression of the 1930s demonstrated that, contrary to general belief, it had been a tragic testament to the great power of monetary policy, not to its impotence. The U.S. Federal Reserve System could have prevented the decline of one-third in the quantity of money that occurred from 1929 to 1933. Had it done so, the evidence indicates, the depression would have been far milder and briefer. Most important of all, extensive empirical research demonstrated that the velocity of circulation of money, far from moving to offset changes in the quantity of money, has generally moved in the same direction and reinforced the effect of these changes.

The result has been a major change in the views of today's followers of Keynes. They attribute far more importance to the quantity of money than they earlier did, regarding the quantity of money demanded as less elastic with respect to interest rates, and investment as more elastic, than they did in the first flush of enthusiasm. Some economists have been waging a counter-revolution in the name of monetary policy, to which the name monetarism has become attached. This doctrine is in an early stage of development and was still, at the beginning of the 1970s, a minority view among professional economists. It had made significant gains, however, and had influenced considerably the views even of those who still regarded themselves as Keynesians.

No counterrevolution ever produces a return to the status quo. The emerging monetarist doctrine has much in common with the earlier quantity theory, but it has not expunged the Keynesian revolution. As one monetarist has put it, Keynes's liquidity preference analysis reinforced the shift of emphasis that had already been going on "from the transactions version of the quantity equation to the cash-balances version—a shift of emphasis from mechanical aspects of the payments process to the qualities of money as an asset." His analysis, though strictly in the cash-balances tradition, was much more explicit in stressing the role of money as one among many assets, and of interest rates as the relevant cost of holding money. The recent work of others "has gone still further in this direction treating the demand for money as . . . concerned with the composition of the balance sheet or portfolio of assets." (Milton Friedman, "A Theoretical Framework for Monetary Analysis," *Journal of Political Economy*, March/April 1970.) The Keynesian emphasis on the plasticity of velocity has led to much more extensive work on the stability of the demand for money, and in particular on the exploration of time lags between monetary changes and economic changes and on the separate effects of monetary changes on prices, output, and interest rates.

Key propositions. For the long run, however, monetarism accepts almost wholly the earlier quantity theory. Its main contribution to the earlier theory is a much more detailed and sophisticated analysis of short-run effects, and a more detailed set of empirical generalizations about these effects. The key propositions of monetarism are as follows:

1. The rate of growth of the quantity of money is consistently, though not precisely, related to the rate of growth of nominal income. That is, if the quantity of money grows rapidly, so will nominal income, and conversely. The velocity of circulation, though not constant, is fairly predictable.

2. This relation is not obvious to the naked eye, mainly because it takes time for changes in monetary growth to affect income.

The time factor in monetary policy

3. On the average, a change in the rate of monetary growth produces a change in the rate of growth of nominal income six to nine months later. But this is an average.

4. If the rate of monetary growth is reduced, then about six to nine months later the rate of growth of nominal income and also of physical output will decline, but the rate of price rise will be affected very little. There will be downward pressure on prices only as a gap emerges between actual and potential output.

5. The effect on prices comes on the average, six to nine months after the effect on nominal income and output, so that the total delay between a change in monetary growth and a change in the rate of inflation averages about 12 to 18 months.

6. The above relationships are not invariable. There is many a slip between the monetary change and the income change.

7. Monetary changes affect output only in the short run—though "short run" may mean five to ten years. Over the longer run the earlier quantity theory seems to hold, and the rate of monetary growth affects only prices. What

happens to output in the long run depends on such "real" factors as the enterprise, ingenuity, and industry of the people; the extent of thrift; the structure of industry and government; the relations among nations; and so on.

8. It follows from these propositions that *inflation is always and everywhere a monetary phenomenon,* in the sense that it cannot occur without a more rapid increase in the quantity of money than in output. There are, of course, many possible reasons for monetary growth—gold discoveries, the manner in which government spending is financed, and even the manner in which private spending is financed.

9. Government spending may or may not be inflationary. It will clearly be inflationary if it is financed by creating money—that is, by printing currency or creating bank deposits—and if the resultant rate of monetary growth exceeds the rate of growth of output. If it is financed by taxes or by borrowing from the public, the main effect is that the government spends the funds instead of someone else. Government fiscal policy is extremely important in determining the fraction of total income that is spent by the government and who bears the burden of that expenditure. But it is not necessarily inflationary.

10. One of the most difficult things to explain in simple fashion is the way in which a change in the quantity of money affects income. Generally, the initial effect is not on income at all but on the prices of existing assets (bonds, equities, houses, and other physical capital). This is the liquidity effect stressed by Keynes; it occurs on the balance sheet, not on the income account. An increased rate of monetary growth raises the amount of cash people (or businesses) have relative to other assets. The holders of the excess cash will try to correct this imbalance by buying other assets. But one man's spending is another man's receipts. All the people together cannot change the amount of cash all hold—only the monetary authorities can do that. However, their attempts will tend to raise the prices of assets and to reduce interest rates. These changes will in turn encourage spending (by businessmen and others) to produce new assets. That is how the initial effect on balance sheets gets translated into an effect on income and spending. In this connection the monetarists stress a far wider range of assets and interest rates than do the Keynesians; they give importance to such assets as durable consumer goods and other real property; they regard market interest rates as only a small part of the whole complex of rates that are relevant.

11. One important feature of this mechanism is that a change in monetary growth affects interest rates in one direction at the outset, and in the opposite direction later on. More rapid monetary growth at first tends to lower interest rates. But later on, as it raises spending and stimulates price inflation, it also produces a rise in the demand for loans that will tend to raise interest rates. That is why, around the world, interest rates are highest in the countries that have had the most rapid rise in the quantity of money and also in prices—countries like Brazil, Chile, and Korea in the 1960s. Taking the opposite case, a slower rate of monetary growth at first raises interest rates but later on, as it reduces spending and price inflation, it lowers interest rates. That is why interest rates are lowest in countries that have had the slowest increase in the quantity of money and in prices—countries like Switzerland and Germany in the 1960s. This inconsistent relation between the quantity of money and interest rates explains why monetarists insist that interest rates are not a good guide to monetary policy.

12. With respect to policy, these propositions clearly imply that monetary policy is important and that what is important about monetary policy is its effect on the quantity of money, not on bank credit or total credit or interest rates. Wide swings in the rate of change of the quantity of money are evidently destabilizing and should be avoided. Beyond this, different monetarists draw different conclusions. Some conclude that the monetary authorities should make deliberate changes in the rate of monetary growth in order to offset other forces making for instability; these changes should be gradual and small and make allowance for the lags involved. Others maintain that not enough is known about the relations between changes in the quantity of money and in prices and output to assure that a discretionary monetary policy will do good rather than harm. They believe that a wiser policy would be simply to have the quantity of money grow at a steady rate over time. They contend that this would provide a stable monetary framework for economic growth without itself being a source of instability and disturbance.

Conclusion. No other subject in economics has been studied longer or more intensively than the subject of money. The result is a vast amount of documented experience and a well-developed body of theoretical analysis. The extent to which the students of monetary problems agree in their basic conclusions is concealed by the tendency of laymen to exaggerate their differences. But even among professional economists there remain important disagreements, centring mainly on empirical judgments about the stability and form of some of the relations between money and other economic magnitudes.

Money Market

The functions of a money market

Every country with a monetary system of its own has to have some kind of market in which dealers in bills, notes, and other forms of short-term credit can buy and sell. The "money market" is a set of institutions or arrangements for handling what might be called wholesale transactions in money and short-term credit. The need for such facilities arises in much the same way that a similar need does in connection with the distribution of any of the products of a diversified economy to their final users at the retail level. If the retailer is to provide reasonably adequate service to his customers, he must have active contacts with others who specialize in making or handling bulk quantities of whatever is his stock-in-trade. The money market is made up of specialized facilities of exactly this kind. It exists for the purpose of improving the ability of the retailers of financial services—commercial banks, savings institutions, investment houses, lending agencies, and even governments—to do their job. It has little if any contact with the individuals or firms who maintain accounts with these various retailers or purchase their securities or borrow from them.

The elemental functions of a money market must be performed in any kind of modern economy, even one that is largely planned or socialist, but the arrangements in socialist countries do not ordinarily take the form of a market. Money markets exist in countries that use market processes rather than planned allocations to distribute most of their primary resources among alternative uses. The general distinguishing feature of a money market is that it relies upon open competition among those who are bulk suppliers of funds at any particular time and among those seeking bulk funds, to work out the best practicable distribution of the existing total volume of such funds.

In their market transactions, those with bulk supplies of

funds or demands for them, rely on groups of intermediaries who act as brokers or dealers. The characteristics of these middlemen, the services they perform, and their relationship to other parts of the financial mechanism vary widely from country to country. In many countries there is no single meeting place where the middlemen get together, yet in most countries the contacts among all participants are sufficiently open and free to assure each supplier or user of funds that he will get or pay a price that fairly reflects all of the influences (including his own) that are currently affecting the whole supply and the whole demand. In nearly all cases, moreover, the unifying force of competition is reflected at any given moment in a common price (that is, rate of interest) for similar transactions. Continuous fluctuations in the money market rates of interest result from changes in the pressure of available supplies of funds upon the market and in the pull of current demands upon the market.

BANKS AND THE MONEY MARKET

Commercial banks. Commercial banks are at the centre of most money markets, as both suppliers and users of funds, and in many markets a few large commercial banks serve also as middlemen. These banks have a unique place because it is their role to furnish an important part of the money supply. In some countries they do this by issuing their own notes, which circulate as part of the hand-to-hand currency. More often, however, it is checking accounts at commercial banks that constitute the major part of the country's money supply. In either case, the outstanding supply of bank money is in continual circulation, and any given bank may at any time have more funds coming in than going out, while at another time the outflow may be the larger. It is through the facilities of the money market that these net excesses and shortages are redistributed, so that the banking system as a whole can at all times provide the means of payment required for carrying on each country's business.

In the course of issuing money the commercial banks also actually create it by expanding their deposits, but they are not at liberty to create all that they may wish whenever they wish, for the total is limited by the volume of bank reserves and by the prevailing ratio between these reserves and bank deposits—a ratio that is set by law, regulation, or custom. The volume of reserves is controlled and varied by the central bank (such as the Bank of England, the Bank of France, or the Federal Reserve System in the U.S.), which is usually a governmental institution, is always charged with governmental duties, and almost invariably carries out a major part of its operations in the money market.

Volume of reserves

Central banks. The reserves of the commerical banks, which are continually being redistributed through the facilities of the money market, are in fact mainly deposit balances that these commercial banks have on the books of the central bank or notes issued by the central bank, which the commercial banks keep in their own vaults. As the central bank acquires additional assets, it pays for them by crediting depositors' accounts or by issuing its own notes; thus the potential volume of commercial bank reserves is enlarged. With more reserves, the commercial banks can make additional loans or investments, paying for them by entering credits to depositors' accounts on their books. And in that way the money supply is increased. It may be reduced by reversing the sequence. The central bank can sell some of its marketable assets in the money market or in markets closely interrelated with the money market; payment will be made by drawing down some of the commercial bank reserve balances on its books; and with smaller reserves remaining, the commercial banks will have to sell or reduce some of their investments or their loans. That, in turn, results in a shrinkage of the outstanding money supply. Central bank operations of this kind are called open-market operations.

The central bank may also increase bank reserves by making loans to the banks or to such intermediaries as bill dealers or dealers in government securities. Reduction of these loans correspondingly reduces bank reserves. Although the mechanics of these lending procedures vary widely among countries, all have one feature in common: the central bank establishes an interest rate for such borrowing—the bank rate or discount rate—pivotally significant in the structure of money market rates.

Money market assets may range from those with the highest form of liquidity—deposits at the central bank—through bank deposits to various forms of short-term paper such as treasury bills, dealers' loans, bankers' acceptances, and commercial paper, and including government securities of longer maturity and other kinds of credit instruments eligible for advances or rediscount at the central bank. Although details vary among countries, the touchstone of any money market asset other than money itself is its closeness—*i.e.*, the degree of its substitutability for money. So long as the institutions making use of a money market regard a particular type of credit instrument as a reasonably close substitute—that is, treat it as "liquid"—and so long as the central bank acquiesces in or approves of this approach, the instrument is in practice a money market asset. Thus no single definition or list can apply to the money markets of all countries nor will the list remain the same through the years in the money market of any given country.

THE INTERNATIONAL MONEY MARKET

Each central bank usually holds some form of reserve that is acceptable in settling international transactions. International monetary reserves are mainly gold, or "money market assets" in some country whose currency is widely used, such as the United States dollar. The monetary laws of all countries provide for the establishment of some kind of parity between their currencies and those of other countries. This parity may be defined either in terms of gold or in relation to a key currency such as the British pound sterling or the United States dollar, which in turn has a fixed parity with gold. A country maintains the "convertibility" of its currency by standing ready to buy and sell gold or other currencies in exchange for its own at prices within a fixed and rather narrow "spread" above or below the "exchange rate" for its own currency that is implied by the declared parity.

The buying and selling of currencies

Because world trade continually gives rise to various needs for payment in various currencies, an international money market must exist so that traders with an excess of one currency can use it to buy another currency for which they have a need. Within the scope of convertibility arrangements, this trading in currencies is carried out by skilled intermediaries, usually banks or specialized foreign exchange brokers and dealers. Trading in currencies is extensive both for immediate use ("spot") and for future ("forward") delivery. Quotations vary according to changes in supply and demand, over the range between the upper and lower buying and selling prices set by official parity. If no parity has been set quotations may fluctuate widely. If a currency is subject to exchange controls, there may be two or more quotations for different uses of the same nominal currency.

Changes in a country's balance of payments may affect the usefulness or prestige of its currency. A sustained and substantial balance of payments deficit (outpayments larger than inpayments), for example, will result in continuous large increases in the world supply of its currency, possibly leading to some decline in its acceptability abroad and to a loss of international monetary reserves. At the same time, an outward drain may reduce the reserves of the commercial banks (the base for the domestic money supply), unless the central bank takes off-setting action.

Since 1944 most of the countries that have domestic money markets or that play a role in the international money market have been joined together in the International Monetary Fund, which represents a pooling of part of the foreign exchange reserves (including gold) of more than 100 member countries. Drawings on the pool may be made by member countries to meet some of the reserve drains arising from balance of payments deficits and in amounts related to the quota that each has subscribed.

The internal money markets of a surprisingly high proportion of the countries of the world are quite rudimentary. The work of the money market in these countries is done largely by transfers of deposit balances, government securities, or foreign exchange among a few banks and between them and the central bank. But in nearly all such cases there is genuine discontent with the rigidity of these limited facilities and a desire to develop a structure, as well as instruments and procedures, which would provide the open-market attributes of the arrangements that have evolved in the leading countries. Several of the more fully developed money markets are described below (see also BANKS AND BANKING; EXCHANGE AND PAYMENTS, INTERNATIONAL).

THE U.S. MONEY MARKET

The Federal Reserve System

The domestic money market in the United States carries out the largest volume of transactions of any such market in the world; its participants include the most heterogeneous group of financial and nonfinancial concerns to be found in any money market; it permits trading in an unusually wide variety of money substitutes; and it is less centralized geographically than the money market of any other country. Although there has always been a clustering of money market activities in New York City and much of the country's participation in the international money market centres there, a process of continuous change during the 20th century has produced a genuinely national money market.

By 1935 the financial crises of the Great Depression had resulted in a basic revision of the banking laws. All gold had been withdrawn from internal circulation in 1933 and was henceforth held by the U.S. Treasury for use only in settling net flows of international payments among governments or central banks; its price was raised to $35 per ounce, and the U.S. dollar became the key currency in an international gold bullion standard. Domestically, the changes included legislative recognition of the primary importance of unified open-market operations by the Federal Reserve System and delegation to the board of governors of the Federal Reserve System of authority to raise or lower the ratios required between reserves and commercial bank deposits. Although about half of the 30,000 separate banks existing in the early 1920s had disappeared by the mid-1930s, the essential character of commercial banking in the U.S. remained that of a "unit" (or single-outlet) banking system in contrast to those of most other countries, which had a small number of large branch-banking organizations.

The unit banking system. This system has led inevitably to striking differences between money market arrangements in the United States and those of other countries. At times, some smaller banks almost inevitably find that the wholesale facilities of the money market cannot provide promptly the funds needed to meet unexpected reserve drains, as deposits move about the country from one bank to another. To provide temporary relief, pending a return flow of funds or more gradual disposal of other liquid assets in the money market, such banks have the privilege, if they are members of the Federal Reserve System, of borrowing for reasonable periods at their own Federal Reserve bank. At times some large banks, which serve as depositories for part of the liquid balances of many of the smaller ones (including those that are not members of the Federal Reserve System) also find that demands converging on them are much greater than expected. These large banks, too, can borrow temporarily at a Federal Reserve bank if other money market facilities are not adequate to their needs. Because these borrowing needs are unavoidably frequent in a vast unit banking system and, as a rule, do not indicate poor management, the discount rate charged by the Federal Reserve banks on such borrowing is not ordinarily put at punitive or severe penalty levels—thus, contrary to practice in many other countries, the central bank does not always maintain its interest rate well above those prevailing on marketable money market instruments. To avoid abuse, there is continuous surveillance of the borrowing banks by the Federal Reserve banks.

Along with this practice of borrowing at a Federal Reserve bank has developed the market for "federal funds." This specialized part of the money market provides for the direct transfer to a member bank of balances on the books of a Federal Reserve bank in return for payment of a variable rate of interest called the "federal funds rate." These funds are immediately available. There are transactions, too, in funds that are on deposit at commercial banks—by means of loans between banks, or through loans by one large depositor to another. Because these must be collected through a clearing process, they are usually called "clearinghouse funds."

Money market instruments. Transactions in federal funds and clearinghouse funds are further supplemented by transactions in which either kind of money is exchanged for some other liquid, money market instrument, most frequently government securities. The magnitude of the market for government securities became so great after World War II that it overshadowed all other elements of the money market. Trading in outstanding "governments" is virtually all done through dealers who buy and sell for their own account at prices which they quote on request (standing ready to "bid" for or to "offer" any outstanding issue). Most of these dealers have head offices located in New York City, but all are engaged in nationwide operations. Their transactions and the lending arrangements through which they finance their own inventories of government securities have evolved into a particularly sensitive indicator of the pressures of supply and demand on the money market from day to day. The most common form of dealer financing is the repurchase agreement, through which dealers sell parts of their inventory temporarily, subject to repurchase.

Closely interrelated, often through trading operations conducted by the same dealers, are the much smaller markets for bank drafts, bills of exchange, and commercial paper. Alongside these other markets and actually somewhat larger in outstanding volume are the markets for securities issued by various "agencies" created by federal statute, such as the Federal Home Loan banks and Federal Land banks. Another money market instrument is the negotiable time certificate of deposit (CD), issued in large volume by commercial banks, which first became significant in 1962. While the owner of a time CD cannot withdraw his deposit before the maturity date initially agreed upon, he can sell it at any time in a secondary market that is conducted by government securities dealers.

Certificates of deposit

The Federal Reserve System conducts day-to-day operations in the money market on its own initiative in order to assist the smooth working of the nation's financial machinery and to exert a general influence aimed at fostering economic growth and limiting economic instability. Its transactions include substantial outright purchases or sales of government securities, relatively small purchases and run-offs of bankers' acceptances, and a considerable volume of loans made for a few days at a time to dealers in government securities or acceptances in the form of repurchase agreements. While it is still the commercial banks as a group that have the greatest continuing need for the combined facilities of the nationwide money market, there is frequent and continuous participation by a great variety of institutional investors who channel the public's savings into various uses and who must always also make some provision for their own liquidity.

Perhaps the most unusual feature in the composition of the U.S. money market is the great importance attained by nonfinancial business concerns and local units of government since World War II. Corporate treasurers and the treasurers of many states and local political subdivisions and authorities have become so keenly sensitive to the profitable possibilities of managing their own liquid holdings instead of relying on the commercial banks as most had done formerly that this group at times provides nearly as large a part of the volatile financing needs of government securities dealers, for example, as comes from the banks. Moreover, banks outside New York City sometimes supply more of the financing needed by these

dealers than do the traditional "money market banks" in New York City. The nationwide character of the money market is also shown by the participation of nearly 200 banks in the federal-funds market—banks that are widely scattered among all Federal Reserve districts, although the bulk of all transactions is executed through facilities located in New York.

While the U.S. money market has become truly national, it still needs a final clearing centre upon which the net impact of changes in overall supply or demand can ultimately converge and where the final balancing adjustments of the market as a whole can be accomplished. In filling that need, New York City continues to be the centre of the national money market.

(R.V.R.)

THE BRITISH MONEY MARKET

The discount houses. In Great Britain the money market consists of a number of linked markets, all of them concentrated in London. The 12 specialist banks known as discount houses have the longest history as money market institutions; they have their origin in the London bill broker who in the early 19th century made the market in inland commercial bills. By selling bills through this market, the growing industrial and urban areas were able to draw upon the surplus savings of the agricultural areas. Quite early many bill brokers began to borrow money from banks in order to buy and hold these bills, instead of simply acting as brokers, and thus became the first discount houses. Since then the major assets held by the discount houses have at different times been commercial bills (first inland bills as described above and later bills financing international trade), treasury bills, and short-dated government bonds. During the 1960s there was a resurgence of the commercial bill, which finally became the discount houses' largest single class of asset, only to be overtaken later by the certificate of deposit.

Important changes were introduced into the British monetary system in 1971, but money at call with the discount houses retained its role as a reserve asset. Such is the safety and liquidity of call money that, despite the fractionally lower rate on it compared with other reserve assets, the banks hold about half of their required reserves in this form. This in turn provides the discount houses with a large pool of funds, which they invest in relatively short-dated assets, of which the most important is sterling certificates of deposit, followed by commercial bills, local authority securities, and treasury bills. This pattern of assets is greatly influenced by the fact that all call loans to the discount houses are secured loans, parcels of assets being deposited *pro rata* with the lending banks as security, and the assets held by the discount houses must therefore be suitable for use as such security.

They also need to hold a substantial proportion of assets that are rediscountable at the Bank of England in case of need, and the Bank of England limits their holding of assets other than public sector debt to a maximum of 20 times their capital resources.

Operations in money

On the liabilities side of the discount house's balance sheet, operating in call money is part of its day-to-day work. A bank that expects to make net payments to other banks during the day (for example, in settlement of checks paid by its customers to their customers) will probably call in some of its call loans, and by convention this is done before noon. Since the banks that have called in money then pay it to other banks, these other banks will have an equal amount to re-lend to the discount houses in the afternoon. Thus the discount houses can "balance their books"—borrow enough money in the afternoon to replace the loans called from them in the morning.

It is not uncommon for perhaps £100,000,000 to be called from, and re-lent to, the discount houses on an active day.

There is one main reason why the money position may not balance in this way. The British government accounts are kept with the Bank of England, which does not lend at call as other banks do. Thus net payments into or out of these government accounts will cause a net shortage or surplus of money for the discount houses in the afternoon and will tend to cause money rates to rise or fall. The Bank of England can allow such shortages or surpluses to affect interest rates, or it can offset them by buying or selling bills or by lending overnight to the discount houses at market rates. Even if the Bank of England does not act in this way to meet a shortage of funds, the discount houses are always finally able to secure the funds they need by their right to borrow from the Bank of England (the lender of last resort) against approved security at the "minimum lending rate" (the penalty rate).

Dealing in assets

On the assets side of their balance sheets, the discount houses are active dealers in a number of the assets they hold. They make the market in sterling certificates of deposit and in commercial bills, quoting buying and selling rates for different maturities. They also quote selling rates for treasury bills that they acquire at the weekly tender in competition with each other and with any other banks that may tender, including the Bank of England. Most of these other banks tender for treasury bills in order to hold them to maturity, but the discount houses sell theirs on the average when only a few weeks of the bills' 91-day life has passed. A large proportion of these bills is sold to the clearing banks, which do not tender on their own account.

The Bank of England minimum lending rate is normally determined for each week 0.5–0.75 percent above the average treasury bill rate at the previous Friday's tender. The bank, however, has the power to fix it at a different level if it so wishes, and this has been done.

Other markets. Important changes have also occurred outside the discount market described above; after the mid-1950s there was steady growth in public borrowing by local authorities. This led to an active local authority loan market conducted through a number of brokers, where money can be lent on deposit for a range of maturities from two days up to a year (and indeed for longer periods). Much more rapid was the growth after the mid-1960s of the interbank market, in which banks borrow and lend unsecured for a range of maturities from overnight upward. This market also is conducted through brokers, often firms that also operate in the local authority and other markets; a number of these firms of brokers are subsidiaries of discount houses.

In addition to the markets mentioned, there is the gilt-edged (government bond) market on the stock exchange; short-dated bonds are held by the discount houses and by banks and other money market participants, as are short-dated local authority stocks and local authority "yearling" (very short-dated) bonds. With flexibility of bank deposit rates (at least for deposits of large denomination), both banks and nonbank transactors are faced with a wide and competitive range of sterling money market facilities in London.

Finally, mention should be made of the Euro-dollar market, because London is its centre; this is an entrepôt market with a very large volume of business in U.S. dollar balances, conducted through brokers (often the same firms that operate in the sterling markets), and U.K. banks are active participants. However, owing to exchange control there has been little significant interaction between the Euro-dollar market and the U.K. domestic money market.

(R.F.G.A.)

THE MONEY MARKETS OF OTHER COUNTRIES

The Canadian money market. The Canadian money market was substantially broadened in 1954 with the introduction of day-to-day bank loans against Government of Canada treasury bills and other short-term government and government-guaranteed securities. Treasury bills of 91 days' and 182 days' maturity are issued weekly with the occasional offering of a longer maturity of up to one year. Government of Canada bonds and Government of Canada guaranteed bonds are issued at less regular intervals.

Groups involved in the money market are the following: the government, as the issuer of the securities; the Bank of Canada, acting as issuing agent for the government and as a large holder of market material; the chartered banks, as large holders and as distributors and potential buyers and sellers of bills and bonds at all times; the security dealers, as carriers of inventories and traders in such securities; and the public (mainly provincial and municipal governments and larger corporations), as short-term investors.

Treasury bills are sold by competitive tender in which the Bank of Canada, the chartered banks, and a small number of investment dealers participate. Bonds are normally issued at a price at which the yield is in line with outstanding comparable issues.

The central bank, through its tender at the weekly treasury-bill sale, active manipulation of its own bill and bond portfolio, and regulation of the money supply, has workable instruments for active monetary control. For both banks and qualified dealers, the Bank of Canada acts as lender of last resort. The rate is set slightly above the average rate of the last treasury bill auction to discourage regular borrowing.

The West German money market. In West Germany, where the money market developed strongly after World War II, transactions are to a large extent confined to interbank loans. In addition, insurance companies and other nonbank investors are also important lenders of short-term funds. Treasury bills and other short-term bills and notes from government agencies (railways and post) were gaining in importance by the 1960s, whereas in 1955 certain nonmarketable securities (the so-called equalization claims, created during the 1948 currency reform) held by the Bundesbank were transformed into short-term marketable securities in order to obtain suitable market material for the open-market operations of the Bundesbank. Banks are not used to dealing in short-term government securities between each other. They generally either hold these securities to maturity or resell them to the central bank at its buying rates, so that a true money market has not developed.

The market for commercial paper is of some significance, and dealing in it takes place from time to time between banks, especially in times of tight market conditions. Comprehensive regulations have been given through the Bundesbank about the rediscountability of the several kinds of commercial paper.

The influence of the Bundesbank on the monetary situation through open-market operations by the 1960s was greatly hampered by the vast liquidity of the banking system as a consequence of the persistence of Germany's favourable balance of payments situation.

The French money market. The French money market is fairly well established, but its size is restricted by the fact that in France currency still plays an important role in the money supply, whereas by regulations the nonfinancial private sector of the economy is excluded from dealing in the market. Banks as well as a few public or semipublic agencies working in the financial sphere and intermediaries—brokers and discount houses—constitute the market. Transactions take place in commercial paper and in treasury bills. The monetary authorities maintain a special bookkeeping system for all the treasury bills held by banks and other financial institutions, under which such bills are not represented by actual certificates but by entries in special accounts administered by the Banque de France for the treasury.

The central bank's open-market operations, which were normally limited to smoothing out disturbances in the local money market, have gained importance in recent years. Open-market transactions are effected to keep domestic money-market rates in line with international rates, in an effort to prevent unwanted capital flows. The possibilities of the central bank's influencing the monetary situation through the money market are limited to the large government needs for short-term funds, no market for long-term government borrowing being established.

(C.G.)

The Japanese money market. In Japan's rapidly growing economy the demand for funds, both short-term and long-term, has been persistently strong. Commercial banks and other financial institutions have therefore had an important role. The monetary authorities (the Ministry of Finance and the Bank of Japan) have been unwilling to allow market forces to equilibrate demand and supply in many financial markets for fear that interest rates would become excessively high. Most interest rates have been set administratively at levels high by international comparison (until the late 1960s) but lower than market forces would have dictated. Monetary policy is implemented by controls on both the availability of credit and its cost.

Under these circumstances Japan has had a very restricted money market. The market for short-term government securities is negligible; the low, pegged interest rate means that the Bank of Japan is the main buyer and that open-market operations are impossible. Transactions in commercial paper are minimal, being discouraged because they would tend to undermine the structure of interest rates and financial institutions.

Call money market in Japan

Only the call money market is well developed. It is restricted to transactions among financial institutions. The interest rate on call money has been relatively free, and persistently above most other short-term and long-term rates. Although small amounts are lent overnight, most are "unconditional loans" (repayment after one day's notice, with a minimum of two days) or "over-month-end-loans" (repayment on a fixed day the following month). The pattern of flows is rather stable, despite seasonal and cyclical fluctuations. City banks are the major borrowers; they have a strong demand for loans by large enterprises and use call funds as a major source of liquidity. Major lenders are local banks, trust banks, credit associations, and agricultural cooperatives, which collect individual urban and rural savings and are attracted by the high yields, liquidity, and low risk of call loans relative to other uses. Call brokers help make a market, though most funds flow directly from one financial institution to another. About three-quarters of the funds flow through the Tokyo market, and there are also call markets in Ōsaka and Nagoya.

Money markets in developing countries. Well-developed money markets exist in only a few high-income countries. In other countries money markets are narrow, poorly integrated, and in many cases virtually nonexistent. Despite the many differences among countries, one can say in general that the degree of development of a country's financial system, including its money markets, is directly related to the level of its economy. Most very-low-income countries have limited financial systems in which money markets play no role. In many former colonies, notably in Africa, expatriate commercial banks had substituted for a local money market; the banks met fluctuations in loan demand by changing their balances at head offices in London or elsewhere. More recently, government policies have encouraged these banks to develop domestic channels for temporary surpluses and deficits. Persistent inflation has been another factor inhibiting the growth of money markets in developing countries, notably in Latin America.

Most developing countries, except those having socialist systems, have the encouragement of money markets as a policy objective, if only to provide outlets for short-term government securities. At the same time many of these governments pursue low-interest-rate policies in order to reduce the cost of government debt and to encourage investment. Such policies discourage saving and make money market instruments unattractive. Nevertheless, a demand for short-term funds and a supply of them exist in all market-oriented economies. In many developing countries these pressures have led to "unorganized money markets," which are often highly developed in urban areas. Such markets are unorganized because they are outside "normal" financial institutions; they manage to escape government controls over interest rates; but at the same time they do not function very effectively because interest rates are high and contacts between localities and among borrowers and lenders are limited. In all developing countries traditional forms of moneylending continue, particularly for agriculture and small enterprise.

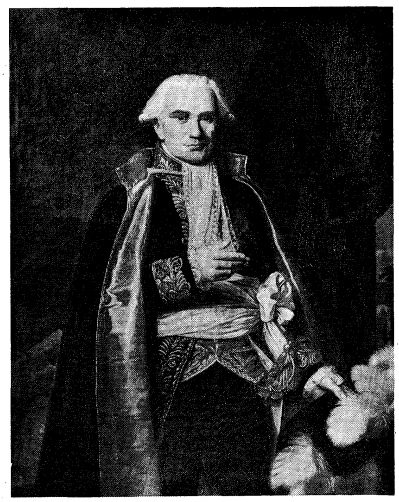
Monge, Gaspard

The French mathematician Gaspard Monge founded the techniques of descriptive geometry and pioneered the development of analytical geometry, both of which have since become part of projective geometry (*q.v.*). As a prominent figure during the French Revolution, he helped to found the École Polytechnique, where his lectures and textbooks substantially advanced mathematics at the beginning of the 19th century.

By courtesy of the Musee des Beaux-Arts de Beaune, France



Monge, detail of an oil painting by Jean Naigeon, 1811. In the Musée des Beaux-Arts de Beaune, France.

Born on May 10, 1746, at Beaune, Monge was educated at the college of the Oratorians at Beaune and at their college at Lyon, where for a time at age 16 he was a physics teacher. During a vacation visit to Beaune in 1762, he made a large-scale plan of the town, devising methods of observation and constructing the necessary surveying instruments. Impressed with the plan, a military officer recommended him to the commandant of the aristocratic École Militaire de Mézières, where he was accepted but as a draftsman only; because his father was an itinerant peddler, he could not be admitted to the commission program.

A further opportunity to display his skill as a draftsman occurred when he was required to work out from data the proper locations of gun emplacements for a proposed fortress. At that time such an operation could be performed only by a long arithmetic process, but Monge, substituting for this a geometrical method, obtained the result so quickly that the commandant at first refused to receive it. On careful examination, Monge's plan was considered of sufficient value that it was guarded as a military secret until 1795, when he was finally allowed to describe it in his lectures. Continuing his researches at Mézières, Monge developed his general method of applying geometry to problems of construction; this subject later became known as descriptive geometry.

Development of descriptive geometry

Between 1768 and 1783 Monge taught physics and mathematics at Mézières; in 1777 he married the widow Madame Horbou, and in 1780 he was appointed to a chair of hydraulics, held concurrently, at the Louvre in Paris. The same year he was elected an associate of the Académie des Sciences. In a paper discussing the problem of earthworks in 1781, "Sur la théorie des déblais et des remblais" ("On the Theory of Excavation and Emplacements"), he used calculus to determine the curvature of a surface. His memoir stated the ordinary differential equation of curvature and established the general theory.

Leaving Mézières permanently about 1783, Monge became increasingly active in public affairs in Paris. Between 1783 and about 1789 he was an examiner of naval cadets; he served on the committee of weights and measures that established the metric system in 1791; from 1792 to 1793 he was Minister for the Navy and Colonies and had occasion to welcome the young artillery officer who became the emperor Napoleon; and in 1795 he participated in the founding of the Institut National de France. Although at times during the Revolution his position was precarious, Monge continued to be influential. When an appeal was made to scientists to assist in producing materials for national defense, he supervised foundry operation and wrote factory handbooks, *Description de l'art de fabriquer les canons* (*The Art of Manufacturing Cannon*) and *Avis aux ouvriers en fer sur la fabrication de l'acier* (*Advice to Iron Workers in Steel Production*). In 1794–95 he taught at the short-lived École Normale, where he was given permission for the first time to lecture on the principles of descriptive geometry he had developed at Mézières.

Particularly important for mathematics was his substantial role in the founding in 1795 of the École Polytechnique, originally for training engineers; he was an administrator and an esteemed teacher of descriptive, analytical, and differential geometry. Since no texts were available, his lectures were edited and published for student use. Among them were two important texts in 1799: in his *Géométrie descriptive*, based on his lectures at the École Normale, he developed his descriptive method for representing a solid in three-dimensional space on a two-dimensional plane, by drawing the projections—known as plans, elevations, and traces—of the solid on a sheet of paper; his text *Feuilles d'analyse appliquée à la géométrie* established the algebraic methods of three-dimensional geometry. Engineering design was revolutionized by his new procedures. Moreover, mathematics education was significantly advanced by his successful texts and popular lectures.

Teaching and writing

In 1796 Monge officially met Napoleon and henceforth became his confidant and one of his closest friends. Napoleon sent him on a commission to Italy to choose the paintings and statues that were taken to help finance his military campaigns; many of these works of art went to the Louvre. From 1798 to 1801 he accompanied Napoleon to Egypt and in Cairo helped to establish in 1798 the Institut d'Égypt, the cultural organization that was patterned after the Institut de France.

With the fall from power of Napoleon in 1814, the Bourbons deprived Monge, as a Bonapartist, of all his honours and excluded him in 1816 from the list of members of the reconstituted Institut.

He died at Paris on July 28, 1818, following a stroke.

BIBLIOGRAPHY. Biographies of Monge include LOUIS DE LAUNAY, *Un Grand Français: Monge, fondateur de l'École*

polytechnique (1933); RENE TATON, *Gaspard Monge* (1950) and *L'Oeuvre scientifique de Monge* (1951); and PAUL V. AUBRY, *Monge, le savant ami de Napoléon Bonaparte, 1746–1818* (1954)—all in French. Shorter studies of Monge's life and work are also found in ERIC T. BELL, *Men of Mathematics* (1937, reprinted 1961); JULIAN LOWELL COOLIDGE, *A History of Geometrical Methods* (1940); GERHARD KOWALEWSKI, *Grosse Mathematiker* (1938); and NIELS NIELSEN, *Géomètres français sous la Révolution* (1929).

Mongolian People's Republic

The Mongolian People's Republic is a vast but sparsely populated highland country lying at the heart of eastern Asia, between the Soviet Union on the north and the People's Republic of China on the south. Its area is 604,000 square miles (1,565,000 square kilometres)—more than twice the size of Turkey, four times that of Japan. Its shape is that of an elongated oval, measuring almost 1,500 miles from west to east—a distance as far as that from Paris to Moscow—and, at its maximum, over 780 miles from north to south. The Soviet frontier accounts for just over 39 percent of its total boundary, the Chinese frontier for the remainder.

Mongolia has an average altitude of almost 5,200 feet above sea level but has a remarkable variety of scenery. The highest point is a towering 14,311 feet (4,362 metres), at the summit of Mönh Hayrhan Uul in the Mongol Altayn Nuruu (Mongolian Altai), one of the three great mountain ranges that thrust into the republic from the north and west. Some of these mountain areas are capped with eternal snow and ice, and their forest-clad slopes alternate with lake-filled basins and valleys cut out by tempestuous rivers. The east of Mongolia is a vast, hilly plain; and to the south lies the plateau of the Gobi, a desert covering a third of the country. Desert conditions proper are found in only about a third of the Gobi, the rest being oasis-dotted semidesert grassland; indeed, a typical Mongolian landscape is one with an undulating steppeland providing fine pastures.

The extent and character of the contemporary country

The Mongolians, who lent their name to one of the three great traditional racial groupings of the globe (the other two refer to peoples of Caucasoid and Negroid stock), have a long prehistory and a most remarkable history. Their ancestors were the Huns, who lived in Central Asia from the 3rd to the 1st century BC. A single Mongolian feudal state was eventually formed from nomadic tribal groupings in 1206, and its leader, Genghis Khan, and his successors plundered and conquered much of Eurasia. By 1691—weakened by internecine strife among the khans and the effects of foreign plundering—the Mongolian state fell prey to Manchurian conquerors. An independent feudal monarchy did not emerge until 1911. Stimulated by the influence of the October Revolution of 1917, Damdiny Sühbaatar, the modern national hero, organized militant antifeudal underground forces that began to drive out both White Russians and Chinese. Sühbaatar's forces achieved power on July 11, 1921, traditionally the founding date of the present state; and the Mongolian People's Republic was officially proclaimed on November 26, 1924, with its capital at Ulaanbaatar (Red Hero).

In 1918 Mongolia had a population of just under 650,000. Although endowed with a rich folk culture, it was unquestionably one of the most backward countries of Asia. The economy was based on centuries of nomadic cattle breeding; modern industry was nonexistent; secular feudal lords and the 100,000 or so religious leaders known as lamas owned 80 percent of the cattle; Chinese usurers and other foreign financial interests had a stranglehold on trade and credit; only 1 or 2 percent of the populace was literate; and mortality rates and health conditions generally were so bad that the population was in danger of extinction. By the 50th anniversary celebrations in 1971, the population had almost doubled, to 1,250,000; an intensive development program had brought industry's share of the national income up to nearly a quarter; agriculture had been transformed by the introduction of Socialist agricultural cooperatives and state farms; and a rapid development of cultivation enabled the country to become a net exporter, rather than importer, of grain. Urbanization was increasing, and Ulaanbaatar alone had a population of over 280,000, and half of its people were under age 20. Social services and cultural life, it was generally acknowledged, had also shown remarkable improvements. Mongolian authorities believe that their country's difficult and historically short transformation, aided by the Soviet Union and other Socialist countries, offers—notably to other nations of the developing world—an early model for development directly from a feudal to a Socialist society, bypassing capitalism. Mongolian plans for the middle and late 1970s called for a further development of industry until it became the predominant factor in the economy. Contemporary Mongolia has thus developed a marked and ever-changing personality of its own, with ancient traditions and an increasingly modern way of life often existing side by side. (The following article surveys life in contemporary Mongolia; for a historical survey, see INNER ASIA, HISTORY OF and MONGOLS; for related information on physical features, see GOBI [DESERT] and ALTAI MOUNTAINS; for geological evolution, see ASIA; see also ASIAN PEOPLES AND CULTURES; CENTRAL ASIAN PEOPLES, ARTS OF; ALTAIC LANGUAGES; and BUDDHISM, HISTORY OF).

(Sh.Nj./D.Go./D.Ds.)

THE LAND

Topography and drainage. Mongolia can be divided into three major topographic zones: the fingerlike mountain ridges that thrust into the northern areas; the basin areas that lie between and around them; and the enormous plateau belt that sweeps across the southern sector.

MONGOLIAN PEOPLE'S REPUBLIC

Size of symbol indicates relative size of town • ⊙ ▣ ▣ ■

Elevations in metres

The mountains. The present relief is due to the geologically recent upheavals of the Alpine mountain-building period. There are three major mountain belts. The highest and the longest spine of mountains is the westernmost, the Altai, which sweeps in from the northwestern tip of the country and thrusts toward the southeast for 1,000 miles. The main range—the only one where contemporary glaciation has developed—is known as the Mongol Altayn Nuruu, and a lesser range splitting off to the southwest is known as the Govĭ Altayn Nuruu (Gobi Altai). The southeastern extremities of the main range also split into a number of smaller hills, all following the same general trend, losing themselves in the expanses of the Gobi. The highest peaks of the Altai are in the west and north. The terrain further south and east is less rugged.

The three major mountain belts

The Hangayn Nuruu (Khangai Mountains), also trending northwest to southeast, forms a solid mountain mass near the centre of the republic, with peaks towering to over 12,000 feet, culminating in Otgon Tenger Uul, 12,811 feet (3,905 metres). A characteristic feature is the gentle slopes and crests, often covered with fine pastures. The higher central portions are nevertheless rugged and precipitous. To the north, the Hövsgöl Nuruu (Khubsugal Mountains), adjoining the vast Sayan Mountains that curve away beyond the Soviet border, have a similar topography.

The third mountain block, the Hentiyn Nuruu (Khentei), is smaller and lower, exhibiting in smaller compass some of the isolated grandeur of the Hangayn Nuruu. The Hentiyn Nuruu lies northeast of Ulaanbaatar, trending southwest to northeast, and reaches heights of between 6,500 and 8,000 feet. The enormous Great Khingan Mountains rise along and beyond the eastern frontier with China.

The northern intermontane basins. Around and between the main ranges mentioned lie an important series of basins, often choked with accumulations of material swept down from nearby mountains. In the northwest of the country, tucked between the Altai, the Hangayn, and the mountains of the Soviet frontier, lies a scenic basin complex known as the Great Lakes region, in which are strewn more than 300 lakes. Another basin complex lies between the eastern slopes of the Hangayn Nuruu and the western foothills of the Hentiyn Nuruu. The southern portion (Tuul Gol–Orhon Gol Basin) is a fertile region important in Mongolian history as the cradle of settled ways of life, and its landscapes are strewn with the ruins of ancient communities. Further north, on the northern flanks of the Hangayn Nuruu, lies the remarkable Khorgo region, in which as many as half a dozen extinct volcanoes and numerous volcanic lakes are found in quite a small area. Swift and turbulent rivers have cut jagged gorges. At the source of the Orhon Gol there is another volcanic region, with a cluster of lakes, deep volcanic vents, hot springs, and the constant roar of the Tsagan-Azraga Mörön (White Stallion River), almost invisible in its deep gorge. Near the northern border, Hövsgöl Nuur (Lake Khubsugal) is the focus of another rugged, lake-strewn region, noted for its huge subterranean caves.

The plateau and desert belt. The eastern part of Mongolia has a rolling topography of hilly steppe plains, supplanted in the extreme east by clusters of small, flat plains lying at altitudes of 2,000 to 2,300 feet. Here and there, small, stubby massifs contain the clearly discernible cones of extinct volcanoes. The Dariganga area of Mongolia's eastern tip contains some 220 such extinct volcanoes. Most of the southern part of the country is a vast rolling oasis-dotted plain, forming the northern fringe of the Gobi, which is predominantly stony, with sands covering only about 3 percent of the terrain. The flat relief is occasionally broken by low, heavily eroded ranges. Several spectacular natural features are found in the Gobi region. Huge basalt columns, arranged in clusters resembling bundles of six-sided pencils, are found in the eastern and central regions. The south Gobi contains three mountain ranges known as Gov Gurvan Saikhan (Three Gobi Beauties) and the famous Yelyn Am (Valley of Condors), now a national park, with deep gorges surrounded by the towering rocky cliffs where the condors have made their nests. This well-watered region offers a startling contrast to the surrounding steppes, which seemingly extend endlessly, covered with stone fragments and brown patches of withered grass.

Features of the Gobi

Rivers and lakes. Throughout the whole country, many streams and rivers, some of which are seasonal, run into salt lakes or the stones and sand of the desert areas. In the northern regions, the turbulent mountain streams and small rivers merge into quite deep, well-developed rivers. In the southern areas, where there are only a few constantly flowing rivers, numerous lakes, saltwater and freshwater springs, and wells draw on subterranean water supplies. The great divide, separating waters that flow into the Arctic and Pacific oceans and into the interior basins of Central Asia, runs along the crests of the Hentiyn, Hangayn, and, in part, the Altai mountains. Mongolia's greatest but third longest river, the Selenge Mörön (Selenga), with its tributaries, the Delger Mörön, Ider Gol, Orhon Gol, and others, drains northward toward Lake Baikal, crossing the Soviet border alongside the Trans-Mongolian Railway. The Mongolian portion of the Selenge Mörön Valley, measuring 109,000 square miles, is in the central northern portion of the country. The second major river, the Onon, and the Kerulen and the Halhïn Gol run latitudinally across the eastern part of the country, finally emptying into the Pacific. The largest river draining to the Central Asian interior is the Hovd (Kobdo), which rises from the glaciers of the Altai and drains part of the northwest corner of the country. A series of rivers runs down from the southern flanks of the Hangayn, ending in salt lakes or disappearing in the Gobi expanses. Generally, the Mongolian rivers are swift and with a steep gradient, offering considerable hydroelectric potential, as well as occasional flood dangers.

There are over 3,000 lakes in Mongolia with an area of half a square mile or more. Hövsgöl Nuur, already mentioned, the deepest lake (1,781 feet [238 metres]) in Central Asia, occupies a structural depression. Many of the lakes are of volcanic origin, as is Terhiyn Tsagaan Nuur on the northern Hangayn slopes. A thick layer of lava once blocked the waters of the Terhiyn Gol to form this 24-square-mile lake, lying at an altitude of 6,760 feet (2,060 metres). In the lake a small island is a famous bird sanctuary. Bayan Nuur, on the western Hangayn slopes, one of the country's loveliest lakes, fringed by golden sand dunes and rich in wild life, is associated with a romantic legend of a former city reputed to have vanished into the depths, a tale given some support by the archaeological remains dredged from the lake. Mongolia also has a number of medicinal springs, one of the best known being associated with Hatan Hayrhan, a heart-shaped massif rising from sand dunes in the western Gobi. The medicinal spring flows from a crevice in its side and has, over the centuries, worn the seven deep basins known locally as the Kettles of Hatan Hayrhan.

Volcanic lakes

Earthquakes. Mongolia is prone to seismic movements, with some earthquakes reaching extreme limits of severity, although their effects are fortunately diminished by the low population density.

Climate. Situated far from the moderating influences of the world's oceans, Mongolia experiences a markedly continental climate, with cold winters and hot summers. The dry mountain air and the tempering of the heat by rainfall, which falls mainly in the summer, nevertheless ameliorate the more extreme conditions. Weather is often unpredictable, and the sudden downpours of the summer months can occasion severe flooding. Spring meltwater, too, can swell the rivers: the spring ice run on the Tengis Gol, which runs through the Hövsgöl area, is an awesome spectacle, with its thunderous cannonading of breaking ice, swept down through gorges by the pressure of meltwater. Heavy snow occurs only in the mountain regions, but fierce blizzards of almost indescribable severity can sweep across the steppes, and even a thin coating of snow can prevent animals from getting at their pasture. One famous feature of the climate is the number of clear sunny days, averaging between 220 and 260 each year. Climatic statistics reveal a contrast between the northern and southern regions. In the Hövsgöl and Hentiyn moun-

tains, the mean annual temperature is about 28.6° to 25.7° F (−1.9 to −3.5° C), and the annual precipitation is from 16 to 20 inches; in the Gobi region, the annual precipitation is not more than 4 to 5 inches and only half this, or less, in some areas. The mean annual temperature is 39° F (4° C). There is great variation between the coldest and hottest months. Mean January temperatures in the north fall to −29° F (−34° C), and in the Gobi to −2.2° F (−19° C), while the corresponding July figures are 59° F (15° C) and 73° F (23° C), respectively. Temperature variations of as much as 55° F (30° C) may occur in a single day, and sand or hail storms may spring up almost without warning. (Sh.Ts.)

Plant and animal life. *Vegetation zones.* Climatic conditions are reflected in soil and vegetation patterns. Soils are predominantly of the chestnut or brown type, but latitudinal and altitudinal belts of vegetation, often changing rapidly over a few miles, are probably the most obvious feature of the local Mongolian landscape. There are four basic divisions running latitudinally from north to south: the forest–steppe zone of the mountains; the mountain–steppe zone; and, in the south and extreme south, respectively, the semidesert and desert zones. In addition, the mountain areas are characterized by two successive altitudinal belts: the mountain–taiga and the alpine zones. The steppes predominate, covering more than three-quarters of the national territory.

The importance of latitudinal and altitudinal belts

The mountain forest–steppe zone, with the two superimposed altitudinal belts mentioned, covers about 30 percent of the country and exhibits the richest diversity of plant and animal life. Forests grow thickest on the northern shady slopes, the most widespread tree being the Siberian larch, followed by the cedar, with a varying admixture of spruce, pine, and fir. Deciduous trees include the birch, aspen, and poplar. Steppe vegetation is found in the intermontane basins, the wide river valleys, and the sunny southern flanks of the mountains. These huge expanses of pastureland are covered with feather grass, couch grass, wormwood, and many fodder plant species. In summer, the steppes are carpeted with a magnificent covering of bright violet, blue, red, and yellow flowers. On the highest mountain slopes, the damp, dark, coniferous forest of the taiga gives way to the thin grasses and occasional flowers of the alpine zone, merging into the bare rocks and rugged glaciers of the summit zone.

Semideserts are found in the Great Lakes intermontane depression and, in general, over the Gobi, giving way to true desert conditions near the southern border. Vegetation is scarce there but heavy enough to feed camels, goats, and sheep. Tracts of saksaul (xerophytic [adapted to very dry conditions] vegetation) and groves of elm and poplars cluster around springs or other underground water sources. Only in the far south is there a narrow belt of the Gobi. This is a typical hammada, or rock-floored desert with gravel cover: only the extreme east has small areas of sandy desert.

Animal life. The varied natural conditions, the interior location, and the sparse human population of Mongolia all contribute to a very rich and diverse wildlife that has attracted international attention and has great commercial importance. Lying on the borders of several distinct zoogeographical regions (the Tibetan, the Afghano-Turkistani, the Siberian, and the North-Chinese-Manchurian), the country has a fauna combining species from each of them. The northern forests harbour lynx, maral (Asiatic red deer), elk, roe deer, musk deer, brown bears, snow leopards, wolverines, boars, squirrels, and sables. The steppes are the home of, among others, the marmot—whose pelts are very important economically—and the lithe Mongolian gazelle. Clustering around water holes in the semidesert and desert region may be found the wild sheep known as *argal*, *kulans* (wild asses), Przewalski's wild horses (*takhs*), wild camels (*khavtgays*), and the Gobi bear (*mazalai*), some of which are extremely rare and found nowhere else in Asia. Domesticated animals include sheep, camels, cattle, the hairy highland yak, goats, dogs, and the famous Mongolian horses. Bird life includes larks, partridges, cranes, bustards, and falcons in the steppes; geese, ducks, gulls, pelicans, swans, and cormorants in the rivers and lakes; the snowy owl, the golden eagle, and the condor, which frequent some areas. The freshwater lakes and rivers harbour some 60 fish species, including salmon, trout, grayling, perch, and pike. Hunting and fishing, for sport and for commercial purposes, are important; but the government has introduced stringent hunting regulations and other conservationist measures, including the establishment of national parks and nature reserves.

(D.Ba./O.Sh.)

The human imprint. *Rural patterns.* The hand of man has long been in evidence in this part of what is sometimes called High Asia; and the ruins of long-abandoned cities, as well as archaeological remains dating back to the earliest days of prehistory, have attracted the attention of Mongolian and international scholars. The huge rural areas of the country have their own charm. The steppelands and other pasture regions cover, in all, 83 percent of all Mongolian territory, and almost two-thirds of the population are livestock breeders and farmers, although a more settled way of life has gradually replaced the old nomadic traditions. A distinctive feature of the countryside is the *gher*, or *yurt*, the traditional Mongolian dwelling. It is a cone-shaped, latticed structure, light, strong, and easy to assemble, transport, and reerect, which offers warmth in winter and coolness in summer. It is still used by herdsmen moving from pasture to pasture, and the clusters of white felt and canvas cones against a green background still dominate the landscape in many areas. As the agricultural population becomes more settled, however, the *yurt* clusters are becoming associated with some 300 enormous cooperatives and state farms, often at centres with more permanent dwellings. The sinking of mines, extension of communications, the development of virgin lands, and extensive irrigation projects were all altering the face of the countryside in the 1970s.

The *gher*

Urban patterns. It is in the cities, however, that Mongolia presents its modern aspect. By the 1969 census, the population defined as urban had reached almost 530,000 (compared with a rural total of 670,000). Ulaanbaatar, with over 280,000 people, is most important by far among the urban centres. It lies on the banks of the Tuul Gol (Tula River) in the north central portion of Mongolia. Formerly known as Urga or Ikh Khuree, it was originally a nomadic princely residence and became settled on the present site in 1639. The old city—which numbered some 60,000 people in 1921—consisted mainly of monasteries, a few adobe structures, and clusters of *yurts*. A number of sections divided according to class and nationality showed marked contrasts between rich and poor areas. By the 1970s, however, the "city of felt" had become transformed into a modern industrial city, with broad avenues and streets, apartment complexes, and massive governmental, cultural, and educational buildings. The *yurt* areas and the fenced-off small houses were a fast diminishing feature of the peripheral regions. A vast urban planning scheme, initiated in 1961, is scheduled to run to 1980, by which time it is planned to divide the capital into 19 districts, each with a modern central complex of service and cultural centres. The contemporary city thus gives the impression of a giant construction site. It grew by 20 percent in the 1965–70 period alone.

Growth of Darhan

The city of Darhan, lying on the Trans-Mongolian Railway link to the north of Ulaanbaatar on the way to the Soviet frontier, is a spectacular example of planned urbanization. Its foundation stone was laid in 1961 in an existing settlement of 1,500 people. By 1970 its youthful population (three out of four people were under 40) had passed the 23,000 mark and was growing rapidly as the new city became the centre of a major industrial complex, second only to Ulaanbaatar itself. Much of the construction was achieved with the help of specialists and workers from other countries of the Socialist bloc, some from as far away as Hungary. Sühbaatar, founded in 1937, is the third largest industrial centre. Choybalsan, in the east, is another new industrial complex. Dzüün-bayan, in the eastern Gobi, is an example of a new town that has sprung up as a result of mining and oil-drilling activi-

ties. A steady growth is also taking place in other, smaller, urban centres, one or more of which are to be found in each of the 18 *aymags*, or provinces. By the 1969 census, the urban percentage in each *aymag* ranged from a low of 15 to a high of 58.9, and further incursions of modernity were expected to continue.

THE PEOPLE

Ethnic, religious, and social background. Anthropologically, the Mongolians are quite homogeneous, with nine out of 10 belonging to the classic physical type to which they lent their name. In appearance, they are of short, stocky build, with yellow to dark-brown skin colour and dark hair, and with eyes characteristically slanted. Ethnically, Kahlka-speaking Mongolians predominate, with just over 75 percent of the total population. Mongolians also form a minority in neighbouring countries, notably in the Inner Mongolian region of China and also in parts of the Soviet Union. The modern republic is also the home of over 60,000 Kazakhs (about 5 percent of the total population) and smaller numbers of Durbet, Buryat, Dariganga, Uryankhai, Dzakhchin, Torgut, Ould, Russian, and other peoples.

The theocratic background

At the time of the founding of the modern state, the social composition was strongly influenced by the then prevailing religious traditions of the lamas, who followed tenets derived from Tibetan Buddhism, with a strong admixture of more primitive elements. About 100,000 monks of all classes (about 40 percent of the entire male population), 20,000 concentrated in the capital alone, inhabited some 700 monasteries and were bound by vows of celibacy. The secular and clerical feudal lords owned half the national wealth (although comprising only about 8 percent of the population); and control lay in the hands of the head of the Mongolian Tibetan Buddhist Church (who was proclaimed the khan of all Mongolia), together with various local khans, hundreds of princes and noblemen, and the higher clergy. The whole theocratic system, it is generally acknowledged, was in a state of extreme backwardness—made worse by various internecine struggles—and served to preclude national development on any modern basis, as well as exposing the country to outside influence. The ensuing dramatic changes in social composition that accompanied the modernization of Mongolia may be seen by comparing 1925, 1956, and 1969 census data. In the first year, workers, employees, and members of their families, taken as a social category, were nonexistent; by 1956 they had formed 25.9 percent, and by 1969, 56.4 percent of the total population. Members of agricultural cooperatives, related artisans, and members of their families again were a nonexistent category in 1925 but formed 11.1 and 43.5 percent, respectively, in 1956 and 1969. Individual (that is, noncollectivized) livestock breeders, related artisans, and their families, however, formed 86.6 percent of the total in 1925, but their share had fallen to 62.8 in 1956 and to less than 1 percent in 1969. Other social groups—chiefly the landowners, secular and clerical—formed 13.4 percent of the total in 1925 but less than 1 percent in 1956 and 1969. The social development indicated by these changes is the key factor underlying contemporary Mongolian life. Although occasionally a lama may be seen striding in his bright robes through the capital, and many aspects of the national cultural traditions are preserved in museums, it is the young, educated Mongolian—often an urban worker —who is increasingly setting the pace of national life.

Demographic trends. At the time of the foundation of the present Mongolian state, a high rate of disease and, particularly, a high infant mortality rate had produced a situation that, if it had been allowed to continue, would, many now believe, have endangered the survival of the entire population. In 1925, for example, the census recorded only two physicians, five medical assistants, and three nurses in the entire country. Since then, a concerted effort at affording the populace a reasonable level of medical care has reduced mortality rates considerably: as a result, contemporary Mongolia has a natural growth rate (excess of births over deaths) of about 3 percent per annum, one of the highest in Asia. The total population doubled in the first half century of the republic's history; and life expectancy also doubled, reaching approximately 65 years. Increasing urbanization and industrialization have already been noted: in absolute terms, the urban population rose from 183,000 in 1956 to 403,000 in 1963 and to 527,000 in 1969; the corresponding rural figures for the same years were 663,000; 614,000; and 670,000, respectively. The population density rose slowly over the first 50 years. In 1918 it was 1.09 per square mile (0.42 per square kilometre); by 1970 it had risen to 2.05 per square mile (0.79 per square kilometre)—a figure still remarkably low by global standards. In the individual *aymags* (first-order administrative divisions), density ranges from a low of 0.41 per square mile (0.16 per square kilometre) in Ömnögovĭ to 3.39 per square mile (1.31 per square kilometre) in Arhangay. Urbanization and an increasingly youthful, fast-growing population seem likely to characterize the demographic structure of the country for decades to come. (B.Gu.)

Population growth

THE ECONOMY

The resource policy background. Mongolia is rich in mineral resources. Geological surveys have confirmed the existence of large deposits of coal and iron, tin, copper, gold, and silver ore and a number of lesser known minerals. Mongolia's biological resources consist largely of the great herds of livestock in the country: in 1918, the total number of livestock was 9,645,600: 228,700 camels; 1,150,500 horses; 1,078,400 cattle; 5,700,100 sheep; and 1,487,900 goats. By 1970 livestock totalled 22,574,900: 633,500 camels; 2,317,900 horses; 2,107,800 cattle; 13,-311,700 sheep; and 4,204,000 goats. Overall per capita livestock figures thus rose from 14.9 in 1918 to 18.1 in 1970, providing a rich agricultural resource base which even enabled some exports of meat to be made. In addition, the northern rivers of Mongolia offer great potential for hydroelectric development, whereas the wildlife of the country offers considerable potential for commercial exploitation, a circumstance attested by the fact that the Mongolian Huntsmen's Association has some 30,000 members who kill, under conservationist restrictions, some 2,000,000 to 3,000,000 animals yearly.

Livestock

The present economic status of the country, however, cannot be understood without noting the development programs that have molded the economy of the country since its inception, because they underlie many of the changes now visible in Mongolian economy and society. In the Mongolian viewpoint, the basic task facing the new state at its inception was to abolish the backwardness of the economy (particularly its exclusive role as a supplier

of raw materials to other countries) by setting it on what was officially characterized as an anti-imperialist, anti-feudal, and noncapitalist path, first by building an agrarian–industrial economy and then by proceeding to the building of an industrial–agrarian state within a Socialist framework. The more than half century of intensive effort along these lines is of considerable interest because Mongolia was the first of the eastern nations of Eurasia to take this difficult course. With not a single industrial unit in existence in the country at its commencement, the foundations of industrialization were laid in the 1930s; and gross industrial output was growing steadily in the 1970s; in 1971 industry was yielding 20 percent of the national income, 36 percent of the gross national product, and 15 percent of the country's exports and was developing at the high annual rate of about 10 percent. Technical and economic assistance from the Soviet Union and other Socialist countries (more recently through the Council for Mutual Economic Assistance, or Comecon) played an important role in bringing this situation about. Agriculture still remained the main branch of the Mongolian economy, and 64 percent of the population were livestock breeders. Agriculture saw many technical advances after the introduction of a cooperative system in the 1950s. This continuing economic transformation has been the foundation of the social and cultural advances in the country.

The role of agriculture. Mongolian agriculture underwent radical changes in the decades after 1921. Until the late 1930s, the main emphasis was on dispossessing the large landowners and state functionaries; and some cooperative trading enterprises were introduced. After the post-World War II economic expansion, the then existing small individual *arat* (herdsmen and farmers) households were officially regarded as increasingly anachronistic, and as a result of an intensive campaign beginning in the late 1950s, agriculture changed over from small, extensive production to large-scale commodity production; and the 200,000 or so *arat* households were replaced by over 270 cooperative agricultural associations and over 30 state farms. On the average, each of these associations has 60,000 head of stock, 1,000 acres (400 hectares) of sown land, seven tractors, and seven motor vehicles. A state farm has, on the average, 27,000 head of stock, more than 32,000 acres (13,000 hectares) of arable land, over 60 tractors, and nearly 30 vehicles. The number of livestock per capita (over 20) is the highest in the world. *Arat* members, in addition to sharing the income from the sale of produce, have the right to pursue personal husbandry, with up to 50 head of stock in the north and 75 in the south. The other major change was the plowing up of virgin lands and a substantial development of crop farming, which contributed about a fifth of the gross agricultural output by the early 1970s. This development has enabled the country to cover its needs in flour, and to grow vegetables and fodder crops on an increasing scale. The introduction of large-scale activities has been accompanied by the mechanization of grain growing, vegetable growing, and hay mowing; and the spread of electricity has aided sheep shearing and milking. Fodder storage and livestock premises—hitherto virtually unknown—help protect against adverse weather conditions. Livestock breeding is now carried out on scientific principles.

The introduction of cooperatives

The role of industry. The introduction and development of industry have been the key to government planning since the foundation of Mongolia. Enormous initial difficulties were encountered, and the lack of technical knowledge and the need for huge capital investment were only overcome by outside assistance from the Soviet Union. The first factories, built in the 1920s and 1930s, processed timber, animal raw materials, and building materials; and mining and power-generation activities were also started. Through a system of producer cooperatives, industry was extended over the 1930s; but the main thrust toward industrialization took place as a result of the 1948–52 and the 1953–57 five-year plans, and the 1958–60 three-year plan. In the late 1950s, the national flour-milling industry, a result of the virgin-lands program, joined earlier endeavours in the light, food, and mining industries. Fuel and power industries were also extended. The heavy program of capital investment in industry was accelerated in the 1960s, when it totalled more than three times the entire investment in the previous 40 years and produced a 250 percent increase in industrial output over the decade. By 1971 industry was contributing almost a quarter of the national income. Emphasis was then placed on diversification, technical efficiency, and overall productivity.

The need for investment capital

The economic outlook. The economic development of Mongolia is by no means complete. Agriculture formerly stimulated industrial development by enabling the processing of animal products to raise overall economic efficiency; but industry in the 1970s was sufficiently important to enable development of the country's great natural mineral wealth. This, in turn, helped to overcome the heavy dependence on animal husbandry in the nation's exports. Animal husbandry, while capable of yielding high quality and cheap produce, is not, unfortunately, free from natural calamities. Thus efforts were directed, in agriculture, at increasing productivity, improving quality of products, and achieving stable crop yields, with the aim of satisfying the ever increasing demands of industry and foreign trade and the needs of the urbanizing population for vegetables and milk. These tasks require the implementation of programs reaching forward to the mid-1980s. Heavy investment in equipment and great emphasis on the rational use of resources in the still relatively new large-scale agriculture units were planned. Full cost accounting and the training of experts were also being emphasized. In industry, plans for the 1970s called for efficient use of scientific and technological knowledge, with special attention to geological prospecting, fuel and power development, and the growth of export industries. The ultimate aim was to transform Mongolia into an industrial–agrarian country with a rational and balanced mining and manufacturing structure and with the various elements of the national economy operating in optimal and efficient combination.

Transportation. Transportation, too, has played a major role in integrating economic development. In 1921, the sole means of transport was the cartage handled by individual *arat* households on the basis of feudal duty, with the purpose of servicing the theocratic state structure. Only camel caravans were used. When the theocratic state structure was overthrown, a new transport system had to be created. The first state-run enterprise was set up in 1925, with meagre funds and seven motor vehicles. In 1929 a Mongolian–Soviet joint stock company known as Mongoltrans was formed to handle the freight and passenger traffic flow along roads and waterways. Bridges and highways were constructed, and in 1936 the entire system was turned over to the Mongolians. The new organization, Mongoltransport, had some 300 vehicles and employed 1,000 persons. Other branches of the system were also developing: as early as 1926 steamships plied the Hövsgöl Nuur and Selenge Mörön routes, handling imports and exports; and in 1938 Mongolia's first railroad linked Ulaanbaatar and Nalayh by a narrow gauge line. A year later the first wide-gauge link was opened between Choybalsan and Soloveysk, on the Soviet border. In 1940 the first air services were introduced. After World War II, further developments occurred. Motor depots were set up in all the *aymags* in the 1950s, vehicle fleets were modernized, and an extensive road- and bridge-building program resulted in a total network of 5,300 miles (8,600 kilometres) of major roads by the 1970s. The construction of the Trans-Mongolian Railway linking Moscow, Ulaanbaatar, and Peking over the 1949–55 period, a major step forward, acted as a stimulus to settlement along its length. In the 1970s air services linked all the *aymags* and almost half of the subsidiary *somons* and state farms. By the early 1970s, railway transport accounted for 71 percent of the freight carried and 30 percent of passenger traffic; motor transport accounted for 28 and 46 percent, respectively; and water and air transport accounted for less than 1 percent of freight carried, although air transport took almost 24 percent of passenger traffic. The annual number of pas-

Mongoltrans

sengers carried exceeded 50,000,000; and freight carriage totalled almost 15,000,000 tons annually. The transport system was expected to undergo further expansion.

(Sh.B./Sh.Nj.)

ADMINISTRATION AND SOCIAL CONDITIONS

Constitutional and political framework. The Mongolian constitution adopted in 1960 states that the country is a Socialist state of workers, *arats* (herdsmen and farmers) organized in cooperatives, and working intellectuals, in the form of a people's democracy. The constitution secures to citizens the right to work, to rest, and to leisure; to material aid in old age and in sickness or disability; and to education. It also safeguards rights of national minorities. It is the parallel duty of citizens to observe the laws, to maintain labour discipline, and to defend the freedom and independence of their country. The national flag incorporates an ideogram known as the *soyombo*, comprised of ancient symbolic elements, including the Yin-Yang principle of opposites. Officially, power is exercised through bodies known as the *khurals* of people's deputies. The Great People's Khural, or Parliament, is the supreme legislative body; and the Council of Ministers is its executive body.

All the *khurals* not only legislate decisions but also are permanently functioning organs, relying in their work on the help and support of the masses. The standing commissions of the *khurals* at every level, set up for every branch of the national economy and culture, take a direct and day-to-day part in their work. By 1972 there were about 1,500 standing commissions in the country, comprising 10,322 deputies, who furthermore involved in their activities vast numbers of the general public. The country is divided into 18 *aymags* (regions), with further local subdivisions into towns, *somons* (districts), and smaller districts known as *hurins*.

Judicial system

Justice is administered through the Supreme Court, which is elected by the Great People's Khural, and through the *aymag* and town courts, which are elected by the corresponding *khurals* of people's deputies. The procurator of the republic, appointed by the Great People's Khural, and the procurators of *aymags* and towns, appointed by the procurator of the republic, supervise the work of the courts.

Mongolia has a one-party system, and the Mongolian People's Revolutionary Party (MPRP), the most experienced of any governing Communist party outside the Soviet Union, is officially characterized as the guiding and directing force of the state. By the 1970s, its members numbered over 56,000. Its most active auxiliary organization, with about 90,000 members, is the Revolutionary Youth League, or Revsomol, which has always played an important role in social and economic transformation. Because one Mongolian in two is under 25, its significance continues to be great. The Mongolian trade unions, with about 220,000 members, are members of another important mass organization: they look after the interests of their members and also play an active role in the implementation of economic and social policy. There are also various cultural and professional bodies (including an important Committee for Afro-Asian Solidarity), as well as a Young Pioneer organization for children. The Organization of Mongolian Women is particularly significant because women had few or no rights in the pre-revolutionary era; and Mongolia was the first Asian country to grant them full equality in the modern sense. Women make up about a quarter of the total number of deputies in the Great Khural, form 70 percent of the medical personnel, about half of all teachers and students, and a third of all research workers.

The place of women

Social services. Educational development has from the first been regarded as one of the most important elements in the building of the new way of life. Until 1940 the main thrust was directed at the eradication of illiteracy, the establishment of a free system of public education, and the creation of a trained intelligentsia. The beginnings were scarcely auspicious, for only a small percentage of the population was literate; the entire country, in 1921, contained but one general educational school and no public secondary school or institution of higher education. By 1924 the country had 16 elementary schools; and by 1940 there were 331 general and seven secondary schools. From the 1940s on, the main educational emphasis passed to the establishment of higher education institutions and the expansion of elementary and secondary facilities. By 1970 there were almost 600 general schools, nearly 20 special vocational schools, and five higher education institutions—the Mongolian State University (established 1942), the Higher Party School, and teachers' training, medical, and agricultural institutes. All school-age children attend rural schools for seven years; and 10 years' urban schooling is compulsory. Illiteracy had been almost completely eradicated by the early 1970s. The ratio of college students per 10,000 inhabitants, always a useful index of national educational attainment, was then 104, exactly double the ratio for France. Mongolian students also were studying abroad, mostly in the Soviet Union. The Academy of Sciences of the Mongolian People's Republic coordinates research institutions, experimental stations, and other scientific establishments and supervises the growing output of work by scholars.

Health services were similarly expanded over the republic's first half century. By the early 1970s, there were about 100 hospital beds for every 10,000 people and one physician for every 550 people—a ratio that compared favourably with many developed countries. Medical treatment is free, and the state also maintains a network of sanatoriums and holiday rest homes. The improved health facilities brought a dramatic rise in population. The total increased by nearly 5 percent between 1940 and 1956 and by over 20 percent between 1956 and 1963. The vast country was still sparsely populated in the 1970s; and the government was encouraging large families by offering various grants and allowances.

Among other social services, the provision of housing has been greatly emphasized. The *gher* remains the main traditional dwelling in the countryside, about 9,000 being produced annually. Increasing urbanization, as well as the introduction of more settled ways in the country, has necessitated the building of modern apartment blocks in the cities and an increasing number of permanent rural structures. Systems of communication were also emphasized. When the republic was founded, these consisted of a horse postal system and a single telephone wire connecting Kyakha and Zamyn-Ude on the southern frontier. The horse post system, dating from medieval times, lasted until 1949. Traditionally, it had quaint features: urgent messages were indicated by a feather; and there were no stamps, although a horse's-hoof symbol placed on each of the corners of a business letter indicated urgent mail, as did inscriptions for "gallop" or "fly, fly" (the latter with the sign of a bird). Motor-transport mail links date from 1924, shortwave communications from 1934–36, and national broadcasting from 1934. A trunk telephone–telegraph link connecting Ulaanbaatar with all the *aymag* centres, established in the late 1940s, was greatly expanded thereafter. In the 1960s, satellite communication systems were used, and in 1967 television broadcasts started.

The horse post system

CULTURAL LIFE

Contemporary cultural life in Mongolia is a unique amalgam of traditional elements—the heritage of centuries—and a growing modern element built up in a scant 50 years. Official policy is to preserve what are regarded as the better elements of the old ways of life, thus avoiding, on the one hand, uncritical adulation, and on the other, an equally uncritical total rejection of old values.

Traditional elements. Mongolian literature evolved a wealth of traditional genres: heroic epics, legends, tales, *yurol* (the poetry of good wishes), and *magtaal* (the poetry of praise), as well as a host of proverbial sayings. These genres are infused by what Mongolians regard as a national characteristic—a good-humoured love of life, with particular fondness for witty sayings and jokes, particularly evident in the image of Dalan Khuldalchi, the hero of humorous folk tales, and in the stories about the *badarchins*, clever but wily wandering monks. The *bataar*

—the popular hero of folk legend—is also a symbolic figure. *Khurchins*—folk poets and singers—carried down the oral epics and ballads; and their mime and gesture gave rise to the popular trenchant satirical vaudevilles, *Sumya Noyon* and *Dunkher Da-Lam*. The religious mysteries, *tsam* and *maidari*, were formerly staged as mass spectacles. Other folk arts include the making of *shirdeg*, richly ornamented felt carpets noted as adorning the entrances to *yurts* by 13th-century European travellers. The Mongolian form of chess, *shatar*, with a stern khan for king; a dog—the cattle breeder's traditional honoured friend—as queen; and a camel as a bishop, has very deep roots and has produced some finely carved chess sets. The ancient faience decoration of glazed earthenware, with exquisite motifs, has been revived. A complicated and dignified ritual still accompanies the traditional offering and acceptance of hospitality in a country where travelling is all-important; and the seating arrangements in the *gher* are likewise carefully arranged. When conversing, Mongolians traditionally place the right palm on that of the left hand, a symbol of mutual esteem, and the same gesture, together with a light bow, expresses gratitude, greeting, or farewell.

The Naadam festival and the Three Manly Sports

The most famous celebration of traditional ways, however, is the annual Naadam festival of the Three Manly Sports, beginning each year on July 11, National Day, and held in all *aymags* and *somons*. The festival has recorded roots going back 2,300 years or more. The first sport is wrestling, prominent in ancient times at religious festivals, and the ritual entry into the arena of several hundred participants, clad in the bright colours of a special tight-fitting costume known as the Dzodog Shudag and simulating the flight of the mythical Garudi bird, is indeed an impressive sight. The contests themselves are also conducted with great ceremony. Titles awarded at the national Naadam festivals are those of Titan, Lion, Elephant, and Falcon. A three-time winner becomes a Darkhan Avraga (Invincible Titan). The second sport is archery; and bowmen vie for the title of Merghen, or Supermarksman, in individual and group contests, shooting at a leather-covered target with weapons of ancient design. Exceptional winners are characterized as Miraculous Archer, Most Scrupulous Archer, and by similar names. The third sport, horse racing, is in many ways the most spectacular because all of the competitors are children, ranging in age from seven to 12. They are highly skilled and wear fine ornamental dresses as they race for about 20 miles across country. National horse-riding competitions for all ages are held during January and February, the Mongolian New Year, and are claimed to date back to the Bronze Age. Marco Polo, a European visitor of the 13th century, describes a gathering of not less than 10,000 white horses held at the behest of the Great Khan. The races are highly competitive, and the riders phenomenally skillful.

Modern elements. Modern sports range from freestyle wrestling (introduced 1962) to motorcycling and gymnastics. A growing number of economic enterprises cater to the various folk arts. The Bogdo Genen Palace Museum has a superb collection of folk art housed in the former winter palace of the khan, built in 1898. The architectural ensemble contains temples housing the famous sculptures of the goddess Tara made by the 17th-century artist Zanabazar. The State Central Museum and related exhibits portray the rich archaeological and paleontological remains of the country. Buddhist relics are exhibited in the Choizin-Lama Temple Museum, built 1903–05. The Erdene Dzu Monastery Museum on the site of Karakorum, Mongolia's ancient capital, is also noteworthy. Each *aymag* now has its own museum of regional studies. The State Public Library contains works of great variety and historical value.

In contemporary literature, the popular poems and short stories of Dashdorjiyn Natsagorj became particularly significant in the 1930s. In the 1940s, literature became more varied in theme and genre, and the autobiographical "Old Scribe's Story" by G. Navaannamzhil became popular. Younger writers in the 1950s and 1960s injected a more contemporary note, attempting to balance psychological and social imagery. The realistic, epic novel continues in popularity.

The State Drama Theatre, founded 1931, shows both Mongolian and classical works, and the State Opera and Ballet Theatre has a deserved reputation. There is a puppet theatre in the capital and internationally known song and dance companies. Practically every community has its own amateur art group, and the Mongolian circus is also very popular. The Mongolkino film studio in the 1970s was making an increasing impact at international festivals: its productions are assisted by the magnificent landscapes and clear air of the country, which help the production of wide-screen epics. Mass radio and television services are of importance because of the great distances in the country, and are now aided by satellite links. About 70 percent of the households have radio sets, and the ownership of television sets is spreading. There are a dozen central and about two dozen local newspapers. The leading official newspaper is *Unen* ("Truth"). There are also about 30 popular and specialist periodicals with total circulation exceeding 1,000,000 copies a year.

THE OUTLOOK

The first half century of the modern republic witnessed a difficult struggle, in which the then younger generation played a major role, to liquidate the economic and cultural backwardness of the country in a historically short period. It is the government's position that, now that a Socialist system of economy has been established, the main task is building a modern industrial–agrarian Socialist state comparable to that of other nations of the Socialist bloc. Although long-term plans ranged into the 1980s, particularly in the growing cities, it was hoped that the completion of the Fifth Five-Year Plan in 1975 would see the fulfillment of the main tasks of this Socialist structure. By 1975 national income was scheduled to rise by about a third, with agricultural production going up by a quarter and industrial output by over a half. Industrial earnings were scheduled to go up by some 8 percent, and agricultural cooperative wage funds were scheduled to go up by almost a half. Housing, as well as the level of cultural and education services, was to receive continued emphasis. While the full working out of these plans lay in the future, there was little doubt that Mongolia had become increasingly important internationally. The country has been a United Nations member since 1961, and a member of the Council for Mutual Economic Assistance, the Socialist trade group, since 1962. Although the bulk of Mongolian trade is still with Comecon, links with capitalist countries were developing in the 1970s, and a growing tourist trade—of well-equipped hunting parties—was making the country better known. As diplomatic and trade links developed, it seemed likely that the unique contribution to the modern world of a developed Asiatic country with a proud tradition would become increasingly known. (Sh.Bi.)

BIBLIOGRAPHY. The rapidly changing nature of Mongolian society renders obsolete many of the publications about the country. The CENTRAL STATISTICAL BOARD OF THE MPR COUNCIL OF MINISTERS has nevertheless produced a statistical survey, *Fifty Years of the Mongolian People's Republic* (1971), which contains a wealth of useful material. The edition is in both Mongolian and English. The illustrated magazine *Mongolia* (monthly since 1971), in English, also contains statistical data as well as feature stories. A series of English-language pamphlets put out from Ulaanbaatar on the occasion of the 50th-anniversary celebrations contain collections of essays on economic, cultural, and geographical topics by experts. The short essay by O. NAMNANDORJ and G. AMAR entitled "National Sports," published in 1971 by the Mongolian Committee of Physical Culture and Sports, is a survey of traditional and modern elements. C.R. BAWDEN, *The Modern History of Mongolia* (1968), contains much material on the contemporary republic from the viewpoint of a British specialist. Another British publication, A.J.K. SANDERS, *The People's Republic of Mongolia* (1968), contains general information culled from the Mongolian and Soviet press. IVOR MONTAGU, *Land of the Blue Sky* (1956), is a travel account. See also the *Memorandum Attached to the Application Submitted by the Government of the Mongolian People's Republic for Membership of the United Nations* (1957).

Mongols

The Mongols comprise one of the principal ethnographic divisions of Asiatic, or Oriental, peoples. Their traditional homeland is centred in Mongolia, a vast plateau in Central Asia now divided politically into an autonomous region of the People's Republic of China (Inner Mongolia) and the Mongolian People's Republic (Outer Mongolia), which lies at the eastern end of what was a great corridor of migration between Manchuria and Hungary throughout history. It is unfortunate, because confusing, that 19th-century physical anthropologists introduced the terms Mongol and Mongolian as descriptive of racial type. The Mongols exhibit a wide range of physical characteristics and should be considered not as a race but as a group of peoples bound together by a common language and a common nomadic tradition.

The geographical origin of the Mongols themselves is the northeast corner of the present Mongolian People's Republic. To the east, the ancient tribal history is mostly that of the Tunguz peoples (including the ancestors of the Manchus) and to the west, that of the Hsiung-nu, or eastern Huns, and their Turkish-speaking successors, whom the Mongols eventually displaced and in part absorbed. As a result of later wars and migrations Mongols are now found in the Mongolian People's Republic, in the Buryat Autonomous Soviet Socialist Republic, in the Chinese Inner Mongolian Autonomous Region which includes a good deal of territory in Manchuria (in Chinese: The Northeastern Provinces), in the province of Ninghsia, on the northern plateau of Tibet, in the Sinkiang Uighur Autonomous Region (Chinese Turkestan), in Afghanistan, in the Tuva Autonomous Soviet Socialist Republic, and the Kalmyk Republic of the U.S.S.R.

ETHNOGRAPHY AND EARLY TRIBAL HISTORY

All Mongols recognize their kinship to each other in varying degrees through legend, written history, and especially language. Dialects vary from east to west more than from north to south, but very few are unintelligible to other Mongols. Historical change in the language is indicated by the fact that reading *The Secret History of the Mongols* (mid–13th century), the oldest major document written in Mongol, is for a Mongol of today like reading Chaucer for a modern Englishman. Pan-Mongolism, the political desire for a reunion of all the Mongols, was always more romantic than practical and today is a dead issue.

Nomadic tradition

The Mongols have always been nomads, though there has also always been some cultivation. But nomadism means the seasonal movement of livestock and camps from one pasture to another, not unfettered wandering. Nomads have a clear concept of the possession of territory, though they sometimes interpret this in socially conflicting ways. Legend and folklore show that among the premodern Mongols the common people considered livestock to be private property and land the collective property of the tribe, while the families of ruling chiefs considered the land as well as the persons of their subjects to be their property.

Traditional society was based on blood relationship traced through a common male ancestor who gave his name to the clan, though evidence exists of a more ancient system of matrilineal descent. Marriage was forbidden between members of the same clan, giving rise to complicated marriage alliances (and also feuds) among the clans. As clans grew and merged into tribes (often inventing a fictitious common ancestor), the most successful families tended to arrogate to themselves claims to "real" ancestry and, at the same time, to control of the tribal territory, while lesser families could claim ancestry only in a vaguer, tribal sense. In this process weak clans fell to a subordinate but not servile status: they owned their own cattle and had their own headmen, but paid tribute to the ruling clan and moved, camped, pastured, and fought under its orders.

Political and military organization was matched to the family–clan–tribe pattern. Every man who could ride and bear arms was both a herdsman and a soldier according to the need of the moment. Raiding other tribes to capture cattle, women, and prisoners was a recognized method of property accumulation. When, however, a tribe rose to notable power, as in the time of Genghis Khan in the 13th century, a decimal form of military organization was adopted, with units of 10, 100, 1,000 and 10,000. Commanders of large units were assigned territories from which they drew the tribute to the supreme khan and mustered their quotas of troops. Mongol society fluctuates between such periods of feudal concentration and those of tribal dispersion.

The first mention in the Chinese chronicles of tribes that can be identified with Mongolia goes back in a shadowy way to the 2nd millennium BC. The first inhabitants of whom there is certainty, however, are the Hsiung-nu, or Huns, about the 4th century BC. It was once thought that they were Turks, or at least Turkish speaking, but in the last quarter of the 20th century the opinion was growing that they spoke a paleo-Asiatic language, represented today by the Ket dialects of the Yenisey Valley in Siberia. The Hsiung-nu created a great tribal empire in Mongolia while China was being unified as an imperial state under the Ch'in (221–206 BC) and Han (206 BC–AD 220) dynasties. After several centuries of war with the Chinese, complicated by civil wars among themselves, the Hsiung-nu confederation broke up. Some of the southern tribes surrendered to the Chinese and were settled within China, where they were eventually absorbed. Some of the northern tribes migrated westward, where they appear in Europe in the 5th century AD as the Huns of Attila. By then, of course, they were a very mixed people.

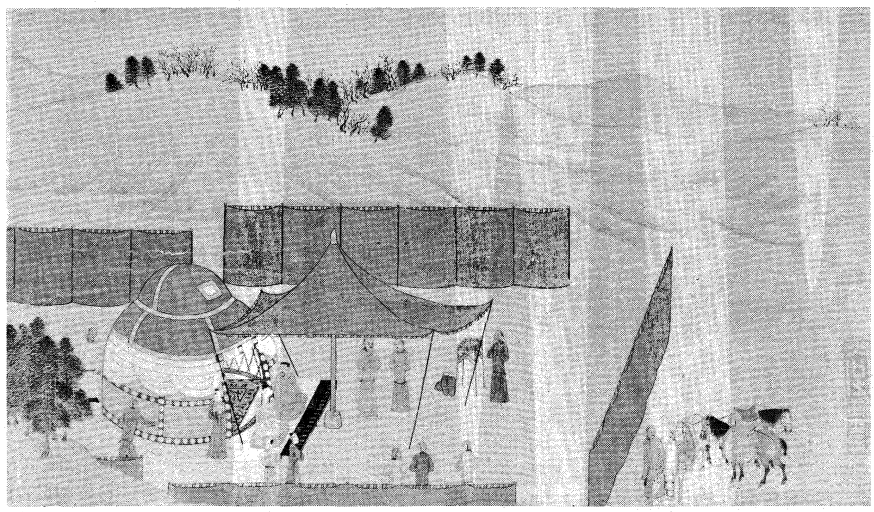
The Hsiung-nu

In Mongolia the Hsiung-nu were succeeded both by Turks, or Turkish-speaking peoples, and by others identified by some scholars as Mongols, or Mongol speaking. There is a lack of convincing archaeological or historical evidence that these groups came to Mongolia from some distant region to fill a void left by the Hsiung-nu departure. Probably they were there all the time as the subjects of the Hsiung-nu, until the breakup of that confederation gave them the opportunity to assert themselves. Among the peoples who have been considered possibly Mongol the most important tribal names are Sienpi (Hsien-pi), who may however have been Tunguz rather than Mongol, recorded in Han dynasty annals, and the Jou–jan (Juan–juan or Geougen) of the 4th to 6th centuries. The latter have been identified by some scholars with the Avars, who migrated into Europe along the plains of the Danube, and were nearly annihilated in Hungary by Charlemagne in the late 8th century.

The Orkhon Turks

According to a legend recorded by the Chinese, the Turks of Mongolia, whose name is recognizable under its Chinese transcription "T'u-chüeh," were a subject tribe ruled by the Jou–jan. The Turks overthrew their masters and soon were in control of all Mongolia, centring their power in the Orkhon Valley in the northern part of the country. The Orkhon Turks were contemporaries of the T'ang dynasty (618–907) in China, and their fortunes rose and fell in counterpoint to periods of T'ang strength and weakness. Comparison of archaeological and historical data, moreover, shows that power in Mongolia was at this time not based simply on levies of nomad horsemen. The khans and great men had fixed headquarters, surrounded by cultivated land that enabled them to breed large, stable-fed horses capable of carrying a man in armour. This situation emphasized a class distinction between the aristocrat on his charger and the herdsman-warrior-archer on his smaller horse. Agriculture also became an element in the economy, and the Uighurs, who came to power after the fall of the Orkhon Turks, enter history as an oasis-centred people.

In the welter of tribes the name Mongol first appears in a tribal list recorded under the T'ang dynasty. It then vanishes, to reappear only in the 11th century, when the Khitan (Kidan, from which comes the word Cathay) ruled in Manchuria and North China, and controlled most of Mongolia. The Khitan, who established the Chinese dynasty of Liao (907–1125), were themselves a Mongol people, but their homeland was in Manchuria rather than in what is now Mongolia. Like other Chinese



A Mongol encampment, showing a central yurt surrounded by felt screens, beside which stand three Mongolian ponies. Detail from the "Wen Chi Scroll," a Chinese handscroll of the Southern Sung period (1126–1279), which illustrates the story of Wen Chi, a Chinese lady captured by the steppe nomads. In a private collection.
By courtesy of Asia House Gallery, New York

dynasties, the Liao exercised its power in Mongolia by playing off the tribes against one another. Liao sources record the existence of a rather shadowy tribal power known in Mongol tradition as Khamag Mongol Uls ("Nation of all the Mongols"), which did not, however, include all of the population who spoke the Mongol language.

When the Khitan fell, their power in China was taken over and extended by the Juchen (Jurchid; Chinese "Ju-chen" or "Nü-chen"), a Tunguz people based farther north in Manchuria. They took the Chinese name of Chin (Kin; "Golden"). In their tribal policy they switched their favour from "All the Mongols" to the Tatars (known in the West as "Tartars," from a medieval pun on *tartarus*, Latin for "hell"). Though Mongols, the Tatars were not part of the tribal league of All the Mongols, centred in the Onon and Kerulen valleys in the eastern half of North Mongolia; the Tatars lived to the east and south of them.

On the whole, though chastened occasionally by punitive expeditions, All the Mongols had been transfrontier allies or auxiliaries of the Khitan-Liao. A contingent of 50,000 Mongols (large for that time) fought on the Khitan side in the last battles of the Khitan Empire. Presumably, this was one reason why the Juchen-Chin transferred their favour to the Tatars, nearer to their frontier. Such alternations, between using the more distant and using the nearer transfrontier and frontier tribes, were frequent in the policies of dynasties in China, and this one had the desired effect of creating a feud between Mongols and Tatars.

Before the era of Genghis Khan a defeated Khitan army had migrated westward at the fall of their Liao Empire. It was led by a prince of the Khitan imperial line, but must have included heterogeneous tribal elements. Moving westward through Mongolia it reached what is now Kazakhstan in the southeast of Soviet Asia and created a new and briefly powerful empire, the Karakitai. It ruled primarily over Turkish-speaking peoples, made up of nomads and city-dwellers in the oases, and the Khitan nucleus had the opportunity to apply its knowledge of how to deal with nomads and its ability in the administration of a bureaucracy.

The Karakitai

THE RISE OF GENGHIS KHAN

Such was the setting in Mongolia when Genghis Khan (his given name was Temüjin) was born, about 1162 (the date now accepted by contemporary Mongol scholars). Genghis was born into a clan that had a tradition of power and rule, being the great-grandson of Khabul (Qabul) Khan, who had been the greatest ruler of All the Mongols. Genghis inherited a feud against the Juchen-Chin dynasty and another against the Tatars, who had betrayed a collateral ancestor of his to the Juchen. His own father was poisoned by Tatars. He also inherited feuds among the ruling clans of All the Mongols, and a feud with the powerful Merkit (Mergid) tribe, from whom his father had stolen his mother.

Genghis was even more deeply a political man than a warrior, and he resorted to war only as an extension of policy by other means. He was orphaned in his teens; his family fell on bad times, and power among the Mongols passed to other clans. Even in such apparently primitive practices as camp-raiding and horse-thieving, he skillfully used ancient customs: marriage alliances; putting himself under the patronage of a stronger prince; making an alliance with Jamuka (later his dangerous rival) by the oath of *anda*, under which men became as if blood-brothers; and recruiting *nökhör* (the modern Mongol term for "comrade"). Unlike the institution of *anda*, which created a fictitious kinship, a man who became a *nökhör* forswore all loyalties of kinship and tribe and declared himself solely "the man" of his chosen leader. Genghis later fell out with his *anda*, but he was never betrayed by a *nökhör*, and his most brilliant generals were *nökhör*.

Genghis broke alliances and betrayed loyalties, but only when he could seem to be acting in "the common cause." By 1206 his success in tribal warfare caused Temüjin to be proclaimed ruler of All the Mongols with the rank of khan and the title of Genghis (Chingis)—a word deriving probably ultimately from the Turkish *tengiz*, meaning "a large body of water, the ocean," although this explanation has not convinced all Mongol scholars. Previous nomads had invaded China, but none had yet ruled the whole of it, chiefly because they had invaded China prematurely, leaving other nomads on their flanks and in their rear. Genghis, however, first united all the "dwellers in felt-walled tents" (*tuurgatan*), probing far back, away from China, to make sure that he controlled all potential nomadic rivals.

Ruler of All the Mongols

His first move was to bring under control the major tribal groups to the west of him in Mongolia, the Naimans and Kereits (Keraits) with whom he had been alternatingly in alliance and rivalry, as well as the tribes fringing the northern frontier of Mongolia with Siberia. He then turned toward China, where at this time the eastern half of North China, down almost to the Yangtze, was ruled by the Juchen-Chin. In the northwest corner of China and the western extension of Inner Mongolia there was a strange state, that of the Hsi Hsia: its rulers were Tanguts from Tibet and under them there were Turkish merchants who exploited the caravan trade, the cultivators of the oases being Turks and Chinese. China south of

the Yangtze was ruled by the Southern Sung dynasty (1126–1279). Although they had lost North China, the Southern Sung were expanding southward toward Indochina, bringing rich new land under cultivation. Among all of these states there was an interplay of diplomacy, alliances made and broken, and open warfare. The Mongols themselves, far from being ignorant barbarians, understood the game and played it skillfully.

Between 1207 and 1215 the Genghis armies probed deep into North China. He made good use of the Khitan of South Manchuria and North China, whose Liao Empire the Juchen-Chin had overthrown and who were now discontented subjects of the Chin. In 1215 Peking itself (from which the Chin emperor had withdrawn southward) was taken and sacked. Realizing, however, that it was premature to commit his main strength to the conquest of China, Genghis withdrew to Mongolia, leaving one of his best generals, Mugali, to ravage and weaken the country. He himself turned westward. When he had defeated the Naiman, the last of the powerful tribes in Mongolia Proper, the son of the last ruler of that tribe, Küchlüg, fled to Karakitai and married the daughter of its last ruler, whom he then overthrew. In that variegated kingdom, which included Semirechiya in Russian Turkestan and the Kashgarian Oases in Chinese Turkestan (Sinkiang Uighur Autonomous Region), he favoured the Buddhist minority and persecuted Islām, the majority religion. This situation made it easy for the Mongols to defeat him. The Mongol general Jebe (Jeb) proclaimed freedom of religion and forbade massacre and plunder. This policy indicates that the Mongols did not massacre out of sheer savagery but only when they thought it necessary to break the power of an opponent.

Taking over the lands of the Karakitai opened the way for Genghis to Khorezm (Khuarezm), the land of the oases along the Syr Darya and Amu Darya in northern Iran. For drawing on the resources of a higher civilization this gave him an alternative to China, and it also secured him against the danger of any other nomadic power organizing, on his flank and rear, a military striking force backed by agricultural and urban resources. This done, he turned back toward China, leaving further campaigning into Russia and the eastern fringes of Europe to his generals and sons. He would not, however, commit his main forces in China until he had dealt with the wealthy Tangut state of Hsi Hsia; it was on this successful campaign in 1227 that he died.

THE SUCCESSOR STATES OF THE MONGOL EMPIRE

Genghis had already dealt with the problem of succession. Each of his four sons was to hold a vassal kingdom: Jochi, the eldest, was given the land from the Yenisey River and the Aral Sea westward "as far as the hooves of Mongol horses have reached"—a wording attributed to Genghis himself; the second son, Chagatai (Tsagadai), received Kashgaria (now the southern part of Sinkiang, China) and most of Mavrannakhar between Amu Darya and Syr Darya; the third son, Ögödei (Ogadai), received Western Mongolia and the region of Tarbagatai (now the northwestern corner of Sinkiang); the youngest, Tolui, inherited the ancient Mongol homeland of eastern Mongolia. Two years later, in 1229, a great Mongol assembly confirmed the succession of Ögödei as the great khan (khagan).

These dispositions made skillful use of ancient traditions. It was the custom among prosperous families that the eldest son, on reaching manhood, was given a wife and his share of the future inheritance; he then moved away and set up his own camp, independent but still allied to his family. The other brothers followed in due order, but each one nearer to the "home camp" than his next older brother. The youngest, as "guardian of the hearth and fire," remained with his parents until their death and received the residual heritage. It was convenient that Jochi could in this way be placed at the greatest distance from the ancient homeland because he got on poorly with his brothers who considered him illegitimate, conceived while his mother was the captive of a hostile tribe. The election of Ögödei as great khan over the head of his elder brother Chagatai (Jochi had already died) did not do violence to nomadic tradition; it was quite acceptable in wartime for the dying ruler to nominate as his successor the son who was considered most able and most acceptable to his brothers.

Tradition of succession

With this first division, further fission was inevitable. Under Batu, the successor of Jochi, there began the formation of the Golden Horde, which ruled or rather drew tribute from the city-states of Russia. In this khanate the Mongols were greatly outnumbered by Turks; the Turkish language soon displaced Mongol, and Islām became the prevailing religion. Because its reservoir of nomad power was in the Kipchak Steppe, the Golden Horde is sometimes known as the Kipchak khanate. By its methods of collecting taxes and tribute it contributed to the rise of the grand dukes of Muscovy, and it was eventually a Moscow-led alliance that broke the power of the Mongols (by then more frequently called Tatars), at the Battle of Kulikovo in 1380. Partly by treachery and partly by guile the Golden Horde was still able to take and sack Moscow, but its power soon disintegrated—an important factor being attacks by Timur, coming from Turkestan.

To the east were the khanates of the House of Chagatai and the Il Khans of Iran (Persia). Like the rulers of the Golden Horde, the rulers of the House of Chagatai considered themselves senior, in genealogy, to the House of Ögödei; they were frequently at odds with the great khan, with each other, and with the Il Khans. On the other hand, the Il Khans (the title itself implies subordination) accepted and supported the authority of the great khans. Like the Golden Horde, again, the House of Chagatai controlled wide pastures and therefore retained a strong nomadic base, while the Il Khans, like the great khans (especially after Kublai [Khubilai] moved his capital into China), were directly affected by the urban influences of an old, highly developed civilization with a rich literary tradition. As in China, this situation led rather rapidly to the passage of real administrative control from Mongol hands into the hands of their subjects. The greatest of the Il Khans was Hülegü (Khulagu, Hulagu), a brother of the great Kublai Khan (*q.v.*) of Mongolia and China, who began the Il Khan tradition of supporting Peking against the House of Chagatai and the Golden Horde.

House of Chagatai

This brief review of the outer khanates helps to explain the subsequent history of the Mongols in Mongolia and the Mongol dynasty in China. As great khan, Ögödei authorized the continuation of Mongol campaigns in Russia and the west and also in China, where the disintegration of the Juchen-Chin dynasty in 1234 had brought the Mongols face to face with the surviving Sung dynasty in the Yangtze Valley. Ögödei was also able to maintain a system of imperial representatives in the appanages of his imperial kinsmen in Central Asia and Iran, but was less able to control the always insubordinate Golden Horde. He died in 1241 and was succeeded, after a stormy regency under his widow Töregene, by his son Güyük (Kuyug) who had already quarrelled with his cousin Batu of

the Golden Horde. Güyük died at Samarkand in 1248, preparing an attack on Batu.

A major change then occurred in the succession. At the next great assembly of the descendants of Genghis Khan, enlarged by the presence of powerful commanders and officials, the great khan chosen (again after much intrigue) was not a son of the House of Ögödei but Möngke (Mungke, Manga), a son of Tolui, the "guardian of the fire and hearth" of the Mongol homeland. This choice was favoured by Batu Khan, and Möngke responded by trying to stabilize and pacify relations among the khanates. Of his brothers he sent Kublai (later Great Khan) to continue the conquest of Sung China and Hülegü to subdue the Ismāʿīli (the fanatical Muslim secret order of assassins) and Baghdad. He was aware of the desire of some of the crusaders for a Mongol alliance against the Saracens, but like Ögödei and Güyük he would not consider this except on terms of the submission of the European rulers and the pope. He himself campaigned deep into southwest China and there died of a fever in 1259.

Kublai Khan

The succession was then disputed between Möngke's second brother, Kublai (Khubilai), and his youngest brother, Arigböge (Ariböx, Arikböge). A third brother, Hülegü, supported Kublai. The dispute was more than a brawl over spoils among barbarian warriors; ideology was involved. Genghis Khan's concept of conquest and rule had been clear: the "people of the felt-walled tents" should remain in the steppes and continue their ancient warrior way of life, drawing tribute from the world of farms, cities, and caravan trade. Kublai and Hülegü, however, favoured moving into the conquered countries and there becoming the new ruling class—even if this meant mingling with the remnants of the conquered ruling class.

In this respect Arigböge was closer to the concept of Genghis than was Kublai, but Kublai prevailed and Arigböge died in honourable captivity. Kublai had himself

The Mongol Empire under Kublai Khan.

proclaimed great khan in Mongolia in 1260. Kublai's reign has been romanticized in the West ever since Marco Polo. Kublai Khan moved the capital from Karakorum (Kharakhorum), which had been built by Ögödei (not Genghis Khan, as is often said), to Peking. He used Mongolia as his base for ascendancy over the other Mongol khanates, but drew his main revenue directly from China. He used foreigners (including Marco Polo and his family) to lessen his dependence on Chinese bureaucrats, but the administrative structure was essentially on the Chinese model; and consequently the Mongols, because they no longer held the real keys to power, lost the throne to the native Chinese Ming dynasty in 1367, only a century after the accession of Kublai and within a decade or two of the end of the Golden Horde and the Il Khanate.

Internecine strife. Although in the first vigour of reconquest the Chinese penetrated deeply into Mongolia and burned Karakorum, they never succeeded in establishing control. Mongol unity was shattered, but Mongols in different regions began to recover. Mongol fission followed several lines. In western Mongolia there arose new lines of chieftains who did not claim descent from Genghis Khan. As a group, these were the Oirat, but at times the names of subgroups or individual tribes, such as the Dzungar (Jüüngar) or the Dörbed (Dörböd), predominated. In the centre, both in Outer and Inner Mongolia, the ruling princes claimed descent from Genghis Khan. In the east, largely in Manchuria, were princes whose ancestor was Khasar, a brother of Genghis Khan. Because there had been bad blood between the two, these princes and the Chingiside princes were always suspicious of each other.

What followed, in the renewed tribal wars and pressure on the frontiers of China in the 15th and 16th centuries, was much more than a resurgent "wave of barbarian invasions." A distinct new period was opening in which all concerned understood that in order to have real power outside the Great Wall of China it was necessary to coordinate nomadic military mobility with towns inhabited by productive artisans, capable of attracting trade from China, and supplied with food by local farming. The lead was first taken by the Oirat, in the far west of Mongolia, who established control over some of the oases of Sinkiang and began to penetrate Tibet. This advance meant that in the regions where the imperial power and economic ascendancy of China under the Ming dynasty (1368–1644) were weakest, the Oirat drew on new resources. Both the Tibetans and the Turkish-speaking oasis people were active merchants, had a literate class whose thinking was independent of the Chinese model, and could keep the records without which a state more advanced than a tribal league was impossible. This stage initiated the long-enduring cleavage between the Oirat and the Khalkha, the main body of what was later to be Outer Mongolia.

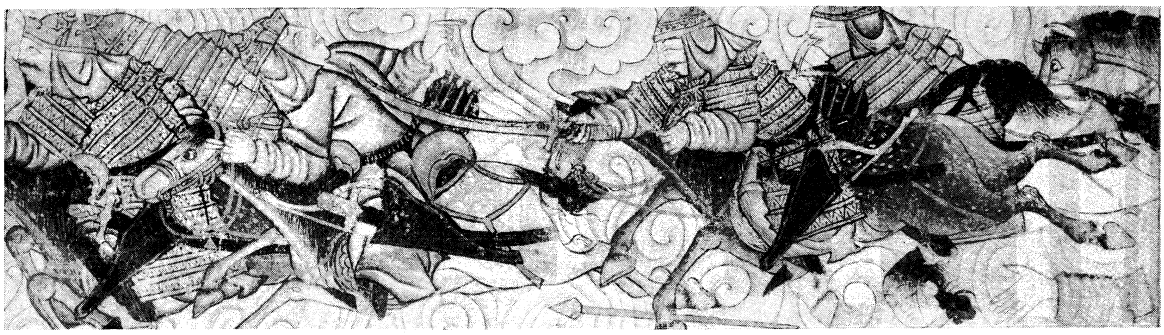
Ascendancy then passed to the Mongols of the Ordos, in the great loop of the Yellow River, under Altan Khan (reigned 1543–83). He exploited a geographical base that enabled him to develop agriculture and trade, to challenge the Oirat in Tibet, and to pressure the Chinese. Meanwhile, the Mongols of the centre, Khalkhas in the north and Chahars (Tsakhars) in the south (there was as yet no "Outer" and "Inner" Mongolia), had lagged behind for lack of a suitably diversified geographical base. The best that they could achieve was a tribal league unification under Dayan Khan, a descendant of Kublai and grandfather of Altan Khan, who was proclaimed khan in 1470 at the age of five and died in 1543. After this, and after the death of Altan Khan, the supremacy over the Mongols of the centre passed to the south to another descendant of Dayan, Ligdan (Legdan, Lingdan) Khan of the Chahars. Using the geographical advantages of the modern Chinese frontier province of Chahar, close to the Great Wall, he tried during his reign (1604–34) to build up a power comparable to that which had been held by Altan Khan. He was too late, however, because of the rise of the Manchus (see below).

Altan Khan

Revival of Buddhism. It was this period that saw the second flowering of Buddhism among the Mongols. In the reign of Kublai, Buddhism in its Tibetan form had been fashionable at court and among some of the Mongol aristocracy, but the people as a whole had not been converted. The new entry of Buddhism was promoted by political considerations. A number of Mongol princes, almost simultaneously, saw that for the kind of power that was now advantageous it was necessary to have not only a religious ethos higher than that of shamanism (whose priests used magic to cure the sick, divine what was hidden, and to control events), but a literate class to provide a bureaucracy. To use the Chinese language meant the risk—as had been proved under the Mongol empire in China—of the absorption of the Mongol ruling class into the Chinese ruling class. Tibet was not strong enough to dominate Mongolia. The Tibetan monastic system had already produced able clerical bureaucrats. Moreover, Tibetan alphabetic writing was easier to use than Chinese hieroglyphs.

Establishment of the Dalai Lama

Thus it was that Altan Khan invited from Tibet a prelate who had claims to primacy in Tibet, but also rivals, and proclaimed him Dalai ("Ocean," "All-encompassing") Lama. Significantly, this title is Mongol, not Tibetan.



Mongol warriors in cavalry pursuit wearing lamellar armour, which covers them from the neck to the elbow and to the lower leg. Miniature from *Jami' at-tawarikh* by Rashīd od-Dīn, 14th century. In the Topkapi Sarayi Museum, Istanbul.

Moreover, a way was found to link church and state. A son of the line of the Tüshētü Khans of Khalkha was conveniently found to be the first "reincarnation" of the line of Jebtsundamba Khutukhtus of Urga. The significance of this device is underlined by the fact that as soon as the Manchus controlled Mongolia, they ruled that no man of the lineage of Genghis Khan could be "discovered" to be a reincarnation or Living Buddha, and also that the Living Buddha of Urga must always be discovered in Tibet. In their rule of Mongolia they thus separated church and state and used them against each other.

At the beginning of the revival of Buddhism in Mongolia there was a great burst of translation of the scriptures from Tibetan (and Sanskrit) into Mongol. The Mongols wanted to use Buddhism as a unifying principle in a new nationalism. When the Manchus won control, however, they threw their support to the use of Tibetan as the "Latin" of the church, further widening the cleavage between clerical and secular authority and bureaucracy. By the end of the Manchu regime there were many monks in Mongolia who were literate in Tibetan, but not in their own language.

THE ASCENDANCY OF THE MANCHUS

The rise of the Manchus, which had such profound effects on the fate of Mongolia, began long before 1644, the year a Manchu emperor was first seated on the throne in Peking. In the late 15th century it was becoming clear that a new barbarian conquest of China was again possible. In competition with the various Mongol princes and tribes already mentioned, the Manchus had the advantage that in South Manchuria, but outside the Great Wall of China, there was a large Chinese population with a number of urban centres and a flourishing trade that, instead of passing by land through the Great Wall, went largely by sea to the promontory of Shantung—to the rear, that is, of the rulers in Peking. These Chinese were somewhat alienated from other Chinese. They had for centuries been accustomed to trading with the barbarians and to farming under the patronage of barbarian princes, and they did not like Peking's periodic attempts to maintain a "closed frontier" along the Great Wall.

The Manchus subjugated these Chinese, but also cultivated their loyalty, and were soon heavily dependent on them not only economically but for military manpower. To balance this dependence they built up a network of alliances with their other neighbours, the easternmost Mongols. Mongol troops took part in the conquest of China; and before they occupied Peking, the Manchus had control of the southern fringe of Mongolia. They organized it as part of their military reserve for the domination of China; this organization is the origin of the institutional and administrative concept of "Inner" Mongolia.

It took the Manchus about a century to add northern or "Outer" Mongolia to their empire, resulting in two Mongolias markedly different from each other, Inner Mongolia being from the beginning much more closely integrated with China.

Meanwhile, the Oirats, under their leading tribe, the Jüüngar, made a belated effort to unite all the Mongols in rivalry with the Manchus. The Oirat were strengthened by their control of a number of the Sinkiang oases, but weakened by rivalries among their chiefs, by the diversion of much of their strength to adventures in Tibet, and by the reluctance of the Khalkha princes to accept the overlordship of princes not descended from Genghis Khan. Led by such great warriors as Galdan (Galdan Boshogt), the Oirat made sweeping campaigns far to the east in Mongolia, but were never quite able to consolidate their gains. In trying to make the Oirat a recognizably distinct nation, the great religious leader, the Jaya Pandita, revised the Mongol alphabet, making it phonetically more accurate, and originated an independent literary tradition.

Attempt at Mongol revival

Unwilling to accept submission to the Oirat as the price of unification, the Khalkha princes rallied more and more to the Manchus who guaranteed their aristocratic privileges and titles in a great convention at Dolonnor, in Inner Mongolia, in 1691. With the added resources of Khalkha, the Manchus were then able to mount a long series of military campaigns in which they annihilated the Oirat power with tremendous slaughter on the scale of genocide.

This conquest, however, was not completed until 1759, and it was complicated by many events, particularly a great revolt against Manchu rule in western Khalkha in the 1750s led by a noble named Chingunjav, who was a coconspirator with an Oirat leader named Amursana, who in turn had first submitted to the Manchus and then rebelled against them. But this was the last period of general warfare involving the Mongols, and it ended with a considerable redistribution of the tribes. Several Khalkha groups that had fled from the Oirat into Inner Mongolia never returned; a few Chahars from Inner Mongolia were settled in Sinkiang as garrisons; numbers of the Oirat group were included in the western part of Khalkha geographically, but not within the tribal organization; some ended their migrations in Ala Shan, at the western end of Inner Mongolia, but not within the Inner Mongolian organization; and some ended theirs far away in the Kokonor-Tsaidam region of Tibet. The most distant Oirat wanderers (mostly Torguuds and Dörbeds) migrated in the early 17th century from the Altai to the Volga, where they took service under the tsars and took part in the Russian conquest of the Caucasus. In 1771 about 70,000 families migrated all the way back to Sinkiang, where they were accepted under Manchu rule and allotted pastures for grazing. The descendants of those who remained on the Volga were known as the Khalimag (Kalmuks).

Mongol dispersion

The ensuing period of peace degenerated into stagnation and economic decline. Chinese camp followers had accompanied the Manchu conquest, and from this grew Chinese control of the caravan trade and of a barter trade exploiting usurious terms of credit. Because Mongol troops were of decreasing use for the control of China, there was no incentive for the Manchus to protect, economically, this source of manpower, and the Manchu authorities relied increasingly on the potentates of the Lama Buddhist church, who were themselves increasing-

ly corrupt, for the control of Mongolia. Chinese colonization began to encroach on the pasture lands of Inner Mongolia and at the end of the 19th century an attempt was made to plant a screen of Chinese colonists along the frontier between Siberia and Outer Mongolia.

THE 20TH CENTURY

In the Russo–Japanese War of 1904–05 both Russians and Japanese enlisted Mongol mercenaries as auxiliaries; from this time on there were Japanese army officers who dreamed of a new Mongol nationalism that could be used against both Russia and China. The Russians were more restrained and were satisfied with Buryatia (Buryat Mongolia). By secret treaties after the war Inner Mongolia east of the meridian of Peking was recognized by Russia as a Japanese sphere of interest.

By 1911, when the Chinese Revolution broke out, unrest was widespread in Mongolia. At the time, the Mongol language and Mongol sources being little known outside Mongolia, most observers thought of Mongolia only in terms of Russian and Japanese intrigue. But a rich documentation now available proves that the unrest was both social and political. The Mongols by this time identified the Manchus with the Chinese, the Chinese with usurious debt, and their own clerical and secular rulers as people who lived in luxury on Chinese loans and passed on the usurious interest to their subjects. The rulers, for their part, saw both the chance of a new government they could control and the danger that if they did not act, they would not be able to control the people.

Independence

Under the leadership of the Jebtsundamba Khutukhtu ("Urga Living Buddha"), the Mongols declared their independence. Uncertain of themselves in world politics, however, they sought to replace Manchu imperial patronage with that of the tsar; but the Russians, because of the secret treaties with Japan and an understanding with Britain about Tibet and Mongolia (which though not secret could hardly be comprehended by the Mongols), would go no further than support of "autonomy," not "independence." This status was ratified after difficult negotiations between the Mongols, the Russians, and the new Republic of China. Union between Inner and Outer Mongolia was similarly frustrated. Some Inner Mongolian leaders saw themselves as the future elite of a united Mongolia because they could draw on an intelligentsia with a knowledge of the language and politics of China, but for the same reason they were distrusted in Outer Mongolia as too Chinese.

This uneasy situation endured with increasing economic distress and social unrest until the Russian Revolution. A Japanese-controlled clique in the Chinese government then sent a military expedition into Mongolia that forced the Mongols to sign a "request" to be taken over by the Chinese Republic. Almost immediately afterward, defeated anti-Bolshevik troops began to retreat into Mongolia. Their most important leader was the "Mad Baron" Ungern-Sternberg, who defeated the Chinese occupation forces and treated the Mongols with unfeeling savagery.

In this period of terror and confusion two secret revolutionary groups, which later merged, were formed by Sükh Baatar, a former trooper and machine gunner in the Mongol forces disbanded by the Chinese and Choibalsan, who had been a boy runaway from a monastery and later a student in Siberia. Choibalsan, though not the principal leader during the lifetime of Sükh Baatar, was in touch with underground Bolsheviks—hiding there as refugees—later massacred by Ungern-Sternberg. Memoirs of the Mongol partisans enlisted by these two show that quite apart from Russian propaganda there was already in Mongolia a geographically widespread and socially embittered demand for radical social and political change. The traditional leaders had been discredited by their inability to handle either the Chinese intervention or the incursions of the anti-revolutionary Russians.

The revolutionaries took the initiative in going to the Bolsheviks for help, which was quickly granted. The remnants of the Chinese warlord forces were driven out and Ungern-Sternberg was handed over to the Bolsheviks for execution. Urga, the capital (now Ulan Bator), was taken by a joint Mongol-Russian column in July 1921, and this is now considered the date of the founding of the present republic, though the first measures of the revolutionary victors were surprisingly moderate. The "Urga Living Buddha" was continued in office, but as a "constitutional monarch," meaning he could sign only documents prepared for him by the new regime.

Sükh Baatar died in 1923 and the Living Buddha in 1924. In Russia Lenin also died in 1924, and in China Sun Yat-sen died in 1925. Mongolia was engaged in a revolutionary process also going forward at different rates of speed in Russia and China. The problem of the Living Buddha was easily solved; no successor was found, and Mongolia was proclaimed a People's Republic—using a wording that exactly follows the Chinese, not the Russian model. The government, and the controlling People's Revolutionary Party, was a coalition of conservative and nationalistic revolutionary elements. Shifts between "rightist" and "leftist" policy ensued, closely affected by the rise of Stalin in the Soviet Union and by the defeat of the Chinese Communists (for the time being) by Chiang Kai-shek. Increasingly important, too, was the Japanese invasion of Manchuria in 1931, followed by their encroachment on Inner Mongolia and North China, and all-out invasion of China in 1937.

Proclamation of the People's Republic

The uncertainty, both internal and external, engendered cliques and conspiracies—some real and others imagined—resulting in an atmosphere of suspicion and fear that cost many lives. The situation began to clear after 1939, when the Japanese, in a thrust toward Siberia, invaded the northeastern corner of Mongolia, testing the Soviet-Mongol alliance. The Mongol border troops fought ferociously and with great professional skill, holding the heights of Nomynkhan and the line of the Khalkyn River until Soviet troops came up. The Japanese defeat was shattering, and it undoubtedly played a major part in their fateful decision not to honour the "Berlin-Tokyo Axis" with Hitler but to make their major effort in the Pacific and Southeast Asia. In Mongolia, the victory dispelled fears that elements of the army might go over to the Japanese; on the contrary, many Inner Mongolian troops recruited by the Japanese went over to the Mongols. The military alliance with the Soviet Union was reconfirmed when the Mongols took part in the short, but devastatingly successful, Soviet campaign against Inner Mongolia and Manchuria in the last two weeks of World War II.

At this time, refugees from Inner Mongolia swarmed into the Mongolian People's Republic. The Japanese had organized a puppet government of Inner Mongolia under Teh Wang (Prince Teh, Demchukdondub). He had, however, tried to minimize Japanese control and to promote Mongol nationalism. When the Chinese Communists came to power, he was condemned as a war criminal but later released.

Postwar plebiscite

Under an agreement made by U.S. Pres. Franklin D. Roosevelt at Yalta, Chiang Kai-shek consented to a plebiscite after the war in Mongolia. The result was overwhelmingly in favour of independence over "autonomy." Full diplomatic recognition did not follow, however, because of a border dispute. Mongolian membership in the United Nations was at first sponsored by Chiang Kai-shek but later opposed by him and by the United States, and it was not until 1961 that Mongolia gained membership. Mongolia now has diplomatic relations with 52 nations, including many in western Europe.

Mongolia's relations with China have been strained because of its unswerving loyalty to the Soviet alliance. Nevertheless, its long frontier with China has been amicably redemarcated. In the meantime, Inner Mongolia has been reorganized as an Autonomous Region within the Chinese People's Republic; but developments in the 1970s indicated that relations were being tightened between the region and the adjacent provinces of China. The Chinese of Inner Mongolia now outnumber the Mongols by perhaps as much as ten to one.

In the Mongolian People's Republic postwar developments were dramatic. Slightly more than 51 percent of all employment became nonpastoral. Coal is mined on a

large scale. Oil was discovered and is refined within the country. Industries include woollen textiles, leather-processing, and meat-packing. Wheat growing has been developed on a large scale, and Mongolia is now a net exporter. Veterinary services—important in a country where livestock outnumber people 25 to 1—are intensively fostered. There is no illiteracy, and industrial employment requires a certificate of eight years of schooling. The urban complex of Ulan Bator, the capital, holds about 25 percent of the population, while rural life is organized under collectives or cooperatives, the members of which are shareholders. The territory of a collective corresponds with that of a county, so that civil life and economic activity are integrated under the Socialist revolution.

BIBLIOGRAPHY. The only good general histories of Mongolia are in Mongol; a history of Mongolia in English, based on work by Mongol and Russian scholars, is being prepared in Moscow under the auspices of UNESCO. For modern history, see C.R. BAWDEN, *The Modern History of Mongolia* (1968), whose author shares the opinion of R.A. RUPEN, *Mongols of the Twentieth Century*, 2 vol. (1964); and G.G.S. MURPHY, *Soviet Mongolia* (1966), that the Mongolian Revolution was largely made in the Soviet Union and exported to Mongolia. For the contrary view that there was widespread support in Mongolia for social and economic as well as political revolution, and genuine Mongol leadership, see OWEN LATTIMORE, *Nationalism and Revolution in Mongolia* (1955), which includes a translation, by the author and URGUNGGE ONON, of the official biography of the revolutionary hero Sükh Baatar; and *Nomads and Commissars: Mongolia Revisited* (1962). For a rounded review, see GERARD M. FRITERS, *Outer Mongolia and Its International Position* (1949). An indispensable handbook for information on contemporary Mongolia is A.J.K. SANDERS, *The People's Republic of Mongolia* (1968).

(O.La.)

Monopoly and Competition

The complexity of market behaviour

This article is concerned with the meaning of the terms monopoly and competition as applied to the complex workings of the marketplace. In popular discussion the issues often become highly simplified. Thus monopoly is usually seen as a kind of octopus devouring the weak, and competition as a band of honest tradesmen serving the public. Economists who analyze actual selling practices find the distinctions among them more difficult to draw. What may be said of the behaviour of sellers in one industry does not necessarily apply to sellers in another. Different industries have different structures, and their structural characteristics determine the behaviour of those who do business. The article begins by defining the fundamental concepts of market structure; it goes on to examine the ways in which the behaviour of sellers differs among industries with different types of market structure; and it ends with an analysis of public policies toward monopoly and competition.

CHARACTERISTICS OF MARKET STRUCTURE

Industries differ, as suggested above, in their structural characteristics. Probably the most critical of these characteristics are (1) the concentration of sellers in an industry, (2) the degree of differentiation among the industry's products, and (3) the ease or difficulty with which new sellers can enter the industry.

Seller concentration. By seller concentration is meant the number of sellers in an industry together with their comparative shares of industry sales. When the number of sellers is quite large, and each seller's share of the market is so small that in practice he cannot, by changing his selling price or output, perceptibly influence the market share or income of any competing seller, economists speak of *atomistic competition*. A more common situation is that of *oligopoly*, in which the number of sellers is so few that the market share of each is large enough for even a modest change in price or output by one seller to have a perceptible effect on the market shares or incomes of rival sellers, and to cause them to react to the change. In a broader sense, oligopoly exists in any industry in which at least some sellers have such large shares of the market, even though there may be an additional number of small sellers. When a single seller supplies the entire output of an industry, and thus can determine his selling price and output without concern for the reactions of rival sellers, a *single-firm monopoly* exists.

Product differentiation. The structure of a market is also affected by the extent to which those who buy from it prefer some products to others. In some industries the products are regarded as identical by their buyers—as, for example, basic farm crops. In others the products are differentiated in some way so that various buyers prefer various products. Notably, the criterion is a subjective one; the buyers' preferences may have little to do with tangible differences in the products but are related to advertising, brand names, and distinctive designs. The degree of product differentiation as registered in the strength of buyer preferences ranges from slight to fairly large, tending to be greatest among infrequently purchased consumer goods and "prestige goods," particularly those purchased as gifts.

Barriers to entry. Industries vary in the ease with which new sellers can enter them. The barriers to entry consist of the advantages that sellers already established in an industry have over the potential entrant. Such a barrier is generally measurable by the extent to which established sellers can persistently elevate their selling prices above minimal average costs without attracting new sellers. The barriers may exist because costs for established sellers are lower than they would be for new entrants, or because the established sellers can command higher prices from buyers who prefer their products to those of potential entrants. The economics of the industry also may be such that new entrants would have to be able to command a substantial share of the market before they could operate profitably.

The effective height of these barriers varies. One may distinguish three rough degrees of difficulty in entering an industry: *blockaded entry*, which allows established sellers to set monopolistic prices, if they wish, without attracting entry; *impeded entry*, which allows established sellers to raise their selling prices above minimal average costs without attracting new sellers, but not as high as a monopolist's price; and *easy entry*, which does not permit established sellers to raise their prices at all above minimal average costs without attracting new entrants.

TYPES OF MARKET STRUCTURE

A system of classification

This discussion of market characteristics suggests a general way of classifying industries according to their market structures:

I. Atomistic competition
  A. With homogeneous products—"pure competition"
  B. With differentiated products—"monopolistic competition"
II. Oligopoly
  A. With homogeneous products—"pure oligopoly"
    1. With blockaded entry
    2. With impeded entry
    3. With easy entry
  B. With differentiated products—"heterogeneous oligopoly"
    1. With blockaded entry
    2. With impeded entry
    3. With easy entry
III. Single-firm monopoly
  A. With blockaded entry
  B. With impeded entry

Under atomistic competition, in which entry is generally easy, there are no barriers to entry. By the same token, product differentiation among sellers is obviously inconsistent with single-firm monopoly.

Comparative importance of each type. The comparative importance of these types of market structure differs among various sectors of the economy. In the manufacturing sector in the United States, which includes about 400 industries, single-firm monopolies are almost completely absent. But in more than half of the manufacturing industries there is enough seller concentration for them to qualify as oligopolies. The remaining industries are more or less atomistic in their market structure. An appreciable degree of product differentiation is found in

about half of the oligopolistic industries and in about half of the atomistic industries. Very strong product differentiation is usually found among oligopolistic industries. Easy entry is typical of atomistic industries, impeded entry of oligopolies. Entry is probably blockaded in a minor fraction of the latter, generally those with very high seller concentration.

The proportions of oligopolistic and atomistic manufacturing industries are about the same in the United Kingdom as in the United States. The incidence of oligopolies is slightly higher in Japan and progressively higher in France, Italy, Canada, and Sweden. Single-firm monopolies in manufacturing are found in a few industries in some of these countries, but they are typically under government ownership.

In the public-utility sector in the United States, single-firm monopolies are typically found in industries supplying gas, electricity, and telephone and telegraph service. Oligopoly, frequently highly concentrated, is typical in the radio and television and transportation industries; entry into these industries is usually very difficult or blockaded. The significance of such structural conditions is lessened, however, by the fact that these industries are subject to various degrees of public regulation. The situation is much the same in other Western countries, except that public utilities are frequently under government ownership.

In the distributive trades (wholesaling and retailing), a number of United States industries are fairly atomistic, while a somewhat larger number are relatively unconcentrated oligopolies in which a few large sellers supply about half the industry's output and a very large number of small sellers supply the remainder. Product differentiation is important. Entry is relatively easy. The service-trade industries in the U.S. display a similar range of characteristics. In the distributive- and service-trade sectors in other Western countries, oligopoly is less frequent and atomistic industries are proportionally more important. The residential-construction industries in the U.S. and elsewhere are relatively atomistic in structure, have significant product differentiation, and are easy to enter. Industries in the agricultural sectors of Western countries generally are typically atomistic in structure, with easy entry. But the significance of these structural conditions is lessened by governmental interference designed to modify the working of market forces.

MARKET CONDUCT AND PERFORMANCE

Sellers' behaviour in different market structures

How do sellers behave in determining their selling prices, outputs, advertising costs, and so forth; and in what ways does this market behaviour differ among industries with different types of market structure? An educated layman might ask, for example, whether sellers cut their selling prices in order to take customers away from each other until some rock-bottom market price is reached just high enough to allow them minimal interest returns on their investments or whether, on the other hand, they agree with each other to set a uniform higher price well above their production costs, sharing the market and reaping excessive profits.

It is helpful to distinguish the related ideas of *market conduct* and *market performance*. Market conduct refers to the price and other market policies pursued by sellers, in terms both of their aims and of the way in which they coordinate their decisions and make them mutually compatible. Market performance refers to the end results of these policies—the relationship of selling price to costs, the size of output, the efficiency of production, progressiveness in techniques and products, and so forth.

Behaviour measuring

Pure competition. Market conduct and performance in atomistic industries provide good standards against which to measure behaviour in other types of industry. The atomistic category includes both pure competition and monopolistic competition. In pure competition, a large number of small sellers supply a homogeneous product to a common buying market. In this situation no individual seller can perceptibly influence the market price at which he sells but must accept a market price that is impersonally determined by the total supply of the product offered by all sellers and the total demand for the product of all buyers. The large number of sellers precludes the possibility of a common agreement among them, and each must therefore act independently. At any going market price, each seller tends to adjust his output to that quantity that will yield him the largest aggregate profit, assuming that the market price will not change as a result. But the collective effect of such adjustments by all sellers will cause the total supply in the market to change significantly so that the market price falls or rises. Theoretically, the process will go on until a market price is reached at which the total output that sellers wish to produce is equal to the total output that all buyers wish to purchase. This way of reaching a provisional equilibrium price is what Adam Smith was referring to when he wrote of prices being determined by "the invisible hand" of the market.

The competitive ideal

If the provisional equilibrium price is high enough to allow the established sellers profits in excess of a normal interest return on investment, then added sellers will be drawn to enter the industry, and supply will increase until a final equilibrium price is reached that is equal to the minimal average cost of production (including an interest return) of all sellers. Conversely, if the provisional equilibrium price is so low that established sellers incur losses, some will tend to withdraw from the industry, and supply will decline until the same sort of long-run equilibrium price is reached.

The long-run performance of a purely competitive industry therefore embodies these features: (1) industry output is at a feasible maximum and industry selling price at a feasible minimum; (2) all production is undertaken at minimum attainable average costs, since competition forces them down; and (3) income distribution is not influenced by the receipt of any excess profits by sellers.

This performance has often been applauded as ideal from the standpoint of general economic welfare. But the applause, for several reasons, should not be unqualified. Pure competition is truly ideal only if all or most industries in the economy are purely competitive and if in addition there is free and easy mobility of productive factors among industries. Otherwise, the relative outputs of different industries will not be such as to maximize consumer satisfaction. There is also some question whether producers in purely competitive industries will generally earn enough to plow back some of their earnings into improved equipment and thus maintain a satisfactory rate of technological progress. Finally, some purely competitive industries have been afflicted with "destructive competition"—the coal industry and the basic agricultural industries, for example. For some historical reason such an industry accumulates excess capacity to the point where sellers suffer chronic losses, and the situation is not corrected by the exit of people and resources from the industry. The invisible hand of the market works too slowly for society to accept. In some cases, notably in agriculture, government has intervened to restrict supply or raise prices. Leaving these qualifications aside, however, the market performance of pure competition furnishes some sort of a standard to which the performance of industries of different structure may be compared.

Monopolistic competition. In the more complex situation of monopolistic competition (atomistic structure with product differentiation) market conduct and performance may be said to follow roughly the tendencies attributed to pure competition. The principal differences are the following. First, individual sellers, because of the differentiation of their products, are able to raise or lower their individual selling prices slightly; they cannot do so by very much, however, because they remain strongly subject to the impersonal forces of the market operating through the general level of prices. Second, rivalry among sellers is likely to involve sales promotion costs as well as the expense of altering products to appeal to buyers. This is a competitive game that all will play but that nobody, on the average, will win, and the long-run equilibrium price will reflect the added costs involved. In return, however, buyers will get more vari-

ety. Third, since not every seller is likely to be equally successful in his sales-promotion and product policies, some will receive profits in excess of a basic interest return on their investment; such profits will come from their success in winning buyers. Monopolistic competition may, like pure competition, include industries that are afflicted with what has been called above destructive competition. This may result not only from a failure to get rid of excess capacity but also from the entry of too many new firms despite the danger of losses.

Monopoly. While single-firm monopolies are rare, except for those that are subject to public regulation, it is useful to examine the monopolist's market conduct and performance in order to establish a standard at the other pole from pure competition. As the sole supplier of a distinctive product, the monopolist can set whatever selling price he chooses provided he is willing to accept the sales that will correspond to that price. Since the market demand will generally be less the higher the price he sets, the monopolist presumably will set that price that produces the greatest profits, given the relationship of production costs to output. By restricting output he can raise his selling price significantly—an option not open to sellers in atomistic industries.

Monopolistic behaviour

The monopolist will generally charge prices well in excess of production costs and reap profits well above a normal interest return on investment. His output will be substantially smaller, and his price higher, than if he had to meet established market prices as in pure competition. The monopolist may or may not produce at minimal average cost, depending on his cost-output relationship; if he does not, there are no market pressures to force him to do so.

If the monopolist is subject to no threat of entry by a competitor, he will presumably set a selling price that maximizes profits for the industry he monopolizes. If he faces only impeded entry, he may elect to charge a price sufficiently low to discourage entry but above a competitive price—if this will maximize his long-run profits.

Oligopoly. Market conduct and performance in oligopolistic industries generally combine monopolistic and competitive tendencies, with the relative strength of the two tendencies depending roughly on the detailed market structure of the oligopoly.

Rivalry among sellers. In the simplest form of oligopolistic industry, sellers are few and every seller supplies a sufficiently large share of the market so that any feasible and modest change in his policies will appreciably affect the market shares of all his rival sellers and induce them to react or respond. For example, if seller A reduces his selling price below the general level of prices being charged by all sellers sufficiently to permit him to capture significant numbers of customers from his rivals if they hold their selling prices unchanged, they may react by reducing their prices by a similar amount, so that none gains at the expense of others and the group has probably reduced its combined profits. Or seller A's rivals may retaliate by reducing their selling prices more than he did, thus forcing a further reaction from him. Conversely, if seller A increases his selling price above the general level being charged by all sellers (thus tending to lose at least some of his customers to his rivals), they may react by holding their prices unchanged, in which event seller A will probably retract his increase and bring his price back to the previous level. But his rivals may also react by raising their prices as much as seller A raised his, in which case the general level of prices in the industry rises and the combined profits of all sellers are probably increased.

Any seller A in an oligopoly will therefore determine whether or not to alter his price or other market policy in the light of his conjectures about the reactions of his rivals. Correspondingly, his rivals will determine their reactions in the light of their conjectures about what seller A will do in response. The process is not likely to bring the industry price level down to minimal average cost (as in atomistic competition). Many different "equilibrium" levels between the competitive and monopolistic limits are possible, depending on further circumstances.

Thus in an oligopoly viable collusive agreements among rival sellers are quite possible. They may be express agreements established by contract or tacit understandings that develop as a pattern of reactions among sellers to changes in each others' prices or market policies becomes customary. In the United States, express collusive agreements are forbidden by law, but tacit agreements or "gentlemen's understandings" are common in oligopolies. In numerous other Western countries, formal collusive agreements (often called cartels if comprehensive in scope) are legal. Whether tacit or explicit, legal or illegal, one may say that oligopolistic prices tend to be "administered" by sellers, in the senses mentioned above, as distinct from being determined by impersonal market forces.

Sellers' dual aims. The varying market performance of oligopolies results from the fact that individual sellers intrinsically have two conflicting aims. One common desire is to establish among themselves a monopolistic level of price (and of selling costs, etc.), which will maximize their combined profits, giving them the largest "profit pie" to divide. But each seller also has a fundamental antagonism toward rival sellers and wants to maximize his own profits even at the expense of theirs. The relative strengths of these conflicting aims—the maximizing of combined profits and the maximizing of individual profits—will likely depend on how concentrated the oligopoly is, because when sellers are fewer and their individual market shares larger, their rivals' reactions are stronger deterrents to independent actions.

Price behaviour in oligopoly

This is why various sorts of market performance are to be expected in oligopolistic industries. When the entry of other sellers is blockaded, collusive or interdependent behaviour may lead to a full monopoly price. If entry is only impeded, the resulting price may be far enough below the full monopoly level to discourage further entry. But prices are not always what they seem. An announced price that is well above cost may be undercut by clandestine price reductions to individual buyers, bringing the average of actual selling prices down somewhat.

If an oligopolistic industry is made up of a "core" of a few large interdependent sellers plus a "competitive fringe" of several or numerous quite small sellers, the competition of the small sellers may induce the large ones to limit the extent to which they raise their prices.

Price behaviour approaching full monopoly pricing seems to be found mainly in oligopolies having very high seller concentration and blockaded entry. Where these characteristics are less pronounced, prices and profits tend to be lower, though they are likely to be somewhat above the competitive level. A few economists maintain, mainly on the basis of abstract theorizing, that oligopolistic prices in general do not significantly differ from atomistically competitive prices, but the bulk of statistical evidence does not support them.

In oligopolies in which product differentiation is important, sales-promotion costs and the costs of product improvement or development will display roughly the same variety of tendencies found in pricing. Where there are a few large interdependent sellers, these costs may be restricted to about the same level as those of a single-firm monopolist; on the other hand, rivalry in sales promotion and product development may be sufficient to raise them higher. Oligopolists may also arrive collusively at relatively high uniform selling prices but simultaneously engage in independent nonprice competition (perhaps more so where seller concentration is lower).

WORKABLE COMPETITION

Since the character of market performance varies among industries along with their market characteristics, efforts have been made to devise some practical standard for identifying the sorts of market structure that engender socially satisfactory performance in a given industry. The term workable competition was coined to denote competition that may be considered as leading to a reasonable or socially acceptable approximation to ideal performance in the circumstances of a particular in-

dustry. The limits of such an approximation are of course debatable, and so the idea of workable competition must remain elusive because it is basically subjective.

Five attributes of workable competition

Without entering into a complex theoretical discussion of the relationship of individual-industry performance to overall welfare, it is plausible to suggest the following principal attributes of workable performance in an industry: (1) In the long term, selling price on the average should be equal to or not significantly above average costs of production, so that profits do not appreciably exceed a normal interest return on investment. Prices should be responsive to basic reductions in costs. (2) In so far as average costs of production are affected by the scales or capacities of plants and firms, the preponderance of industry output should be from plants and firms of the most efficient scale or with closely comparable technical efficiency. (3) The industry should not have chronic excess capacity—*i.e.*, significant plant capacity that is persistently unused even in periods of high general economic activity. (4) The industry's sales-promotion costs should not be substantially greater than needed to keep buyers informed of the availability, characteristics, and prices of products. (5) The industry should be adequately progressive in introducing more economical production techniques and improved products—balancing the costs of progress with the gains.

While the first three of these attributes are easier to appraise than the others, certain generalizations are possible concerning the workability of different market structures: (1) Unregulated single-firm monopolies tend to generate unworkable market performance, mainly in the form of output restriction, prices well above costs, and consequent excess profits. They have undesirable effects on the uses to which resources are put and on income distribution. (2) Oligopolies with high seller concentration and also very high barriers to entry tend toward unworkable performance, like that of single-firm monopoly. In general, however, they do not show significant degrees of technical inefficiency resulting from inefficient plant scales or excess capacity. (3) Oligopolies with fairly high seller concentration but only moderate barriers to entry are also prone to unworkable performance of the sort just mentioned, but not to as high a degree. (4) Oligopolies with only moderate seller concentration and moderate-to-low barriers to entry tend toward workable performance both in price-cost relations and in technical efficiency, except that some of them may have recurrent chronic excess capacity due to periodic overentry. (If cartels are legalized and their provisions are not rigorously controlled by government, the last two categories of oligopoly may have the same sort of unworkable performance as do very highly concentrated oligopolies.) (5) Industries of atomistic structure tend generally toward workable performance unless they suffer from destructive competition as described above.

In industries with significant differentiation of products among sellers—and especially in oligopolies of this sort—there is a tendency for minor but significant fractions of income to be devoted to persuasive (as distinct from informational) advertising and other sales promotion and also to more or less idle variations of product design, with the result that resources are in a sense "wasted" and costs increased.

By the criteria of workable competition, a purely rational society would presumably favour industries with moderate to low seller concentration, moderate to low barriers to entry, and without extreme product differentiation—all this from the standpoint of enhancing overall material welfare. The argument that oligopolistic and atomistic industries generally need legal protection from destructive competition may be discarded on the basis of evidence. Price and other market warfare in such industries has been extremely rare in industrial countries in the last 50 years.

GOVERNMENT POLICIES

Government policies toward monopoly and competition vary considerably among Western countries. These countries differ in their treatment both of cartels or other collusive arrangements on the one hand and of very high or increasing concentration on the other. The actual policies applied are not always spelled out in full by the legislation supporting them; the vigour of administration varies widely and so do the attitudes of the public commissions that administer the laws.

Efforts to maintain competition

The United States has in general the longest standing and the strongest policy of maintaining effective competition in its economy, under a variety of statutes usually designated as antitrust laws. This article will deal with two major parts of the relevant legislation, and the way they have been administered in recent years.

The Sherman Act. The basic law is the Sherman Anti-Trust Act (passed in 1890). It declares illegal every agreement in restraint of interstate trade among competing sellers, and its prohibitions apply not only to formal cartels but also to any agreements to fix prices, limit outputs, share markets, exclude competitors, and so forth. The existence of an illegal collusive agreement need not depend on a written document but may be, and most frequently is, inferred from circumstantial evidence. The reasonableness of such an agreement in purpose or effect does not make it legal; the intent to restrict competition alone suffices to establish its illegality.

The Sherman Act also declares illegal the "monopolization" of any part of trade or commerce in the country. As currently construed by the courts, this means that no firm may gain or maintain a "dominant occupancy" of an industry through "predatory" or "exclusionary" tactics or through normal commercial practices having the same purpose and effect. This prohibition may also be applied to several dominant oligopolists in an industry who jointly and in concert similarly act to eliminate or exclude competitive sellers.

Both major provisions of the Sherman Act are enforceable by the Department of Justice through litigation in the federal courts. It may bring either "criminal" actions, seeking fines and possible imprisonment as penalties for violations, or "civil" actions seeking court orders to terminate violations. The civil remedy for an agreement restraining trade is usually an injunction forbidding continuation of the agreement. Civil remedies for monopolization may be confined to injunctions against various "monopolizing" activities or at the extreme may extend to ordering dismemberment of the offending firm or firms to create a more competitive market structure.

The prohibition against collusive agreements has been fairly vigorously and successfully enforced in recent decades with the result that many such agreements have been terminated, but the scope of enforcement is probably not great enough to reach more than a minor fraction of potential violators. Moreover, simple parallelism of pricing and other action within concentrated oligopolies is alone not sufficient evidence of violation of the law. The major effects of the prohibition of collusive agreements, aside from actually stopping some of them, are two. First, there are no cartelized industries in the United States, so that the public does not suffer from the most effective and potentially pernicious sort of collusive agreement. Second, such collusion as does exist is tacit, driven "underground" to the level of gentlemen's agreements and is correspondingly much less effective in restricting competition than are cartels.

The prohibition against monopolization has been periodically enforced but never intensively, in part because the substantial dominance of an industry by one firm is very rare in the United States, and in part because of difficulties in demonstrating that probable offenders have actually pursued the practices and policies forbidden. In general, successful actions for joint monopolization cannot be brought against a very large majority of oligopolistic industries in the U.S. But a number of actions have succeeded in establishing illegal monopolization, and in some of these the severe penalty of dismemberment of the offending firm or firms has been secured. The major effects of the enforcement of the antimonopolization law have probably been to discourage the growth of single-firm monopolies and inferentially to encourage the development of oligopolies as a substi-

tute. Enforcement has also substantially discouraged the use of predatory and exclusionary tactics to eliminate or exclude competitors.

The Clayton Act. The other most significant procompetition law in the United States is the Celler-Kefauver Act of 1950, amending Section 7 of the older Clayton Anti-Trust Act. It prohibits mergers of firms, or acquisition of one firm by another, whenever the effect may be substantially to lessen competition or to tend to create a monopoly. It is directed against increases in concentration that probably or possibly will restrict competition.

This law has been rather intensively enforced with the result that a large number of important mergers or acquisitions have been dissolved or stopped, and many others have not been attempted. Continued enforcement of the law has been encouraged by judicial interpretations giving it very broad application; relatively minor effects on competition have been considered substantial enough to make the mergers that would produce them illegal, and even mergers of companies in different industries have been forbidden if some substantial lessening of competition might result. The Celler-Kefauver Act has thus served as a major deterrent to increases of concentration by merger. Nonetheless, a large amount of merger activity has not been deterred by the law, especially "conglomerate" mergers of firms in different and quite unrelated industries.

Before leaving the subject of United States policy it should be noted that, in some industries, the federal government has actually endeavoured to restrict competition. These include industries afflicted with chronic distress or destructive competition, as in agriculture, and industries in which large firms are tending to displace small firms, as in the distributive trades. In agriculture, for example, the government has imposed or sponsored price supports and output restrictions of crops in order to raise prices above competitive levels. In the distributive trades, various measures have aimed to reduce competition and lessen the competitive advantages of chain stores and other mass distributors, but with indifferent success. Both sorts of competition-restricting policies have been poorly designed to remedy basic ills afflicting the industries in question, being oriented much more to preserving "competitors" than to preserving competition.

European policies. Other industrialized Western countries follow policies toward monopoly and competition that differ a good deal from those in the United States. They place much less emphasis on competition or tend to legalize agreements in restraint of competition subject to governmental supervision. Such procompetitive policies as they do have are generally much "softer" than the American, and less comprehensive.

How national attitudes differ

These other Western countries, with minor exceptions, do not have laws prohibiting monopoly or monopolization nor laws preventing mergers and acquisitions that would tend to lessen competition. High concentration within industries, and increasing concentration, are not officially discouraged; in a number of countries the public authorities even encourage increased concentration via mergers or otherwise, although some countries have drawn the line at the acquisition of control of their domestic companies by foreign companies.

In some Western countries—*e.g.*, France and especially Italy—government-owned firms have been established in a number of major industries in which they operate in general rivalry with private firms. But whether their price policies check or modify the monopolistic pricing tendencies of private firms is not readily apparent.

The general tendency in these other Western countries is either to accept and recognize formal cartels or, alternatively, to forbid cartels but accept less formal agreements in restraint of trade, and then to supervise and to some extent control these cartels or other agreements through governmental commissions. In France and Italy, for example, formal cartels are permitted and recognized, but a commission investigates them and distinguishes between "good" (acceptable) and "bad" (unacceptable) cartels. Since the applied criteria of what is good and bad are not evident, the extent to which cartelized restriction of competition is reduced is unclear. Sweden permits numerous cartels but requires them to register with a government agency that employs publicity and the pressure of public opinion to combat antisocial cartel practices. Japan permits or requires cartels on a wide variety of grounds and apparently does not closely supervise them. In the United Kingdom, formal cartels are prohibited but looser agreements in restraint of competition are allowed; the latter are investigated by a commission and eliminated "if necessary."

In general, the policies toward cartels and agreements restraining competition in other Western countries are much more permissive than in the United States. Correspondingly, monopolistic or quasi-monopolistic tendencies in pricing are doubtless stronger and more frequent, and the automatic regulatory forces of markets weaker.

TRENDS AND ALTERNATIVES

The stability of present market structures

There seem to be no strong recent trends in Western countries toward either more or less competition within industries. In the United States, the average degree of seller concentration in individual industries has been remarkably stable since the 1930s. For example, roughly a third of the manufacturing industries show no appreciable change in concentration, another third show increases in concentration, and the remaining third show decreases of about the same magnitude. Few of the changes in concentration have been dramatically large. Between 1947 and 1963 the share of business in all manufacturing industries done by the largest 25 to 50 firms increased somewhat, but this is reconcilable with the previous statement on a number of grounds—*e.g.*, the largest firms are located in the largest and most rapidly growing industries. In other Western countries there is little evidence of dramatic increases in concentration in the postwar period. Some of these countries, like Japan and Germany, were in the process of re-establishing prewar concentrations that had been broken down under occupation governments in the immediate postwar period.

Restriction of competition by cartels or other agreements is certainly no more important in the United States now than in the 1930s and perhaps less so because of more intensive enforcement of the antitrust laws since 1938. A significant minor fraction of industrial output is now purchased by departments of government—especially the military—through negotiation with sellers, and this sort of buying practice is probably somewhat restrictive of competition. In a number of other Western countries the postwar tendency to subject cartels to some governmental supervision and regulation probably tended to lessen the restrictive effects of cartels. The same general tendency was observable in countries like the United Kingdom, where stricter supervision and control of looser types of collusive agreements was imposed.

A final question is whether broad changes in governmental policies toward monopoly and competition are desirable. The argument in favour of increasing seller concentration and stronger cartelization in order to avert cutthroat competition and to reduce uncertainty on the part of business firms is not well supported in theory and is discredited by experience, particularly that of the United States. The price paid would be unduly high in terms of misallocation of resources, effects on income distribution, and deterrents to the sort of progress that active market rivalry generates. On the other hand, in that minority of industries chronically afflicted with destructive competition, constructive steps should be taken to eliminate excess capacity and to shift labour to other occupations.

Some critics of American antitrust policies have recommended that highly concentrated oligopolies that persistently generate unworkable performance be dismembered (unless this would destroy the cost-savings of very large firms), thus creating more numerous and smaller sellers. This is probably not politically feasible in the United States or abroad, but it has its attractions.

BIBLIOGRAPHY. E.H. CHAMBERLIN, *Theory of Monopolistic Competition*, 8th ed. (1962), a classic and germinal contribution to the theory of markets, notable for its revival and development of the theory of oligopoly and for its introduction

and development of the concept of product differentiation; J. ROBINSON, *Economics of Imperfect Competition* (1933), a penetrating theoretical analysis of monopolistic and quasi-monopolistic pricing, complementing Chamberlin's work in many important ways; W.J. FELLNER, *Competition Among the Few: Oligopoly and Similar Market Structures*, rev. ed. (1949), a highly sophisticated and stimulating development of the theory of oligopoly; G.J. STIGLER, *The Theory of Price*, 3rd ed. (1966), a superior general textbook treatment of price theory, furnishing background for the somewhat more specialized works previously cited; E.S. MASON, "Price and Production Policies of Large-Scale Enterprise," *American Economic Review*, vol. 29 suppl., pp. 67–74 (May 1939), a germinal essay of great importance that pointed the way to feasible techniques for exploring the relation of market structures to market performance; J.S. BAIN, *Barriers to New Competition: Their Character and Consequences in Manufacturing Industries* (1956), introduction of the notion of barriers to entry and discussion of their character, sources, and consequences as aspects of market structure, including empirical tests of their effects on competition; and *Industrial Organization*, 2nd ed. (1968), a general textbook covering theoretical and empirical aspects of problems of monopoly and competition, including a treatment of American public policies promoting or restraining competition; C. KAYSEN and D.F. TURNER, *Antitrust Policy: An Economic and Legal Analysis* (1959), a superior analysis and criticism of the working of American antitrust policies, coupled with detailed proposals for revision in these policies; C. WILCOX, *Public Policies Toward Business*, 3rd ed. (1966), a high-grade general textbook on public policies toward business, including extensive treatment of policies affecting monopoly and competition.

Monotheism

Monotheism and polytheism

Monotheism and polytheism, the beliefs in one god or many gods, are often thought of in rather simple terms; *e.g.*, as a merely numerical contrast between the one and the many. The history of religions, however, indicates many phenomena and concepts that should warn against oversimplification in this matter. There is no valid reason to assume, for example, that monotheism is a later development in the history of religions than polytheism. There exists no historical material to prove that one system of belief is older than the other, although many scholars hold that monotheism is a higher form of religion and, therefore, must be a later development, assuming that what is higher came later. Moreover, it is not the oneness of god that counts in monotheism but his uniqueness; one god is not affirmed as the logical opposite to many gods but as an expression of divine might and power.

The choice of either monotheism, or polytheism, however, leads to problems, because neither can give a satisfactory answer to all questions that may reasonably be put. The weakness of polytheism is especially revealed in the realm of questions about the ultimate origin of things, whereas monotheism runs into difficulties in trying to answer the question concerning the origin of evil in a universe under the government of one god. There remains always an antithesis between the multiplicity of forms of the divine manifestations and the unity that can be thought or posited behind them. The one and the many form no static contradistinction: there is rather a polarity and a dialectic tension between them. The history of religions shows various efforts to combine unity and multiplicity in the conception of the divine. Because Christianity is a monotheistic religion, the monotheistic conception of the divine has assumed for Western culture the value of a self-evident axiom. This unquestioned assumption becomes clear when it is realized that for Western culture there is no longer an acceptable choice between monotheism and polytheism but only between monotheism and atheism.

THE SPECTRUM OF VIEWS: MONOTHEISMS AND QUASI-MONOTHEISMS

The basic monotheistic view. Monotheism is the belief in the existence of one god or, stated in other terms, that God is one. As such it is distinguished from polytheism, the belief in the existence of a number of gods, and atheism, the denial of the belief in any god or gods at all. The God of monotheism is the one real god that is believed to exist or, in any case, that is acknowledged as such. His essence and character are believed to be unique and fundamentally different from all other beings that can be considered more or less comparable; *e.g.* the gods of other religions. The religious term monotheism is not identical with the philosophical term monism, referring to the view that the universe has its origin in one basic principle (*e.g.*, mind, matter) and that its structure is one unitary whole in accordance with this principle; that is, that there is only a single kind of reality, whereas, for monotheism, there are two basically different realities: God and the universe.

The God of monotheism

God in monotheism is conceived of as the creator of the world and man; he has not abandoned his creation but continues to lead it through his power and wisdom; hence, viewed in this aspect, history is a manifestation of the divine will. God has not only created the natural world and the order existing therein but also the ethical order to which man ought to conform and, implicit in the ethical order, the social order. Everything is in the hands of God. God is holy—supreme and unique in being and worth, essentially other than man—and can be experienced as a *mysterium tremendum* ("a fearful mystery") but at the same time as a *mysterium fascinans*, ("a fascinating mystery"), as a mystery approached by man with attitudes of both repulsion and attraction, of both fear and love. The God of monotheism, as exemplified by the great monotheistic religions—Judaism, Christianity, and Islām—is a personal god. In this respect the one god of monotheism is contrasted with the conception of the divine in pantheism, which may also affirm one god or a divine unity. The god of pantheism, however, is impersonal, rather a divine fluid that permeates the whole world including man himself, so that Hinduism can say: *tat tvam asi*, literally "that is you," where "that" refers to the single, supreme reality or principle.

In monotheistic religions the belief system, the value system, and the action system are all three determined in a significant way by the conception of God as one unique and personal being. Negatively considered, the monotheistic conviction results in the rejection of all other belief systems as false religions, and this rejection partly explains the exceptionally aggressive or intolerant stance of the monotheistic religions in the history of the world. The conception of all other religions as "idolatry" (*i.e.*, as rendering absolute devotion or trust to what is less than divine) has often served to justify the destructive and fanatical action of the religion that is considered to be the only true one.

The concept of idolatry

The symbolic language of the monotheistic belief system has no proper terms of its own in speaking of God that cannot be found elsewhere also. God as Creator, Lord, King, Father, and other descriptive names are expressions found in many religions to characterize the various divine beings; the names do not exclusively belong to the religious language of monotheism. This common language is understandable because the monotheistic conception of God differs essentially only in one respect from that of other religions: in the belief that God is one and absolutely unique. Then, consequently, God is regarded as the one and only Creator, Lord, King, or Father. The conception of a divine Word is also to be found in a large number of religions, in accordance with the widespread belief that creation takes place through the word, or speech, of a god.

The extreme positions. The above is the basic monotheistic view. There is, however, a wide range of positions between exclusive monotheism at one extreme and unlimited polytheism at the other. A survey of the various positions may serve to provide a more adequate picture of the complex reality involved in the monotheisms and quasi-monotheisms.

Exclusive monotheism. For exclusive monotheism only one god exists; other gods either simply do not exist at all, or, at most, they are false gods or demons; *i.e.*, beings that are acknowledged to exist but that cannot be compared in power or any other way with the one and only true God. This position is in the main that of Judaism, Christianity, and Islām. While in the Old Testa-

ment the other gods in most cases were still characterized as false gods, in later Judaism and in Christianity as it developed theologically and philosophically the conception emerged of God as the one and only, and other gods were considered not to exist at all.

Ethical and intellectual monotheism

There are two types of exclusive monotheism: ethical monotheism and intellectual monotheism. In ethical monotheism man chooses one god, because that is the god whom he needs and whom he can adore, and that god becomes for him the one and only god. In intellectual monotheism the one god is nothing but the logical result of questions concerning the origin of the world. In many African religions the one god postulated behind the many gods that are active in the world and in the life of man is little more than the prime mover of Aristotle's philosophy, the ultimate source of motion in the universe. He is the intellectual apex necessitated by the system. In Christian theology, heavily influenced as it is by Greek philosophy, both conceptions can be found, usually together.

Unlimited polytheism. On the other hand, there is the extreme position of unlimited polytheism as, for instance, in the classical religions of Greece and Rome: each god has his own name and his own shape, and these are unalienably his and cannot be exchanged with those of any other god (not counting, of course, those cases in which gods are practically each other's duplicate and only bear a different name). The number of divinities is large and in principle unlimited. There are differences of status and power among the gods, of function and sphere of influence, but they are all equally divine. There is, in fact, an ordered pantheon. In unlimited polytheism, the number of gods that are actually worshipped seldom exceeds a few hundred within one religion, but in theory, as in India, millions and millions of gods may be thought to exist (see also POLYTHEISM).

The middle positions. Between the extremes of exclusive monotheism and unlimited polytheism are the middle positions of inclusive monotheism and henotheism.

Inclusive monotheism. Inclusive monotheism accepts the existence of a great number of gods but holds that all gods are essentially one and the same, so that it makes little or no difference under which name or according to which rite a god or goddess is invoked. Such conceptions characterized the ancient Hellenistic religions. A well-known example is that of the goddess Isis in the Greco-Roman mystery religion that is called after her. In *The Golden Ass* of Apuleius, the goddess herself speaks: "My name, my divinity is adored throughout all the world, in divers manners, in variable customs, and by many names." Then there follows a number of divine names, and this enumeration ends: "And the Egyptians, which are excellent in all kind of ancient doctrine, and by their proper ceremonies accustomed to worship me, do call me by my true name, Queen Isis."

Henotheism, or kathenotheism. Henotheism (from Greek *heis theos,* "one god")—a belief in worship of one god, though the existence of other gods is granted—also called kathenotheism (Greek *kath'hena theon,* "one god at a time")—which literally implies worship of various gods one at a time—has gone out of fashion as a term. It was introduced by the eminent 19th-century philologist and scholar in comparative mythology and religion Max Müller (1823–1900). Many later authors prefer the term

Monolatry

monolatry—which is the worship of one god, whether or not the existence of other deities is posited—to the term henotheism. Both terms mean that one god has a central and dominating position in such a way that it is possible to address this god as if he were the one and only god, without, however, abandoning the principle of polytheism by denying or in any other way belittling the real existence of the other gods, as the above-mentioned forms of monotheism do. Henotheism as a religious concept is at home in cultures with a highly centralized monarchical government. It was especially prevalent in some periods in the history of Babylonia and Egypt.

Alternate positions. *Pluriform monotheism.* The complicated relations that exist between monotheism and polytheism become clear when pluriform monotheism is considered, in which the various gods of the pantheon, without losing their independence, are at the same time considered to be manifestations of one and the same divine substance. Pluriform monotheism is one of the efforts to solve the problem of the coexistence of divine unity and divine pluriformity (multiplicity of forms), which was not recognized by an older generation of scholars, although part of the material was already available. It seems, indeed, that in many parts of the world and in many times religious thinkers have struggled with the perplexing problem of the unity and the pluriformity of the divine.

Nuer and Shilluk religion

The Nuer, a Nilotic pastoral people of the eastern Sudan, venerate a being called Kwoth, the Nuer term for "spirit" (also translated as "God"). He is considered to be the spirit in or of the sky. Like all spirits Kwoth is invisible and omnipresent, but he manifests himself in a number of forms. Each of these manifestations bears a name of its own, but though they are addressed and treated as separate entities, they are essentially nothing but manifestations of the one spiritual being Kwoth and are themselves considered spirits and called *kwoth.* A sacrifice offered to one of these manifestations—*e.g.,* a spirit of air, totem, or place—is not at the same time an offering to another; but all sacrifices, to whatever spirit they are offered, are sacrifices to the supreme Kwoth, or God. Nuer religion is certainly no clear monotheism as it is understood in the Bible and in the Qur'ān (the sacred book of Islām), but neither is it polytheism in the popular sense of the word.

The case of the Nuer is not unique. The related Shilluk people have similar conceptions, and here again the idea of a kind of divine substance that manifests itself in various shapes and under different names is encountered. To give one instance, Macardit is God, but this pronouncement cannot be turned the other way round—it is not permissible to say that God is Macardit. The divine being Macardit represents the dire and fatal aspect of the divinity who orders everything; that is to say, who also sends misfortune and death. In Macardit the contradiction between the creative and constructive and the destructive forces of the divinity is resolved. The positive function of this representation of God lies in the fact that, without diminishing either the power or the justice of the total divinity, it enables man to find an answer for the vexing question of theodicy—the problem of affirming divine justice and goodness in the face of physical and moral evil. That this question is a difficult one, indeed, becomes clear when the reactions of the tribes of Patagonia in a case of death are compared. These tribes believe in a high god, a supreme being, who rules everything and is also responsible for misfortune and death. When someone dies they accuse their god of murder.

Many other instances of pluriform monotheism could be mentioned, and many more presumably still await detection. An interesting pluriform system is that of the Oglala Indians of the central plains of the United States, who venerate 16 gods divided into four groups of four. Each group of four forms one god. Thus there are four gods, but these four gods again are one god, Wakan Tanka—the Great Spirit or the Great Mystery.

Religious dualism. Some religions are in the main dualistic; they view the universe as comprising two basic and usually opposed principles, such as good and evil or spirit and matter. Insofar as the conception of a god and antigod rather than that of two gods is encountered, this kind of religion can be considered as another variation of monotheism. In some Gnostic systems (ancient heresies based on esoteric knowledge and the dualism of matter and spirit), Christianity came near to this idea: the demiurge who created the world and man is considered as an evil being and contrasted to the good god. The most important instance of a dualistic religion is the Persian religion Zoroastrianism as founded by Zoroaster (7th–6th century BC) in which Ormazd (the good god) and Ahriman (the evil god) are each other's opposite and implacable enemies. Dualism, the existence of two contrary and, as a rule, mutually inimical principles, must not be confused with the notion of polarity, in which both principles are mutually dependent so that the one cannot

Zoroastrian dualism

exist without the other. Within the religion of Zoroaster, this notion is also found. In the Zoroastrian variation known as Zurvanism, as it is called after the god Zurvān *akarana* (boundless time), good and evil proceed from one and the same source and in the end they come together again (see also DUALISM, RELIGIOUS).

Pantheism and panentheism. Pantheism and panentheism are not necessarily connected with the notion of either monotheism or polytheism. In both cases the conception of the god or gods is impersonal, which tends, of course, to the conception of one god, of one divine substance, like Spinoza's *deus sive natura,* "god or nature." In pantheism god is immanent, in monotheism god is mostly transcendent, but in polytheism the gods may be either. Pantheism, however, is in most cases more a philosophical than a religious category. Sometimes the term panentheism is used to distinguish between the view that all is in God and that god is in all (see also PANTHEISM AND PANENTHEISM).

Primitive monotheism. In connection with monotheism it is necessary to mention the so-called high gods—the remote gods, usually sky gods, found in many primitive and archaic cultures—because this type of divine being has given rise to the theory of primitive monotheism (*Urmonotheismus*). After the Scottish scholar Andrew Lang (1844–1912) had drawn attention to these gods, the Austrian scholar Wilhelm Schmidt (1868–1954) based on their existence in primitive culture and beliefs the theory that the oldest religion of mankind had been monotheistic and that polytheism as well as magic were later degenerations in the course of the history of a pure primeval religion. This theory, defended with great skill and an enormous mass of ethnological material by Schmidt and his collaborators, has long since been proved unsound and was abandoned even by his own students. The connection postulated between the high gods and monotheism has in most respects obscured rather than illuminated the situation. It is true that in many cultures the particular high god is considered as the creator, the founder of the order of the world, and also in some cultures as the reigning god according to whose will everything now happens, but such a god is rarely considered to be the one and only god that counts. Exclusive monotheism is not to be found in either primitive or archaic religions, according to present knowledge. The high god, however, can become a god of exclusive monotheism when circumstances are favourable, at least if he belongs to the active type of high god and not to the intellectual type, which serves mainly as an idea to answer the questions concerning the ultimate origin of things. (See the distinction above between ethical and intellectual monotheism.) This transformation probably occurred in the case of the Islāmic god Allāh. It seems to be more common, however, even for the active type of high god gradually to disappear behind a host of other, often minor, deities who are more concerned with the daily affairs of mankind.

The Deism of the 17th and 18th centuries is often compared to the conception of high gods as *dei otiosi,* "inactive gods," who have created the world and put it into order but after their work was done retreated from the world and left it to run in accordance with the order installed at the creation (see DEISM). Not all high gods, however, are inactive.

MONOTHEISM IN THE WORLD RELIGIONS

Classical monotheism. *Religion of Israel and Judaism.* There may be some reason to speak of the Old Testament conception of God as monolatry rather than as monotheism, because the existence of other gods is seldom explicitly denied and many times even acknowledged. The passionate importance given to the proclamation of Yahweh as the one god who counts for Israel and the equally passionate rejection of other gods, however, make it truer to speak of the monotheism of Israel; as in what became the Judaic affirmation of faith, "Hear, O Israel, the Lord is our God, one Lord" (from New English Bible) (Deut. 6:4). The eminent Dutch Old Testament scholar Theodorus C. Vriezen writes: "It is striking how the whole life of the people is seen as dominated by Yahweh and by Yahweh alone. Even if one cannot speak of a strictly maintained monotheistic way of thinking, it is yet clear that faith in Yahweh is the foundation of life for the Israelite." Monotheism is not a matter of mathematics—of opting for the number one as against other numbers—but the conscious choice of a person or group committing himself or themselves to one god rather than to any other ones and putting their faith in that one god; Joshua proclaims: "But as for me and my house, we will serve the Lord" (Josh. 24:15). In Israel the ethical aspect was as important as the exclusiveness of their one god; the prophets stressed the ethical elements of an essentially exclusive God. The God of Israel was a jealous god who forbade his believers to worship other gods. In this respect he differed from other gods in the ancient Near Eastern religions who, as a rule, did not put such exclusive obligation on their adherents.

Yahweh, the God of Israel

In later times—beginning in the 6th century BC and continuing into the early centuries of the Christian Era—Judaic monotheism developed in the same direction as did Christianity and also later Islām under the influence of Greek philosophy and became monotheistic in the strict sense of the word, affirming the one God for all men everywhere.

Christianity. Among the three great monotheistic religions, Christianity has a place apart, because of the trinitarian creed of this religion in its classic forms, in contradistinction to the unitarian creed of Judaism and Islām. The Christian Bible, including the New Testament, has no trinitarian statements or speculations concerning a trinitary deity, only triadic liturgical formulas invoking God the Father, Son, and Holy Spirit. It is true that Christianity also has had its Unitarians, such as the 16th-century Italian theologian Faustus Socinus, but this religion in its three classic forms of Roman Catholicism, Eastern Orthodoxy, and Protestantism acknowledges one God in three Persons: God the Father, God the Son, and God the Holy Spirit. According to Christian theology, this acknowledgment is not a recognition of three gods but that these three persons are essentially one, or as the dogmatic formulation, coined by the early Church Father Tertullian (*c.* 160–after 220), has it: three Persons and one substance. This conception was not accepted without contradiction as is proved by theological disputes of the 3rd and 4th century. It is evident that trinitarian speculation greatly resembles the way of thinking of pluriform monotheism. It is, of course, unlikely that there are any historical connections between these phenomena; both, however, try to solve what is more or less the same problem in more or less the same manner. The main distinction is that Christianity as a monotheistic religion restricts itself to three Persons, though primitive religions have no reason to restrict the number of possible forms of the one divine substance. Like other religions that cover a large territory and have a long history, Christianity appears in a multitude of variations: there is Christian pantheism, Deism, and even, paradoxically, Christian atheism, as exemplified in the mid-20th-century Death of God theologies.

Trinitarianism

Islām. No religion has interpreted monotheism in a more consequential and literal way than Islām. According to Islāmic doctrine the Christian dogma of a trinitarian god is a form of tritheism—of a three-god belief. There is no issue upon which this religion is so intransigent as the one of monotheism. The profession of faith, the first of the so-called Five Pillars of Islām (the basic requirements for the faithful Muslim), states clearly and unambiguously that "there is no God but Allāh," and in accordance with this principle the religion knows no greater sin than *shirk* ("partnership"), the attribution of partners to Allāh; that is to say, polytheism, or anything that may look like it—*e.g.*, the notion of a divine trinity. The Qur'ān declares: "Say: He, Allāh, is one. Allāh, the eternal. Neither has he begotten, nor is he begotten. And no one is his equal" (112). This profession of faith in Allāh as the one god is encountered in a more popular form, for example, in the stories of *The Thousand and One Nights*: "There is no god except Allāh alone,

he has no companions, to him belongs the power and he is to be praised, he gives life and death and he is mighty over all things." In only one respect has the uncompromising monotheism of Islām shown itself to be vulnerable; *i.e.,* in the doctrine of the Qur'ān as uncreated and coeval with Allāh himself.

Monotheistic elements in ancient Near Eastern and Mediterranean religions. *Egyptian religion.* Egyptian religion is of special interest with regard to the various topics treated in this article, for in it are found polytheism, henotheism, pluriform monotheism, trinitary speculations, and even a kind of monotheism. Especially in the time of the New Kingdom (16th–11th century BC) and later, there arose theological speculations about many gods and the one god, involving concepts that belong to the realm of pluriform monotheism. These ideas are especially interesting when related to trinitarian conceptions, as they sometimes are. In a New Kingdom hymn to Amon are the words: "Three are all gods: Amon, Re and Ptah . . . he who hides himself for them [mankind] as Amon, he is Re to be seen, his body is Ptah." As Amon he is the "hidden god" (*deus absconditus*); in Re, the god of the sun, he becomes visible; as Ptah, one of the gods of the earth, he is immanent in this world.

Monotheistic reform of Akhenaton

Much attention has been given to the reform of Egyptian religion as effected by the pharaoh Akhenaton (Amenophis IV) in the 14th century BC. This reform has been judged in many ways, favourably and unfavourably; it is, however, clear that Akhenaton's theology, if not fully monotheistic, in any case strongly tends toward monotheism. It is even possible to follow the gradual development of his ideas in this direction. At first he only singled out Aton, one of the forms of the sun god, for particular worship, but gradually this kind of henotheism developed in the direction of exclusive monotheism and even took on the intolerance peculiar to this religious concept. The names of the other gods were to be deleted. This un-Egyptian intolerance was probably the main reason for the speedy decline of this creed.

Babylonian religion. As far as is known, monotheism was largely absent from Babylonian religion. There henotheism seems to have been very important, since a person could choose one god for particular worship as if he were the only god.

Greco-Roman religions. The classic religions of Greece and Rome were in the main purely polytheistic, but in later times tendencies arose, partly stimulated by philosophy and later also by Judaism and Christianity, toward inclusive monotheism. The hymn to Zeus by the Stoic philosopher Cleanthes (*c.* 330–*c.* 230 BC) is the best known document of this process. It praises Zeus as the essence of divinity in all gods, creator and ruler of the cosmos, omnipotent, the giver of every gift, and the father of mankind. In the mystery religions of the Greco-Roman world and in the religious philosophies of later antiquity, such as Neoplatonism, Neopythagoreanism, and others, inclusive monotheism was more or less the rule.

Monotheistic elements in Indian and Chinese religions. The religions of India and China show an astonishing multiplicity of form, but exclusive monotheism, unless imported or stimulated by foreign influences, seems to be absent. All other phenomena treated in this survey of monotheism, however, are to be found in their religions. Inclusive monotheism and pantheism fit very well with the Indian notions of religion, particularly in Hinduism, as is witnessed by the reflections on Brahman, the self of the world, and *Ātman*, the self of individual man. As the *Upaniṣads* say: "Truly, in the beginning existed this Brahman, that only knew itself, saying: I am Brahman." Although in many cases one god, such as Śiva (Shiva) or Viṣṇu (Vishnu), receives nearly all the attention of the faithful, this emphasis never leads to a negation of other gods as such. Jainism does not differ in this respect. Only the religion of the Sikhs, heavily influenced by Islām, can be said to teach a kind of exclusive monotheism.

Buddhism teaches in essence that there are no gods in the full sense of the word. Gods are higher beings, but they belong to the cosmos and are as much in need of salvation as man is.

The ancient Chinese religion of the heaven (Shang Ti T'ien) is comparable to the religions that proclaim a high god as creator and ruler of the world, but monotheism has not resulted from this conception. Neither has Taoism led to monotheism.

BIBLIOGRAPHY. General works include: JOSIAH ROYCE, "Monotheism," in the *Encyclopaedia of Religion and Ethics,* vol. 8 (1928); "Monotheismus und Polytheismus," in *Religion in Geschichte und Gegenwart,* vol. 4 (1913); T.P. VAN BAAREN, *Doolhof der goden* (1960); G. VAN DER LEEUW, *Phänomenologie der Religion* (1933; Eng. trans., *Religion in Essence and Manifestation,* 2 vol., 1963); and R. OTTO, *Das Heilige* (1917; Eng. trans., *The Idea of the Holy,* 2nd ed., 1950). For primitive religions, see T. P. VAN BAAREN, *Menschen wie wir* (1964); and P. RADIN, *Monotheism Among Primitive Peoples* (1954); on the high gods, see H. ZWICKER, *Das Höchste Wesen* (1970); and E.O. JAMES, *The Concept of Deity* (1950), the only general systematic study of recent date treating the problems of monotheism. H.R. NIEBUHR, *Radical Monotheism and Western Culture* (1960), is a modern, incisive Protestant theological presentation of absolute monotheism.

Monotremata

The Monotremata (monotremes) are a distinctive order of primitive mammals, the only surviving members of the subclass Prototheria.

Monotremes lay eggs and are reptilelike in many other ways but possess such essentially mammalian characters as mammary glands, hair, a large brain, and a complete diaphragm.

GENERAL FEATURES

Only two monotreme types, the platypus (*Ornithorhynchus anatinus,* family Ornithorhynchidae) and the echidnas, or spiny anteaters (*Tachyglossus aculeatus* and *Zaglossus bruijni,* family Tachyglossidae), are known. The earliest monotreme fossils known come from the Australian Pleistocene (2,000,000 or more years ago), and they are essentially the same as the living forms, which range in body length from about 30 to 80 centimetres (12 to 32 inches) and weigh from about one to ten kilograms (two to 22 pounds).

The platypus, found in eastern Australia from north Queensland to Tasmania, is one of the most remarkable of all mammals. It has a ducklike "bill," webbed feet, and a flattened beaver-like tail. When the first stuffed specimens reached England around the end of the 18th century, they were thought to be fakes, made by sticking together bits of different animals.

The echidnas also rank high among the world's most interesting mammals and are readily kept in captivity for physiological studies. Superficially, they are quite unlike the platypus. They are recognized by their sharp-pointed spines and tubelike noses. *Tachyglossus* is found throughout Australia, including Tasmania, and part of New Guinea. *Zaglossus* has an extensive distribution in New Guinea.

Neither the platypus nor the echidnas are readily seen by the casual visitor, but they may be fairly common in some areas. Platypuses are not kept in zoos outside Australia.

The monotremes do not appear to be carriers of diseases harmful to man. Both monotreme types are now wholly protected by law in Australia.

NATURAL HISTORY

Ecology. The platypus is amphibious, with a habitat ranging from alpine waters at an altitude of 1,500 metres (about 4,900 feet) in southeastern Australia to the sluggish subtropical Queensland coastal streams. It digs winding burrows with side branches in the banks of the streams and lakes that it inhabits. These burrows are usually five to ten metres (15 to 30 feet) long but may be as long as 30 metres (100 feet). The entrance is normally above the water level, however during floods it may be submerged.

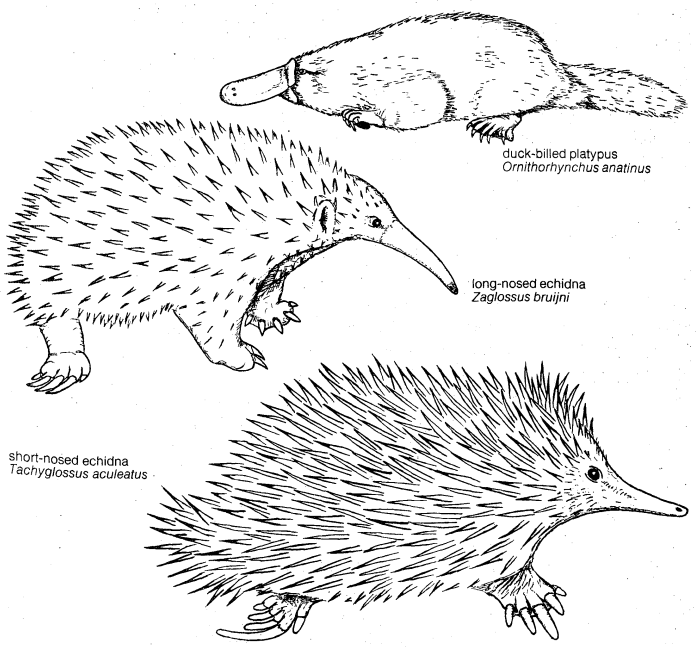

Figure 1: The three extant monotreme species.
Drawing by A.G. Lyne

Enemies of the platypus

The platypus has few natural enemies. It was formerly hunted extensively for its valuable velvet-like fur but for many years has been completely protected by law, and as a result it has increased in numbers. It appears to be relatively free of competition from other species in the water, where it feeds mainly on insect larvae, small crayfish, tadpoles, and other aquatic animals. Some authorities have suggested that the introduced rabbit (*Oryctolagus cuniculus*), which burrows in the banks of streams where the platypus once dwelt in quiet seclusion, is responsible for the disappearance of the platypus from many settled regions.

The echidnas are terrestrial animals, living in forests, scrubland, and deserts. Although usually encountered only by accident, *Tachyglossus* is one of the most widely distributed mammals in Australia. In New Guinea the habitats of *Zaglossus* include the humid forests that are almost continually blanketed by cloud cover. The animal has a known altitudinal range in these forests from about 1,100 to about 2,900 metres (3,600 to 9,500 feet).

Tachyglossus lives largely on ants and termites. The one element common in all the habitats occupied by this echidna is the presence of ants; termites are present in only some of the localities occupied.

Unfortunately, little is known of many aspects of the ecology of the monotremes, such as population density and social behaviour.

Life cycle and reproduction. The platypus breeds once annually, from July to August in the northern part of its range and to October in the southern part. Mating is believed to occur in the water, and it has been suggested that the spurs on the hind legs of the male may be used to hold the female. No spur grip was noted in an observation of copulation recorded by Australian zoologist D.H. Fleay in the course of an extensive study. An unusual courtship precedes mating, in which, among other manoeuvres, the male grabs the female's tail and the pair swim in circles.

In the breeding season, the female platypus digs a special burrow that twists and turns and may be very long. She then builds a nest of grass, leaves, and other plant material in a chamber at the end of the breeding burrow. This special burrow is blocked with earth in one or more places by the female during the period when she is laying and incubating the eggs. Only the left ovary is functional, and the eggs are always found in the left uterus. One to three, usually two, leathery-shelled eggs are laid. When there are two or three eggs they adhere together, but the sticky fluid that covers the eggs when they are laid soon dries and loses its stickiness. The eggs vary from 16 to 18 millimetres (about 0.60 to 0.70 inches) in length and from 14 to 15 millimetres in breadth.

The platypus has been bred in captivity on one occasion only, by Fleay in 1943. His observations suggest that the period from mating to egg laying is probably 12 to 14 days and the incubation period an additional ten to 12 days. The young are not more than about 18 millimetres long at hatching and do not leave the breeding burrow until they are about 17 weeks old. At this age they are fully haired and about 34 centimetres (13 inches) long. Because the female platypus has no teats, the milk is apparently sucked from the skin as it exudes from the ducts of the mammary glands. The life-span of the platypus is said to be ten to 15 or more years; at least one captive animal has lived more than ten years.

More research has been done on the echidna *Tachyglossus* than on the platypus, mainly because it is less difficult to maintain in captivity. In southeastern Australia, echidnas breed once a year from late June to late September. The period between copulation and egg laying is at least 16 days and may be as long as 28 days. Both ovaries are functional.

Egg laying in the echidna

In the breeding season the female echidna develops an abdominal pouch. Egg laying has not been observed, but there is circumstantial evidence that the egg is laid directly into the pouch by the female's curving her body during this process. One egg (rarely two or three) is laid at a time; it is creamy yellow and the shell has a rubbery texture. The eggs of echidnas are slightly smaller than those of the platypus, being from 14 to 17 millimetres long and from 13 to 15 millimetres wide. Within the pouch the egg is not stuck to the hairs but is quite loose and from time to time is located in different positions, apparently retained by the apposition of the lips of the pouch. The incubation period of the egg in the pouch is ten to 10.5 days, and the newly hatched echidna is about 15 millimetres (0.6 inch) long and weighs about 0.38 gram (about 0.01 ounce). After hatching, the young lives in the pouch and imbibes milk by sucking two special areas of the skin—the mammary areolae—where the ducts from the mammary glands open to the exterior on either side of the midline of the pouch. As in the platypus, no teats are present.

Authorities disagree on whether the young echidna takes milk by sucking or by licking. After detailed observations, an Australian zoologist, Mervyn Griffiths, stated that advanced pouch young take milk by sucking and not by licking it off the hairs in the mammary region, but he considered it possible that newly hatched and early stages of pouch young get their milk by licking it up as it is ejected onto the surface of the skin.

Information on how long the young stay in the pouch and what happens to them when they are cast out is meagre. One of the echidnas studied by Griffiths increased in body weight from 240 grams (about 0.5 pound) to 850 grams (about 1.9 pounds) in 43 days, a mean daily increase in weight of about 14 grams per day. The young was cast out of the pouch when it reached a body weight of 400 grams (about 0.9 pound). Thereafter, the mother's pouch regressed quickly, but she continued to suckle the young for some time. At the time when the young was dropped from the pouch, its eyes were open and the sharp spines projected from the skin. In wild echidnas it has been reported that the mother deposits the young in a burrow when its spines emerge and it is too large to be carried in the pouch.

Tachyglossus has been bred in captivity on only three occasions, once in Berlin and twice in Basel in Switzerland. In captivity *Tachyglossus* has lived up to 50 years, and *Zaglossus* up to about 30 years.

Behaviour and locomotion. Both the platypus and echidnas exhibit extreme specializations for feeding and locomotion.

The platypus emerges from its burrow for feeding usually in the early morning or late afternoon, but is sometimes in the water at other times of the day. When it is burrowing or walking on land the web of the front feet, which extends beyond the claws, is folded under the

Swimming by the platypus

palms. The muzzle and the claws of the front feet are used in burrowing. The platypus swims gracefully and expertly, using the front feet. The hind feet, in conjunction with the flattened tail, are used mainly for stabilization. The tail also assists the platypus in diving. The animal often swims along the surface with only the upper part of the muzzle and a small part of the head and body above the water. When submerged, the eyes and ears are closed by a fold of skin. The sensitive muzzle is an important organ for guiding the platypus while it swims blind, often close to the bottom. It may stir up the mud or move stones to locate its food. It surfaces often to breathe and to chew the prey, which it stores in cheek pouches while it is submerged. It can rest near the bottom for a few minutes by wedging itself under stones or logs. In captivity, the platypus has an enormous appetite, devouring each day the equivalent of half or more of its own body weight.

Echidnas are generally solitary. They appear to be more uncommon than they are because of the inaccessible nature of the places they choose to hide in and because of their remarkable ability to dig vertically into the ground and cover themselves with dirt when disturbed.

Observations on *Tachyglossus* in various parts of Australia indicate that its activity is closely related to the ambient temperature. In north Queensland, they are active primarily at night; but in the more temperate parts of eastern Australia, they are active both day and night. In desert regions they retire into crevices in rock outcrops during the day, where the humidity is higher and they are protected from intense sunlight.

Although echidnas are well adapted for digging, they do not excavate burrows, and they dig primarily to obtain food and escape enemies. They also retreat into hollow logs or under rocks or roots and wedge themselves into crevices and even into slight depressions in such a way that it is practically impossible to dislodge them. They can withdraw their appendages and erect their spines, as does a hedgehog. Echidnas walk with the legs fully extended so that the undersurface of the body is relatively high off the ground and with the hind toes directed outward and backward. They can run and climb well. *Tachyglossus* is extremely powerful and can tear apart rotten logs in search of termites or dig down to ant nests in rocky terrain.

FORM AND FUNCTION

General characteristics. One of the most striking features of the monotremes is that they lay eggs from which the young are subsequently hatched. These eggs are like those of reptiles in that they have large yolks and rubbery shells. Other interesting reptilian features are seen in the structure of the urogenital organs and in the skeleton. In both sexes of the monotremes, as in all reptiles, the intestine, bladder, and reproductive organs all open into a common chamber, the cloaca, with only one external opening. The penis of monotremes is used solely for delivering sperm and not also for urination as in most other mammals. In the skeleton, the shoulder girdle not only retains well-developed coracoid bones, which are reduced to vestiges in other mammals, but also an interclavicle. The pelvic girdle carries epipubic bones, which, as in some reptiles and marsupials, act as supporting structures for the ventral (abdominal) body wall.

Similarities to reptiles

The skull of monotremes has a smooth, rounded cranial portion, terminating in a long rostrum, or snout. Both monotreme types are toothless as adults, and the echidnas are toothless throughout life. The platypus has teeth when young, but they are shed before the animal becomes adult and are replaced by horny pads. The testes are abdominal and there are no teats and no vibrissae (whiskers). The limbs are modified for digging or swimming. The posture of the platypus resembles that of reptiles, especially lizards. In the echidnas, however, the limbs support the body well off the ground, even when the animals are stationary or walking slowly.

An interesting feature of the digestive system of monotremes is that the whole inner surface of the stomach is lined with a cornified (horny) epithelium. There are no glands of any kind. Particularly interesting is the lack of those that produce hydrochloric acid and peptic enzymes, which together initiate the digestion of protein in other mammals. Some other insectivorous mammals also have cornified epithelium covering most of the stomach lining, but there is a small glandular area. It has been suggested that the breakdown of food in the stomach of *Tachyglossus* is assisted by the grinding action of ingested dirt.

Platypus. The platypus has a flattened body covered with dense, short, fine hairs and coarse guard hairs, usually dark brown on the back and much paler on the belly. There is practically no neck. The tail is broad and flat like that of a beaver. It is covered with coarse hair, which is usually worn off on the under surface. The adult male is 50 to 60 centimetres (20 to 24 inches) in total length and the adult female is 40 to 50 centimetres (16 to 20 inches). An average-sized male weighs nearly two kilograms (4.5 pounds). One of the most conspicuous features of the platypus is its elongated and flattened muzzle, which bears a superficial resemblance to a duck's bill. This muzzle is covered with a soft, rubbery, naked, and sensitive skin, which is a blue-gray colour on its upper surface and pale pinkish or mottled below. Dorsal (toward the back) and ventral flaps, or shields, of naked skin extend backward from the muzzle over the adjacent hair. The nostrils are located on the upper surface of the muzzle near its anterior end. The eyes are small and there are no external ears. Both the eyes and ears open into a facial furrow that is closed when the platypus is below the surface of the water. There are cheek pouches in which food is stored until it can be chewed. The limbs are short and the feet webbed. The webbing on the hind feet reaches to the base of the claws, and on the front feet beyond the claws, making extra large paddles for swimming.

Venom apparatus of the platypus

The male platypus has a sharp, movable, horny poison spur on the inner side of each hind limb near the heel. Each spur is about 15 millimetres (0.6 inch) long and connected by a duct to a venom-secreting gland, called the crural, or poison, gland, situated on the dorsal aspect of the upper part of the hind limb. The function of the venom apparatus is unknown. An Australian zoologist, J.H. Calaby, stated that "If, as is generally believed, the crural gland is actively secreting only during and near the breeding season it seems very likely that the chief use of the venom apparatus would be combat between males for territory or females." The poison is not fatal to man but causes intense pain.

Echidnas. Superficially, the echidnas are quite unlike the platypus. They have a rounded body covered on the back and sides with stout, sharp-pointed spines and some hairs. The spines of *Tachyglossus* may measure up to six centimetres (2.5 inches) in length, those of *Zaglossus* up to about three centimetres. The undersurface is covered with coarse hair and is usually without spines. The colour of the spines and hair ranges from light brown to almost

black, depending on species and individual variation. Adult males are larger than adult females. There is a long, naked, and sensitive muzzle, a very short tail, and no neck. In some echidnas a definite external ear is present, but in others it is inconspicuous. The nostrils open near the tip of the muzzle. The mouth is small, only sufficient for the protrusion of the long, sticky tongue. The limbs are short and powerful and have strong claws for digging. In *Tachyglossus* one of the claws of the hind foot is particularly elongated and is used for scratching the skin between the spines.

The echidnas resemble the platypus in that there is a venom apparatus on each hind leg, but the spur and crural gland are smaller. In *Tachyglossus*, the spur (about five to ten millimetres long), which is situated on the inside of the ankle, is present in all males and some females. No observations on the use of the venom apparatus by the echidnas have been published.

Temperature regulation and hibernation. Monotremes are better able to control their body temperature than are reptiles. Except during hibernation, or torpidity of some species, the eutherian, or placental, mammals maintain a high and virtually constant body temperature usually between 36° and 40° C (97° and 104° F). The body temperature of most reptiles varies with that of the surroundings. The body temperature of the monotremes, however, does not quite reach that of the eutherian mammals, being about 31° to 32° C (88° to 90° F). The monotremes are usually described as physiologically primitive in regard to temperature regulation. It has been shown, however, that *Tachyglossus* is an excellent temperature regulator in some situations but less capable in others. It is probably no poorer in this respect than many eutherian mammals (*e.g.*, anteaters, armadillos, and sloths). In cold surroundings the echidna maintains a well-regulated body temperature. Studies of temperature regulation and torpor in *Tachyglossus* have shown that this echidna appears to be a true mammalian hibernator, with the ability to arouse from torpor without the aid of heat from external sources. This ability is lost after repeated periods of torpor in the laboratory at 5° C (41° F). The echidna resembles other hibernators in that torpor is not continuous but is interrupted by frequent arousals. Continuous periods of torpor lasting 9.5 days, with intervening periods of wakefulness ranging from 30 hours to 11 days, have been recorded for the echidna.

The platypus has periods of hibernation or semihibernation, at least in southeastern Australia. In captive animals, Fleay found that the hibernation periods were short and irregular during the cooler months, the longest single period being 6.5 days.

Laboratory studies have shown that the platypus is slightly superior to *Tachyglossus* in temperature regulation. The platypus has sweat glands on the muzzle and over the body surface, whereas *Tachyglossus* has them only in the pouch area. The heat tolerance of *Zaglossus*, which has many well-developed sweat glands distributed over the body, has not been studied. In its natural environment it is unlikely that the platypus will be exposed to high heat loads. The highly insulating coat of the platypus would protect it against heat loss in water and allow it to exploit cold environments.

EVOLUTION, PALEONTOLOGY, AND CLASSIFICATION

The monotremes are without living relatives outside Australia and New Guinea, and, apart from the presence of fossil monotremes in the Australian deposits of the relatively modern Pleistocene Epoch (the last 2,500,000 years or so), little is known of their ancestry. The fossils so far discovered differ from the existing forms only at the species level. It is interesting to note, however, that large echidnas of the genus *Zaglossus*, which now live only in New Guinea, were common and widespread in Australia during the Pleistocene.

Although the existent monotremes are highly specialized in many of their features, their possession of such typically mammalian characters as mammary glands, hair, and a large brain carries the suggestion that such characters are primitive features of early mammals.

Origin of the order

Most authorities regard the order Monotremata as the sole group of the subclass Prototheria and believe that it originated from a line of mammal-like reptiles different from that which gave rise to the other mammals. It has been suggested, because of the similarities between marsupials and monotremes, that they should be grouped together in a subclass of the Mammalia, the Marsupionta, but the idea has not gained wide acceptance. It does not take into account the many similarities between marsupials and eutherian mammals. It has also been postulated that a group of early prototherian mammals, of which the monotremes are specialized derivatives, gave rise to the marsupials and the eutherian mammals, but this view is not accepted by most biologists.

The ducklike muzzle, or "bill," alone distinguishes the platypus from all other mammals. Although platypuses have been divided into several subspecies, based mainly on differences in size, all authorities agree that the family Ornithorhynchidae has only a single genus and species, *Ornithorhynchus anatinus*.

Two genera of echidnas are recognized in the family Tachyglossidae; in *Tachyglossus* (short-nosed echidnas) the elongated muzzle is straight and not greatly prolonged, and in *Zaglossus* (long-nosed echidnas) the elongated muzzle is greatly prolonged and curved downward.

Although Griffiths recognized *Tachyglossus aculeatus* as the only species of the genus, he distinguished six subspecies, some of which he considered of doubtful validity. Some authorities consider that the relatively hairy Tasmanian echidna is a distinct species (*T. setosus*). Some mammalogists who have studied *Zaglossus* in detail have concluded that only one variable species, *Z. bruijni*, should be recognized. It can be seen that much more work on the biology of the monotremes needs to be done to clarify the place these extraordinary animals occupy in nature.

Monroe, James

As the fifth president of the United States, James Monroe made a significant and lasting contribution to his country's foreign policy in the Monroe Doctrine—a warning to the governments of Europe not to intervene in the affairs of the American hemisphere. He was born on Monroe's Creek, in Westmoreland County, Virginia, on April 28, 1758. His father was of Scottish, and his mother of Welsh descent. At the age of 16 he entered the College of William and Mary, but in 1776 left to fight in the U.S. War of Independence. In 1780 he began the study of law under Thomas Jefferson, then governor of Virginia, and between the two men there developed an intimacy and a sympathy that had a powerful influence upon Monroe's later career.

He was elected to the Virginia House of Delegates in 1782, and though only 24 years of age was chosen a member of the governor's council. From 1783 to 1786 he served in the Congress under the Articles of Confederation, the first constitution of the new nation. During his term he vigorously insisted on the right of the United

States to navigate the Mississippi River, then controlled by the Spanish, and attempted, in 1785, to secure for the weak Congress the power to regulate commerce and thus remove one of the great defects in the existing central government. In 1786 he married Elizabeth Kortright of New York by whom he had two daughters. Retiring from Congress, he began practicing law at Fredericksburg, Virginia, and was chosen a member of the Virginia House of Delegates in 1787, and (1788) a member of the state convention at which Virginia ratified the new federal Constitution. In 1790 he was elected to the U.S. Senate, where he vigorously opposed Washington's administration; but in 1794 Washington, nevertheless, nominated him as minister to France.

Diplomatic career. It was the hope of the administration that Monroe's well-known French sympathies would secure for him a favourable reception and that his appointment would also conciliate France's friends in the United States. His warm reception in France and his enthusiastic republicanism displeased the Federalists (the party of Alexander Hamilton which encouraged close ties to England) at home; he did nothing, moreover, to reconcile the French people to the Jay Treaty, which regulated commerce and navigation between the United States and Great Britain during the French Revolutionary Wars. Without real justification, the Franch regarded the treaty, as a violation of the French-American treaty of commerce and amity of 1778, and as a possible *casus belli.* Monroe led the French government to believe that the Jay Treaty would never be ratified by the United States, that the administration of George Washington would be overthrown as a result of the obnoxious treaty, and that better things might be expected after the election of 1796 when a new president, perhaps Thomas Jefferson, should take office. Washington, though he did not know of this intrigue, sensed that Monroe was unable to represent his government properly, and, late in 1796, recalled him.

Minister to France

Monroe returned to America in the spring of 1797, and in the following December published a defense of his course in a pamphlet of 500 pages entitled *A View of the Conduct of the Executive, in the Foreign Affairs of the United States.* Washington seems never to have forgiven Monroe for this stratagem, though Monroe's opinion of Washington and Jay underwent a change in his later years. In 1799 Monroe was chosen governor of Virginia and was twice re-elected, serving until 1802.

At this time there was much uneasiness in the United States when Spain restored Louisiana to France by the Treaty of San Ildefonso in October 1800. The Spanish district administrator's subsequent withdrawal of the United States' "right of deposit" at New Orleans greatly increased this feeling and led to much talk of war. Resolved upon peaceful measures, President Jefferson in January 1803 appointed Monroe envoy extraordinary and minister plenipotentiary to France to aid Robert R. Livingston, the resident minister, in purchasing the territory at the mouth of the Mississippi—including the island of New Orleans—authorizing him at the same time to cooperate with Charles Pinckney, the minister at Madrid, in securing from Spain the cession of East and West Florida. On April 18 Monroe was further commissioned as the regular minister to Great Britain.

Louisiana Purchase

Monroe joined Livingston in Paris on April 12, after the latter's negotiations were well under way; and the two ministers, on finding Napoleon willing to dispose of the entire province of Louisiana, decided to exceed their instructions and effect its purchase. Accordingly, on May 2 (antedated to April 30) they signed a treaty and two conventions whereby France sold Louisiana to the United States. The fact that Monroe signed the treaty along with Livingston did not hurt his political career at home, but he is not entitled to much credit for the diplomatic achievement.

In July 1803 Monroe left Paris and entered upon his duties in London; and in the autumn of 1804 he proceeded to Madrid to assist Pinckney in his efforts to define the Louisiana boundaries and acquire the Floridas. After negotiating until May 1805 without success, Monroe returned to London and resumed his negotiations concerning the impressment of American seamen and the seizure of American vessels. As the British ministry was reluctant to discuss these vexing questions, little progress was made, and in May 1806 Jefferson ordered William Pinkney of Maryland to assist Monroe. The result of the deliberations was a treaty signed on December 31, 1806, which contained no provision against impressments and provided no indemnity for the seizure of goods and vessels. Accompanying its signature was a British reservation maintaining freedom of action to retaliate against imminent French maritime decrees. In passing over these matters Monroe and Pinkney had disregarded their instructions, and Jefferson was so displeased with the treaty that he returned it to England for revision.

Monroe returned to the United States in December 1807 and was elected to the Virginia House of Delegates in the spring of 1810. In the following winter he was again chosen governor, serving from January to November 1811, and resigning to become secretary of state under James Madison, a position he held until March 1817. The direction of foreign affairs in the troubled period immediately preceding and during the War of 1812, with Great Britain thus fell upon him. On September 27, 1814, after the capture of Washington, D.C., by the British, he was appointed secretary of war, and discharged the duties of this office, in addition to those of the Department of State, until March 1815.

Presidency. In 1816 Monroe was elected president of the United States. In 1820 he was re-elected, receiving all the electoral votes but one. The chief events of his calm and prosperous administration, which has been called the "era of good feeling," were the Seminole War (1817–18); the acquisition of the Floridas from Spain (1819–21); the Missouri Compromise (1820), by which the first conflict over slavery under the Constitution was peacefully adjusted; recognition of the new Latin-American states, former Spanish colonies, in Central and South America (1822); and—most intimately connected with Monroe's name—the enunciation, in the presidential message of December 2, 1823, of the Monroe Doctrine, which has profoundly influenced the foreign policy of the United States.

Monroe Doctrine

Not until 1852 did the phrase Monroe Doctrine come into use. The "principles of President Monroe," as the message was referred to in Congress, consisted of three openly proclaimed dicta: no further European colonization in the New World, abstention of the United States from the political affairs of Europe, and nonintervention of Europe in the governments of the American hemisphere. In the diplomatic correspondence preceding the proclamation of these principles in the president's message was a fourth dictum not publicly associated with the Doctrine until 1869: the United States opposed the transfer of any existing European colonies from one European sovereign to another.

It is generally concluded that Secretary of State John Quincy Adams was undisputed author of the noncolonization principle of the Doctrine; the principle of abstention from European wars and politics was common to all the fathers of American independence, inherited and expressed by the younger Adams all his professional life; in Cabinet meetings, Adams also urged the dictum of nonintervention in the affairs of the nations of the Western Hemisphere. But Adams had no idea of proclaiming these dicta to the world. Monroe took responsibility for embodying them in a presidential message that he drafted himself. Modern historical judgment considers the Monroe Doctrine to be appropriately named.

On the expiration of his second term Monroe retired to his home at Oak Hill, Virginia. In 1826 he became a regent of the University of Virginia, and in 1829 was a member of the convention called to amend the state constitution. Having neglected his private affairs and incurred large expenditures during his missions to Europe, he was compelled to ask Congress to reimburse him for his expenses in the public service. In 1826 Congress finally authorized the payment to him of $30,000, and after his death appropriated a small amount for the purchase of his papers from his heirs. He died in New York City on July 4, 1831, while visiting his daughter. In 1858, the centennial year of his birth, his remains were reinterred with impressive ceremonies at Richmond, Virginia.

Thomas Jefferson, James Madison, John Quincy Adams, and many other prominent statesmen of Monroe's time all spoke loudly in his praise; but he suffers by comparison with the greater men of his time. Possessing none of their brilliance, he had, nevertheless, to use the words of John Quincy Adams, "a mind . . . sound in its ultimate judgments, and firm in its final conclusions."

Monsoons

Monsoons are seasonal winds that blow for approximately six months from the northeast and six months from the southwest, principally in Africa and southern Asia. Summer monsoons have a dominant westerly characteristic and a strong tendency to converge, rise, and produce rain. Winter monsoons have a dominant easterly characteristic and a strong tendency to diverge, subside, and cause drought. Both are the result of differences in annual temperature trends over land and sea. Changes are large over land, small over the oceans. The existence of these seasonal winds between East Africa, Arabia, and India was known to the ancient Greeks and Romans. Arab geographers of the Middle Ages gave accurate descriptions of them and spread the use of the term; an Arab pilot with a sound knowledge of the monsoons guided Vasco da Gama from East Africa to India in 1498.

The monsoon has been regarded variously as: (1) a seasonally reversing wind, northeast in winter, southwest in summer as part of a dominant wind; (2) a general circulation of semipermanent cells (wind systems that tend to recur in the same atmospheric location) that are maintained by the seasonal thermal contrasts of the continental and ocean surfaces; (3) an anomaly in the planetary air circulation; (4) an equilibrating flow between two regional pressure patterns; (5) a climatic event that takes place during warm, humid, rainy summers and dry, sunny winters. These characterizations are not necessarily mutually exclusive, but none of them is wholly correct or adequate by itself.

The delimitation of a monsoon region varies with each of the explanations above, and the general relevance of the explanations can best be understood by consideration of the principal monsoons and monsoon regions of the world. This article treats the causes, characteristics, and occurrence of monsoons with respect to monsoon regions (see CLIMATE; WINDS AND STORMS; CYCLONES AND ANTICYCLONES; HURRICANES AND TYPHOONS; THUNDERSTORMS; and PRECIPITATION).

THE INDIAN MONSOON

At the Equator, the area near India is unique in that dominant or frequent westerly winds occur at the surface almost constantly throughout the year; the surface easterlies reach only to 20° N in February, and even then they have a very strong northerly component. They soon retreat northward and drastic changes take place in the upper air circulation. This is a time of transition between the end of one monsoon and the beginning of the next. Late in March the high-sun season reaches the Equator and moves further north. With it go atmospheric instability, convectional (rising, turbulent) clouds, and rain. The westerly Subtropical Jet Stream still controls the flow of air across northern India and the surface winds are northeasterlies. As the high-sun season moves northward during April, India becomes particularly prone to rapid heating because the highlands to the north protect it from any incursions of cold air. In May the southwesterly monsoon is well established over Ceylon. There are three distinct regions of relative upper tropospheric (the troposphere is the lowest part of the atmosphere) warmth, namely (1) above the southern Bay of Bengal, (2) above the highlands of Tibet, and (3) across the still dry trunks of the peninsulas. The relatively warm area above the southern Bay of Bengal occurs mostly at the 500–1,000 millibar level (pressure at sea level is about 1,012 millibars, which corresponds to 14.7 pounds per square inch; 500–1,000 millibars occurs at 6,000–16,000 metres or 20,000–50,000 feet). It does not appear at a lower level and is probably caused by the release of condensation heat (associated with the change from water vapour to liquid water) at the top of towering cumulonimbus clouds along the advancing intertropical convergence.

Atmospheric instability and rapid heating

In May the dry surface of Tibet (above 4,000 metres) absorbs and radiates heat that is readily transmitted to the air immediately above. At about 6,000 metres an anticyclonic cell arises causing a strong easterly flow in the upper troposphere above northern India. The Subtropical (westerly) Jet Stream suddenly changes its course to the north of the anticyclonic ridge and the highlands, although occasionally it may reappear to the southward for very brief periods. This change of the upper tropospheric circulation above northern India from westerly jet to easterly flow coincides with a reversal of the vertical temperature and pressure gradients between 600 and 300 millibars. On many occasions the easterly aloft assumes jet force. It anticipates by a few days the "burst", or onset, of the surface southwesterly monsoon some 1,500 kilometres (900 miles) further south, with a definite sequential relationship, although the exact cause is not known. Because of India's inverted triangular shape, the land is heated progressively as the sun moves northward. This accelerated spread of heating, combined with the general direction of heat being transported by winds, results in a greater initial monsoonal activity over the Arabian Sea (at late spring time), where a real frontal situation often occurs, than over the Bay of Bengal. The relative humidity of coastal districts in the Indian region rises above 70 percent and some rain occurs. Above the heated land the air below 1,500 metres (5,000 feet) becomes un-

stable, but it is held down by the overriding easterly flow. This does not prevent frequent thunderstorms in late May.

During June the easterly jet becomes firmly established at 150 to 100 millibars. It reaches its greatest speed at its normal position to the south of the anticyclonic ridge, at about 15° N from China through India.

In Arabia, it decelerates and descends to the middle troposphere (3,000 metres or 10,000 feet). A stratospheric belt of very cold air, analogous to the one normally found above the intertropical convergence near the Equator, occurs above the anticyclonic ridge, across southern Asia at 30°–40° N and above the 6,000 metres (500 millibars) level. These upper air features that arise so far away from the Equator are associated with the surface monsoon and are absent when there is no monsoonal flow. The position of the easterly jet controls the location of monsoonal rains, which occur ahead and to the left of the strongest winds and behind them to the right. The surface flow, however, is a strong, southwesterly, humid, and unstable wind that brings humidities of more than 80 percent and heavy, squally showers that are the "burst" of the monsoon. The overall pattern of the advance follows a frontal alignment, but local episodes may differ considerably. The amount of rain is variable from year to year and place to place. Most spectacular clouds and rain occur against the Western Ghats, where the early monsoonal airstream piles up against the steep slopes, then recedes, and piles up again to a greater height. Each time it pushes thicker clouds upward until wind and clouds roll over the barrier and, after a few brief spells of absorption by the dry inland air, cascade toward the interior. The windward slopes receive from 2,000 to 5,000 millimetres of rain in the monsoon season: various factors, and especially topography, combine to make up a complex regional pattern. Oceanic air flowing toward India below 6,000 metres is deflected in accordance with the Coriolis effect (moving objects are deflected to the right over the earth's northern hemisphere). The converging, moist oncoming stream becomes unstable over the hot land and is subject to convectional turmoil. Towering cumulonimbus clouds rise thousands of metres, producing violent thunderstorms and releasing latent heat in the surrounding air. As a result, the upper tropospheric warm belt migrates northwestward from the ocean to the land. The main body of air above 9,000 metres (30,000 feet) maintains a strong easterly flow.

Precipitation patterns

Later, in June and July, the monsoon is strong and well-established to a height of 6,000 metres (less in the far north), with occasional thickening to 9,000 metres (Figure 1 top). Weather conditions are cloudy, warm, and moist all over India. Rainfall varies between 400 and 500 millimetres, but topography introduces some extraordinary differences. Cherrapunji, on the southern slopes of the Khāsi Hills at only 1,300 metres (4,300 feet), where the moist airstreams are lifted and overturned, has an average rainfall of 2,730 millimetres (110 inches) in July, with record totals of 897 millimetres (35 inches) in 24 hours in July 1915, over 9,000 millimetres (350 inches) in July 1861, and 16,305 millimetres (642 inches) in the monsoon season of 1899. Over the Ganges Valley the monsoon, deflected by the Himalayan barrier, becomes a southeasterly air flow. By then the upper tropospheric belt of warmth from condensation has moved above northern India, with an oblique bias. The lowest pressures prevail at the surface.

It is mainly in July and August that waves of low pressure appear in the body of monsoonal air. Fully developed depressions appear once or twice a month. They travel from east to west, more or less concurrently with high-level easterly waves and bursts of speed in the easterly jet, causing local strengthening of the low-level monsoonal flow. The rainfall consequently increases and is much more evenly distributed than it was in June (Figure 1 bottom). Some of the deeper depressions become tropical cyclones before they reach the land, and these bring torrential rains and disastrous floods. A totally different development arises when the easterly jet moves farther north than usual because the monsoonal wind rising over the southern slopes of the Himalayas brings heavy rains and local floods. The weather over the central and southern districts, however, becomes suddenly drier and remains so for as long as the abnormal shift lasts. The opposite shift is also possible, with midlatitude upper air flowing along the south face of the Himalayas and bringing drought to the northern districts. Such dry spells are known as "breaks" of the monsoon. Those affecting the south are similar to those experienced on the Guinea coast during extreme northward shifts of the wind belts (as later discussed), whereas those affecting the north are due to an interaction of the middle and low latitudes. The southwest monsoon over the lower Indus Plain is only 500 metres (1,600 feet) thick and does not hold enough moisture to bring rain. On the other hand, the upper tropospheric easterlies become stronger and constitute a true easterly jet stream. Western Pakistan, Iran, and Arabia remain dry (probably because of divergence in this jet) and thus become the new source of surface heat.

Associated dry spells

By August the intensity and duration of sunshine have decreased, temperatures begin to fall, and the surge of southwesterly air diminishes spasmodically almost to a standstill in the northwest. Cherrapunji still receives over 2,000 millimetres (80 inches) of rainfall at this time, however. In September dry, cool, northerly air begins to circle the west side of the highlands and spread over northwestern India. The easterly jet weakens and the upper tropospheric easterlies move much farther south. Because the moist southwesterlies at lower levels are much weaker and variable they are soon pushed back. The rainfall becomes extremely variable over most of the region, but showers are still frequent in the southeastern areas and over the Bay of Bengal.

By early October variable winds are very frequent everywhere. At the end of the month the entire Indian region is covered by northerly air and the "winter monsoon" takes shape. The surface flow is deflected by the Coriolis effect and becomes a northeasterly flow. This causes an October–December rainy season for the extreme southeast of the Deccan (including the Madras coast) and eastern Ceylon, which cannot be explained by topography alone because it extends well out over the sea. Tropical depressions and cyclones are important contributing factors.

Most of India thus begins a sunny, dry, and dusty season. The driest period comes in November in the Punjab; December in Central India, Bengal, and Assam; January in the northern Deccan; and February in the southern Deccan. Conversely, the western slopes of the Karakoram and Himalayas are then reached by the midlatitude frontal depressions that come from the Atlantic and the Mediterranean. The winter rains they receive, moderate as they are, place them clearly outside the monsoonal realm.

Because crops and water supplies depend entirely on monsoonal rains, it became imperative that quantitative, long-range weather forecasts be available. For a forecast to be released at the beginning of June, it is necessary to use, in April, South American pressure data and Indian upper wind conditions (positive correlation) and in May, rainfall in Rhodesia and Java and easterly winds above Calcutta (negative correlation).

THE MALAYSIAN-AUSTRALIAN MONSOON

Southeast Asia and northern Australia are combined in one monsoonal system which differs from others because of the peculiar and somewhat symmetrical distribution of land masses on both sides of the Equator. In this respect, the northwest monsoon of Australia is unique. The substantial water masses between Asia and Australia have a moderating effect on tropospheric temperatures, weakening the "summer monsoon." The many islands (Philippines, Indonesia, etc.) provide an infinite variety of topographic effects. Typhoons that develop within the monsoonal air bring additional complications.

Effects of water areas and topography

It would be possible to exclude North China, Korea, and Japan from the monsoonal domain because their seasonal rhythm follows the normal midlatitude pattern—a predominant outflow of cold continental air in winter, and frontal depressions and rain alternating with fine, dry

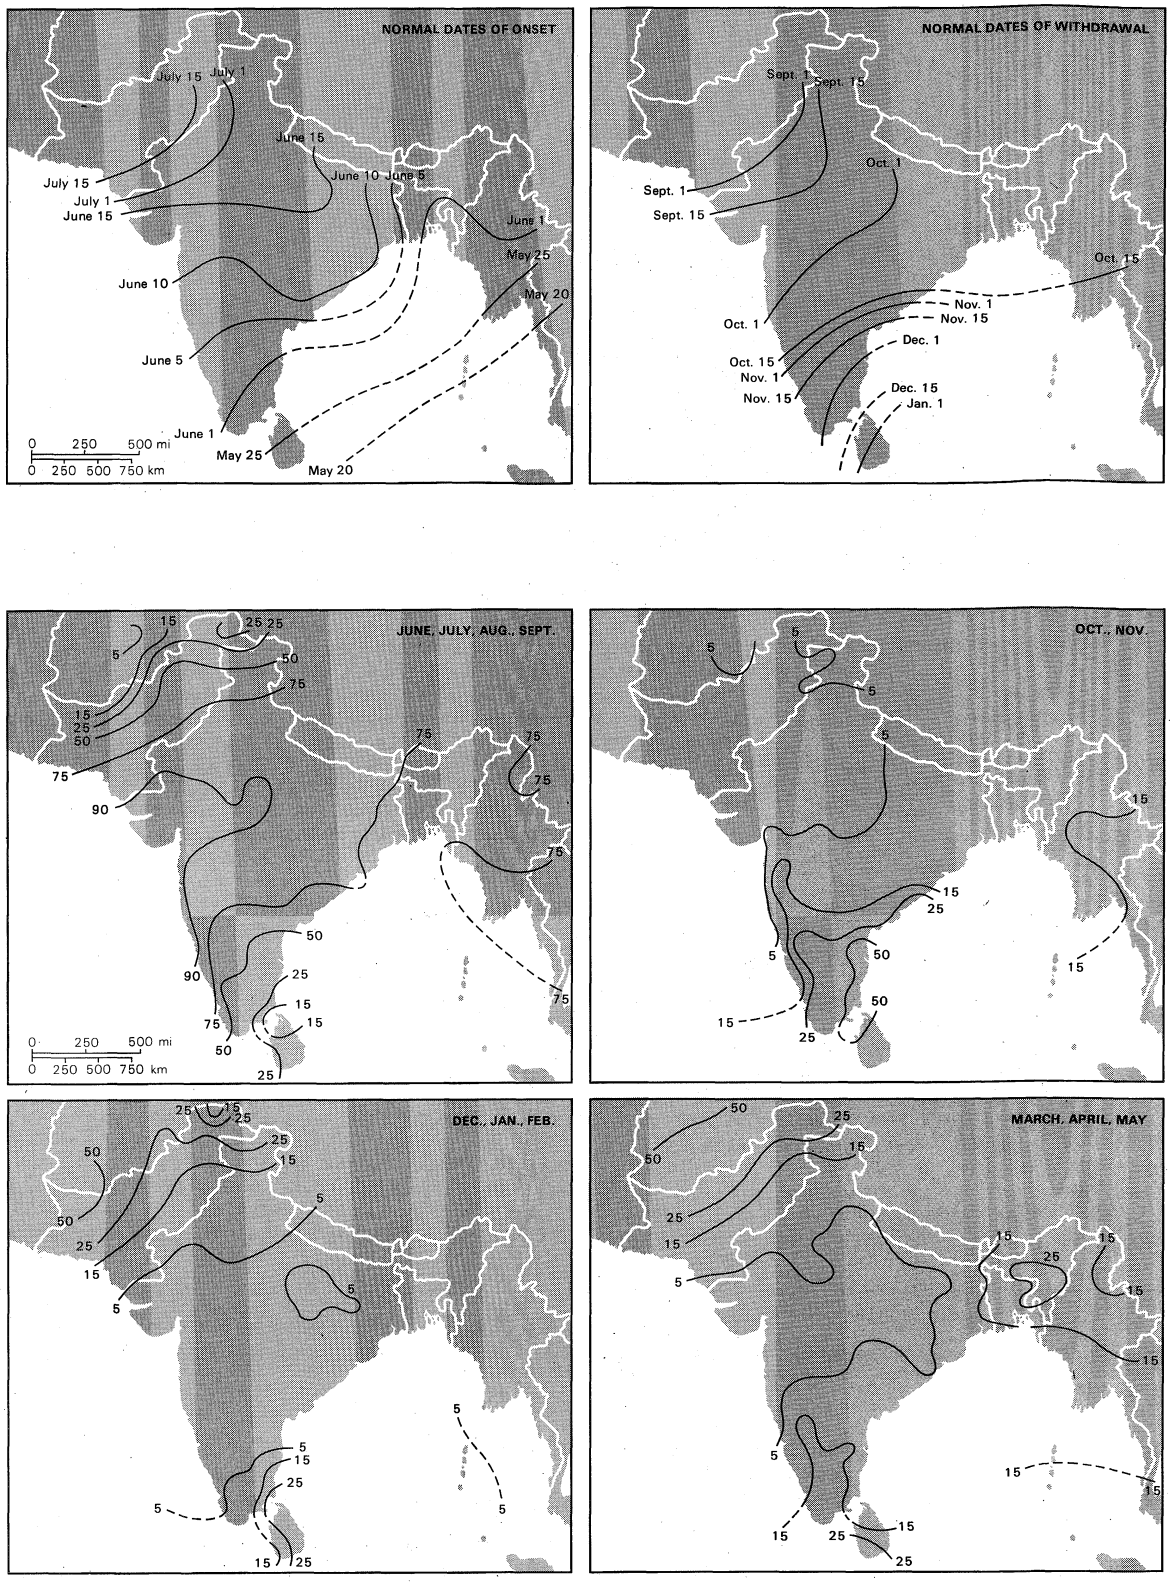

Figure 1: *The monsoonal system in the Indian subcontinent.*

anticyclonic weather in the warm season. On the other hand, the seasonal reversal of wind direction in this area is almost as persistent as that in India. The winter winds are much stronger because of the relative proximity of the Siberian anticyclone. The tropical ridge of high pressure is the natural boundary between these nonmonsoonal areas and the monsoonal lands farther south.

The northern limit of the typical monsoon may be set at about latitude 25° N. Farther north, the summer monsoon is not strong enough to overcome the effect of the travelling anticyclones normally typical of the subtropics. As a result, monsoonal rains occur in June and also in late August and September, separated by a mild anticyclonic drought in July. In South China and the Philippines the trade winds (tropical easterlies) prevail in the October–April (winter) period, strengthened by the re-

From L. Welter and P. Suraud, *Monographie No. 8 de la Meteorologie Nationale* (November 1957)

gional, often gusty, outflow of air from the stationary Siberian anticyclone. Their disappearance and replacement by opposite (southwesterly) winds in the May–September (summer) period is the essence of the monsoon. In any case, these monsoonal streams are quite shallow, about 1,500 metres (5,000 feet) in winter and 2,000 metres (6,500 feet) in summer. They bring rain only when subject to considerable cooling, as happens to the windward anywhere on the steep slopes of the Philippines and Taiwan. On the larger islands there are contrasting effects, the slopes facing west getting most of the rain from May to October and a drought from December to April, whereas the slopes facing east receive orographic rains (those produced when moist air is forced to rise by topography) from September to April and mainly convectional rains from May to October.

In Vietnam and Thailand the summer monsoon is more strongly developed because of the wider expanses of overheated land. The southwesterly stream flows from May to October, reaching a thickness of 4–5 kilometres (2–3 miles); it brings a plentiful but not extraordinary rainfall. November to February is the cool, dry season, and March to April the hot, dry one when the highest temperatures prevail; in the far south the coolness is only relative. Along the east coast and on the eastward slopes more rain is brought by the winter monsoon. In the summer, somewhere between Thailand and Cambodia in the interior, there may be a faint line of convergence between the southwesterly Indian-Burmese monsoon and the southeasterly Malaysian monsoon.

Vietnam, Thailand, and Indonesia

Over Indonesia, because of the water expanses and the low latitude, monsoonal winds are very weak, but their seasonal reversal is very definite. From April to October the Australian southeasterly air flows, whereas north of the Equator it becomes a southwesterly. It generally maintains its dryness over the islands closer to Australia, but farther north it carries increasing amounts of moisture. The northeasterly flow from Asia, which becomes

northwesterly south of the Equator, is already laden with moisture when it reaches Indonesia, bringing cloudy and rainy weather between November and May. The wettest months are December in most of Sumatra and January elsewhere, but rainfall patterns are highly localized. In Java, for instance, at sea level alone there are two major climatic regions, an "equatorial" west with no dry season and a "monsoonal" east with extreme drought in August and September.

Because of its relatively small size and compact shape, Australia shows relatively simple monsoonal patterns. The north shore is subject to a clear-cut wind reversal between summer (November–April, northwesterly) and winter (May–September, southeasterly), but with two definite limitations: first, the northwesterly, rain-bearing monsoonal wind is often held offshore and is most likely to override the land to any depth during January and February; and secondly, even in summer there often are prolonged spells of southeasterly trade winds issuing from travelling anticyclones, separating the brief monsoonal incursions. The Australian summer monsoon is thus typical in direction and weather type but quite imperfect in frequency and persistence. Its thickness is usually less than 1,500 metres (5,000 feet) over the sea and 2,000–2,500 metres (6,500–8,000 feet) over the land.

Much less typical are the marginal monsoonal manifestations. On the northwest coast there frequently is a northwesterly air flow in the summer (December–March), as opposed to the winter southeasterlies, but this stream is very shallow and does not bring any rain; *i.e.*, its weather is not monsoonal although its direction is so. On the northeast coast the onshore air is humid and brings rain, but its direction is only partly modified in summer. It comes in mostly as a northeasterly, while at other times it is mostly southeasterly.

THE WEST AFRICAN MONSOON

The main characteristics of the West African seasons were known over two centuries ago. The southwest winter monsoon flows as a shallow (less than 2,000 metres) humid layer of surface air, overlain by the primary northeast trade wind, which blows from the Sahara and the Sahel as a deep stream of dry, often dusty air. As a surface northeasterly it is generally known as the harmattan, gusty, dry, and thirsty in the extreme—cool at night and scorchingly hot by day. As in a thorough monsoonal development, upper tropospheric anticyclones occur at about 20° N, while the easterly jet stream may occur at about 10° N, much closer to the Equator than they are in the Indian region.

Alternation with the harmattan

The West African monsoon is the alternation of the southwesterly wind and the harmattan at the surface. As seen in Figure 2, such alternation is normally found between latitudes 9° and 20° N. There are northeasterlies farther north all the time, but only southwesterlies farther south. The whole year is more or less dry at 20° N except for erratic rains in the high-sun season. The drought becomes shorter and less complete farther south. At 12° N it lasts about half the year, and at 8° N disappears completely. Farther south a different, lighter drought begins to appear in the high-sun months when the monsoonal southwesterly is strongest. It is due to the arrival of dry surface air issuing from anticyclones formed beyond the Equator, in the Southern Hemisphere, and is thus similar to the monsoonal drought in Java. Like the "break" of the monsoon in southern India, however, it occurs beyond the Equator.

The moist southwesterly stream, particularly frequent between 5° and 10° N, can reach much further north, bringing warm, humid nights and moderately hot but still humid days. The harmattan brings cooler nights, but the extreme daily heating causes a thermal range of 10° to 12° C (18° to 22° F). Even in the daytime, the harmattan may give a sensation of coolness to the human skin as it evaporates moisture from it. The alternation of the two winds is seasonal on the basis of overall frequency, but in fact it varies considerably with the synoptic pressure patterns. The harmattan comes in spells that mostly last from a few days to over a week.

The advancing fringe of the southwest monsoon is too shallow (under 1,000 metres or 3,000 feet) for many thunderstorms and disturbances. They usually occur 200–300 kilometres (125–200 miles) in arrears, where the moist air is deeper (1,000–2,000 metres), but the ground is still hot enough to make it very unstable. The tops of the cumulonimbus may reach 12,000 metres (40,000 feet), well above freezing level (4,200–4,500 metres or 14,000–15,000 feet). The disturbances are usually along a given longitude line that is slightly curved and may in fact form one long line squall. They also reach 12,000 metres or more, travelling steadily westward at 20 to 30 knots (25 to 35 miles per hour). This suggests that they originate in the primary trade wind aloft and as in India are probably related to the tropical easterly jet stream. The southwest monsoon dominates the weather, and clouds and rain abound; the rain is mostly due to coalescence of droplets, the clouds being mostly below 3,500 metres (11,500 feet). The humidity is very high and the daily range of temperature remains around 4° C (7° F).

Seasonal changes

If it were not for the change in wind direction when the southeast trades have crossed the Equator, the monsoon system of West Africa could not be distinguished from the weather system, caused by the seasonal shift in the latitude of the intertropical convergence, as experienced over most of Central Africa. There is a rainy season (in this case, the monsoon season), which on the west coast lasts two to three months at latitude 16° N, three to four months at 14° N, six to seven months at 10° N, eight months at 8° N.

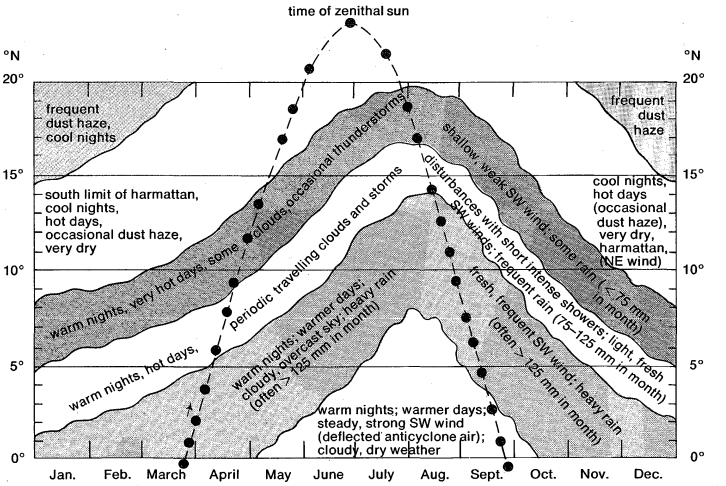

Figure 3: Distribution of climatic characteristics associated with monsoons in West Africa.

On the south coast, which is at latitude 4° N to 6° N, the southwest monsoon (as the intertropical convergence) may occur at any time, but the results are quite atypical for various reasons. In the low-sun season (December–February) the southwesterly is rare and ineffective, and the weather is cloudy but dry. From April to June the midday sun is at its highest and insolation (radiation received at the earth's surface) is most intense. Because the southwest wind is most frequent, the consequent building up of clouds leads to the main rainy season. In July and August (the short drought) cloudy conditions prevail, but the air issues direct from anticyclones further south and is dry, although its direction of flow does not change. Although cloudiness decreases after the second high-sun season in September and October, there is a period of occasional rains just sufficient to constitute a secondary maximum.

Toward the north, conditions are more distinctly monsoonal: by latitude 8° N the two wet seasons have merged into one long "wet" with two subdued peaks, which last approximately 7 to 8 months (March–October). The "dry," which is controlled by northeast winds, lasts from November to early March. There is one rainfall maximum (in August or September) only a short distance farther north although the wet season is only a few weeks shorter.

MONSOONAL TENDENCIES IN EUROPE AND NORTH AMERICA

There are monsoonal tendencies in central Europe, where the average wind direction in summer differs some 30° to 40° from that of the Atlantic, not as a continuous flow but intermittently within frontal depressions, bringing cool, cloudy weather, rain, and thunderstorms. Some see in this climatic pattern a true monsoon, but it is obvious that it is only an "embryo monsoon" that results in weather singularities. The latitude is too high for a true monsoon to arise.

In North America the relatively low latitude and the orientation of the land–sea boundary on the Gulf of Mexico are quite favourable to monsoonal developments. During the summer, low atmospheric pressure is frequent over the heated land; the northeasterly trade winds are consequently deflected to become easterly, southeasterly, or even southerly winds. Texas and the Gulf country generally may be completely overrun by a shallow sheet of oceanic air, which may continue for a long distance inland. The rainfall regime does not reveal any marked monsoonal pattern. There are mostly two, three, or even four minor peaks in the sequence of monthly rainfall totals. In the winter there often occur northers, which are offshore winds caused by the general anticyclonic flow of air from the cold land. Neither the summer onshore wind nor the winter offshore wind is persistent enough to constitute a monsoonal sequence, although monsoonal tendencies are quite evident.

Central American cycle

In Central America a true monsoonal cycle occurs over a small area facing the Pacific, between 5° and 12° N. Not only is there a complete seasonal reversal of the wind, but the rainfall regime is typically monsoonal. The winter period (November to January and March to April according to latitude and other factors) is very dry. The rainy season begins earlier (May) in the south and progressively later farther north, coming at the end of June in southern Mexico. It finishes at the end of September in the north and as late as early November in the south. The result is a rainy season that lasts three months in southern Mexico increasing in duration with decreasing latitude, to last six to seven months in Costa Rica. Latitude for latitude, this is a subdued replica of the monsoon of India.

BIBLIOGRAPHY. INDIA METEOROLOGICAL DEPARTMENT, *Symposium on Monsoons of the World, Delhi, 1958* (1960), is a comprehensive volume containing papers on the surface and upper air climatology of the monsoons, their dynamics, variability, rain and cloud systems, their place in the general circulation of the atmosphere, depressions and other disturbances in the monsoons, and on monsoon forecasting. WORLD METEOROLOGICAL ORGANIZATION WITH THE INTERNATIONAL UNION OF GEODESY AND GEOPHYSICS, *Proceedings of the Symposium on Tropical Meteorology, Rotorua, N.Z., 1963* (1964), ed. by J.W. HUTCHINGS, also contains several important papers on this subject, with special regard to India. Two fundamental papers on monsoons in China may be found in the ACADEMIA SINICA, *Collected Scientific Papers—Meteorology 1919–1949* (1954). P. PEDELABORDE, *Les Moussons* (1958; Eng. trans., *The Monsoons*, 1963), is a series of lectures that presents a clear exposition of earlier views. Most recent and comprehensive is C.S. RAMAGE, *Monsoon Meteorology* (1970).

(J.G.)

Montaigne, Michel de

Michel de Montaigne was a skeptical student of himself and of mankind, who stood for tolerance during the fanatical French religious civil wars of the later 16th century and spoke out for a man-centred morality. To express his views, but perhaps more to determine what they were for himself, he created the essay, which was a new literary form. He called the *Essais* (*Essays*), for which he is known, "a book consubstantial with its author, concerned with my own self, an integral part of my life."

Early career and works. Michel Eyquem was born in the Château de Montaigne, 30 miles east of Bordeaux, on February 28, 1533. His father, Pierre Eyquem, once mayor of Bordeaux, was a prosperous merchant whose grandfather had purchased the seigneury (a feudal territory) of Montaigne with its title of nobility; his mother was descended on her father's side from a family of Spanish-Jewish origin that had recently been converted to Catholicism. The oldest of eight surviving children, Montaigne had a brother and sister who became Protestants.

Montaigne, portrait by an unknown French artist, 16th century. In the Musée Condé, Chantilly, France.
Giraudon

He was brought up gently and was taught to speak only Latin until he was six years of age, when he began to learn French. After seven disappointing years at the Collège de Guyenne in Bordeaux, he may have studied law at Toulouse. From 1554 to 1557 he may have served in the Cour des Aides, a new tax court in Périgueux.

The court was abolished in 1557, and its members were incorporated into the Parlement of Bordeaux, one of eight regional bodies that composed the Parlement of France, the king's highest court of justice. Montaigne remained for 13 years in one of its lower chambers, working conscientiously but without enthusiasm. He was barred from rising higher because he had close relatives in the upper chambers.

Friendship with La Boétie

The one joy of these years was his friendship with another counsellor, Étienne de La Boétie, a bond that proved to be the strongest of his life. A man of letters slightly older than Montaigne, married, a linguist, poet, and respected magistrate, La Boétie was sure of his stoical Catholic views and goals, whereas Montaigne was still a talent in search of a function. Both men pronounced the friendship unique and mysterious; it fulfilled Montaigne's deepest need for complete communication. Indeed, had La Boétie lived, Montaigne might not have written his *Essays*. The friendship continued for four (or perhaps six) years, when La Boétie contracted dysentery and died; Montaigne never ceased to mourn him.

After seeking distraction for two years in various amours, in 1565 Montaigne married Françoise de La Chassaigne, whose Catholic family was prominent in the Parlement. Although fond of women, he accepted marriage unenthusiastically as a social duty. Françoise bore him six girls; all died in infancy except one, Léonor. Otherwise his marriage was not a close bond.

Translator of Raymond Sebond

Montaigne's first publication appeared in 1569: his translation into French, at his father's request, of the 1,000-page "Book of Creatures, or Natural Theology," in Latin, by the 15th-century Spaniard Raymond Sebond (Ramón Sabunde). It sought to demonstrate God's existence and nature and man's duty toward him by analogies between the human and divine drawn from the levels of the creation. Its prologue, full of extravagant claims, was put on the Roman Catholic Church's Index of Forbidden Books. Montaigne's version was never condemned. He made an excellent translation, reshaping Sebond's pedestrian prose and sharply cutting his claims in the prologue.

In June 1568, his father died, leaving Michel the lord of Montaigne. Two years later he sold his Parlement position (in the manner of the time), published most of La Boétie's works with his own dedicatory letters, and retired to his estate, intending to collect his ideas and write.

The "Essays": Books I and II. He spent the next nine years (1571–80) working chiefly on the first two books of *Essays*, but his retirement was not complete, for he continued to make frequent trips to court in Paris, and, in 1574, the Governor of Bordeaux sent him to confer with the army commander in the southwest over a disputed command in one of the religious wars of the time. In 1571 he received the Order of Saint Michael; by 1573 he was a gentleman of the chamber to the Catholic king Henry III and, in 1577, to King Henry of Navarre, who was the future King Henry IV of France and leader of the Protestants. Montaigne, a staunch but moderate Catholic loyalist, may have owed this last distinction to an unsuccessful attempt at mediation, made some time between 1572 and 1576, between Navarre and Duc Henri de Guise, who was to become the leader of the ultra-Catholic Holy League and who would violently oppose succession of the crown to a Protestant.

Content and themes of the *Essays*

The first two books of the *Essays* include 94 chapters; the earliest are short, relatively impersonal, and are strings of anecdotes with brief conclusions. The most interesting among them reveal the problems preoccupying Montaigne at that time: inconsistency, ambition, and, above all, pain and death. We must prepare for death, he writes, as "the goal of our career . . . the necessary object of our aim," and "learn to meet it steadfastly and to combat it." Similarly with pain: "We must resist it and tense ourselves against it." Still influenced by La Boétie, Montaigne now sees life as beset by ills, and he resolves to summon up reason and will to resist them.

The *Essays* of 1574–75 show a growing wariness of stoical solutions to life's problems. In "Of Practice," Montaigne draws on an experience—a dangerous collision on horseback—to help him come to terms with death, and he recognizes that premeditation may only magnify the problem. In the essay "Of Drunkenness," he finds extreme stoical heroism against pain incompatible with consistency and wisdom. He begins "A Custom of the Island of Cea" by rehearsing ancient arguments in favour of suicide but then turns about and attacks it as un-Christian, cowardly, and unnatural.

These chapters lead to Montaigne's attack on Stoicism, and indeed all dogmatism, in his longest chapter by far, the skeptical "Apology for Raymond Sebond," in which he draws on the skepticism of the Greek philosopher Pyrrhon of Elis. He admits the fallibility of the human mind to know anything with certainty and takes as his motto "What do I know?" The "Apology" may be divided into six unequal parts, of which the last five are a counterattack against Sebond's dogmatic critics. In the first part he discusses Sebond, his book, and the two main criticisms of it: that in religion reason cannot supplant faith and that Sebond's reasons for faith are easily overthrown. Second, he shows that animals are the virtual equals of man; third, he demonstrates by man's ignorance of God and of himself that man has no knowledge; fourth, he very briefly warns an unnamed princess, for whom the chapter is written, that what follows—abandoning one's own weapon (reason) to make one's adversary lose his—is indeed a last resort; fifth, he argues that man cannot have knowledge because he is a creature of flux and therefore can know neither flux nor being; and finally, he concludes that not Stoicism but God alone can raise men above humanity.

Content of the "Apology"

The "Apology for Raymond Sebond" is puzzling because it belies its title. It is the most apologetic of apologies; less than one-tenth of the work deals with Sebond at all, and his arguments are often refuted. Some have considered it a perfidious attack on Christianity; others have thought that Montaigne forgot Sebond even while defending him. A likelier view is that Montaigne wrote most of it by 1576 as a treatise on presumption and the vanity of reason and with little if any thought of Sebond. The princess addressed in the warning, recognizable as Marguerite de Valois, was in Gascony in 1578, among Protestants eager to convert her. Knowing Montaigne and having enjoyed Sebond, presumably in his translation, she apparently asked Montaigne to defend him; and Montaigne, never a real admirer of Sebond, probably reluctantly decided to enlarge his earlier piece into the "Apology."

Montaigne's attack on human knowledge leaves knowledge of self unscathed. The "Apology" repeatedly asks: "If we cannot know ourselves, what can we know?" When Montaigne, apropos of recognition of our limitations, wrote, "At least we must become wise at our own expense," he implied that self-knowledge is a possibility, the beginning of wisdom as well as of knowledge. It is in this way that the skepticism of the "Apology" leads him from dogmatic philosophy to the study of himself.

Self-study leads him directly and comfortably to self-portrayal: in style as well as content, the portrait must be faithful, changing as the subject changes. The essays for Montaigne were trials, probings, samplings of the self he is examining and even the power of judgment with which he examines it.

Mood of the later essays

The *Essays* of 1578–80 are optimistic, as Montaigne turned his attention from human limitations to human resources. Intellectually he had freed himself from tutelage in the "Apology"; the test of experience remained. This came in the summer of 1578 with the agonizing pain caused by the kidney stone. His father had suffered from the same illness, and Montaigne had long dreaded such an attack. Eighteen months later, assessing the results, he found that his fear had been worse than the pain and felt he had taken the measure of pain. Whereas he had formerly seen virtue only in struggle, his model now became the effortless virtue of Socrates.

Earlier Montaigne had written a largely negative critique of education. Now, in "Of the Education of Children," he showed what good training could do: not fill the memory but fashion the judgment and thus form a morally independent man who loves virtue and hates vice, not from fear but for themselves.

Travel. After the first two books of *Essays* were published (Bordeaux, 1580), Montaigne went north, presented a copy to Henry III, served in his army at the siege of La Fère, in Normandy, and set out with a brother, two friends, and servants on a 15-month trip (September 1580–November 1581) through France, Germany, Switzerland, and Austria to Italy. His main reasons were his health, heartsickness over the state of France, weariness of domesticity, eagerness to see Rome, and sheer love of travel.

He left a 300-page record of his trip, his *Travel Journal*, not intended for publication and published only in 1774. No masterpiece, it further reveals aspects of Montaigne's self-portrait: his consuming interest in all religions, delight in mechanical gadgetry, and outgoingness.

Mayor of Bordeaux. In September 1581, while at La Villa, in Italy, Montaigne learned he had been elected mayor of Bordeaux. Feeling ill and unfit, he returned to France expecting to decline; but Henry III politely ordered him to accept. His first term (1581–83) was uneventful; the second was not so. The city was loyal to the Catholic king, but intransigent Holy Leaguers held important posts within; Protestant forces were nearby, and a collision between them was always imminent. Montaigne stresses his detachment from his office, but his letters reveal his vigilant efficiency. He was outside the city, as he often had to be, when his term ended in July 1585, and did not return to transfer authority to his successor.

One peaceful year at home followed. Then in July 1586, a large League army besieged Castillon, five miles away. Montaigne was suspect to extremists on both sides. Plague broke out again and spread to Montaigne's estate, driving him and his family to seek asylum for six months before returning home to his *Essays*.

Role as mediator in war of the three Henrys

During this time he attended the conferences at Saint-Brice near Cognac, where Catherine de Medicis summoned him to try—in vain—to persuade Henry of Navarre to abjure his Protestantism and return to court. In October 1587, three days after Navarre's important victory over a royalist army at Coutras, Navarre paid his second overnight visit to Montaigne, who probably helped to persuade him not to expand his victory into rebellion. Three months later (February 1588) Montaigne went to Paris on a secret mission from Navarre to Henry III,

seeking to bring them closer together against the menacing League. Again suspect to both extreme factions, Montaigne was seized on his way and briefly detained by Protestants, and that summer he was imprisoned—again briefly—by Leaguers in the Bastille.

The "Essays": Book III. While in Paris in 1588, Montaigne supervised the publication of the fifth edition of the *Essays*, the first edition to contain the 13 substantial chapters of Book III. His sense of human solidarity had been fostered by the favourable reception of the first *Essays*, by his friendly relations with people of other nations, by being twice chosen to govern Bordeaux, and by his warm feeling for his peasant neighbours who had behaved heroically during the plague.

Almost from the start of Book III, Montaigne proclaims his new sense of unity—in the race and in the individual: "Each man bears the entire form of man's estate. . . . There is no one who, if he listens to himself, does not discover in himself a pattern all his own, a ruling pattern . . . " Now his self-portrait becomes also a portrait of man.

His heightened confidence leads to greater candour and greater concern with public behaviour. He studies himself more than any other subject, for, in so doing, one can learn best to control his conduct. Moreover, self-study is a school of human nature. He adds but does not correct; as an author he felt he must not suppress anything he has written. His ideas follow one another, but sometimes from afar; he loves the free, gambolling, poetic gait. His chapter titles are often allusive, not descriptive; he rejects artificial signposts and an inattentive reader. He is always ultimately a moralist, seeking to understand in order to judge. The highest human wisdom and happiness, he finds, would be to know our exact duty to others and to ourselves. Against the glamour of public action he upholds private life as more demanding, for in it man needs virtue, not its semblance. Private life seeks man's most important knowledge: how to live in conformity with his natural condition. Through self-examination and self-control, it leads to moral independence. Because others cannot know us as we ourselves can, we must learn to be our own judges: "I have my own laws and my court to judge me, and I address myself to them more than anywhere else."

Montaigne's portrait of man

Man, Montaigne now believes, would be happier and better if he accepted himself for what he is. It is a dangerous temptation to try to be more than human. Self-acceptance is no enemy of self-improvement but, indeed, a condition of it. He rarely repents, and he questions the validity of any overall repentance not sent by God. Self-portrayal commits him to practice what he preaches; his rule is to dare to say all that he dares to do. His aim is truth and harmony. Having learned from his illness to accept pain as interdependent with pleasure and to harmonize them, Montaigne rejoices in the legitimate joys of living: "I love life and cultivate it just as God has been pleased to grant it to us." The last pages of the *Essays* are a hymn of gratitude for life.

Last years. Relatively little is known about his last four years. Early in 1588 he met his "covenant daughter," an enthusiastic admirer who became his literary executrix, Marie de Gournay. He followed the King when he fled the revolt (instigated by Henri de Guise) from Paris to Chartres and Rouen. He attended the Estates-General in Blois, where Henry III had Henri de Guise killed. Around the end of 1588, Montaigne returned south and assisted in keeping Bordeaux loyal first to Henry III and then, after his assassination (1589), to Henry IV. Two letters of 1590 to his new king reveal the acknowledgment of an invitation to join the King and a regret that he could not do so because of illness, though he would have been a firm, frank counsellor. He continued to work on his *Essays*. The best account of his death reports that a quinsy left him speechless for his last few days. On September 13, 1592, at the age of 59, he died peacefully hearing mass in his room.

Montaigne had written no new books or chapters of his *Essays* since 1588 but had added about a thousand passages that reveal a further sharpening of his views and greater boldness in five main areas: self-revelation, obscenity, his plan to portray himself, the state of religion in France, and his independent morality. He has learned how self-portrayal forms a man, delineating his inner self more sharply. He writes indignantly against the cruelty and hypocrisy of the civil wars and blames the Catholics as well, though not as much, as the Protestants. In his boldest plea for moral autonomy, he criticizes any virtue that is not all our own, even that motivated by religion and law, as a slave morality.

Some of his earlier views are modified, and this growth of the essays by accretion is one of their most appealing features. His rejection of stoical rigour is sharper. The arbitrariness of the soul, its freedom to shape and colour the reports of the senses, was a proof of our ignorance in the "Apology"; now it proves our capacity for happiness: "Our good and our ill depend on ourselves alone."

Montaigne's view of death changes completely. Whereas he had once called it the goal of man's career, he now pronounces it the end—but not the goal—of life. No longer is pain always to be avoided: to eliminate it would eliminate pleasure "and in fine would annihilate man."

Assessment. In the four centuries since he wrote, views of Montaigne have changed much as he did himself. His contemporaries deplored his self-portrait and admired his stoical sententiae. The 17th century saw mainly the skeptic and *honnête homme*, a gentleman adhering to the rules of good manners. Jean-Jacques Rousseau and later Romantics were drawn to his self-portrait and his free, pre-Neoclassical style. Sainte-Beuve in the 19th century was struck by his natural, independent morality; this and the universality of his self-portrait have impressed the last century of readers.

Translated into English in 1603, Montaigne was promptly adopted by Anglo-Saxon admirers, including Francis Bacon, John Marston, John Webster, William Shakespeare, Sir Richard Burton, Lord Byron, William Makepeace Thackeray, Ralph Waldo Emerson, Robert Louis Stevenson, Aldous Huxley, and Virginia Woolf.

Influence on Anglo-Saxon writers

In the 20th century, he is fully recognized in all his aspects as a great writer, and his public is worldwide. Most of his readers see him as friend, mentor, and master of the essay, of the "art of being truthful," and of the art of living.

MAJOR WORKS

EDITIONS: *Essais de messire Michel Seigneur de Montaigne*, 2 vol. (1580); *Édition seconde, reveue et augmentée*, 2nd ed. (1582); *Cinquiesme édition, augmentée d'un troisième livre et de six cens additions aux deux premiers*, 5th ed., 3 vol. (1588); *Les Essais de Michel seigneur de Montaigne, édition nouvelle, trouvée après le déceds de l'autheur, reveüe & augmentée par luy d'un tiers plus qu'aux précédentes impressions*, ed. with a preface by Mlle de Jars de Gournay, 3 vol. (1595); *Les Essais de Michel de Montaigne, publiés d'après l'exemplaire de Bordeaux, avec les variantes manuscrites & les leçons des plus anciennes impressions, des notes, des notices et un lexique*, ed. by F. Strowski, F. Gébelin, and P. Villey, 5 vol. (1906–33). (TRANSLATIONS): *The Essays or Morall, Politike and Millitarie Discourses of Lo: Michaell de Montaigne . . . Now done into English by . . . John Florio* (1603); *The Essays of Michel de Montaigne*, trans. and ed. by J. Zeitlin, 3 vol. (1934–36); *Essays*, trans. with an introduction by J.M. Cohen, "Penguin Classics" (1958).

OTHER WORKS: *Journal du voyage* (1774). See also *Oeuvres complètes*, ed. by A. Armaingaud, 12 vol. (1924–41) and *The Complete Works of Montaigne*, trans. by D.M. Frame (1957).

Biographies: DONALD M. FRAME, *Montaigne* (1965); PAUL BONNEFON, *Montaigne, l'homme et l'oeuvre* (1893), an excellent study but now somewhat outdated; ROGER TRINQUET, *La Jeunesse de Montaigne* (1972).

Critical works: HUGO FRIEDRICH, *Montaigne*, 2nd rev. ed. (1967), with emphasis on his intellectual background (in German); HERBERT LUTHY, "Montaigne, or the Art of Being Truthful," *Encounter*, 1:33–44 (1953, reprinted in QUENTIN ANDERSON and JOSEPH A. MAZZEO (eds.), *The Proper Study*, pp. 319–336, 1962); PIERRE VILLEY, *Les Sources et l'évolution des Essais de Montaigne*, 2nd ed. rev. and enl., 2 vol. (1933), establishes the chronology of the *Essays*.

(D.M.F.)

Montana

Although its name is derived from the Spanish *montaña* ("mountainous region"), Montana has an average elevation of only 3,400 feet, the lowest among the Rocky Mountain states. The mountains sweep down from the Canadian province of British Columbia into the western third of the state, into Idaho on Montana's western and southwestern border, and southward into Wyoming. The eastern two-thirds of the state, however, is a gently rolling landscape with far horizons and a big sky, with millions of grazing cattle and sheep, and with only scattered evidences of human habitation. It forms a part of the northern Great Plains, shared with the provinces of Alberta and Saskatchewan to the north, North and South Dakota to the east, and northeastern Wyoming.

Only three states—Alaska, Texas, and California—have an area larger than Montana's 147,138 square miles (381,086 square kilometres), which is, in fact, larger than that of Japan; and only three—Alaska, Wyoming, and Nevada—have a lower population density than Montana's 4.8 persons per square mile. The 694,409 inhabitants counted in the census of 1970 are relatively far from the markets for their cattle, grain, lumber, metals, and petroleum, as well as from the nation's manufacturing and supply centres. Nature is omnipresent, and the state is strongly oriented toward the out-of-doors, toward summer and winter sports, toward hunting and fishing, and toward the long-distance trip for socializing and entertainment or as a cure for the imaginary but chronic prairie- or mountain-born restlessness, cabin fever.

In spite of its northern location, the Montana of the 1970s is very much a Western state, with high-heeled cowboy boots more fashionable than shoes and cattle rustling not merely a memory from the past. The main street of the capital, Helena, is Last Chance Gulch, the city's original name and a reminder of the prospectors who invaded the hills in the 1860s to pan for gold. By 1889, when Montana became the 41st state of the Union, the cattle drive was an institution, and the state had begun to emerge as the copper-mining capital of the nation. (For information on related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; NORTH AMERICA; GREAT PLAINS; and ROCKY MOUNTAINS.)

THE HISTORY OF MONTANA

Settlement. The first white men known to have set foot in Montana were the members of the Lewis and Clark Expedition in 1805–06, though French fur traders were in the area as early as the 1740s. Other trappers and traders followed, setting up forts to trade with the Indians. The only early trading post to become a permanent town was Fort Benton, which was established in 1846 and became an important port on the Missouri River and head of navigation for steamboats from St. Louis. Jesuit missionaries followed the fur traders. Father Pierre-Jean De-Smet, a Belgian, established St. Mary's Mission near present Stevensville in 1841, and Father Anthony Ravalli, an Italian, joined him in 1845.

Gold miners and vigilantes

Miners and adventurers flocked in after rich placer gold deposits were discovered at Bannack in 1862 and Alder Gulch in 1863. A secretly organized gang of holdup men and murderers, known as road agents and led by Sheriff Henry Plummer, was identified late in 1863. The hastily formed Committee of Vigilance destroyed the gang by hanging more than two dozen road agents in a few weeks in 1864. Montana Territory, formerly part of Idaho Territory, was established in that year, with Bannack its first capital and Virginia City, on Alder Gulch, its second. Farmers settled in the Bitterroot, Deer Lodge, and Gallatin valleys to raise grain and vegetables.

Large-scale cattle and sheep raising began with the first big herd of cattle being driven overland from Texas in 1866. The vast grasslands of central Montana were ideal for cattle, but in the severe winter of 1886–87, some owners lost 90 percent of their herds to freezing and starvation. Since that time, stock growers have raised hay for winterfeed.

As pressure from settlers increased, the native Indians fought to protect the hunting grounds that provided the necessities of life for their people. Sioux and Cheyenne won their last major victory in June 1876, at the Battle of the Little Bighorn, also known as the Custer Massacre. A band of Nez Percé under Chief Joseph won a battle in the Big Hole Basin the following year and fled toward Canada, only to be met and defeated by United States troops a few miles south of the "Medicine Line," the international boundary. Montana entered the Union in 1889, with Joseph K. Toole as the first governor.

Growth of the state. As gold mining declined in importance, world demand for copper increased, and the immense ore deposits at Butte, known as "the richest hill on earth," attracted outside capital. From 1895 to 1905 the so-called copper kings—William A. Clark, Marcus Daly, and Frederick Augustus Heinze—fought for control of the mines and of the state government, which became notoriously corrupt.

Economic booms and busts

After 1909, homesteaders poured into the plains country to claim farms of 320 acres. During the "county-busting era," from 1910 to 1925, the number of counties doubled from 28 to the present 56, most of the new ones lying in the grain-growing part of the state in the east and north. The expected population growth did not materialize, however, for, after a few years of bumper wheat crops and high prices, a cycle of drought years brought financial disaster. Hundreds of mortgages were foreclosed and more than 200 banks closed permanently between 1920 and 1926. Thousands of settlers sought livelihoods elsewhere; since then, farming methods suitable for the semi-arid prairie land have been developed.

Thus, Montana was already depressed when the nationwide depression began in 1929. Droughts continued, many mines closed, and markets for forest products were few. The federal government undertook several big irrigation and soil-conservation projects. Fort Peck Dam, a multipurpose project on the Missouri River, was completed in 1940. During World War II both mining and agriculture returned to their boom levels of past years.

Petroleum production, which had begun in a small way in 1915, was expanded in 1951 with major discoveries in the Williston Basin in the northeast. A very rich field at Bell Creek near Broadus was opened in 1967. In that year the state's longest and costliest strike took place against the Anaconda (Mining) Company, the state's largest private employer, lasting 250 days and costing about $34,000,000 in wages.

THE NATURAL AND HUMAN LANDSCAPE

The heavily forested western third of Montana includes the tumbled, rugged Rocky Mountains and the Continental Divide, contrasting with the generally treeless, gently rolling eastern portion, which is broken by buttes, tree-bordered streams, and small, isolated mountain ranges.

Rivers and lakes. The state is unusual in that its waters contribute to three major drainage systems. On the west side of the divide, streams flow into the Clark Fork and Kootenai rivers and then, through the Columbia River, into the Pacific Ocean. East of the divide, the Madison, Jefferson, and Gallatin rivers meet at Three Forks to form the mighty Missouri, which, with its major tributary, the Yellowstone, finally joins the Mississippi. From parts of Glacier National Park, in the northwest, streams drain northward into Hudson Bay by way of the Belly and St. Mary rivers. Cruise boats ply the upper Missouri, notably in the spectacular trip through the Gates of the Mountains, above Helena.

Richness of water resources

Most of the natural lakes are in the Rockies, and some of the most beautiful are in Glacier National Park. Flathead Lake, with a surface area of 197 square miles, is the largest in the state. A new lake was formed in 1959 when an earthquake toppled a mountain into the Madison River northwest of West Yellowstone, the resulting body of water becoming known as Quake Lake or Earthquake Lake. Some large man-made lakes are reservoirs backed up behind multipurpose government dams. Major dams are Fort Peck on the Missouri River near Glasgow; Canyon Ferry on the Missouri near Helena; Hungry Horse on the South Fork of the Flathead near Columbia Falls;

Yellowtail in the Bighorn River Canyon, creating Bighorn Lake, which extends into Wyoming; and Libby Dam on the Kootenai, producing Koocanusa Lake, part of which lies in British Columbia.

Climate. Montanans tend to be defensive about their climate, and they do not react gratefully to expressions of sympathy from New Yorkers, New Englanders, or North Dakotans. The state was called "the icebox of the nation" before Alaska achieved statehood. A temperature of −70° F (−57° C) was registered at Rogers Pass on January 20, 1954, but the cities of Duluth, Minneapolis, and St. Paul, in Minnesota, have lower average temperatures. In July, the warmest month, Montana's average is about 65° F (18° C); in January, the coldest, about 15° F (−9° C). Humidity is generally low, and the same aridity that requires dryland farmers to be ingenious about conserving moisture makes both summer and winter more comfortable than thermometer readings suggest.

Average precipitation is low—about 18 inches in the west and 13 inches in the east—resulting from the position of the Rocky Mountains and the state's interior location on the continent. The Rockies sometimes warm part of the east and north by creating a chinook wind, which melts snow rapidly and gives quick relief from cold. Destructive hailstorms sometimes occur in July and August, damaging unharvested grain.

Soils and vegetation. Montana's soils differ widely. Eastern, prairie soils are mature, underlaid by lime deposits, and productive when enough moisture is available. Many mountain soils are immature and thin because erosion has carried the richer decomposed materials into the valleys. The grasslands east of the Rockies make Montana one of the great range states. Only Texas outranks it in the number of cattle raised on native grasses; Texas and Wyoming exceed it in range-raised sheep. About one-fourth of the state is classified as forest land, and about one-third of this is also suitable for grazing. In general, where there are mountains, there are forests. Most of the trees, and all those cut for timber, are softwood conifers. There are no hardwood forests.

Animal life. Large game animals abound, mainly in the mountains. They include moose, elk, mule and white-tailed deer, grizzly and black bears, bighorn sheep, and mountain goats. Herds of pronghorn antelope run free on the prairie. A few bison, once abundant beyond counting, were saved from extinction, and a herd of between 300 and 400 is maintained on the National Bison Range, near Moiese. A herd belonging to the Crow Indians, which had to be destroyed because of undulant fever, is being rebuilt. There is some trapping of mink, beaver, and muskrat for their fur. Predators include mountain lions, bobcats, and coyotes.

Prevalence of wildlife

Game birds are abundant, including grouse, ducks, pheasant, partridge, and geese. About 700 trumpeter swans, once almost extinct, live in the area of Yellowstone, Hebgen, and Red Rock lakes, forming the largest colony of these birds in the United States. Kokanee and silver salmon, whitefish, and several kinds of trout predominate as attractions for recreational fishermen.

Human inroads. Air travellers can fly over Montana's prairie for miles without seeing a town, a road, or a railroad track. This is grazing country for cattle and sheep. In dryland-farming areas the fields are big; and where wind blows the soil, green swaths of growing grain alternate with brown swaths of fallow ground, on which last year's stubble catches and holds such rain and snow as fall. In the mountains, forests are dark on steep slopes and in deep canyons, with occasional scars of logging roads and patches of timber burned in forest fires.

The main urban settlements developed from mining camps; from trading centres for farmers, stockmen, and forest workers; and from early railroad division points. With improved roads and plentiful automobiles, rural communities have lost stores, banks, and other businesses. Billings, the largest city, boomed when it became the business centre for the state's oil industry. Hydroelectric power was responsible for the growth of Great Falls, the second largest city.

THE PEOPLE OF MONTANA

In the early years of the 20th century, many families from northern Europe settled on homesteads to farm on the eastern prairie, and immigrants from across Europe came to work in the mines. Their descendants have been well assimilated. Place-names such as Belgrade, Glasgow, Havre, Harlem, and Malta do not indicate the national origin of the settlers but were bestowed by railroad officials when the towns were established. If there is a social status in the state, it is conferred less by wealth than by descent from pioneers.

Ethnic minorities. Several Indian tribes, usually on the move in search of game, lived in Montana when the first explorers arrived. Indians now constitute the state's only large racial minority group, with about 27,000 of the about 31,000 nonwhites in 1970. About three-quarters of Montana's Indians live on seven reservations: Blackfeet, Crow, Northern Cheyenne, Rocky Boy's (Chippewa and Cree Indians), Fort Peck (Sioux and Assiniboin), Flathead (Flathead or Salish, Kutenai, and Pend d'Oreille), and Fort Belknap (Assiniboin and Atsina or Gros Ventre). Most of the reservations are poor in natural resources except for grazing land, much of it leased to non-Indian stock growers. The reservations are partially self-governing through tribal organizations, and the federal Bureau of Indian Affairs is the principal agency overseeing Indian activities. Employment opportunities on the reservations are few, and most Indians find it difficult to tear themselves away from traditionally strong family ties to work among strangers. Life is even harder for the landless Indians, who came to the state after the reservations were established and do not have a legal right to live on them. About half of the nearly 2,000 Negroes live in the Great Falls area.

Indian reservations

Religion. About half the people in Montana are affiliated with an organized religious group, with slightly more than half of them Roman Catholics. Through vigorous missionary activity the Mormon Church, centred in nearby Salt Lake City, Utah, has been increasing its membership for several years.

Demography. The population in 1970 represented an increase of only about 3 percent in ten years. Since births outnumbered deaths by almost 78,000 in the decade, it is obvious that many thousands of persons left the state. Only eight cities had more than 10,000 population in the census of 1970: Billings (61,581), Great Falls (60,091), Missoula (29,497), Butte (23,368), Helena (22,730), Bozeman (18,670), Havre (10,558), and Kalispell (10,526).

During the 1960s, population moved not only out of the state but from east to west within it, from farms and ranches to the more industrialized areas. Of the 56 counties, 41 lost population, all but one of them rural. Only four eastern counties showed a gain, and the only significant increase there was 15 percent in Powder River County, due to oil-drilling activity at the Bell Creek field. Twenty-one counties have less than 5,000 inhabitants, and two of these, Golden Valley and Petroleum, have less than 1,000. In the same decade the urban population increased to 53.4 percent from 50.2 percent of the total.

THE STATE'S ECONOMY

Montana's imbalance between dependent persons below 19 and over 65 years of age and those of working age tends to reduce per capita income and tax-paying capacity in comparison with the entire nation. Between 1948 and 1970, per capita personal income declined from more than 110 percent of the national average to only 86 percent. The state government has relatively little power to influence economic growth. Montana specializes in industries that, nationally, are growing slowly if at all. Some tax concessions are offered to new businesses. A 1972 popular vote to legalize gambling was not (1973) implemented by the legislature. Tourism is an important if only seasonal source of employment in the state. Trade unions are strongest and most active in communities where one or two major employers predominate: in Butte, Anaconda, and Great Falls.

Agriculture. The state's largest single source of income is agriculture, with livestock accounting for about two-thirds of cash income, and crops the remainder. Montana's national rank in livestock at the beginning of the 1970s was tenth in beef cows, third in sheep, and 28th in hogs. The state ranked second in the nation in barley and seventh in wheat production, 10th in sugar beets, fifth in flaxseed, and 13th in oats. Following a nationwide trend, the number of farms has been diminishing, while the average size of individual farms has increased for several decades.

Mining. Copper is the leading metal, representing nearly half of the state's metal production. Gold, the basis of pioneer settlement in the 1860s, is now only a by-product of copper mining, along with silver and lead. Among other mineral resources are phosphates, used in manufacturing fertilizers and elemental phosphorus; vermiculite; bentonite; sand and gravel; and gypsum. Montana has enormous low-sulfur coal reserves, estimated at more than 2,000,000,000 tons, that can be strip-mined at low cost. Although visible coal deposits in southern Montana were noted by a military expedition in 1876, these resources have scarcely been touched. Coal is now gaining importance as a fuel to produce electrical power. Legislation adopted in 1971 required mine operators to restore the surface of the mined land for other uses, such as grazing. Petroleum was discovered in commercial quantities at Elk Basin in 1915. The Elk Basin, Kevin-Sunburst, and Cut Bank fields led in production for several years. The great Williston Basin was developed in 1951, but more recently the Bell Creek field in Powder River County has been the most productive.

Exploitation of natural resources

Forestry. Lumbering and forest-products manufacture are vital to western Montana. Of the more than 17,000,000 acres of commercial forest land, more than three-quarters is owned by the federal and state governments. More than 9,000 persons are employed in the forestry industry, including the manufacture of plywood and of pulp and paper products. About half of Montana's forest products are sold to states in the Middle West.

Military presence. The beginning and the ending of big military installations have had profound effects in Montana. Malmstrom Air Force Base, built in 1942, is of continuing economic importance to Great Falls. The economic shock produced in the early 1970s by the construction of an anti-ballistic-missile installation in north central Montana was followed by an opposite upheaval when the project was later abandoned. Closing of the Glasgow Air Force Base in 1968, after 11 years, jolted the economy of that area, and closing of an air force radar base in 1971 lost for Lewistown the benefits of a significant annual payroll.

Transportation. Under Amtrak, administered by the quasi-governmental National Railroad Passenger Service Corporation, the Burlington Northern in 1971 continued passenger service across the northern part of the state but maintained it only provisionally to the six largest cities in the state farther to the south. In-city bus lines operate only in Butte, Anaconda, and Billings.

In 1970 the state had more than 1,200 miles of interstate highways. There were almost 6,000 miles of primary highways and the same amount of secondary roads. Several major airlines and air-taxi lines serve the state, and many small planes are privately owned.

ADMINISTRATION AND SOCIAL CONDITIONS

Constitution. The only copy of Montana's first proposed state constitution was mislaid on the way to the printer in St. Louis, Missouri, in 1866, and its contents must remain a subject of historical curiosity. A second attempt to achieve statehood failed in 1884; but Pres. Grover Cleveland signed an enabling act in 1889, and the third constitutional convention produced a constitution of 21 articles. As the state grew and its people's needs changed, so many amendments were added that in 1970 voters called for a constitutional convention. The new constitution was adopted by the electorate in 1972.

State government. Allegiance is so evenly divided between the Republican and Democratic parties that election patterns are not predictable. Ticket splitting is common. The governor and the lieutenant governor, formerly elected separately, now are elected on one ticket. The state has an open primary; voters need not declare party affiliation, and registration is permanent unless a voter misses a general election.

The political process

The executive branch was reorganized so that in 1973 some 160 state boards and agencies were consolidated into 19 cabinet-style departments, with virtually all appointments directly controlled by the governor. The voting age was lowered to 19 in 1969, and Montana was one of the first states to ratify the amendment to the United States Constitution permitting 18-year-olds to vote.

The two-house legislature, which under the state's new constitution meets every year, was composed, in early 1973, of 50 senators and 100 representatives.

Judges are elected without party designation. The highest court is the five-man Supreme Court. The state is divided into 18 judicial districts, in which 28 district judges serve. On the lowest level are justices of the peace, who serve organized townships, and police judges, whose authority is limited to cases involving municipal ordinances.

Income from taxation on personal property, the most important source of tax revenue, varies widely from county to county because of differences in valuation by county assessors. A major political issue in the legislature in the early 1970s revolved around the choice of increasing the personal income tax or imposing a sales tax. Personal income tax increased in 1971.

Local government. The county is the highest level of local government. Its powers and duties are defined and limited by state statutes. Three elected commissioners are the chief administrators, though a full-time manager may be employed instead. Government in low-population counties is especially expensive and burdensome. Municipal governments, like those of counties, have no inherent powers but derive all their authority from the state. They can, however, enact local ordinances, whereas counties cannot.

Law enforcement. Municipalities have police forces, whereas organized townships have elected constables whose major duty is to serve legal papers. Each county has an elected sheriff, who appoints his deputies and has jurisdiction outside towns and cities. Because cattle rustling is a continuing problem, some sheriffs and deputies act as brand inspectors to prevent the sale of stolen livestock.

Health, education, and welfare. Montanans pay various penalties for the wide-open spaces they enjoy. An increasing number of communities have no physician, dentist, or hospital. Although rural schools continue to consolidate and introduce bus transportation, many children attend small and not always adequate one- or two-teacher country schools. Beaverhead County, larger than the state of Connecticut but with only 8,000 inhabitants, has only two high schools, one with fewer than 100 pupils. School districts are corporate bodies headed by a county superintendent of schools and governed by elected school boards.

The state's system of higher education, chartered in 1893, includes universities at Missoula and Bozeman and four-year colleges at Billings, Butte, Havre, and Dillon. There are church-affiliated private colleges in Great Falls, Helena, and Billings; junior colleges in Miles City, Glendive, and Kalispell; and public postsecondary vocational–technical schools in Great Falls, Billings, Missoula, Helena, and Butte.

Montana's welfare program is state supervised and administered by county departments of public welfare. Because of sparse population and few private social-service agencies, costs are relatively high. Welfare departments are caught between pressures from the public to tighten up the programs and from organized low-income groups to provide wider services. Special problems exist on Indian reservations, where winter allowances are provided to help recipients of public assistance meet clothing and fuel costs in the cold months. Tuberculosis, once endemic among Indians, is now under control.

CULTURAL LIFE AND INSTITUTIONS

The arts. Most artistic activity centres in the cities with colleges and universities, several of which sponsor visits of lecturers and professional artists of various kinds in addition to presenting the work of faculty members and students. Six cities have symphony orchestras that include some professional musicians.

State cultivation of the arts

The Montana Institute of the Arts, founded in 1948, is a grass-roots organization that ties together the scattered, often isolated practitioners of various arts and crafts through publications, an annual festival, and traveling exhibits. The Montana Arts Council, a state agency affiliated with the National Endowment for the Arts, funds dozens of local cultural organizations up to 50 percent with federal money, primarily for music, drama, dance, literature, and the visual arts. Among other activities, it provides short poet-in-residence programs for children in the public schools of small communities. In addition to dramatic performances by students in various colleges, there are summer theatres in more than a half dozen communities; and the Montana Repertory Theater, based in Missoula, tours both inside and outside the state.

Folk culture. Several Indian tribes hold traditional dance ceremonies at which outsiders are welcome. Crow Indians and whites cooperate in an annual re-enactment of the Battle of the Little Bighorn on the Crow Indian Reservation. Rodeos abound, as do games on horseback known as *o-mok-sees* and square-dance groups. In Red Lodge an annual nine-day Festival of Nations, originated to ease tensions among several European ethnic groups of coal miners, has become a proud tradition.

Museums. The Montana Historical Society maintains a fine museum, art gallery, and specialized library in Helena. The Trigg-Russell Memorial Gallery in Great Falls, specializing in the works of the cowboy artist Charles Marion Russell, is the property of the city. Billings has the Yellowstone County Fine Arts Center, operated in a former city jail, and the Yellowstone County Museum. The excellent, small Museum of the Plains Indians is in Browning, the agency town for the Blackfeet tribe. Many communities nurture art galleries and small museums of local historical interest.

Communications and libraries. Montana has 14 daily newspapers and 77 weeklies, 52 AM radio stations, ten FM stations, and ten commercial television stations. Most communities depend on community-antenna television or on booster systems for reception from stations in Salt Lake City, Utah; Spokane, Washington; Williston, North Dakota; and Lethbridge, Alberta. Only about 40,000 of Montana's scattered people do not have access to public-library services. Larger cities and towns all have municipal or county libraries, and nine bookmobiles operated by multicounty federations serve other areas. The Montana State Library, in Helena, lends books to supplement the holdings of local libraries.

Prospects. While admitting that a small population and a scarcity of employment opportunities have some drawbacks, Montanans take great pride in their wide-open spaces. Many persons remain in the state, return to it, or move into it because of the lack of crowding and the recreational advantages—although they might well earn more money elsewhere. There are no traffic-choked streets or highways, and distances are usually described in terms of hours of driving time rather than in miles. There is every likelihood that the population will continue to grow at well below the national average. Montana is one of the few states in the nation about which it may be said that little change appears likely, but this is a condition that will continue to satisfy a large percentage of the residents.

Montesquieu

Remembered now mainly as a liberal political philosopher, Montesquieu was one of the outstanding Frenchmen of the 18th century. His seminal *L'Esprit des lois* was a major contribution to political theory, but he was as well-known in his own time as a prominent social figure, an acute satirist, and a brilliant stylist.

Early life and career. He was born Charles-Louis de Secondat in the 15th-century château of La Brède, near Bordeaux, on January 18, 1689. His father, Jacques de Secondat, belonged to an old military family of modest wealth that had been ennobled in the 16th century for services to the crown, while his mother, Marie-Françoise de Pesnel, was a pious lady of partial English extraction. She brought to her husband a great increase in wealth in the valuable wine-producing property of La Brède. When she died in 1696, the barony of La Brède passed to Charles-Louis, who was her eldest child, then aged seven. Educated first at home and then in the village, Charles-Louis was sent away to school in 1700. The school selected was the Collège de Juilly, close to Paris and in the diocese of Meaux. It was then much patronized by the prominent families of Bordeaux, and the priests of the Oratory, to whom it belonged, provided a sound education on enlightened and modern lines.

Montesquieu, oil painting by an unknown artist, 1718. In the Académie Nationale des Sciences, Belles Lettres et Arts de Bordeaux, France.

Charles-Louis left Juilly in 1705, continued his studies at the faculty of law at the University of Bordeaux, graduated, and became an advocate in 1708; soon after he appears to have moved to Paris in order to obtain practical experience in law. He was called back to Bordeaux by the death of his father in 1713. Two years later he married Jeanne de Lartigue, a wealthy Protestant, who brought him a very respectable dowry of 100,000 livres and in due course presented him with two daughters and a son, Jean-Baptiste. Charles-Louis admired and exploited his wife's business skill and readily left her in charge of the property on his visits to Paris. But he does not appear to have been either faithful or greatly devoted to her. In 1716 his uncle, Jean-Baptiste, baron de Montesquieu, died and left to his nephew his estates, with the barony of Montesquieu, near Agen, and the office of deputy president in the Parlement of Bordeaux. The *parlements* were regional courts of law and at this time

were laying some claim to political authority. His position was one of some dignity. It carried a stipend but was no sinecure.

The young Montesquieu, at 27, was now socially and financially secure. He settled down to exercise his judicial function (engaging to this end in the minute study of Roman law), to administer his property, and to advance his knowledge of the sciences, especially of geology, biology, and physics, which he studied in the newly formed academy of Bordeaux. His intellectual horizons might have become fixed in the southwest of France, but Montesquieu had already been attracted by the capital. He had enjoyed what he saw of the small intellectual and social coteries that flourished in Paris, in which new and bold ideas were canvassed and in which young men like himself might meet established figures. Throughout his life his loyalty to Bordeaux was challenged, though never overcome, by the lure of Paris, and Montesquieu was at once the feudal *seigneur* and the witty man of letters.

In 1721 he surprised all but a very few close friends by publishing his *Lettres persanes*, in which he gave a brilliant satirical portrait of French and particularly Parisian civilization, supposedly seen through the eyes of two Persian travellers, Usbek and Rica. This exceedingly successful work mocks the reign of Louis XIV, which had only recently ended; pokes fun at all social classes; discusses, in its allegorical story of the Troglodytes, the theories of Hobbes relating to the state of nature; makes an original, if naïve, contribution to the new science of demography; continually compares Islām and Christianity; reflects the controversy about the papal bull *Unigenitus*, which was directed against the dissident Catholic group known as the Jansenists; satirizes Roman Catholic doctrine; and is infused throughout with a new spirit of vigorous, disrespectful, gay, and iconoclastic criticism. The work's anonymity was very soon penetrated and Montesquieu became famous. The new ideas fermenting in Paris had received their most scintillating expression.

Social progress in Paris

Montesquieu now sought to reinforce his literary achievement with social success. Going to Paris in 1722, he was assisted in entering court circles by the Duke of Berwick, the exiled Stuart prince whom he had known when Berwick was military governor at Bordeaux. The tone of life at court was set by the rakish regent, the Duc d'Orléans, and Montesquieu did not disdain its dissipations. His notebooks and his correspondence hint at a number of amorous adventures, and it was in their background that he produced his *Temple de Gnide* (1725), a mild essay in eroticism written, it is thought, for the royal princess Mademoiselle de Clermont. He frequented the dissolute, gay society of Belébat, the country house of an adventuress called Madame de Prie, who was known also to Voltaire. On a more serious level, he was admitted to the literary salon of Madame de Lambert, regarded by many as the anteroom to the French Academy. He appears to have visited the Club of the Entresol, a kind of political academy the members of which included the Marquis d'Argenson and the abbé Castel de Saint-Pierre, both of them advanced and unconventional political thinkers.

It was during this period that he made the acquaintance of the English politician Viscount Bolingbroke, whose political views were later to be reflected in Montesquieu's analysis of the English constitution. Montesquieu is thought to have read to the Entresol a short work, elegant but superficial, called *Dialogue de Sylla et d'Eucrate*, but if he did so, his reception was in no way memorable. The members of the Entresol and of the salon of Madame de Lambert certainly influenced Montesquieu's developing political ideas, and these received expression in an essay on duty (*Traité général des devoirs*), now lost but clearly, from extracts surviving, inspired by Cicero and the German jurist Samuel von Pufendorf. These extracts he read in 1725 to the Academy of Bordeaux, which was one of the strongest links binding him to Bordeaux. His interest, however, in the routine activities of the Parlement had dwindled. He resented seeing that his intellectual inferiors were more successful than he in court. His office was marketable, and in 1726 he sold it, a move that served both to re-establish his fortunes, depleted by life in the capital, and to assist him, by lending colour to his claim to be resident in Paris, in his attempt to enter the Académie Française. A vacancy there arose in October 1727. Montesquieu had powerful supporters, with Madame de Lambert's salon firmly pressing his claims, but success seemed likely to elude him because of the objection of Cardinal Fleury (who was the most powerful political figure in France at this time) to certain passages in the *Lettres persanes* that were hostile to religion. He succeeded, however, in appeasing Fleury and was elected, taking his seat on January 24, 1728.

Experiences on the grand tour

This official recognition of his talent might have caused him to remain in Paris to enjoy it. On the contrary, though older than most noblemen starting on the grand tour, he resolved to complete his education by foreign travel. Leaving his wife at La Brède with full powers over the estate, he set off for Vienna in April 1728, with Lord Waldegrave, nephew of Berwick and lately British ambassador in Paris, as travelling companion. He wrote an account of his travels as interesting as any other of the 18th century.

In Vienna he met the soldier and statesman Prince Eugene of Savoy and discussed French politics with him. He made a surprising detour into Hungary to examine the mines. He then entered Italy, and, after tasting the pleasures of Venice, proceeded to visit most of the cities of Italy. Conscientiously examining the galleries of Florence, notebook in hand, he developed his aesthetic sense. In Rome he heard the French minister Cardinal Polignac and read his unpublished Latin poem *Anti-Lucretius*. In Naples he skeptically witnessed the liquefaction of the blood of the city's patron saint. He became aware of the works of both the notoriously persecuted historian Pietro Giannone and the then obscure but original philosopher of history Giambattista Vico. From Italy he moved through Germany to Holland and thence (at the end of October 1729), in the company of the statesman and wit Lord Chesterfield, to England, where he remained until the spring of 1731. His account of his visit to England was destroyed by his grandson, and much less is known of it than of the Italian journey.

Montesquieu had a wide circle of acquaintances in England, especially among the Tories and the dissident Whigs. He was presented at court, and he was received by the Prince of Wales, at whose request he later made an anthology of French songs, many of them of a dubious character. He became a close friend of the dukes of Richmond and Montagu. He was elected a Fellow of the Royal Society. He attended parliamentary debates and read the political journals of the day, especially Bolingbroke's *Craftsman*. He became a Freemason. He bought extensively for his library. His stay in England was one of the most formative periods of his life.

Major works. During his travels Montesquieu did not avoid the social pleasures that he had sought in Paris, but his serious ambitions were strengthened. He thought for a time of a diplomatic career but on his return to France decided to devote himself to literature. He hastened to La Brède and remained there, working for two years. Apart from a tiny but controversial treatise on *La Monarchie universelle*, printed in 1734 but at once withdrawn (so that only his own copy is extant), he was occupied with an essay on the English constitution (not published until 1748, when it became part of his major work) and with his *Considérations sur les causes de la grandeur des Romains et de leur décadence* (1734). He had thought of publishing the two together, thus following an English tradition, for, as Voltaire said, the English delighted in comparing themselves with the Romans. Montesquieu was not a professional historian, and his book on the Romans was ill received by the learned. Certainly it was technically defective. It shows a disregard for archaeology surprising in an enthusiastic traveller in Italy, and its documentation is uncritical. In these respects Montesquieu was behind his time. But his comments on the history of Rome are penetrating and vigorous, and his approach to the study of historical causation is particu-

larly interesting. In the distinction that, under the influence of the 17th-century French philosopher Nicolas Malebranche and of Italian writers, he draws between cause and occasion, he finds a formula for the reconciliation of free will and historical determinism. He shows a unifying grasp of the varied aspects of civilization that few before him could rival. The hatred of despotism that characterized the *Lettres persanes* is here flanked by a devotion to liberty as the major political good. This is a mature and well-written book.

Preparation of *L'Esprit des lois*

Montesquieu's literary ambitions were far from exhausted. He had for some time been meditating the project of a major work on law and politics. After the publication of the *Considérations*, he rested for a short time and then, undismayed by failing eyesight, applied himself to this new and immense task. He undertook an extensive program of reading in law, history, economics, geography, and political theory, filling with his notes a large number of volumes, of which only one survives, *Geographica, tome II*. He employed a succession of secretaries, sometimes as many as six simultaneously, using them as readers and as amanuenses, but not as précis writers. An effort of this magnitude was entirely foreign to what was publicly known of his character, for he was generally looked on as brilliant, rapid, and superficial. He did not seek to disabuse the world at large. Only a small number of friends knew what he was engaged in. He worked much at La Brède, devoting himself also to the administration of his estates and to the maintenance of his privileges as a landed proprietor. But he continued to visit Paris and to enjoy its social life. He kept there a second library and also made use of the Bibliothèque du Roi. He attended the Académie, visited the salons, and enjoyed meeting Italian and English visitors. At the same time he persistently, unostentatiously pressed on with the preparation of the book that he knew would be a masterpiece. By 1740 its main lines were established and a great part of it was written. By 1743 the text was virtually complete, and he began the first of two thorough and detailed revisions, which occupied him until December 1746. Now the actual preparation for the press was at hand. A Geneva publisher, J. Barrillot, was selected, further corrections were made, several new chapters were written and in November 1748 the work appeared under the title *De l'esprit des loix, ou du rapport que les loix doivent avoir avec la constitution de chaque gouvernement, les moeurs, le climat, la religion, le commerce, etc.* (*The Spirit of Laws*, 1750). It consisted of two quarto volumes, comprising 31 books in 1,086 pages.

Montesquieu had once before astonished the public when, known as a provincial magistrate, he had produced the satirical *Lettres persanes*. Now, known rather as a wit, he produced the massive treatise comparable with Aristotle's *Politics*. Fame came to him immediately.

L'Esprit des lois is one of the great works in the history of political theory and in the history of jurisprudence. Its author had acquainted himself with all previous schools of thought but identified himself with none. Of the multiplicity of subjects treated by Montesquieu, none remained unadorned. His treatment of three was particularly memorable. The first of these is his classification of governments, a subject that was *de rigueur* for a political theorist. Abandoning the classical divisions of his predecessors into monarchy, aristocracy, and democracy, Montesquieu produced his own analysis and assigned to each form of government an animating principle: the republic, based on virtue; the monarchy, based on honour; and despotism, based on fear. His definitions show that this classification rests not on the location of political power but on the government's manner of conducting policy; it involves a historical and not a narrow descriptive approach.

Analysis of the separation of powers

The second of his most noted arguments, the theory of the separation of powers, is treated differently. Dividing political authority into the legislative, executive, and judicial powers, he asserted that in the state that most effectively promotes liberty, these three powers must be confided to different individuals or bodies, acting independently. His model of such a state was England, which he saw from the point of view of the Tory opposition to the Whig leader, Robert Walpole, as expressed in Bolingbroke's polemical writings. The chapter in which he expressed this doctrine—book xi, chapter 6, the most famous of the entire book—had lain in his drawers, save for revision or correction, since it was penned in 1734. It at once became perhaps the most important piece of political writing of the 18th century. Though its accuracy has in more recent times been disputed, in its own century it was admired and held authoritative, even in England; it inspired the Declaration of the Rights of Man and the Constitution of the United States.

The third of Montesquieu's most celebrated doctrines is that of the political influence of climate. Basing himself on doctrines met in his reading, on the experience of his travels, and on experiments—admittedly somewhat naïve—conducted at Bordeaux, he stressed the effect of climate, primarily thinking of heat and cold, on the physical frame of the individual, and, as a consequence, on the intellectual outlook of society. This influence, he claims, is not, save in primitive societies, insuperable. It is the legislator's duty to counteract it. Montesquieu took care (as his critics have not always realized) to insist that climate is but one of many factors in an assembly of secondary causes that he called the "general spirit." The other factors (laws, religion, and maxims of government being the most important) are of a nonphysical nature, and their influence, compared with that of climate, grows as civilization advances.

Society for Montesquieu must be considered as a whole. Religion itself is a social phenomenon, whether considered as a cause or as an effect, and the utility or harmfulness of any faith can be discussed in complete independence of the truth of its doctrines. Here and elsewhere, undogmatic observation was Montesquieu's preferred method. Sometimes the reader is beguiled by this into the belief that Montesquieu maintains that whatever exists, though it may indeed stand in need of improvement, cannot be wholly bad. It is then that a bold parenthesis or a rapid summing-up reminds one that for Montesquieu certain things are intrinsically evil: despotism, slavery, intolerance. Though he never attempted an enumeration of the rights of man and would probably have disapproved of such an attempt, he maintained a firm belief in human dignity.

In the final books of *L'Esprit des lois*, added at the last moment and imperfectly assimilated to the rest, he addressed himself to the history of law, seeking to explain the division of France into the two zones of written and customary law, and made his contribution to the much discussed controversy about the origins of the French aristocracy. Here he displays not only prudence and common sense, but also a real scholarly capacity, which he had not shown before, for the philological handling of textual evidence.

Reactions to *L'Esprit des lois*

After the book was published, praise came to Montesquieu from the most varied headquarters. The Scottish philosopher David Hume wrote from London that the work would win the admiration of all the ages; an Italian friend spoke of reading it in an ecstasy of admiration; the Swiss scientist Charles Bonnet said that Montesquieu had discovered the laws of the intellectual world as Newton had those of the physical world. The philosophers of the enlightenment accepted him as one of their own, as indeed he was. This, however, had grim consequences also. The intellectual life of Paris was bitterly divided at this time, and alignment with the Philosophes meant incurring the hostility of their enemies. The determinism that could be read into his theory of climate, the objectivity of his attitudes to monarchy and to religion, and his insistence on toleration and on liberty were all controversial, and a variety of denunciatory articles amd pamphlets appeared. Attacks made in the Sorbonne and in the general assembly of the French clergy were deflected, but in Rome, in spite of the intervention of the French ambassador and of several liberal-minded high ecclesiastics and notwithstanding the favourable disposition of the Pope himself, Montesquieu's enemies were successful, and the work was placed on the Index in 1751. This, though it

dismayed Montesquieu, was but a momentary setback. He had already published his *Défense de L'Esprit des lois* (1750). Subtle and good-humoured, but forceful and incisive, this was the most brilliantly written of all his works. His fame was now worldwide.

Last years. Renown lay lightly on his shoulders. His affability and modesty are commented on by all who met him. He was a faithful friend, kind and helpful to young and unestablished men of letters, witty, though absent-minded, in society. It was to be expected that the editors of the *Encyclopédie* should wish to have his collaboration, and d'Alembert asked him to write on democracy and despotism. Montesquieu declined, saying that he had already had his say on those themes but would like to write on taste. The resultant *Essai sur le goût*, first drafted some 25 years earlier, was his last work.

His affection for his country estate at La Brède remained unaltered, and he planned to retire there to continue literary work. But a short illness brought him to his death in Paris on February 10, 1755. The controversies that marked his last years surrounded his death also. He appears to have acknowledged a belief in God, to have been absolved, but to have refused to surrender to the church a notebook of corrections to the *Lettres persanes*.

MAJOR WORKS

Lettres persanes (1721; *Persian Letters, Translated [from the French of Montesquieu] by Mr. Ozell*, 2 vol., 1722); *De la monarchie universelle en Europe* (1734); *Considérations sur les causes de la grandeur des Romains et de leur décadence* (1734; *Reflections on the Causes of the Grandeur and Declension of the Romans. by the author of the Persian Letters, etc.*, 1734); *De l'esprit des loix, ou du rapport que les loix doivent avoir avec la constitution de chaque gouvernement, les moeurs, le climat, la religion, le commerce, etc.* (1748; *The Spirit of Laws, Translated [by Thomas Nugent] . . . with Corrections and Additions Communicated by the Author*, 2 vol., 1750; *The Spirit of Laws, by C. de Secondat, Baron de Montesquieu, translated by Thomas Nugent, revised by J.V. Pritchard, including On the Origin of Inequality, On Political Economy, The Social Contract, by Jean Jacques Rousseau*, trans. by G.D.H. Cole, 1952); *Défense de L'Esprit des loix à laquelle on à joint quelques éclaircissements* (1750).

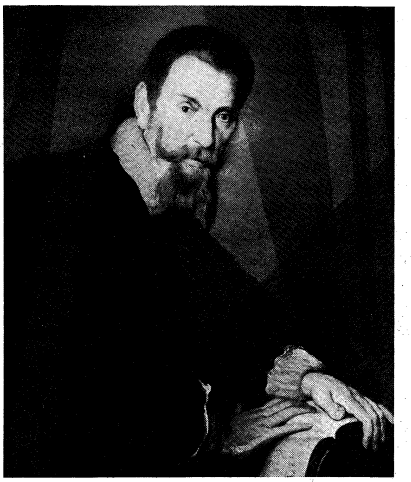
BIBLIOGRAPHY. R. SHACKLETON, *Montesquieu: A Critical Biography* (1961); J. DEDIEU, *Montesquieu, l'homme et l'oeuvre* (1943); the best edition of the *Oeuvres complètes* is by ANDRE MASSON, 3 vol. (1950–55). The "Bibliothèque de la Pléiade" has a useful edition by R. CAILLOIS, 2 vol. (1949–51). The best edition of *De l'esprit des loix* is by J. BRETHE DE LA GRESSAYE, 4 vol. (1950–61); the 18th-century English translation has been reprinted (1949). D.C. CABEEN, *Montesquieu: A Bibliography* (1947), is useful.

(R.Sh.)

Monteverdi, Claudio

Of all the composers who participated in the musical revolution that centred in Italy at the end of the 16th century, Claudio Monteverdi accomplished most in the new genres of opera and oratorio and in writing in the new style of accompanied melody, rather than weaving independent melodic lines in the old polyphonic style. In the late 19th century, historians regarded him as *the* revolutionary who was responsible for the decline of that style, which had culminated its long development in the 16th-century church music of Palestrina; later research, however, showed that Monteverdi was only one of those involved in this trend. He based his work on the belief that music must "move the whole man"; that is, that it must express man's deepest feelings, even in the lightest songs, and that, to do so, it must be joined with words. Even in his earlier madrigals (*i.e.*, unaccompanied secular vocal pieces in a complex polyphonic style), he demonstrated his skill in combining contrasting emotions into a satisfying unit. The same gifts made him a supreme composer of operas in which the characters are as alive as those in the works of Mozart and Verdi.

Early career at the Gonzaga court. Claudio Monteverdi was baptized in the north Italian town of Cremona on May 15, 1567, the son of a barber-surgeon and chemist. He studied with the director of music at Cremona Cathedral, Marcantonio Ingegneri, a well-known musician who wrote church music and madrigals of some distinction in an up-to-date though not revolutionary style of the 1570s. Monteverdi was obviously a precocious pupil, since he published several books of religious and secular music in his teens, all of them containing competent pieces in a manner not far from that of his master. The culmination of this early period occurred in two madrigal books published by one of the most famous of Venetian printers in 1587 and 1590. They are full of excellent, attractive works, somewhat more modern in approach than Ingegneri's, perhaps the result of studying the madrigals of Luca Marenzio (1553–99), the greatest Italian madrigalist of the time, and others. As yet, however, Monteverdi's aim appears to be to charm rather than to express passion; it is exemplified at its best in such a madrigal as the well-known setting of the poem "Ecco mormorar l'onde" ("Behold the Murmuring Sea") by Torquato Tasso, the greatest Italian poet of the late Renaissance.



Monteverdi, oil painting by Bernardo Strozzi (1581–1644). In the Tiroler Landesmuseum Ferdinandeum, Innsbruck, Austria,
By courtesy of the Museum Ferdinandeum, Innsbruck

It is not known exactly when Monteverdi left his home town, but he entered the employ of the Duke of Mantua around 1590 as a string player. He immediately came into contact with some of the finest musicians, both performers and composers, of the time. Most influential on him seems to have been the Flemish composer Giaches de Wert, a modernist who, although no longer a young man, was still in the middle of an avant-garde movement in the 1590s. The crux of his style was that music must exactly match the mood of the verse and that the natural declamation of the words must be carefully followed. Since he chose the highly concentrated, emotional lyric poetry of Tasso and Tasso's rival Battista Guarini, Wert's music also became highly emotional, if unmelodious and difficult to sing. It had an immediate effect on Monteverdi, whose next book of madrigals, published in his first year at Mantua, shows the influence of the new movement on him, though his understanding was imperfect. It represented a complete change of direction for him. The melody is angular, the harmony increasingly dissonant, the mood tense to the point of neurosis. Guarini is the favoured poet, and every nuance of the verse is expressed, even at the expense of musical balance.

Monteverdi's role in the avant garde

The new style and ambience seems to have upset his productivity. Although he went on composing, he published very little for the next 11 years. In 1595, he accompanied his employer on an expedition to Hungary, and four years later to Flanders. About 1599 he married a singer, Claudia Cattaneo, by whom he had three children, one of whom died in infancy. When the post of *maestro di cappella*, or director of music, to the Duke became vacant on the death of Wert in 1596, Monteverdi was embittered at being passed over, but in 1602 he achieved the position, at the age of 35. He published two more books of madrigals in 1603 and 1605, both of which contain masterpieces. The avant-garde manner was now better assimilated into his idiom. While his aim was still

to follow the meaning of the verse in great detail, he solved the purely musical problems of thematic development and proportion. Although the dissonances became more severe and the melody sometimes still more angular, the total effect was more varied in emotion and less neurotic. If Guarini's eroticism stimulated a sensual musical style, Monteverdi often gave his mature madrigals a lightness and humour, seeing the essence of a poem rather than its detail.

It was the advanced musical means, especially the use of intense and prolonged dissonance, that provoked attacks by the conservatives on Monteverdi, who became a figurehead of the avant-garde group. The attacks by a Bolognese theorist, Giovanni Maria Artusi, in a series of pamphlets, made Monteverdi the most famous composer of the age and provoked him to reply with an important aesthetic statement of his view on the nature of his art. He disclaimed the role of revolutionary, saying that he was only the follower of a tradition that had been developing for the last 50 years or more. This tradition sought to create a union of the arts, especially of words and music, so that he should not be judged simply as a composer using conventional musical devices. Moreover, the artwork must be powerful enough to "move the whole man," and this again might mean the abandonment of certain conventions. On the other hand, he declared his faith in another and older tradition, in which music was itself supreme, and which was, in effect, represented by the pure polyphony of such composers as Josquin des Prez and Palestrina. Thus, there were two "practices," as he called them; and this view, which became immensely influential, was to prove the basis of the preservation of an old style in certain types of church music, as opposed to a modern style in opera and cantatas, a dichotomy that can be found well into the 19th century.

Monteverdi's credo

If the madrigals of this time gave him a reputation well outside northern Italy, it was his first opera, *Orfeo*, performed in 1607, that finally established him as a composer of large-scale music rather than of exquisite miniature works. Monteverdi may have attended some of the performances of the earliest operas, those composed by the Florentine composers Jacopo Peri and Giulio Caccini, and he certainly had written some stage music in previous years. In *Orfeo* he showed that he had a much broader conception of the new genre than did his predecessors. He combined the opulence of dramatic entertainments of the late Renaissance with the straightforwardness of a simple pastoral tale told in recitative (*i.e.*, a speechlike vocal style, with the emphasis on the narrative text), which was the ideal of the Florentines. His recitative is more flexible and expressive than theirs, based on the declamatory melody of his madrigals rather than on their theories about heightened speech. Above all, he had a greater gift for dramatic unity, shaping whole acts into musical units, rather than assembling them from small sections. He also showed a sense of matching the climaxes in the drama by musical climaxes, using dissonance, the singer's virtuosity, or instrumental sonorities to create the sense of heightened emotion.

His first opera

A few months after the production of *Orfeo*, Monteverdi suffered the loss of his wife, seemingly after a long illness. He retired in a state of deep depression to his father's home at Cremona, but he was summoned back to Mantua almost immediately to compose a new opera as part of the celebrations on the occasion of the marriage of the heir to the duchy, Francesco Gonzaga, to Margaret of Savoy. Monteverdi returned unwillingly and was promptly submerged in a massive amount of work. He composed not only an opera but also a ballet and music for an intermezzo to a play. Further disaster occurred when the opera, *L'Arianna*, was in rehearsal, for the prima donna, a young girl who had been living in Monteverdi's home, possibly as a pupil of his wife, died of smallpox. Nevertheless, the part was re-cast, and the opera was finally produced in May 1608. It was an enormous success. The score has been lost, except for the famous "Lamento," which survives in various versions and is the first great operatic *scena* (*i.e.*, a scene of especially dramatic effect, usually with arias).

After this enormous effort, Monteverdi returned again to Cremona in a condition of collapse, which seems to have lasted for a long time. He was ordered back to Mantua in November 1608 and refused to go. He eventually returned but thereafter he hated the Gonzaga court, which he maintained had undervalued and underpaid him, though he gained a raise in pay and a small pension for his success with *L'Arianna*. He does not, however, appear to have been uncreative, though the music he wrote in the next year or so reflects his depression. He arranged the "Lamento" as a five-voiced madrigal and wrote a madrigalian threnody on the death of his prima donna, the sestina, published later in the sixth book of madrigals, which represents the peak of dissonant, agonized music in this style. In a more vigorous vein, he wrote some church music, which he published in 1610 in a volume containing a mass in the old style and music for Vespers on feasts of the Blessed Virgin Mary. The mass was a remarkable achievement, a deliberate attempt to show that the polyphonic idiom was still possible when everywhere it was dying. Still more remarkable is the Vespers music, a virtual compendium of all the kinds of modern church music possible at the time—grand psalm settings in the Venetian manner, virtuoso music for solo singers, instrumental music used for interludes in the service, even an attempt to use up-to-date operatic music to set the expressive, emotional words of the Magnificat. Yet, though this music is as "advanced" as possible, Monteverdi makes it an extension of the old tradition by using plainsong tunes—ancient unaccompanied liturgical chants—as the thematic material for the psalms and Magnificats. Above all, this is music of the Counter-Reformation; using all means, traditional and new, secular and religious, it is designed to impress the listener with the power of the Catholic Church, and its Maker, in the face of the challenge of the rise of Protestantism.

The volume containing this music was dedicated to Pope Paul V, and Monteverdi visited Rome apparently to present it in person. He may also have been seeking a new post, in order to leave Mantua, but nothing came of this. Nothing is known of his life for the next two years. Then, Francesco Gonzaga succeeded to the duchy on the death of his father and suddenly dismissed Monteverdi from his service in July 1612 for reasons that are unknown today. Without a job, Monteverdi again went back to his father's house, with his two sons, and remained there for about a year.

Three decades in Venice. When the *maestro di cappella*—that is, the director of music—of St. Mark's in Venice died, Monteverdi was invited to take his place, after an audition of some of his music in the basilica. He finally took up his appointment in the autumn of 1613.

He was appointed largely because the musical establishment of St. Mark's was in need of an experienced director after some years of decline. The last of the native Venetian composers of any distinction, Giovanni Gabrieli, had recently died. Although Monteverdi had not been primarily a church musician, he took his duties extremely seriously and within a few years completely revitalized the music in the basilica. He hired new assistants (including two future composers of note, Francesco Cavalli and Alessandro Grandi), wrote much church music, and insisted on daily choral services. He also took an active part in music making elsewhere in the city, directing the music on several occasions for the fraternity of S. Rocco, an influential philanthropic brotherhood, on the annual festival of its patron saint.

His letters in those early years in Venice reveal a complete change in his state of mind from what it was in Mantua. He felt fulfilled and honoured, well (and regularly) paid, and he seems to have been reasonably prolific. He kept up his links with Mantua, largely because there was little chance of producing opera in Venice, while opportunities came quite regularly from the Gonzaga court. In his correspondence, a philosophy of dramatic music emerges that was not only to mold Monteverdi's later work but also to influence the history of opera in general. The older type of opera had developed, on the one hand, from the Renaissance intermezzo, a

The old and the new opera

short, static musical treatment, often allegorical and with scenery, of a subject from the play with which it was given, emphasizing the wishes of the gods; and, on the other hand, from the pastoral, with its highly artificial characterizations of shepherds and shepherdesses. Monteverdi, however, was increasingly concerned with the expression of human emotions and the creation of recognizable human beings, with their changes of mind and mood. Thus, he wished to develop a greater variety of musical means, and in his seventh book of madrigals, published in 1619, he experimented with many new devices. Most were borrowed from the current practices of his younger contemporaries, but all were endowed with greater power. There are the conversational "musical letters," deliberately written in a severe recitative melody in an attempt to match the words. The ballet *Tirsi e Clori*, written for Mantua in 1616, shows, on the contrary, a complete acceptance of the simple tunefulness of the modern aria. In addition, all this work shows an astonishing renewal for a man of about 50 years of age.

Later musical theories

His attempt to create a practical philosophy of music went on throughout the 1620s, leading to still further stylistic innovations. Following ideas derived from Plato, he divided the emotions into three basic kinds: those of love, war, and calmness. Each of these could be expressed by differing rhythms and harmonies. A further ingredient in his theories was a frank acceptance of realism—the imitating of the sounds of nature in various ways. All these ideas are to be found in his dramatic cantata, *Il combattimento di Tancredi e Clorinda* (*The Combat of Tancredi and Clorinda*), a setting of a section of Tasso's "Gerusalemme Liberata," which was first performed in Venice in 1624. In this work, the rapid reiteration of single notes in strict rhythms and the use of pizzicato—plucking strings—to express the clashing of swords show important steps forward in the idiomatic use of stringed instruments.

These trends were continued in a comic opera, *La finta pazza Licori* (*Licoris Who Feigned Madness*), probably intended for the celebrations of the accession of Duke Vincenzo II of Mantua in 1627. The score of this piece has been lost, but a sizable correspondence survives. At this time, Monteverdi suffered more anxiety since his elder son, Massimiliano, was imprisoned in Bologna, where he was a medical student, for reading books banned by the Inquisition. It took some months before he was finally cleared of the charge. In the same year, 1628, Monteverdi also fulfilled a commission to write music (now lost) for the intermezzi to Tasso's *L'Aminta* and a tournament given in Parma in celebration of the marriage of Duke Odoardo Farnese to Margherita de' Medici. This was in fact the last occasion when Monteverdi was to receive a commission from the northern Italian courts. The War of the Mantuan Succession broke his link with the Gonzagas, who were ruined by the war. Monteverdi may have written an opera for performance in Venice in 1630, but the plague that broke out in that year effectively stopped all musical activities in Venice and the provinces for about 18 months.

Monteverdi and his family seemed to have emerged unscathed, and Monteverdi himself took holy orders during this period. He wrote a grand mass for the thanksgiving service in Saint Mark's when the epidemic was officially declared over in November 1631. The "Gloria" from it still survives and shows him applying some of the theories concerning the diversity of mood suggested by the words. Both this and some other church music probably written about this time, however, show a calm and majestic approach rather than the passion of his earlier years. A book of lighthearted songs and duets published in the following year is much the same. There is also a detached quality about much of the music in the final collection of his madrigals assembled by Monteverdi himself in 1638. A vast retrospective anthology of music dating from 1608 onward, it sets out to display Monteverdi's theories, as its title, *Madrigali guerrieri et amorosi* (*Madrigals of War and Love*), denotes. It contains much fine music, especially the "Lament of the Nymph," another reworking of his mood of 1608, after he lost his wife, and of *L'Arianna*. in terms of later technical devices. It seems to indicate that the agony of the period was never completely forgotten.

Though this collection, put together when Monteverdi was over 70, might seem the end of his career, chance played a part in inspiring him to an Indian summer of astonishing productivity: the first public opera houses opened in Venice in 1637. As the one indigenous composer with any real experience in the genre, he naturally was involved with them almost from the beginning. *L'Arianna* was revived again, and no fewer than four new operas were composed within about three years. Only two of them have survived in score—*Il ritorno d'Ulisse in patria* (*The Return of Ulysses to his Country*) and *L'incoronazione di Poppea* (*The Coronation of Poppea*) —both are masterpieces. Although they still retain some elements of the Renaissance intermezzo and pastoral, they can be fairly described as the first modern operas. Their interest lies in revealing the development of human beings in realistic situations. There are main plots and subplots, especially in *Poppea*, allowing for a great range of characters—the nobility, their servants, the evil, the misguided, the innocent, the good. The music expresses their emotions with astonishing accuracy. Monteverdi shows how the philosophy of music evolved during his early years in Venice could be put to use, using all the means available to a composer of the time, the fashionable arietta (*i.e.*, a short aria), duets, and ensembles, and how they could be combined with the expressive and less fashionable recitative of the early part of the century. The emphasis is always on the drama: the musical units are rarely self-contained but are usually woven into a continual pattern, so that the music remains a means rather than an end. There is also a sense of looking toward the grand climax of the drama, which inspires a grand *scena* for one of the main singers, Ulisse, Nero, or Poppea. At the same time, there are enough memorable melodies for the opera to seem musically attractive.

With these works, Monteverdi proved himself to be one of the greatest musical dramatists of all time. That he was held in the highest esteem by his Venetian employers is shown by their gifts of money in these last years and by their granting him leave to travel to his native city in the last few months of his life. The Venetian public showed its esteem at his funeral, when after his death on Nov. 29, 1643, following a short illness, he was buried in the Church of the Frari, where a monument to him still remains.

MAJOR WORKS

Secular

OPERAS: Seven operas of which only three survive: *La favola d'Orfeo* (1607); *Il ritorno d'Ulisse in patria* (1641); *L'incoronazione di Poppea* (1642). Also surviving, the "Lamento" from *L'Arianna*.

OTHER DRAMATIC WORKS: *Il ballo delle ingrate* (1608), *Tirsi e Clori* (1616), and *La vittoria d'Amore* (1641, music lost), three ballets; *Il combattimento di Tancredi e Clorinda* (1624), a secular oratorio.

MADRIGAL COLLECTIONS: *Canzonette a tre voci, libro primo* (1584); seven books of madrigals (1587–1619); *Madrigali guerrieri et amorosi* . . . (1638), eighth book of madrigals; *Madrigali e canzonette* . . . (1651), ninth book of madrigals, published posthumously; *Scherzi musicali* (1607, 1632).

Sacred

COLLECTIONS: *Sacrae cantiunculae tribus vocibus* (1582); *Madrigali spirituali a quattro voci* (1583); *Sanctissimi Virginis Missa senis vocibus ad ecclesiarum choros ac Vesperae* . . . (1610), which includes *Missa da capella a sei voci* . . . and *Vespro della Beata Vergine* . . . ; *Selva morale e spirituale* (1640); *Messa a quattro voci et Salmi, a una, due, tre, quattro, cinque, sei, sette & otto voci* . . . (1650, published posthumously).

BIBLIOGRAPHY. Monteverdi's music is available in a modern collected (though not always accurate) edition in 16 volumes (some divided into several fascicules) by G.F. MALIPIERO (1926–42, reprinted *c.* 1950–67). A supplementary volume was published in 1966. Monteverdi's ample correspondence is printed in G.F. MALIPIERO, *Claudio Monteverdi* (1930); an English translation of the more important letters is contained in DENIS ARNOLD and NIGEL FORTUNE (eds.), *The Monteverdi Companion* (1968). There is as yet no standard biography in

any language, though the essential documentation of his life is contained in the classic study by E. VOGEL, *Claudio Monteverdi* (1887). There are three accurate biographies in English: H.F. REDLICH, *Claudio Monteverdi: Leben und Werk* (1949; Eng. trans., 1952); L. SCHRADE, *Monteverdi: Creator of Modern Music* (1950); and DENIS ARNOLD, *Monteverdi* (1963).

(D.M.Ar.)

Montevideo

Montevideo, the principal city and the capital of Uruguay and of the department (jurisdictional division) of Montevideo, is on the northern shore of the Río de la Plata Estuary, 120 miles (190 kilometres) east-southeast of Buenos Aires. Perhaps nowhere else in the world does a city predominate in a nation's political, industrial, commercial, and cultural life to the extent that Montevideo does in Uruguay. The city, the largest in the country and one of the great cities of South America, has an area of about 150 square miles (400 square kilometres). Its population in 1967 was 1,280,000. The area of the department, the southernmost, smallest, and most important in Uruguay, is about 200 square miles. The estimated population of the department in 1969 was 1,375,000. The name is derived from the hill (Spanish *monte*) that rises at the entrance to the bay. The hill itself, known as the Cerro (also means hill), surmounted by its light, looms up, a famous landmark, as the city is approached from the sea.

History. Montevideo was founded in 1726 by Bruno Mauricio de Zabala, governor of Buenos Aires, to counteract the Portuguese advance into the area from Brazil. The first families came from Galicia and the Canary Islands, lured by offers of cattle, sheep, and respectability in the form of the title hidalgo. During its early years, Montevideo was mostly a Spanish garrison town. Trade expanded toward the end of the colonial period, and Montevideo's merchants played an important part in securing Uruguayan independence. From 1807 to 1830 Montevideo was alternately occupied by British, Spanish, Argentine, Portuguese, and Brazilian forces, and its trade and population suffered. Independence, which came in 1830, did not bring stability. Uruguay was the scene of complicated interaction of local, Argentine, and Brazilian influences that culminated in the nine-year great siege of Montevideo by a combined Argentine-Uruguayan army from 1843 to 1851. Montevideo defenders were assisted by French and English forces that blockaded Buenos Aires. The result, surprisingly, was that Montevideo flourished during the siege and became the major port of the Río de la Plata. The city's population in 1843 was estimated at 31,197, of whom 15,252 were non-citizen Europeans. The end of the great siege in 1851 and the restoration of normal trade patterns disrupted Montevideo's economy. In the 1870s the gradual development of the Uruguayan interior, spurred by railroad building outward from Montevideo and the installation of modern public utilities in the city gave Montevideo new life. A speculative building boom opened new suburbs. Its collapse in the 1890s slowed the city's growth, but in the 20th century its development has been rapid. A contributing factor has been the port, a government-operated enterprise that was opened in 1901. Formerly, ships had to be unloaded in the harbour by lighters, but after the port's modernization it could dock the largest ships for loading and unloading.

The city's five governments

For the political, economic, and social history of the city in the 20th century, see URUGUAY, HISTORY OF.

The modern city. *The site.* The site of the original city is a low rocky headland projecting westward between the estuary and an almost circular bay that forms the harbour, the headland sloping gently to its western extremity at Punta Sarandí and to the water's edge on either side. The city has expanded eastward over rolling country and northward around the eastern shore of the bay.

Climate. The climate of Montevideo, somewhat blustery in winter, is moderate, with the mean annual temperature around 61° F (16° C). Rainfall is adequate, around 40 inches (1,000 millimetres) a year.

City plan. The harbour district opens out into the Old City (Ciudad Vieja), which once was colonial Montevideo. The buildings there, for the most part, are old, and the streets are narrow; but the Old City is still the financial and business heart of Uruguay. The stock exchange (*bolsa*), the Banco de la República Oriental del Uruguay (Bank of the Republic of Uruguay), head offices of private banks, foreign bank branches, shipping firms, export–import houses, and lawyers locate there. The Old City culminates in the Plaza de la Constitución, with the cathedral on one side and the *cabildo,* the colonial municipal building and for many years the home of the Uruguayan legislature, on the other. Calle Sarandí, a narrow shopping centre, connects the Plaza de la Constitución with the more recent Plaza de la Independencia, Montevideo's major square. The traditional gesture for distinguished foreign visitors is to place a wreath of flowers at the foot of the mounted statue of the hero of national independence, José Gervasio Artigas, in the centre of the plaza. Government House is on the right of the statue, the modernistic Victoria Plaza Hotel on the left. Facing the statue is the Palacio Salvo, the city's first skyscraper. Leading off the Plaza de la Independencia is the Avenida 18 de Julio, lined with shops, theatres, cafés, and business houses. Part way up the Avenida 18 de Julio, the Avenida Agraciada, cut diagonally through city blocks, connects with the marble legislative palace, the most lavish public building in Uruguay. Avenida Agraciada is Montevideo's modernistic showplace. At the end of Avenida 18 de Julio is an obelisk at the entrance of Parque José Batlle y Ordóñez, location of the football stadium.

The Old City

Transportation. The port is the hub of the city's international transport. It is also served by the airport at Carrasco. Four railroads converge on the city, and roads lead to other principal cities. Internally, buses, Montevideo's basic public transportation, taxis, and private cars, although directed by one of South America's few traffic-light systems, crowd the streets and avenues.

Population. The population of the department of Montevideo in 1860 was 58,000. By 1908 the population was 300,000, and by 1963 (the next census) it was about 1,200,000, representing 46 percent of the nation's total. The population in 1969 was 1,375,000. Because of immigration from the interior, it is growing at an annual rate of 16.7 per thousand, more than twice as fast as the rest of the country. Population density in the department is more than 6,900 per square mile.

In the 1800s Montevideo attracted immigrants of many nationalities, predominantly Spanish and Italians but also including Basques, Frenchmen, Navarrese, and Canary Islanders. The present population is predominantly white, mostly the descendants of the 19th- and 20th-century European immigrants.

Economy. The port of Montevideo handles the vast bulk of Uruguay's foreign trade. Most of the country's manufacturing industry is there, too. The steady influx of migrants from the countryside, coinciding with the serious economic crisis of the 1950s and 1960s, meant high unemployment (estimated at almost 8 percent in 1971), strikes, the inability of the government to finance municipal services, and general deterioration of the city. Electric power failures and bus stoppages were taken for granted. Frustration with economic deterioration resulted in the formation of Montevideo's revolutionary urban guerrilla group, the Tupamaros, in the 1960s. Yet, Montevideo's size gave Uruguay a metropolis with urban cultural and economic opportunities far exceeding those a country with such a small population otherwise could afford.

The products of the interior are shipped for direct use, processing, and export. About 90 percent of Uruguay's exports are wool, meat, and hides from its ranches. Numerous establishments in the capital process wool, and refrigerated packing plants in the Cerro district are equipped to prepare meats. In addition to export-oriented processing industries, Montevideo possesses the largest portion of Uruguay's internally oriented and economically depressed consumers' goods industries. Textile, shoe, soap, match, and clothing factories are scattered throughout the city. Wines and dairy products, mostly for local consumption, also are produced in Montevideo.

Principal exports

Uruguay's well-known state enterprises—under-capitalized because of the nation's galloping inflation, overstaffed as the result of political patronage, and operating under serious deficits—the ANCAP (Administración Nacional de Combustibles, Alcohol y Portland) oil refineries and cementworks, railway shops, and electric-power system are concentrated in Montevideo. Public employees are a large segment of the city's consumers. Much of the city's economy revolves around providing varied services for its large population, which is notably spread out territorially. The city's growth has urbanized and industrialized that part of the department lying outside the city. Nevertheless, truck gardens, vineyards, dairy and poultry farms, orchards, and commercial flower growers send products into the city.

Government. As the capital of the country, Montevideo is the seat of the principal institutions, agencies, and offices of the national government. The city itself is governed by an elected alcalde (mayor) and a municipal council that also has jurisdiction over the department.

Public utilities and services. Montevideo is one of the few South American capitals in which the public water supply, brought from the Río Santa Lucía is totally safe to drink from the tap, but the city's rapid growth has outstripped expansion of the water-pipe system.

Social services

Public health, sanitation, and welfare services have been among the best in South America as measured by such standards as the number of persons per physician, hospital beds per thousand, and infant mortality, but severe economic depression in the 1960s and early 1970s strained all agencies' abilities to cope with the growing needs.

Education. Primary and secondary education is free and compulsory but has not been able to keep up with growing needs. Higher education in Uruguay is available only in the capital, although plans for a university in the north were under way in the early 1970s. The Universidad de la República was founded in 1849. It has ten schools, including the schools of humanities and sciences, engineering, and medicine. The Universidad del Trabajo del Uruguay provides vocational training through industrial and night schools.

Cultural facilities. Montevideo has had theatres since the Casa de Comedias opened in 1795, followed by the San Felipe Theatre. The Solís Theatre, still in existence, was opened in 1856. The city also has the Museo Histórico Nacional (1900), Museo Nacional de Historia Natural (1837), the Museo Nacional de Bellas Artes (1911), and the Biblioteca Nacional del Uruguay (National Library), as well as the many plazas, buildings, and other historic sites.

The British, who occupied the city in 1807, published the first newspaper in Montevideo, *The Southern Star.* The city has had newspapers ever since, especially newspapers and other publications presenting the views of all political parties and factions. The media are now strongly supplemented by radio and television broadcasts.

In addition to Batlle y Ordóñez Park, site of the football stadium, recreational facilities include many other parks, as well as a line of beaches extending out to the Atlantic, where new resorts continue to arise.

Montfort, Simon de

Simon de Montfort, earl of Leicester and leader of the baronial revolt against Henry III of England, was the son of Simon de Montfort l'Amaury, leader of the crusade against the heretical Albigenses. Born about 1208 at Montfort in the Île-de France, Simon was wholly French by birth and education. On coming of age, he renounced to his eldest brother Amaury his claims on the family lands in return for the sole right to revive the Montfort claim to the English earldom of Leicester. This claim derived from his father's mother, Amicia, sister of Robert IV (died 1204), the last Beaumont earl of Leicester, whose lands had been divided between Amicia and her younger sister Margaret, countess of Winchester. King John had recognized Simon's father as earl (*c.* 1205) but had deprived him as a French subect (1207), and the Montfort claim had then lapsed.

Simon came to England in 1229 and, helped by his cousin Ranulf, earl of Chester, the tenant of the confiscated estates, obtained the honour of Leicester and did homage to Henry III in 1231, though he was not formally styled earl of Leicester until April 1239. He speedily became one of Henry's favourites, receiving an annual fee of 500 marks to compensate for the divided inheritance and exercising the hereditary stewardship at the coronation of Queen Eleanor (Eleanor of Provence; 1236). Henry arranged for his sister Eleanor to marry Simon on January 7, 1238, thus breaking Eleanor's earlier vow of chastity and offending the English noblemen, who

were not consulted. Henry's brother, Richard, earl of Cornwall, led an angry baronial protest, and Henry, alarmed, turned against Simon and Eleanor, driving them from England (August 1239). Simon went on crusade (1240–42) with Richard, with whom he was now reconciled, and won great prestige among the lords of the Latin Kingdom of Jerusalem, who asked their absentee king, the emperor Frederick II, to appoint Simon as his viceroy there. Returning to England, Simon joined Henry's disastrous invasion of France (1242), winning distinction by covering Henry's escape after his defeat at Saintes. Reconciled with Henry, and accepting an unfavourable settlement of Countess Eleanor's dower claims, Simon now made Kenilworth Castle (a royal grant) his headquarters. He cultivated the friendship of the radical reformer Robert Grosseteste, bishop of Lincoln, and took Robert's friend, the Oxford Franciscan Adam de Marisco, as spiritual director. Although regarded as a king's man, Simon was one of the committee of 12 appointed to handle the acute crisis of 1244 between Henry and his angry barons. He also took part in many important embassies to the French, papal, and imperial courts, and as a result he won many influential friends.

The influence of Grosseteste

In 1248 Henry asked Simon to pacify the English-held duchy of Gascony, in southwestern France. Simon, eager to join Louis IX's crusade, accepted reluctantly, stipulating for full powers as regent for seven years, without fear of recall and with full refund of expenses incurred. Treating the Gascon nobles as faithless rebels outside the law, he ruthlessly crushed the revolt and restored order; the Gascons appealed to Henry, accusing Simon of illegal procedure and oppression, and threatening to renew their revolt. The matter was complicated by Simon's personal contest with Gaston de Béarn, the leading rebel. Henry, frightened, recalled Simon for trial on the rebels' charges; the English magnates acquitted him (1252) and he returned to Gascony to suppress the renewed revolt, but Henry now terminated his lieutenancy. Simon, accepting a partial financial settlement, withdrew to France, though Henry had to implore his help in his own campaign against the rebels in 1253. Such was Simon's international reputation that when Louis IX's mother, Blanche of Castile, died (November 1252) while Louis was still on crusade, the French magnates invited Simon to succeed her as regent.

Henry's behaviour over Gascony, though not wholly unjustified, convinced Simon that Henry was unfit to rule, and the king's disastrous undertaking, at Pope Innocent IV's behest, to conquer Sicily for his son Edmund, strengthened this conviction. Discussions with Grosseteste, Marisco, and other Franciscan intellectuals had fired Simon's mind with visions of a new order in both church and state, and he joined the other leading English barons in forcing upon Henry the revolutionary Provisions of Oxford (June 1258). The reformers began well, but by October 1259 divisions appeared between the conservative wing, led by Richard de Clare, earl of Gloucester, that sought only to limit abuses of royal power, and the radical element, led by Simon, that sought to bind the entire baronage to observe the reforms forced upon the king and his officers. Simon exacerbated the quarrel by his arrogant vehemence and put himself in the wrong by attempting to use Henry's subordination to secure settlement of his own and his wife's justifiable personal claims on Henry. Henry, allying with the Gloucester faction, shattered baronial unity early in 1260, and Simon emerged leading the extremist defenders of the reforms. By October 1261 Henry had isolated Simon, who went abroad; but the king's annulment of the Provisions, after he had received papal absolution from his oath to observe them, revived general disaffection (1262), and Simon returned (April 1263) to lead a rebellion that restored the Provisions (July 1263). But baronial unity had vanished, and despite passionate support from the lesser barons, the county knights, the men of London and the Cinque Ports, and many clergy, Simon was forced to accept arbitration by Louis IX (December 1263). By the Mise of Amiens (January 1264) Louis totally annulled the Provisions and all consequent reforms: Simon rejected the award and after unsuccessfully attempting direct negotiations, defeated Henry at Lewes (May 14, 1264), capturing Henry and his son, the lord Edward.

Rebellion against Henry III

Simon then governed England by military dictatorship, striving unsuccessfully for a legal basis of consent, both by negotiations with Henry's supporters and by calling representatives of both shires and boroughs to Parliament (1265) to counterbalance his lack of baronial support. But his monopolization of power alienated his chief ally, the young Gilbert de Clare, earl of Gloucester, who joined the royalist Marcher lords and secured the Lord Edward's escape at Hereford (May 1265). By rapid and skillful manoeuvring, Edward isolated Simon behind the Severn, destroyed at Kenilworth (August 1) the large army coming to his rescue, and trapped Simon's little force at Evesham (August 4, 1265), slaying Simon and most of his followers.

The most outstanding English personality of his day, Simon is remembered as an early advocate of a limited monarchy, ruling through elected councillors and responsible officials, and of parliaments including county knights and burgesses as well as the great nobles.

KNOWLES, *Simon de Montfort, 1265–1965* (1965), a critical review of historians' ideas on de Montfort; and M.W. LABARGE, *Simon de Montfort* (1962), a good, general biography. CHARLES BEMONT, *Simon de Montfort, comte de Leicester* (1884), contains a valuable appendix of original documents, which has not been included in the English translation, *Simon de Montfort, Earl of Leicester* (1930).

(R.F.Tr.)

Montgolfier, Jacques-Étienne and Joseph-Michel

The Montgolfier brothers, sons of a wealthy 18th-century French paper manufacturer, invented the hot-air balloon, conducted the first free flights, and experimented with hydrogen-filled balloons. Their flights were spectacular applications of new concepts in physics and chemistry. Modifications and improvements of the basic Montgolfier design were incorporated in the construction of larger balloons that, in later years, opened the way to exploration of the upper atmosphere.

The Montgolfier family, originally from Frankenthal, Germany, settled in the 13th century in Ambert, Auvergne, where they introduced the paper industry. A member of the family had learned papermaking in Damascus during the preceding century while being held there as a slave after one of the crusades. In 1695 the family transferred the industry to the small town of Vidalon, near Annonay, in southern France. Joseph and Étienne were two of the 16 children of Pierre Montgolfier, whose paper factories insured the financial support of their balloon experiments.

The family's origins

Joseph-Michel Montgolfier was born on August 26, 1740, at Annonay, where, early in life, he showed talent

for chemical and mechanical experimentation; he developed, for example, a new technique for making the dye Prussian blue. After assisting his father in the family firm, in about 1770 he took over the management of a branch of the firm at Rives, where he introduced improvements in papermaking. He also invented a special air pump for removing paper from molds and a vacuum distillation apparatus. In 1771 he married his cousin, Thérèse Filhol, who, through her sound business sense, was an important asset to him. Since he was adept at new inventions, Joseph's attention eventually turned to the project that brought him fame rather than to day-to-day problems of industrial production. Undoubtedly a man of genius, he could solve physical or mechanical problems even though he lacked extensive formal education in science and mathematics; he even tried to build a steam-operated vehicle. Moreover, he developed basic insights in physics, such as the principle that motion is conserved when transmitted through two or more contiguous bodies.

Born at Annonay on January 6, 1745, Jacques-Étienne Montgolfier was educated in physics, chemistry, and architecture in Paris, where for a time he assisted in designing new churches and factories; he was also employed by a famous wallpaper firm. Although devoted to his brother, Étienne was much different in temperament. Charming, good-natured, and amiable in disposition, he made friends with the intellectuals of the day. In 1772 Étienne's father summoned him home to manage the paper plant at Vidalon; there he introduced a procedure for crushing paper pulp and began the production of vellum and drawing paper. These improvements soon attracted the attention and recognition of the inspector general of French industry.

It is not known exactly what event or idea led the Montgolfier brothers to entertain the idea of aerial navigation. But Joseph began the experiments, in which he was quickly joined by his younger brother, that resulted in the hot-air balloon. Often in collaboration, but sometimes working separately, the brothers conducted many different tests aimed at keeping heavy objects aloft. Having learned of the "inflammable gas" that was lighter than air (called hydrogen by Antoine Lavoisier in 1789), they found that it could easily inflate a paper or cloth container. But they could not prevent its escape through the thin, porous material; the gas also was expensive and cumbersome to prepare, and no one yet realized how dangerous it was to use. Joseph also thought of electrically charging large, air-filled containers so that an "electric fluid" would thereby be formed around them; this weightless zone would increase the buoyancy of the container, thus causing it to rise. Although he may not have realized that hot air expands and becomes lighter in density, Joseph nevertheless acted on the observation that the products of combustion generally rise. It is not known whether or not he thought of smoke as a special kind of gas; but in November 1782, in Avignon, he devised a means to inflate a small silk container with hot air by suspending it over a fire. He was then able to demonstrate in public the ascension of a three-to-four-cubic foot (0.08-to-0.1-cubic metre), oblong-shaped balloon that he had constructed of silk. At once he notified his brother Étienne in Annonay. In the coming months they built and launched even larger hot-air balloons with considerable success.

The first flights

On June 5, 1783, the two brothers launched, in the presence of local government officials in Annonay, a spherical balloon made of linen and paper; 30 feet (nine metres) in diameter, when inflated, and open at the bottom to receive hot air from a fire on the ground, the balloon rose about 6,000 feet (about 2,000 metres) and remained aloft for ten minutes. This event caused great astonishment in France. An official record was sent to the Academy of Sciences in Paris, which immediately invited the Montgolfier brothers to make a special demonstration. Their craft was later called a Montgolfière, or fire balloon.

While making preparations in Paris, Étienne, on August 27, 1783, assisted at the launching of the first hydrogen-filled balloon, which was invented by Jacques-Alexandre-César Charles, who also is noted in chemistry for his law relating the volume of a gas to its temperature. Charles had prepared the silk envelope by covering it with varnish, thus solving the problem of porosity that had baffled the Montgolfiers. His type of balloon was henceforth called a hydrogen balloon (and also a Charlière). On September 12 Étienne attempted to launch his own hot-air balloon for the Academy of Sciences, but it was destroyed on the ground by wind and rain. He then hurriedly constructed a new model made of reinforced linen. On September 19, 1783, in the courtyard of the palace at Versailles, academicians, and throngs of curious spectators (including Benjamin Franklin) witnessed the inflating and launching of an elaborately decorated, almost spherical balloon. About 57 feet high, it carried three passengers —a sheep, a rooster, and a duck—suspended beneath in a wicker basket; it floated for about 8 minutes and landed safely about two miles from the launch site. These first balloons could remain aloft only for short periods, since they were inflated over a fire. Weighted at the bottom for stability, they would quickly rise when released, and then, as the hot air dissipated, would float gently Earthward. Étienne then constructed a balloon to carry human passengers, and many of its features were incorported in later designs. Its large envelope of 79,000 cubic feet (2,300 cubic metres; inflated) was oval-shaped; suspended beneath the open neck, 16 feet (five metres) in diameter, was a circular gallery for carrying passengers, a stove for providing the hot air, and fuel of sticks and straw. Beginning on October 12, 1783, he conducted a series of methodically graded trial ascents from a Parisian garden, with the balloon secured to the ground by ropes between upright poles.

On October 15, he invited the physicist Jean François Pilâtre de Rozier to board his craft, which, tethered to the ground, rose about 80 feet (25 metres). This was, to the best of modern knowledge, the first time that man left the Earth. On October 19, another passenger accompanied Pilâtre de Rozier on further trial ascents, rising to a height of about 324 feet (99 metres). On November 21 occurred the first free flight by man: guided by Pilâtre de Rozier and François Laurent, marquis d'Arlandes, Étienne's balloon was launched from the jardins de la Muette in the Bois de Boulogne in Paris. After floating for about 25 minutes at low altitude over the city, it landed safely at La Butte-Aux-Cailles, a few miles to the south. (Étienne Montgolfier himself never made a flight.)

Meanwhile, in October 1783, Joseph, who was attempting to solve the problem of steering, conceived the idea that a propulsive force could guide a ship when afloat so that it need not drift at the mercy of the wind; hot air might be forced from one or more openings in the side of the ship opposite from the direction in which the ship was to go. Somewhat later he designed and partially constructed a large, lenticular-shaped, hot-air balloon that

could be more easily pointed in any desired direction and so float at will in the air. Joseph was invited to Lyons to supervise the construction of a giant balloon, named "Le Flesselles," after the government official who sponsored the project. It was 102 feet (31 metres) in diameter, 126 feet (38 metres) high, and 700,000 cubic feet (20,000 cubic metres) in volume, with a gallery large enough to hold six people, fuel, water buckets, and a stove to provide the hot air. After preliminary inflations and tethered ascents, made difficult by the cold weather, a manned flight took place on January 19, 1784, with Pilâtre de Rozier assisting Joseph Montgolfier at the controls. They were accompanied by five dignitaries, the balloon remained aloft 16 minutes; but when the fabric suddenly split, there was a rapid escape of hot air, which caused the balloon to descend abruptly, and Joseph was slightly injured. This was his only flight.

Later accomplishments

The Montgolfier brothers' remarkable balloons quickly attracted attention in Europe and gained for them national recognition. Joseph was named a member of the Academy of Sciences and Étienne a corresponding member of the National Institute in December 1783. King Louis XVI raised their father to the peerage, further honouring the brothers with this hereditary title. During the French Revolution, Joseph used his new authority to protect numerous persons from quarrelling factions and thus saved many lives. Étienne was named administrator of a new provincial subdivision, where he served his constituency with considerable independence and also saved numerous persons from execution and the family firm from confiscation.

In 1792 Joseph invented the hydraulic ram (a completely new device that forces running water to a higher level), and in 1801 he was summoned to Paris to assist in organizing the Conservatoire des Arts et Métiers, where he served as instructor and administrator. Étienne died on August 2, 1799, while enroute home to Annonay from Lyons. Joseph survived until June 26, 1810; he died at Balaruc-les-Bains, following a stroke.

The Montgolfiers' fire balloons drew attention to the technical problems involved in constructing lighter-than-air vehicles: how high a balloon of a given size could go; control of inflation, ascent, and descent; reinforcement of the envelope; and the interaction of volume, temperature, wind, and altitude. Many manned ascents were made with both hot-air and hydrogen balloons.

Short-lived was an attempt to combine a Montgolfière and a hydrogen balloon, in which a hot-air balloon that was used to regulate position and direction was suspended beneath a hydrogen balloon that provided buoyancy. The first flight of this craft ended in a fiery crash on June 15, 1785, and took the life of Pilâtre de Rozier, its inventor, who was attempting to cross the English Channel. Technical and safety problems received great attention in the subsequent development and construction of hydrogen balloons, which in turn opened the way to the scientific exploration of the upper atmosphere.

Joseph Montgolfier, . . . le lue en séance générale, le 11 mai 1814* (1814, reprinted 1883); FELIX DIGONNET, *L'Invention de l'aérostation à Avignon en 1782 et les premières ascensions dans cette ville* (1906), detailed on Joseph and Etienne, with information also on their families; LEON ROSTAING, *La Famille de Montgolfier, ses alliances, ses descendants* (1910, reprinted 1960); and the well-illustrated COMTE HENRY DE LA VAULX and PAUL TISSANDIER, *Joseph et Etienne de Montgolfier* (1926). The eyewitness account of BARTHELEMY FAUJAS DE SAINT-FOND, *Description des expériences de la machine aérostatique de MM. de Montgolfier*, 2 vol. (1783–84), should be consulted for a study of the first balloon flights. The technical problems encountered by the Montgolfiers, and those that followed them, are discussed by GASTON TISSANDIER in *Histoire des ballons et des aéronautes célèbres*, 2 vol. (1887–89). For a more recent study, see the fully illustrated CHARLES DOLLFUS and HENRI BOUCHE, *Histoire de l'aéronautique* (1932).

(Ch.Do.)

Montreal

The most populous city of Quebec Province and of Canada, Montreal is one of the world's most uniquely situated cities. The present city proper occupies about one-third of Île de Montréal (Montreal Island), the largest of the 234 islands of the Hochelaga Archipelago, one of three archipelagos near the confluence of the Ottawa and St. Lawrence rivers. Built around and up Mont-Royal, which rises 763 feet (233 metres) above sea level (some 660 feet above the island shores), its 58-square-mile (150-square-kilometre) area is interspersed with several independent cities and towns of the 462-square-mile metropolitan area that covers Montreal and other islands, as well as both shores of the St. Lawrence. Montreal is the major seaport on the St. Lawrence River and Seaway, lying between the navigable waters of the open Atlantic Ocean to the east and of the Great Lakes to the west. The population of the city, according to the 1971 census, was 1,214,352; and of the metropolitan area, 2,743,208, representing growths of 2 and 30 percent, respectively, during the preceding decade.

Montreal is said to be the second largest French-speaking city (French and English are Canada's two official languages) in the world (after Paris), a boast more or less belied by its increasingly cosmopolitan character. A stroller through various districts of the city might come to believe himself in Italy, China, or Greece, as he might in New York City or San Francisco. In some areas of this "second largest French-speaking city in the world," however, a French-speaking wanderer or worker must express himself in English to be understood fully. This phenomenon reflects decades of dominance over Montreal's economic life by the English-speaking minority. It also accounts in large measure for the growing agitation within the French community of the city and province for greater economic and political concession from the national government.

In spite of politics and unrest, Montreal remains a city of great charm, of vivacity, and of gaiety, one of the most appealing in North America, as well as one of unquestioned modernity in its physical appearance and way of life. Thus it was chosen as the site of the International World Exposition in 1967—Expo 67. No great objections were raised when the event was perpetuated for the public each summer under the title Man and His World —Terre des Hommes in French.

The history of Montreal. *The early settlement.* The site of Montreal was called Hochelaga by the Huron Indians when Jacques Cartier, a French navigator and the discoverer of Canada, visited it in 1535–36 on his second voyage to the New World. More than 1,000 Indians welcomed him on the slope of a mountain that he named Mont Réal, or Mont-Royal. More than half a century elapsed before other Frenchmen returned, this time with Samuel de Champlain, the founder of Quebec city. Hochelaga, it seems, had disappeared, replaced on the shores of the St. Lawrence by a settlement that Champlain called Place Royale.

The founding fathers

It was not until May 6, 1642, that Paul de Chomedey, sieur de Maisonneuve, founded today's Montreal. He built dwellings, a chapel, a hospital, and other structures, protecting the settlement against Indian attack with a stockade. He named the aggregate Ville-Marie.

The community was granted its first civic charter by King Louis XIV in 1644, and Chomedey became its first governor. The first hospital, the Hôtel-Dieu, was founded in 1645 by Jeanne Mance and the first school for girls in 1653 by Marguerite Bourgeoys. Almost immediately a society of priests, Les Messieurs de Saint-Sulpice, took charge of education for boys.

The real development of Montreal began during the first half of the 18th century. Land grants were made, and farming was developed outside the original fortifications. Colonization was initiated under the French seigniorial system, in which a landowner leased portions of his holdings to numerous farming families. For long, Montreal was a base for explorers and traders, and by the end of the 18th century outlying settlements—Saint-Henri and Lachine to the west and Longue-Pointe and Pointe-aux-

Central Montreal and (inset) its metropolitan area.

Trembles to the east—had taken roots, later to become part of the city or of the Montreal Urban Community.

By 1672 the population of Montreal had reached 1,200, but it did not obtain city status for another 120 years. The city surrendered peacefully to British forces in 1760 and, with all of New France, became part of the British North American empire in 1763. In November 1775, Montreal was occupied by American Revolutionary forces, who retreated in the spring following the abortive siege of the city of Quebec by Benedict Arnold and thus failed to secure Canada for the new United States. In 1796, Canada's first public library was opened in Montreal, and in

Central Montreal, looking eastward down Dorchester Boulevard with the Jacques-Cartier Bridge in the background.

the following year daily postal service was established between Montreal and the United States.

Beginnings of the modern city. In 1809, John Molson —entrepreneur, brewer, banker, carrier, etc.—linked Montreal and Quebec by water with the first Canadian steamship. The Bank of Montreal, the country's first, was founded in 1817, and the Lachine Canal, forerunner of the St. Lawrence Seaway, was started in 1821. In 1825, Molson, the "Montrealer *par excellence*," provided his city with a splendid theatre, and gas lighting appeared by 1838. A Board of Trade was founded in 1822, and three years later Montreal became the capital of Canada until 1849. On April 25 a mob put fire to the Parliament building, possibly on the ground that it had lost its vocation. The year 1847 saw telegraph links with the cities of Quebec and New York; 1853 a shipping service between Montreal, Liverpool, and the Continent; 1856 a railroad to Toronto; 1858 a transatlantic cable to Europe; and 1861 the city's first horse-drawn tramways.

Sequence of civic firsts

Fires destroyed hundreds of buildings in the early 1850s, and an economic slump provoked numerous bankruptcies in 1857. The present Confederation of Canada was proclaimed in 1867, and ten years later the city had its first labour strike and first telephone conversation with Quebec; it had its first electric lighting in 1882, electric tramways in 1892, and the first automobile along its streets and moviehouses along its sidewalks in 1903.

The 20th century. By 1900, Montreal's population reached 270,000, and it began to annex several cities, towns, and villages on its outskirts. It purchased St. Helen's Island (Île Sainte-Hélène) in 1908, the site, with two neighbouring man-made islands, of Expo 67. Montreal's famous ice-hockey teams, the Canadiens was founded in 1909, and by the early 1970s it had won more world championships than any other professional team. In 1922 several mergers gave birth to the Canadian National Railways Company (CNR), which, like the Canadian Pacific in 1881, established its head office in Montreal.

The world wars gave impetus to the economic life of Montreal, as they did to most industrial centres of North America, and in January 1947 the United States Senate authorized the nation to enter into a joint venture with Canada for building the St. Lawrence Seaway. In 1959 the need for a Montreal Metropolitan Corporation was recognized by the Quebec provincial government (which, like others in Canada, has exclusive jurisdiction over municipalities). The next year saw the opening of Metropolitan Boulevard, a throughway encircling Montreal. In 1962 construction was started on Le Métro, the Montreal subway that was supervised by engineers from the Paris Métro and inaugurated six months before the opening of Expo 67. With the growing recognition of Montreal as a major world centre following this universally acclaimed exposition, it became the first non-United States city to be awarded a major-league-baseball franchise. Its players first took the field in 1969 as the Montreal Expos.

The contemporary city. *Physical plan.* The layout of Montreal has been affected throughout its history by the river and the natural rises of the terrain from it, including the slopes of Mont-Royal. These factors produced a general southwest–northeast pattern of growth, and since its incorporation the city has been divided by St. Lawrence (or Saint-Laurent) Street (or Boulevard) into western and eastern sections. Such designations as street, avenue, and boulevard are virtually interchangeable in Montreal, and the ensuing confusion is enhanced by the occurrence of the place-names of thoroughfares and other city and suburban sites in both French and English.

Modernization of the city

Since about 1958 the centre of Montreal has been transformed significantly, abetted by post-World War II prosperity, by preparations for Expo 67 and the exposition itself, and by an administration intent upon grand designs. Built with the aid of U.S. capital and developers, Place Ville-Marie comprises a 45-story cruciform building and many underground shops, restaurants, and theatres, linked to which are nearby skyscrapers with similar underground complexes. Together, this new downtown provides the Canadian metropolis with an answer to New York City's Rockefeller Center, with an underground commercial, culinary, and artistic life among the most advanced in the Western Hemisphere. Similar change has spread throughout the city, often obliterating historic landmarks, but the city has preserved the historic centre known as Old Montreal. There, seekers after nostalgia stroll amid reminiscences of the past that are in striking contrast to the city's overall momentum into the vanguard of urban modernity.

The people of Montreal. The 1871 population of Montreal proper—about 133,000—increased some tenfold in the following century, but the pace of metropolitan planning in the early 1970s promised ongoing growth in addition to annexation of adjacent areas. Immigration from abroad practically ceased during World War I, but a steady flow of people continued from other parts of Canada and from the U.S. Although the birth rate among Canadians of French descent dropped markedly, immigration from the Continent reduced the percentage of Montrealers of British descent after World War II. French-speaking citizens currently account for more than 60 percent of the population, with the English proportion increasingly eroded by Jews, Italians, Germans, Greeks, central Europeans, and others. Religious affiliations generally follow ethnic traditions, with Roman Catholicism by far the dominant faith.

Social and political tensions

On the other hand, newcomers to Montreal quickly learn that English is the more practical tongue, for in Montreal as in most of Canada—except Quebec city and smaller centres of Quebec Province—English is the primary language of commerce and industry. The economic upper classes are mostly old Montreal-bred English-speaking families, with a sprinkling of French and others. The middle classes are more mixed, whereas the lower economic stratum continues to be made up mainly of French- and Irish-Canadians and of recent immigrants. Thousands of blacks have immigrated from the U.S. in recent decades, most of them settling in the lower part of Montreal-Ouest. The instabilities of Montreal and of Quebec Province as a whole are largely the result of the continuing sociolinguistic separateness of and economic disparity between the two major ethnic groups. Majority political power has been achieved by the French community, but equivalent weight in other areas has been slower to arrive.

The city's economy. Montreal is a corporate-headquarters city, especially for the largest Canadian banks, railroad lines, and insurance companies, as well as for the International Civil Aviation Organization, the trade association of the world's major airlines. Its importance as a shipping and an industrial centre often is overlooked, however. The centuries-long colonial fur trade that penetrated the new continent to its westernmost territories formed the city's earliest commercial ventures, while soapmaking, brewing and distilling (among John Molson's main civic legacies), and wood and leather fabrication are long-time Montreal industries. Innumerable other products of a modern manufacturing economy emanate from the city's factories, along with millions of gallons of processed petroleum each day from Montreal East refineries.

Shopping areas abound throughout the city, in the more remote residential sections as well as throughout the supermodern underground city of streets and shops that has aided Montrealers to carry on in spite of the five to ten feet of snow dumped on the city each winter. This deluge of snow from November through April is among the most significant factors in Montreal's life, costing the city an average of $5,000,000 to $8,000,000 annually to remove it from the approximately 1,000 miles of streets. In early March 1971 the entire city was paralyzed, forcing police to use snowmobiles throughout the entire city and Les Canadiens to postpone a game for the first time in their history.

Municipal and regional administration. From the present city hall, sixth in the city's history. Montreal is governed by a mayor and a 52-member council, all elected for four years, and a six-man executive committee selected by the council. A Montreal Urban Community replaced the Montreal Metropolitan Corporation in 1969. Its responsibilities, for the whole of Montreal Island and Bizard Island, to the north, includes assessment and tax collection, traffic control, water and sewage services, police and fire protection, antipollution activities, and the like. The Urban Community is governed by a general council of 82 members (54 for Montreal proper, 28 for the suburbs) and an executive committee of 12 members (7 from Montreal, 5 from the suburbs).

The entire metropolitan area, as defined by the Canadian Bureau of Statistics and reaching beyond the Urban Community, embraced 23 cities (including Montreal), 34 towns, nine villages and parishes, and one Indian reserve. The changes in the region's economic structure and increasing business and white-collar employment, intensified by the growing modernization of the city, have brought about some of the main administrative problems in recent years. The French-speaking majority, most of whom were relegated to blue-collar jobs for decades, reacted to this historical pattern with growing hostility.

Public transportation. The perennial grumbling of Montrealers about municipal transportation is more an exercise of democratic rights than a reflection of reality. Compared with other large cities, bus and Métro lines allow easy movement throughout the area at relatively low cost. The 400 Métro cars serve three lines running a total of 21 miles under the city and to Longueuil on the south shore of the St. Lawrence. Each of the 22 stations is different in architectural design and artistic decor. Public transportation dates from 1847, and by 1868 buses mounted on sleighs replaced rail cars during the winter. By 1894 the entire system had been electrified and the last horsecars withdrawn from service.

The modern Métro

Educational and health services. As throughout Quebec, a dual school system for Roman Catholic and Protestant students is supported from the public treasury. The language of instruction—French or English—rigidly follows the religious division.

Montreal is probably the outstanding city of Canada in terms of higher education. McGill University (founded 1821) and Sir George Williams University (1929) offer mainly English-language instruction, whereas the Université de Montréal (1876) and the Montreal branch of the Université du Québec (1968) serve the French-speaking population. The city has some 30 general hospitals, and there are faculties of medicine in McGill and Montréal universities.

Cultural life and institutions. With its Place des Arts, completed in the 1960s, its museums, public libraries, art galleries, bookshops in most European languages, symphony orchestra, publishing houses, theatre companies, and free public lectures at the universities, Montreal must be accounted a major culture centre.

The Place des Arts is a complex of concert and theatre halls in downtown Montreal. Art instruction is given, among other places, at the Museum of Fine Arts. Besides a conservatory of music, faculties or schools of music offer instruction at the universities. The Man and His World exhibition, the site of Expo 67, has a museum of contemporary art.

Some 40 years ago only three real bookshops in French and as many in English existed, but today they are found everywhere, in all districts and shopping centres; and "new Canadians," as recent immigrants are called, can buy books, reviews, and magazines in their native languages. The Civic Library has several branches, and more than 25 special libraries are scattered throughout the city. Publishing houses, English and French, are prospering.

In addition to being readers of books, Montrealers are great readers of newspapers. On weekdays they may choose from among four morning French-language newspapers and one in English; in the afternoon there is one in each language. On Sundays they have a choice among four in French, one in English, and several special-feature journals. Foreign newspapers, reviews, and magazines—mostly from the U.S., France, and Britain—are widely available, in addition to some 60 weekly or monthly scandal and gossip sheets. Montreal has about 20 television and radio stations, besides the headquarters of the French-language network of the Canadian Broadcasting Corporation—Radio-Canada in French.

In addition, Montrealers find time for sports, both as spectators and as practitioners. Hockey and baseball are foremost, but other indoor and outdoor sports have many adherents. In winter the slopes of the Mont-Royal are covered with women, men, and children. Montreal has also two very popular racetracks, and golf courses sur-

round the city. In 1976, Montreal was to be the site of the international Summer Olympic Games.

BIBLIOGRAPHY. Firsthand accounts are the narrative journals of JACQUES CARTIER and CHAMPLAIN, the Jesuit *Relations* and the *Histoire de Montréal* of DOLLIER DE CASSON (1672). Standard works include: W.H. ATHERTON, *Montreal*, 3 vol. (1914); STEPHEN LEACOCK, *Leacock's Montreal*, rev. ed. by J. CULLITON (1963); and K. JENKINS, *Montreal: Island City of the St. Lawrence* (1966). JOHN IRWIN COOPER, *Montreal: A Brief History* (1969), is a good summary although some interesting details are omitted. Also of interest is the article on Montreal in the *Encyclopedia Canadiana* (1957; rev. 2nd ed., 1967). The numerous publications of the MONTREAL ECONOMIC RESEARCH BUREAU, including the annual *Abridged History of Montreal*, are both informative and reliable.

(C.Fe.)

Moon

The Moon, like the Earth and the other terrestrial planets (Mercury, Venus, and Mars), has a solid body, nearly spherical in shape. The Moon's radius is about 1,738 kilometres (1,080 miles), only 0.2725 that of the equatorial radius of the Earth; this difference, with the fact that the Moon's mass is only $\frac{1}{81.3}$ of the Earth's mass, is largely responsible for the difference between the atmospheres of the two bodies. The Moon is a natural satellite of the Earth, but it is sometimes described as a planet, because it is large compared to most known, natural, planetary satellites and, because of its size, has many of the properties of a small planet such as Mercury. The escape velocity of a particle from the surface of the Moon is about 0.213 that from the Earth, and, if past temperature conditions were much like present ones, the gas molecules and atoms of any early lunar atmosphere would have slowly escaped in a time short compared with the Moon's lifetime (see below).

The Moon's mean density is about 3.34 grams per cubic centimetre, close to the density of the Earth's mantle; but studies of rocks returned from the Moon's surface indicate that the Moon's interior composition is not the same as that of the Earth's mantle and that in the Moon there is only a very small (possibly no) core. Many of the rock samples retrieved from the large, dark, relatively smooth areas of the face of the Moon called the maria are best described as basalts, but they are quite uncharacteristic of any known terrestrial rock or meteorite. They are about the colour of graphite—charcoal gray.

The lunar rocks differ from those on Earth

The whole Moon reflects less than one-tenth of the light that falls on it. The low reflecting power of the Moon had been known for a long time from estimates of its overall albedo. "Albedo" is a Latin word meaning "whiteness." While it is relatively easy to measure the relative brightness, or reflecting power (normal albedo), of flat surfaces illuminated and viewed normally in the laboratory, it is more difficult to assess the overall Bond albedo of a spherical planet. The brightness of the Moon varies through its phases because of the roughness of its surface and the resulting variable amount of shadow. The Full Moon, when the Sun, Earth, and Moon are in the same line, is ten times as bright as the Moon at First Quarter, the position of the satellite when it has completed one-quarter of its orbit around the Earth. When ¾ of the orbit is completed, the Moon is said to be in the Last Quarter.

This article is divided into the following sections:

I. The motion of the Moon
  The apparent motion of the Moon
    The month
    Optical and physical librations
  The actual motion of the Moon
    Pre-Newtonian history
    Analytic theory
    Numerical lunar theory
    Interpretation of small irregularities in the motion
II. The mass and gravitational field of the Moon
  Underlying theory
  Discovery of the lunar mascons
III. The physical nature of the Moon: selenology
  Observations from the Earth and from space vehicles
    Limits of resolution
    Small-scale details
    Results from manned lunar landings
    Data from closeup photographs
  Types of lunar feature
    Lunar craters
    Lunar lineaments
    Temporary or transient changes on the Moon
    The photometric function
    Lunar polarization studies
    Infrared (heat) studies
    Analysis of returned radar signals

I. The motion of the Moon

THE APPARENT MOTION OF THE MOON

The lunar orbit is nearly circular, with the Earth as centre, the average eccentricity being only 0.0549, but it is more accurately described as an ellipse focussed on the Earth. In relation to the Sun, however, the Moon sweeps in a sinuous path, because, as it orbits the Earth, the centre of gravity of the Earth–Moon system (considered as a double planet) travels in an elliptical orbit around the Sun.

The month. The Moon's motion around the Earth may be judged by reference to the Sun or to the stars. The Sun appears to move each year across a background of fixed stars simply because all Earth-based observers are moving about the Sun once every 365¼ days, approximately. The Moon also moves across the sky in front of the remote stellar background, but its motion appears to be faster, because it completes its orbit of the Earth in a fraction of a year. A celestial meridian is an imaginary line in the celestial sphere, fixed relative to the stars, similar to a meridian denoting longitude on Earth. The Moon will be observed to cross any particular celestial meridian every 27.32166 days, which is the sidereal period of the Moon, or sidereal month. An observer on Earth sees only one-half of the lunar globe, and, because the Moon also rotates about its axis in 27.32166 days, this half is always approximately the same. Its axial rotation and sidereal period are said to be synchronous.

By the time the Moon has completed one revolution of the Earth relative to the stars, the Earth–Moon system has itself moved a fractional distance along its orbit around the Sun. Therefore, the time between successive Full Moons or successive New Moons (called syzygies) is a little longer than the time between successive lunar crossings of the imaginary celestial meridian. The period between one Full Moon and the next Full Moon, called the synodic period, synodic month, or lunar month, is 29.5306 days. The synodic period is measured using the Sun–Earth–Moon alignment as reference.

Direction of revolution

Viewed from the north, the Moon revolves in counterclockwise fashion around the Earth, as does the Earth around the Sun. The senses of rotation of the Earth and the Moon on their axes are also the same—counterclockwise if viewed by an observer in the northern celestial hemisphere. Because the Earth spins from west to east in a time that is short compared with the synodic month, the Moon, like the Sun and stars, rises in the east and sets in the west, even though its motion relative to the stars is from west to east.

If the orbital plane of the Moon were in the ecliptic (the plane of the Earth's orbit around the Sun), there would be a lunar eclipse (caused by the Earth's shadow) at the time of every Full Moon. The lunar orbit is inclined at 5°09′ to the ecliptic, and the ascending and descending nodes of the Moon's orbit—the points at which the Moon crosses the ecliptic into the northern and southern celestial hemispheres, respectively—regress (move clockwise

if seen from the north) to complete a whole revolution after 18.6 years. The interval of time between the Moon's successive crossings of a given node is referred to as the tropical month. The inclination of the Moon's orbit to the ecliptic causes lunar eclipses to be less frequent than they would be if the inclination were zero; the regression of the nodes, caused principally by the disturbing gravitational force of the Earth's equatorial bulge, leads to a repetition of eclipse phenomena every 18.6 years. This period is known as the saros (see ECLIPSE, OCCULTATION, AND TRANSIT for further details).

Earth–Moon distance

The mean Earth–Moon distance is 384,400 kilometres (about 238,900 miles), but, because of the elliptical shapes of the orbits of both the Moon and the Earth, the actual distance between them varies from 363,000 kilometres to 406,000 kilometres (226,000 to 252,000 miles). At its closest approach to the Earth in any one circuit, the Moon is said to be at perigee: at its most distant it is at apogee. The anomalistic month is the time interval between two consecutive perigee or apogee passages.

Optical and physical librations. The Moon rotates on its axis at a nearly uniform rate, but its orbital motion is much less uniform. Its orbit speed near perigee is greater, and that near apogee less, than its mean orbital speed of 1.03 kilometres (0.64 mile) per second. Hence, to a patient observer on the Earth, the Moon appears to oscillate as the orbit speed loses or gains on the constant rotation and shows more or less of its eastern or western limbs (apparent edges of the disk) at different positions in its orbit. When the Moon is north of the ecliptic, more of the lunar southern hemisphere can be seen; when to the south, more of the northern polar regions of the Moon. Furthermore, the observer can move from pole to pole, or from east to west, on the Earth, adding a small amount to the total, about 57 percent, of lunar surface visible from the Earth. The apparent oscillations of the Moon are known as optical librations and can amount to Moon-centred angular displacement of about 6.8 degrees in latitude and about 8° in longitude.

The Moon also has a very small but real oscillation, known as the physical libration, about its centre of mass. The physical libration amounts only to a few hundredths of a selenocentric (*i.e.*, moon-centred) degree and arises largely because the distribution of mass in the Moon is not quite that of spherical symmetry. There is more mass in a unit section around the Earthward-directed axis of the Moon than there is along either of the other principal lunar axes in the plane of the sky. This is why one face of the Moon persists in pointing toward the Earth: the gravitational pull of the Earth on the excess mass tends to restore the Moon to its mean orientation with respect to the Earth following any small movement away from that orientation.

The harvest-Moon phenomenon

The so-called harvest Moon is the Full Moon occurring on or nearest to September 23, the autumnal equinox. At that time, the apparent motion of the Moon is such that a terrestrial observer in the Northern Hemisphere may witness a minimum delay in the time of the Moon's rising on successive evenings, and, if the Moon is full, the phenomenon can be notable. (G.Fi.)

THE ACTUAL MOTION OF THE MOON

The mathematical treatment of the Moon's actual geocentric motion is called the lunar theory. Customary astronomical terminology distinguishes between an analytic procedure, called a theory of general perturbations, and a numerical method, called a theory of special perturbations. Because of the Moon's nearness to Earth and of its rapid angular motion, the lunar theory has long played a major role in formulating and testing dynamical theory.

Pre-Newtonian history. In ancient times, the Moon's phenomena were of great religious importance. Thus, considerable attention was paid to its motions; and the observations made were of an exactitude unsought in recording terrestrial phenomena. The Babylonians devised numerical methods for predicting eclipses and heliacal risings. The Greek astronomer Hipparchus in the 2nd century BC discovered the eccentricity of the lunar orbit, the motions of perigee and node, and the inclination of the orbital plane to the ecliptic. He explained the motion as being uniform in a circular orbit with the Earth placed eccentrically, and this was adequate to represent the observations then available. The numerical values of the parameters were derived from eclipse observations, some dating to Chaldean times. Although his results were superior to previous attempts, the restriction to eclipse observations led Hipparchus to an incorrect value of eccentricity, through inability to distinguish the major inequality (departure from uniform motion, true value 6.29 degrees), due to eccentricity, from the greatest solar perturbation. The latter inequality, called evection (1 ° 27), was discovered by the Greek astronomer Ptolemy (flourished mid-2nd century AD). Little significant improvement in the knowledge of the lunar motion was secured until the 16th-century Danish astronomer Tycho Brahe discovered the other great inequality caused by solar attraction, called the variation. This term, whose amplitude is 0 ° 66, vanishes when the Moon is new, full, or in quadrature. The explanation of these inequalities by adequate treatment of the Moon's motion required the discovery of universal gravitation.

Analytic theory. The analytic treatment of the lunar motion is carried out in two stages. In what is termed the "main problem," it is assumed that the Sun, Earth, and Moon behave as point masses and that the barycentre, or centre of gravity, of the Earth–Moon system describes a fixed ellipse around the Sun. After the solution of the main problem, the remaining effects are introduced as small corrections to the main solution. These effects include the perturbing forces of the planets acting on both Earth and Moon, the forces caused by the irregular shapes of Earth and Moon, corrections due to use of a non-inertial coordinate system, and relativistic corrections.

The solution of the main problem gives the coordinates as harmonic series in which the arguments are linear combinations of the time-variant angles l, l', F, and D. The periods of revolution of the arguments l, F, and D are the anomalistic, draconic, and synodic months. That for l' is the anomalistic year in the Earth's heliocentric motion. The series coefficients are power series in these parameters: e (= 0.055) the eccentricity and γ (= 0.045) the sine of half the inclination of the lunar orbit, m (= 0.075) the ratio of average angular velocities of Earth and Moon, α (= 0.0025) the ratio of average geocentric distances of Moon and Sun, and e' (= 0.017) the eccentricity of the Earth's orbit. The values of these parameters are determined from observation. The perturbations developed in the second stage of the analysis introduce the planetary orbit periods and the motion of the Moon's node into the arguments, as well as additional secular effects in the harmonic terms of the solution to the main problem.

A purely algebraic method is elegant and permits rigorous use of improved parameter values but is very laborious. It is more common to adopt numerical values for one or more of the parameters (particularly m) from the outset, relying on algebraic approximations to the effects of changes in these parameters.

Isaac Newton based his theory of gravitation largely on the comparison of the motion of Moon with that of bodies falling freely near Earth. He succeeded in proving that the principal periodic inequalities, as well as the motions of node and perigee, were caused by the solar attraction. Although his work produced new inequalities that were not previously deduced from observations, the motion of perigee was only about half the observed value. Extant manuscripts indicate that this disparity was later reduced to about 8 percent. Newton's theory was published in geometrical form in his *Principia*, but the method of fluxions (developed later into the integral calculus) was probably used in the actual derivation. No substantial advance was made beyond Newton's work until 60 years later, and further improvements followed.

In the 19th century, the outstanding lunar theories were those obtained by Peter Andreas Hansen, by Charles Eugène Delaunay, and by George William Hill and Ernest William Brown, many such advances being now known by

the names of the distinguished scientists responsible. Hansen's theory was the most nearly numerical of the analytic theories and was of greater accuracy than any other before Brown; it was used internationally from 1862 to 1922. Corrections by Simon Newcomb were applied after 1883. Hansen's work has served as the basis for orbit computations for artificial satellites.

The most complete algebraic development of the lunar theory until the current time was the monumental work of Delaunay, which was never adequate for comparison with observations but which has been valuable in theoretical studies, the extension of other lunar theories, and the discussion of the orbits of natural satellites of other planets.

In the late 19th century, Hill developed methods with which results of given accuracy could be achieved with much reduced labour. These methods have been effective in the discussion of the general problem of three bodies (see CELESTIAL MECHANICS) as well as in the practical solution of the lunar problem. The two principal features were (1) the introduction of the value of the ratio of the mean motions of the Earth and Moon from the outset to avoid convergence difficulties and (2) the use of a rotating rectangular coordinate system. Hill developed a rather elegant method of determining the motion of perigee that was also applied by John Couch Adams to the motion of the node. Hill's methods were used by Brown to develop the lunar theory that has been generally used to compute the coordinates of the Moon since 1923, although the theoretical motions of node and perigee were still unsatisfactory and were replaced by the observed values.

Brown's series contain about 1,500 terms, five times as many as in Hansen's theory. The evaluation of these series is very laborious, and Brown, like some of his predecessors, prepared tables for the simplification of this work. They filled 650 quarto pages, and one man working alone could extract the coordinates just fast enough to keep up with the real Moon. The advent of the digital electronic computer has relieved this burden and also made feasible the direct evaluation of the series. Direct calculations of the coordinates for the years 1952–71 were compiled by the U.S. astronomer Wallace J. Eckert and coworkers, and these have been contained in the national ephemeris volumes since 1960. A correction due to the variability of the Earth's rotation rate was introduced in this computation.

When Brown's solution was completed, the accuracy was more than adequate for comparison with the best observations, but subsequent improvements in observing techniques have surpassed the accuracy of the theory. Eckert and his collaborators determined corrections to Brown's theory, but studies during the late 1960s have indicated that further extension to higher accuracy may be unfruitful. An entirely new solution of the main problem that contains over 6,000 terms, including those as small as 0″.00002 (about four centimetres), has been completed. It had not yet been published at the time of Eckert's death in 1971.

Use of computers

Recent innovations in the usage of electronic computers have brought a resurgence of interest in the purely algebraic approach abandoned after Delaunay. The technique of non-numeric manipulation has been applied to the complete solution of the main problem, particularly by André Deprit, who has subsequently attacked the problems of the second stage in the solution process. Deprit's theory contains not only the coordinates but also the necessary functions for determining or applying corrections to the lunar orbit parameters, an important innovation.

Numerical lunar theory. Although strictly numerical theories have long been constructed for some solar system objects, this was impractical for the lunar motion before the development of the electronic computer. The nearest approach to a special theory was the attempt by the English Astronomer Royal George Biddell Airy in 1883. The attempt was unsuccessful, and the idea was abandoned.

In recent years, the necessities of space exploration have been primarily responsible for the application of numerical integration of the equations of lunar motion, as the available general theories are now inadequate for high-precision usage. The first such widely available ephemeris in practical use was constructed by J. Derral Mulholland and collaborators, who pioneered this method. The procedure has the advantage of arbitrarily high precision but the disadvantage of uncorrectability; changes in parameter values require a completely new integration to be performed.

Interpretation of small irregularities in the motion. Study of the lunar motion not only provided Newton with the key to universal gravitation but has more recently shed light on the dynamics of Earth's rotation; shown up flaws in the theory of the Earth's heliocentric motion; and, in conjunction with new observing methods of unprecedented accuracy, promises in the near future to provide information on the interior structure of Earth and Moon and a possible test between relativity theories.

In the 19th century gravitational theory could not account for all of the observed motion. For some time it was thought that this was due to some oversight in the theory, but it was later shown to be due to fluctuations in the Earth's rotation. The magnitude of the effect on the observed motion of a celestial object is greater for more rapidly moving bodies, so it first appeared in the lunar motion. From 1954, the lunar motion was used to correct the time determined by the rotation of the Earth, although by the 1970s this practice was being replaced by the use of atomic clocks.

Much smaller discrepancies in the lunar theory are now observable than was heretofore possible because of the introduction of the two new observing methods of grazing occultation and laser ranging. A grazing occultation occurs when the Moon occults a star at the edge of its disk, so that the star disappears behind lunar mountains but reappears in the valleys between. This method provides latitude measures the accuracy of which is limited only by the knowledge of the star's position and thus comparable with the accuracy of photoelectric longitude measures from normal occulations. These data are being applied to improve the parameters of the lunar orbit, the location of the equinox, knowledge of the shape of the Moon, and of the effects of tidal friction in the Earth.

The Apollo 11 crew deployed a reflector array on the lunar surface (see also below), which permits direct distance measures from a laser-equipped telescope on Earth to a fixed point on the Moon. Similar arrays were later landed by Luna 17, Apollo 14, and Apollo 15. A short laser light-pulse is emitted through the telescope and reflected off the lunar target back to Earth, where the light travel-time is measured with high precision. Such measurements, first made at Lick Observatory, are now being made regularly from the McDonald Observatory with a resolution of ±30 centimetres (12 inches); higher precision is achievable. Other observatories are expected to establish regular programs. After these data are used to improve the lunar orbit parameters, qualitatively new irregularities of still smaller size will be observable, including the effects of solid-body tides in both Earth and Moon; the rotational irregularities of both bodies (symptomatic of peculiarities in internal structure); and tectonic motions of the Earth's crust. In addition, just as the lunar motion provided a decisive test for Newtonian dynamics, these new observations will provide a test between alternative theories of realistic dynamics, since the Brans-Dicke scalar-tensor theory and the Einstein theory predict lunar motions that differ by amounts of the order of one metre (about three feet). (J.D.Mu.)

II. The mass and gravitational field of the Moon

Several space probes had flown past or made physical contact with the Moon before the Soviet probe Luna 10 in April 1966 became the first artificial lunar satellite. Successive orbital rendezvous with the Moon were then made by several space probes, the orbits of which have yielded information about the Moon's mass and gravitational field.

UNDERLYING THEORY

The Moon is spherical to within a fifth of 1 percent of its radius, and it is a reasonable assumption that it is also essentially spherically symmetrical. The gravitational potential (indicated V) at a distance r from the centre of a spherically symmetrical planet of mass M is equal to that due to a similar mass at the centre of the planet; that is, if G denotes the gravitational constant, $V = -GM/r$. The gravitational force (F) is given by the negative gradient of V, $-\partial V/\partial r$ (rate of change of potential with distance), and which gives $F = GM/r^2$. Gravitational attraction is a force that varies with the inverse square of the separation between two point masses. Now, the gravitational force exerted on a small unit mass by a planet of mass M is measured by multiplying the acceleration (g) due to the gravity of the planet by that unit mass. For points at a distance (r) greater than the radius (a) of the planet—that is, outside the surface—acceleration (g) is equal to the product of the mass M and the gravitational constant divided by the square of distance: $g = GM/r^2$. This formula for g shows that, as an object approaches the Moon, the radial acceleration of the object increases rapidly as r decreases to its final, minimum value equal to the radius of the Moon, and the final value of g, the acceleration that is caused by gravity at the surface of the Moon, is a function of the mass M and radius a of the Moon.

As lunar probes approached the Moon, radio frequency signals from them were received on Earth, and measurements of the final phases of the acceleration of the vehicles, as they fell freely, allowed improved estimates to be made of the gravitational force from the Moon. The assumption that the Moon is spherical is not, however, strictly correct, and the final value of the radius, r, at any particular place of impact may be less than or greater than the mean radius. Observations of the Moon-orbiting vehicles have shown that even the interior departs slightly from spherical symmetry. Thus, a single encounter of the type described cannot be used to determine the Moon's mass to a high degree of accuracy.

The Earth and the Moon describe elliptical paths around their common centre of gravity and the semi-major axes of the Earth's and Moon's ellipses around the centre of gravity of the Earth–Moon system are in the ratio of the respective masses of the Moon and the Earth. The mass of the Moon (7.35×10^{25} grams [about 8×10^{19} tons]) may be determined from knowledge of the distance (384,400 kilometres) of the Moon, the distance (4,670 kilometres) of the joint centre of gravity from the centre of the Earth, and the mass of the Earth (about 6×10^{27} grams). Determinations of the mass of the Moon have been based upon the trajectories of planetary space probes departing from the Earth–Moon system, beginning with the Mariner 2 vehicle in 1962.

Effects of gravitational irregularities on satellite orbits

For less than half its orbit period, while the satellite is above the far side of the Moon, the radio signals from a lunar satellite are, in general, lost. Information on complete orbits may nevertheless be built up from those signals that are monitored. The manner and extent in which observed orbits differ from ellipses are functions of the Moon's particular gravitational irregularities and the gravitational action of the other astronomical bodies (principally, the Earth) on the lunar satellite.

The motion of a satellite around the Moon is made more complicated because the Moon, in addition to presenting more mass along and around the Earth-directed axis than in either of the other, mutually perpendicular axes, has a noncircular equator. More precisely, if the Moon's moment of inertia about the Earth-pointing axis of inertia is A, that about the perpendicular axis, which is approximately in the plane of the orbit, is B, and that about the rotation axis is C, then A is less than B, and B is less than C. Although it is not possible to determine any of these moments of inertia directly, ratios such as $(C - A)/B$ have been derived from studies of physical librations. Studies of the motions of close lunar satellites have, in addition, yielded values of the functions $C/Ma^2 - (A + B)/2Ma^2$ and $(B - A)/Ma^2$, and, by combining the two methods, it is possible to derive the important ratio C/Ma^2. The value of this ratio is 0.4001 and the amount by which this differs from the value 0.4000, which corresponds to a sphere of uniform density, limits the nature and size of the Moon's core. If the Moon had an iron core, for instance, its radius would probably have to be less than one-fifth of the Moon's radius.

DISCOVERY OF THE LUNAR MASCONS

Formulas such as C/Ma^2 describe the bulk properties of a planet but give no information about the detailed distributions of mass in the planet. Methods of spherical harmonic analysis have been applied to investigate how the gravitational potential of a planet differs from that of a spherically symmetrical body. The potential may be expressed as a mathematical series of terms involving the position of an artificial satellite in its orbit and the constants describing the orbit. Low-order harmonics give terms in the series, and these are important in the case of features such as an equatorial bulge; progressively higher order harmonics show, in a close satellite's motion, progressively smaller scale gravitational irregularities. The more gravitationally complex a planet is, the more numerous the observations of satellite positions at given times have to be in order that the harmonic-series equations may be solved.

The points at which a satellite crosses the equatorial plane of the Moon are called the nodes. They rotate around the Moon's polar axis as a consequence of the low-order departures of the Moon from sphericity. A circumlunar satellite in an orbit inclined to the lunar equator so as to pass vertically over a predetermined, maximum latitude passes vertically, at some time during the course of many orbits, over all parts of the Moon on this selected parallel of latitude.

Space vehicles have been placed in orbits highly inclined to the Moon's equator and thus have been in a position to survey a large fraction of the Moon. Irregularities in the motion of one such satellite were noted in 1968: when it passed over certain of the maria, the inwardly directed radial acceleration had shown small differences that appear to be due to the presence of excess mass (gravitational anomalies) in the Moon. It was suggested that the anomalous accelerations were a consequence of concentrations of mass—mascons—below the points in the orbit at which the residual accelerations were found. A big mascon was associated with Mare Imbrium. Analyses of later lunar satellite orbits showed that there are mascons associated with the Maria Orientale, Serenitatis, Crisium, Smythii, Nectaris, and Humorum, and lesser ones with the crater Grimaldi, Sinus Aestuum, Mare Humboldtianum, an area north of Theophilus, and one east of Vendelnius. (Investigation of gravitational anomalies on the far side of the Moon is difficult.) It is also known that in one or two cases, notably that of Mare Orientale, which has a concentric-ring type of structure composed of alternate areas, or annuli, of lunabase (dark, mare-type material) and lunarite (brighter, highland-type material), the lunabase displays positive anomalies, while the highland, lunaritic zones display negative anomalies (weaker gravity).

A positive or negative gravitational anomaly can be produced in a number of ways. Geophysicists attempt to match the observed gravity profiles of parts of the Earth with those computed for particular models of subsurface structure and density contrasts. Independent geological or geophysical evidence of crustal structure can be of great assistance in this procedure. Unique models are even then only rarely determined. In the case of the Moon, even the topographic profile of a mascon site is not well-known. In the absence of much relevant information it is uncertain, for instance, whether mascons derive from very dense, deeply buried, condensed material or from near-surface accumulations of dense but more widely dispersed material.

Extensive basic lava flows in the prominent mascon area Mare Imbrium have been described (see below). All the positive gravity anomalies are associated with areas that are predominantly of mare-type material, the lunabase. (On the other hand, not all areas of lunabase display

anomalies.) It seems reasonable to conclude that lateral transport of mass has occurred in some places on the Moon. Processes that might have been involved are meteoric impact, the differentiation of material, the migration of magma (molten rock), and the eruption and flow of lava. An observer on Earth with normal, unaided eyesight can distinguish the separate, dark maria and the bright highland areas of the Moon. With a magnification of a few times it is possible to locate other features—for example, the bright ray craters Tycho (diameter 85 kilometres [53 miles]) and Copernicus (diameter 92 kilometres [57 miles]) at Full Moon or the Apennine Mountains (up to 4,000 metres [13,000 feet] high and several hundreds of kilometres in lateral extent) at First Quarter, when shadowing throws them into relief.

III. The physical nature of the Moon: selenology

OBSERVATIONS FROM THE EARTH AND FROM SPACE VEHICLES

Limits of resolution. Lunar craters of the order of 100 metres (300 feet) in diameter may be seen from the Earth under the best conditions using moderately sized telescopes, and, because, in practice, resolution depends on the shape of an object and on its contrast with the surroundings, the same instruments can be used to view lunar lineaments (linear features), such as rilles, considerably smaller than 100 metres in width, provided they are many times longer than 100 metres. The best Earth-based photographs of the Moon show some (the sharpest) craters as small as 500 metres in diameter. Photographs from space vehicles have resolved details in some cases as small as a metre. The first camera was put into an orbit passing behind the Moon (October 1959) by the U.S.S.R. Its useful photography was confined to some 70 percent of the Moon's averted hemisphere lit by a high Sun, and both the picture quality and the resolution were poor by the standards of Earth-based telescopic photography. Useful far-side photographs were obtained from another Soviet space vehicle, which completed the lunar far-side coverage in July 1965, and from a third, which provided higher resolution coverage of a limited portion of the far side. A number of ray craters (see below) were readily identifiable, but the most surprising observation was that most of the far side of the Moon contained no maria. Major crater chains, up to 1,000 kilometres (600 miles) long, were found.

The first far-side pictures

Small-scale details. The photography from a series of vehicles designed to crash-land on the Moon and relay television pictures to Earth prior to crashing was not successful until July 1964, when an American probe approached and crashed in a part of Mare Nubium. The area was renamed Mare Cognitum by the International Astronomical Union. For the first time, more and more small craters were seen as the vehicle effectively decreased the lunar-surface resolution to a limit of about 50 centimetres (20 inches). Craters of various shapes, rock blocks, and ridges 100 to 1,000 times smaller than anyone had seen before were recorded during the last minutes of descent. The Moon was found to be cratered more heavily than had been predicted, and the substantial excess of craters was attributed both to the mechanism of secondary cratering—that is, crater formation by objects ejected from a primary meteoric (or volcanic) cratering event—and to endogenic cratering—that is, crater formation by internal processes such as outgassing or collapse. A few dimple-shaped craters, probably the result of drainage of the Moon's veneer of fragmental rock into subsurface fractures, were discovered. Many more were later found in Mare Tranquillitatis and in the 110-kilometre- (70-mile-) diameter structure Alphonsus. None of these craters has the bowl- or saucer-shaped profile characteristic of a fresh, sharply sculptured (eumorphic) explosion crater or of an older, denuded (submorphic) explosion crater. On the other hand, the majority of the sub-kilometre-sized craters could well be explosion craters produced either by high-speed impact or by violent outgassing (explosive volcanism).

Mare Cognitum is traversed by faint rays of lighter hued material. The lunar rays that emanate from many craters are generally thought to be composed of small craters and blocks of rock. A certain proportion of the craters set in rays may be secondary-impact craters. In one cluster of craters, chains, or linear arrays, of both sharply sculptured and older craters trend in a given, narrow range of azimuth. It is not known whether the two types of crater were formed as respective secondaries when hard and soft material landed to produce craters at the same time and at the same distance from some primary crater; or the eumorphic and submorphic craters were formed internally at widely different times, the latter being formed first and then undergoing denudation.

The principal erosive force on the Moon at the present time is probably that of meteoric impact. Primary meteoroids are increasingly the more numerous with diminution in size, so that micrometeoroids are probably the principal factor involved in the attrition of freshly formed surfaces on the Moon. The net direction of movement of material sprayed from a meteoric cratering event is downslope; and this downward migration of rock fragments tends to level the lunar terrain and to generate a ubiquitous veneer of particles that is variable in thickness from one locality to the next. This layer, known as the lunar regolith, is composed of fines, particles less than one centimetre and mostly much less than one millimetre in size, and of larger fragments of rock. The process of impact mixing of the lunar soil and the particles of the regolith is sometimes referred to as "impact gardening."

The lunar regolith

Some of the blocks of rocks photographed on the Moon appear to be partially buried in the regolith, and a first estimate of the strength of the lunar-surface materials was made from considerations of the depth of penetration of these blocks and the distances they had been thrown. A bearing strength of about one kilogram (2.2 pounds) per square centimetre found for this part of the Moon showed that it was strong enough to support a man clad in a spacesuit or any of the planned soft-landing craft. Following the first soft landing of a spacecraft, Luna 9, on the Moon, in February 1966, the Soviets determined the soil in Oceanus Procellarum to have a bearing strength of at least several kilograms per square centimetre.

It appears to have been confirmed that some of the small craters of the Moon are of internal origin, though it is still believed that the vast majority of these craters are of impact origin. Several chains of contiguous craters are generally thought to be secondary craters from the 85-kilometre- (53-mile-) diameter crater Theophilus, even though many of them run nearly parallel to tectonic lineaments such as linear ridges and troughs—a situation indicative, instead, of an endogenic origin of these craters. The blocks of rock, up to 100 metres in diameter, are commonly scattered in and around craters that were probably deep enough to cut through the friable regolith into cohesive bedrock. This bedrock would have been excavated and tossed, as blocks, from a crater during its formation, it was argued.

Many rilles (lunar trenches of lengths up to a few hundred kilometres and widths up to a few kilometres) have been photographed by space vehicles. Those recorded are particularly interesting because of the intimate connection between the rilles in the floor of the crater Alphonsus and dark halo craters that lie in the rilles. Exceptionally dark deposits encircling these craters have tended to obliterate underlying relief and, locally, fill the rilles. The craters themselves are elongated along the axis of a rille and are without raised rims—characteristics that point to internal origins. The associated dark deposits were probably erupted as sprays of rock and lava.

The rilles

In the next phase of lunar exploration, closeup television photographs of the landing feet of a soft-landing vehicle in June 1966 (within a 100-kilometre- [60-mile-] diameter ring structure, known as Flamsteed P, in Oceanus Procellarum) showed that the feet had penetrated a few centimetres into the ground and had disturbed the soil around them, giving it a darker appearance in the process. Stones and blocks of rock were found to vary considerably in appearance. Some appeared to be partly buried, their surfaces smoothed by erosion. Some ap-

peared to have been put on the surface and to have remained in their original, angular configurations. Some had different shapes and numbers of pores (vesicularity), structure (layering and differential denudation), or, possibly, composition (tonal differences and the presence of inclusions).

Similar results were found from other probes soft landed in Mare Tranquillitatis and in Sinus Medii in missions meant to examine possible landing areas and analyze the soil. One mission was sent 42° south of the lunar equator to examine, for the first time, part of the Moon's highland domain. It landed (January 1968) successfully within what was, by comparison with the area of the highlands around Tycho, a fairly smooth area. The television cameras, however, showed the terrain to be strewn with many more blocks of rock per unit area than had been found in the maria. The most revealing discovery concerned the composition of the rocks; the percent weights of elements in rocks were estimated, and the landing area was found to be similar in composition to the mare samples, with the exception that the iron-group elements (mass numbers 47 to 65) were less abundant in the highlands.

Data on rock composition

The elemental composition of the rocks at three sites approached that of some terrestrial basalts, types of dark igneous rock. The tested areas of the Moon were compositionally unlike chondrites—the most common kind of meteorite—and analyses have indicated that the Moon had been differentiated and heated. The theory that the Moon originated as a cold body and has never been heated suffered a serious blow, although the heating might have been the local result of major impacts. Later analyses of rocks returned to Earth provided further information on heating (see below).

Soviet Union and United States spacecraft both first entered circumlunar orbits in 1966. The emphasis in the Soviet series has been on physical measurements in the vicinity of and pertaining to the Moon; the prime purpose of the first U.S. orbiters was to provide photographs of several alternative astronaut-landing sites dispersed along the equatorial belt in the smoother, mare areas.

A camera in one such craft was able to survey in sequence the whole of the lunar surface. Some areas not recorded or not well-photographed by earlier cameras were later examined.

One consequence of all this lunar photography has been good coverage showing fine detail over most of the lunar globe. Topographic and geological maps of parts of the Moon's near side have been prepared with horizontal errors of about one kilometre. Detailed photographic and visual observations of the lunar surface were made in 1969 to evaluate the terrain characteristics during the close approaches of the lunar module.

Results from manned lunar landings. The first manned lunar landing was made in July 1969 in Mare Tranquillitatis. Some 22 kilograms (49 pounds) of lunar rocks were collected and returned to Earth for study.

Later manned landings were in Oceanus Procellarum, in the Fra Mauro highlands, and in Mare Imbrium between the Apennine Mountains and the Hadley Rille, each adding to the store of lunar rocks returned to Earth. Each crew left behind functioning observing instruments, including a seismometer, a device commonly used to measure earthquakes.

Moonquakes

Though the first seismometer failed after only a short operating time, later ones worked simultaneously and, in registering the vibrations generated by impacts and moonquakes, have provided valuable information about meteoroids that encounter the Moon and the slight, relative movements of rocks along lunar faults or other slip surfaces, as well as about the behaviour of lunar material at depth and the probable nature of the rocks at various depths and localities.

Missions have also landed a type of optical reflector on the Moon, capable of returning to Earth extremely accurately timed laser pulses for reception by large telescopes. Timing of these pulses on their journey to the Moon and back reveals very small changes in the Earth–Moon distance and can improve knowledge of the present rate of recession of the Moon from the Earth. The so-called secular acceleration of the Moon provides information about the origin of the Moon, discussed below. The accuracy of measurement of the Moon's distance by laser measurements is a small fraction of a metre (there is approximately one nanosecond in two-way time delay resulting from about 10 minutes of observation; this is equivalent to about 15 centimetres). Given a suitably wide network of laser reflectors on the Moon, additional studies on the Moon's figure and physical liberation can be performed. The precise shape of the Moon and the amount of its free libration also have a bearing on its past history.

Laser measurement of Earth–Moon distance

Other instruments left behind on the various manned landings provide continuing physical and geophysical data. Earlier measurements of the physical properties of the lunar environment using crash-landing and orbiting vehicles were valuably supplemented or completely superseded by the results drawn from the later missions.

Data from closeup photographs. Increasingly valuable photographs of the Moon were taken by the astronauts on succeeding missions, both from orbit and from the surface. Many of the rock samples were photographed in relation to their surroundings prior to removal from the Moon's surface, to assist in later interpretations (the broad setting from which a rock is drawn is important to an investigator in any comprehensive geological study).

The lunar photographs by no means record all possible bits of lunar surface, even down to a size as coarse as a kilometre, but vast amounts of unmeasured, unprocessed data are stored in existing photographs. From them, lunar craters have been measured for size, shape, and depth (from shadow measurements): crater counts have been used in estimates of the terrain roughness and in statistical studies bearing on the origin of the craters. The roughness of lunar rock blocks, estimated from photographs as well as from returned samples, has been related to theories of denudation (erosion) and aging. Lunar-surface processes, such as transport of the material and impact mixing, have been studied using photographs alone. Lava flows covering large areas of the maria have been detected and mapped using Earth-based infrared and ultraviolet photographs in combination with photographs taken from lunar orbit. The brightness contrasts displayed by different rock units have been measured from Full Moon photographs. Slopes have been assessed from shadows under different Sun angles. Topographic maps have been prepared. Texturally distinct geological units have been mapped and used to produce a lunar stratigraphic column of relative ages. Faults and other tectonic lineaments have been recognized on the photographs.

TYPES OF LUNAR FEATURE

Lunar craters. The ubiquitous nearly circular features on the Moon have all come to be known as craters; the traditional terms ring plain and walled plain describe, respectively, round and irregular lunar features with walls encompassing relatively smooth, level floors.

Forms of craters

Lunar craters, in the broad sense, may be classified, first, on the basis of their form. Many intermediate-sized craters, in particular, display mountain blocks or hills near their centres. The inner (and, to a smaller extent, the outer) walls of many craters are terraced, with interterrace benches.

Although in a lunar photograph (see Figure 1) the majority of the lips of crater rims (walls) appear to be approximately circular, it is common to find that, in detail, the actual shapes approximate better some polygon or an ellipse. A number of lunar craters have ellipticities greater than 30 percent. Some of the so-called craters have a spiral inner ringwall lower than the outer; there are craters with eccentrically placed inner craters and plateau craters that seem to have been filled with dark material. The impact or successful lunar landing sites are shown in Figure 1 and described in the Table.

Bowl-shaped craters with parts of the floor darker than the inner slopes are common among lunar craters less than 20 kilometres (12 miles) in diameter. They may be

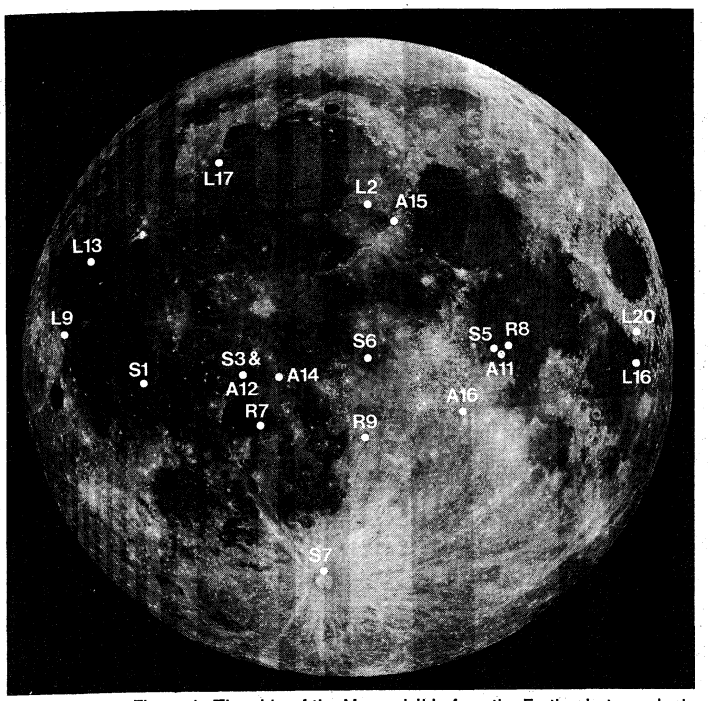

Figure 1: The side of the Moon visible from the Earth, photographed at Full Moon. The approximate points of impact are shown of selected U.S. and U.S.S.R. spacecraft of the Apollo (A), Ranger (R), Surveyor (S), and Luna (L) series. Three dark "seas," left to right, just above centre, are Mare Imbrium (Sea of Rains), Mare Serenitatis (Sea of Security) and Mare Tranquillitatis (Sea of Tranquillity).

as much as three kilometres deep, with inner slopes of up to 50° and outer rims sloping at up to 20° near the lip. The shallowest "saucer" craters have the surfaces of their rims inclined to the horizontal at no more than a few degrees. Crater pits are those without raised rims. Funnel- or dimple-shaped crater pits with convex inner walls near their lips have been discovered in some of the photographs.

Impact or Landing Sites of Successful Lunar Spacecraft

name and launch date	remarks
Luna 2 Sept. 12, 1959	first man-made craft to impact the Moon
Ranger 7 July 28, 1964	first craft to obtain high-resolution (one metre) television pictures
Ranger 8 Feb. 17, 1965	similar mission to Ranger 7
Ranger 9 March 21, 1965	similar mission to Ranger 7, but in highland region
Luna 9 Jan. 31, 1966	first craft to soft-land and relay panoramic and close-up pictures from lunar surface
Surveyor 1 May 30, 1966	first U.S. craft to soft-land and relay panoramic and close-up pictures from lunar surface
Luna 13 Dec. 21, 1966	similar to Luna 9, but also tested lunar soil hardness
Surveyor 3 April 17, 1967	similar to Surveyor 1, also first craft to dig trenches
Surveyor 5 Sept. 8, 1967	similar to Surveyor 1, also first craft to analyze lunar mare soil
Surveyor 6 Nov. 7, 1967	similar to Surveyor 5
Surveyor 7 Jan. 7, 1968	similar to Surveyor 5 and 3, first soft landing in highlands
Apollo 11 July 16, 1969	first manned landing (Mare Tranquillitatis)
Apollo 12 Nov. 14, 1969	first manned landing near an unmanned craft (Surveyor 3)
Luna 16 Sept. 12, 1970	first unmanned craft to return lunar soil to earth
Luna 17 Nov. 10, 1970	first unmanned craft to deploy a roving vehicle (Lunakhod 1)
Apollo 14 Jan. 31, 1971	first manned landing in highland region (Fra Mauro)
Apollo 15 July 26, 1971	first manned landing to use roving vehicle (Hadley Rille)
Luna 20 Feb. 14, 1972	similar to Luna 16, but highlands sample instead of mare
Apollo 16 April 16, 1972	similar to Apollo 15, but in highland region (Descartes)
Apollo 17 Dec, 7, 1972	similar to Apollo 16, but sampled highland and adjacent valley

Ray and dark-halo craters

A crater may be classified also by the neighbouring craters or other features that appear to be associated with it. Thus, craters such as Tycho (Figure 2), Aristarchus, Copernicus (Figure 3), and Kepler are known as ray craters, being major centres of subradial systems of bright rays that are now known to consist of numerous small, bright craters and blocks of light-toned rock. The rays of Tycho are up to 1,900 kilometres (1,100 miles) long. A number of kilometre-sized craters are known as dark-halo craters; these have associated dark-toned rings or halos around them that may be pyroclastic (volcanic) deposits. Other craters are associated with subradial linear formations that are distinct from rays and others again with adjacent positive elements of terrain known as deltoids. Dome-top craters are conspicuous because each occupies the summit of a broad, topographic swelling. Small craters often seen on the summits of hills or mountain peaks may form a class of their own (summit craters). It is common to find an unexpectedly high number of craters on ridges in the maria or centred in the crests of crater walls. Such craters have been referred to as parasitic or ringwall craters. A crater that is one member of a linear progression, or chain, of craters may be described as a chain crater, particularly if other members of the progression are of a common and distinct morphological type. Other mutually similar craters form arcuate chains. Consanguineous craters with strong morphological similarities to one another may be numbered among the many members of a chain, but they are commonly found in close pairs also. The walls of interlocking craters may pass across one another without interruption. Finally, rille craters are those single or chained craters that are set in and form part of the lunar rilles, which are trench-like features. A rille crater may be circular or markedly elliptical and may be the centre of a dark halo.

Height measurements from shadows

Height measurements form an essential element in profile construction. In principle, the height (h) of a lunar mountain peak above the lunar ground where the tip of the mountain's shadow, of some length (ℓ), lies is determined by simple geometry provided the mountain is near the centre of the Moon's disk or measured on a photograph taken vertically. Taking the elevation of the Sun over the mountain as θ degrees, the height h of the mountain is calculated with the formula $h = \ell \tan \theta$; the angle θ (theta) can be obtained from regularly published tables. For mountains not viewed under these conditions, it is necessary to use a more general formula for h.

The near side of the Moon has been surveyed fairly intensively, but, until recently, methods employed to measure the Moon's overall shape, or figure, have been complex and laborious. Unlike the Earth, with its oceans, the Moon has no natural datum from which to measure altitudes. The physical librations (see above) show that the Moon cannot be both spherical and homogeneous. An accurate evaluation of the Moon's figure has become important in modern discussions of the origin of its surface features as well as being relevant in discussions of its internal constitution.

In the limb seen from Earth, the Moon departs from a circle by only about 100 metres (300 feet); but the equivalent length of the lunar axis that points toward the Earth is about 1,000 metres greater than the Moon's polar axis. The maria are generally lower than the lunar highlands by an average of about 1,000 metres. Individual mountains attain heights of up to four or five kilometres (about three miles) above their bases, and this is also the order of depth of the deepest lunar craters commonly measured from the rim crest of the enclosing ramparts, which are in some cases over 200 kilometres (120 miles) in diameter.

Smaller craters are progressively less deep: whereas the deepest and largest craters of the Moon have a depth-to-diameter ratio of only 0.08, lunar craters of ten-kilometre-diameter may have a depth-to-diameter ratio of 0.15. The latter, however, are the eumorphic (sharply defined) craters; and all ten-kilometre-sized craters, taken together, show a wide spread in the depth–diameter ratio. The tendency in the case of eumorphic lunar craters is for the depth-to-diameter ratio to increase as the size of a crater diminishes, a generalization known as Ebert's rule, after Hermann Ebert, a German physicist.

Ebert's rule and Schröter's rule

Schröter's rule, named for a German astronomer, Johann Hieronymous Schröter, states that the volume of crater-rim materials lying above the mean level of the local terrain is approximately equal to the volume of the crater depression below that mean level. Schröter's rule has been repeatedly quoted as evidence supporting the impact origin of the vast majority of lunar craters, yet the data on which it was based were inadequate, and exceptions are known, in which the volume of a crater's rim materials exceeds the volume of the space inside it. Mechanisms that might have contributed to the filling of craters are, for example, isostatic adjustments (movements of matter caused by differences in surface loading); infilling through erosion, transport, and deposition; and lava flooding.

The deepest and largest craters of the lunar near side are concentrated in the central meridional belt of the Moon's southern hemisphere. The deepest craters tend not to be near the maria. The encircling walls of the oldest craters have slumped into the craters or have been cut across by faults or graben; the craters themselves have been overlapped and partially obliterated by smaller craters formed later. In addition, the topography of large craters is often softer than that of many of the sharply sculptured, more recent craters, presumably because of changes resulting from denudation (erosion).

Dense cratering is found in the lunar highlands, and many of the older craters are difficult to observe. About four times as many craters between ten and 50 kilometres (five and 30 miles) in diameter are found per unit area of the nearside highlands as in the same area of the average mare.

Placement of craters

Standard statistical methods applied to lunar-crater data have shown clearly that the lunar craters are not distributed across the lunar surface in the random fashion expected as a result of meteoric impacts.

The maria abut on the highland domains, and mare materials are found in craters with breached walls on the peripheral zones of maria. Geologists believe that the

mare surfaces are younger than the highlands, and it is clear that late phases of mare lava outpourings could blanket craters and render their overall distribution nonrandom. The maria themselves differ in age, as stratigraphic maps and dated rocks returned to Earth show. There are, even in a single mare, distinct geological units (such as individual lava flows), each with its own characteristic population of craters.

An attempt to distinguish by statistical methods between craters of impact (including secondary-impact) origin and endogenic craters in the lunar maria has been made. The ratio of internally formed craters probably varies from one unit to the next, and, of the craters with diameters between 50 metres and hundreds of metres, it is not uncommon for up to half to be arrayed with the trends of known tectonic lineaments (large-scale linear features; see above). Such craters are probably of internal origin.

Lunar lineaments. *Mare ridges.* Lunar lineaments (linear features) are of many different types. Mare ridges (Figure 4) are numerous in the maria and may be much

By courtesy of the Lunar and Planetary Laboratory, University of Arizona

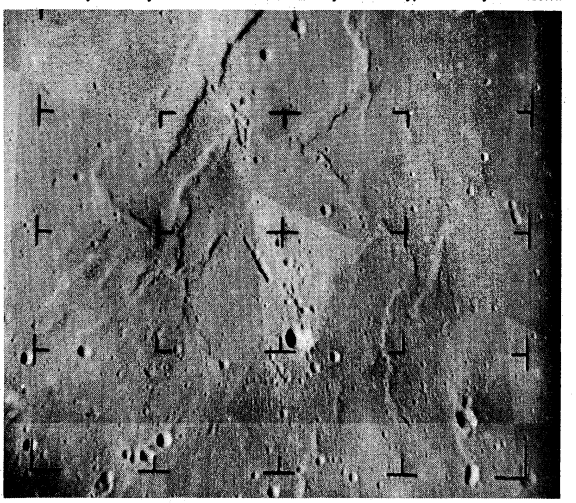

Figure 4: Part of Mare Tranquillitatis, showing dimple craters and mare ridges. Area shown is about 19 kilometres (12 miles) square.

longer than the brighter highland-type or lunaritic ridges. Mare ridges are also found in dark-floored craters and, rarely, may be traced beyond a mare into highland-type material. In transverse profile they consist, typically, of broad, low rises sloping at only a degree or so for ten or more kilometres, capped by slightly steeper, relatively narrow ridges. Typically, the major mare ridges rise to an altitude of about 200 metres (650 feet) above the surrounding country. In plan, they lack continuity and are broken, offset, or arranged *en echelon*. The higher, narrower parts of the ridges show a strong tendency to be in short sections, or segments. While the overall trend of these ridges in a subcircular mare is generally aligned with the curved border of radially more distant mountains, the directions of the mare-ridge lineaments often follow other preferential directions. Like the lunaritic ridges, they may also belong to families of ridges that trend over much of the lunar surface in set ranges of azimuth—a fact that labels many of them as tectonic; *i.e.*, produced by deformation of the crust.

The lunar grid system. Other lineaments, such as linear graben (depressed regions between faults), crater chains, rilles, and faults, together with the ridge network, form the lunar grid system. Near the centre of the Moon's near-side face the principal trends of the grid system are at about 45° to the central meridian. Interference between these dominant directions and other directions of lineaments that are subradial to certain of the maria, notably Mare Imbrium, makes recognition of the Moon-wide topographic pattern difficult. Many of the mare ridges, from which extensive flows of lava have derived, have evidently been built up by extrusion of basic lavas from fractures. Because of their tendency to form an overall grid pattern, many of the fractures must have been produced by uniformly acting crustal stresses of tectonic origin.

Regional lineaments subradially oriented (*i.e.*, somewhat offset from a radial direction) with respect to Mare Imbrium and Mare Orientale are easy to locate; fewer ridge lineaments are associated with Mare Nectaris and Mare Humorum. Such regional fracture or fault systems extend into and are modified by the older terrain around the mare. The circular mare sites on the Moon are at present thought to have been blasted out by gigantic impacts, and the basins so created later filled with lavas from inside the Moon. Much faulting and possibly the extrusion of lavas in the regions surrounding each mare basin would be generated in such major events. Fractures in a previously unstressed homogeneous medium will be radial and tangential at some distance from an explosion site. The systematic deviations of the mare lineament systems from these directions in association with the more general grid system suggest influence from preexisting fractures or weaknesses in the lunar crust.

Similar patterns are found around certain large craters, and these may be detected most readily in mare material. Around the crater Aristillus, bundles of lineaments, rather than a set of precisely radial ridges and troughs, are found. Only the central, longest lineament of each bundle is radial to the crater, while the other members are progressively offset from the radial direction. The central lineament of a bundle tends to be aligned with one of the principal directions of the grid system. The ultimate explanation of these minor sets of subradial lineament is expected to be analogous to that pertaining to the maria.

Where the grid system abuts on the larger craters, northeast- and northwest-trending ridges commonly intersect and sometimes pass inside the northern or southern ringwalls. Well-developed nests of crisscrossing ridges found in such localities have been called lattice patterns. A quite different feature, named the deltoid, also commonly occurs outside the northern or southern walls of certain craters. Deltoids are raised elements of the lunar terrain in the form of a delta, or gothic arch, the base of which abuts on the rim of a crater.

Of the subcircular maria, some tend to be polygonal. As in the case of the polygonal craters, the shape might be due to crustal weaknesses existing before the mare was formed. The peripheries of other areas of lunabase, including some maria, are irregular. In addition to craters and mare ridges, maria also contain features known as rilles (German *Rille*, "trench," "groove," "channel"; Latin *rima*, a term used principally on official maps), which are, however, found also in the lunabase generally, in certain of the larger craters, and in the lunarite.

Normal rilles

Rilles. One class of rille, called the normal rille, appears to be an exclusively lunar phenomenon. This is a linear or broadly arcuate trench without raised rims (except when it cuts through higher ground) and with gently insloping walls. The largest rilles are up to five kilometres (three miles) wide, a few hundreds of kilometres long, and up to several hundreds of metres deep. The floors of normal rilles are relatively level (unless they are so narrow that fallen rocks and dust from the opposing walls meet in the bottom) or are humped or strewn longitudinally with blocks. They slice through the mountainous walls of some craters and traverse the lunarite for great distances. They tend to occur in parallel families, in arcuate paths generally just within the mountain ranges or hills that border maria or the larger craters, and to run in preferential directions suggestive of lines of probable crustal weakness and tectonic control. Some are arranged *en echelon*, a characteristic of strike-slip faults on Earth.

Single or contiguous craters without raised rims define parts of the walls and floors of some normal rilles; these have sometimes been termed crater rilles. The craters appear to be of the collapse type, with flattish floors. Lunaritic ridges traverse some normal rilles (such as the Ariadaeus and Hesiodus rilles) and appear to have sagged or subsided into the rilles. Such ridges seem to be older than the rilles that they cross without a break; and this shows also that the rilles are not partially filled fis-

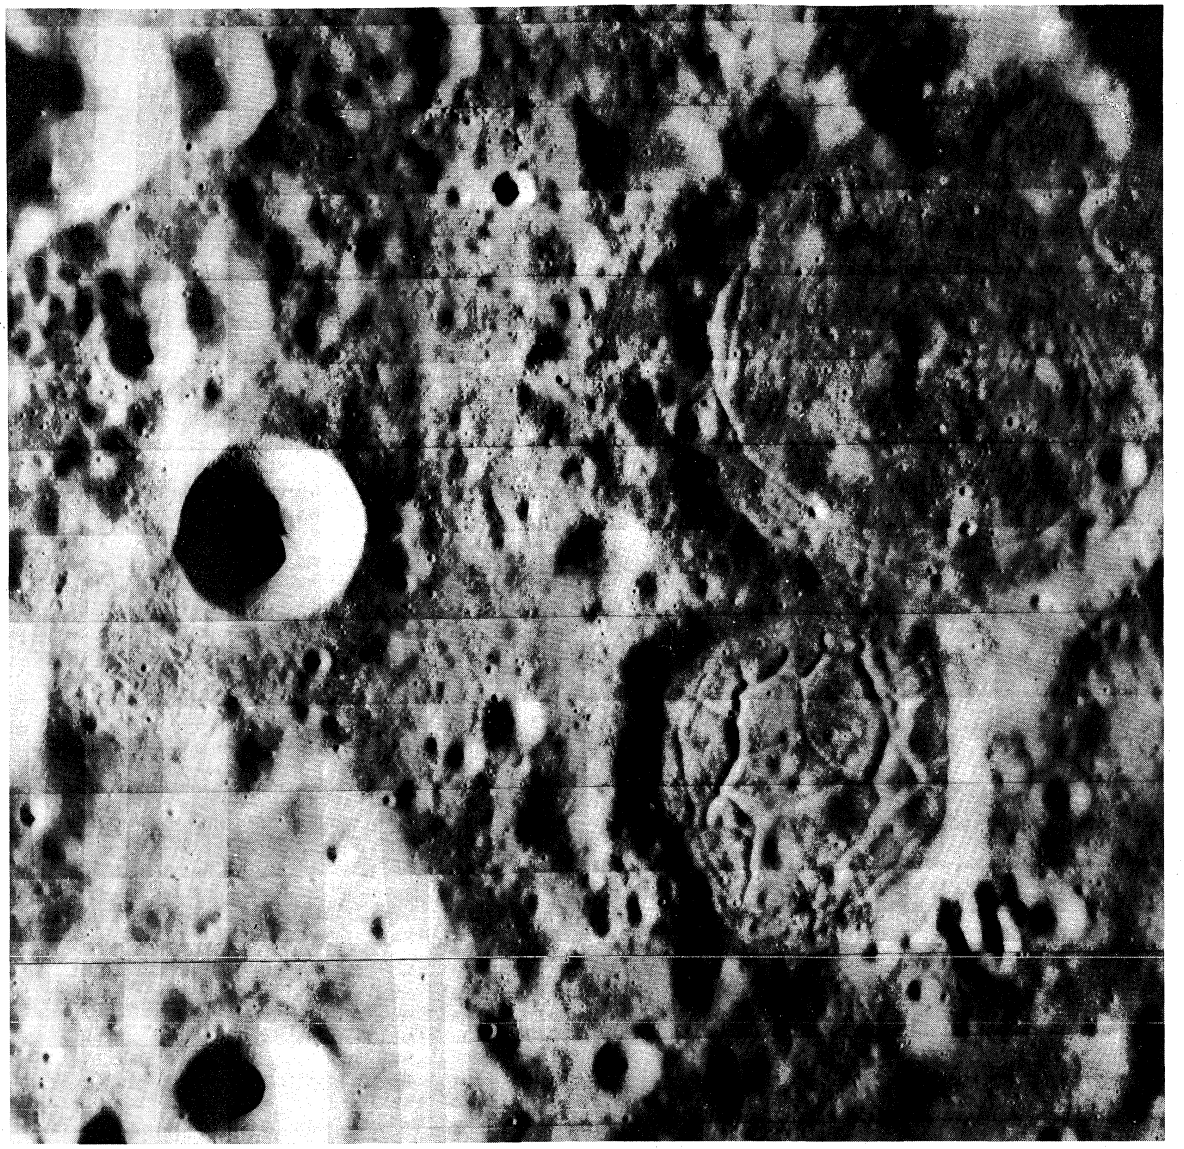

Figure 5: An unusual fractured crater floor on the hidden side of the Moon, photographed by Lunar Orbiter 1. The fractures appear as an irregular pattern similar to a dried mudflat. The heavily fractured crater (bottom right), which may be a source of volcanic materials, is 15 miles wide; the larger crater just above it (to the north) is about 24 miles across at its widest point.

By courtesy of National Aeronautics and Space Administration

sures. These observations suggest that the normal rilles are graben, or collapse features, and are probably controlled by underlying fractures or faults.

In many striking instances, normal rilles run into or connect with other normal rilles at sharp angles and with faults, chains of craters, or mare ridges, suggesting that the rilles in question are controlled by tectonic fractures.

Sinuous rilles

During the 1960s, examination of space photographs stimulated much discussion of another type of lunar rille—the sinuous rille (Figures 2, 5). Some parts of sinuous rilles, like normal rilles, appear to be controlled in direction by tectonic lines of weakness. Other parts have features resembling meanders in a terrestrial river. The superficial resemblance to dry rivercourses—particularly to those cut by rivers draining inland into desert areas—led to a revival of interest in water on the Moon. But later detailed measurements of the geometrical parameters of sinuous rilles lent weight to another hypothesis—that these rilles were shaped by the flow of lavas. Many of the sinuous rilles have one end marked by a probable (elongated) source crater, and many degenerate into a chain of craters that are commonly elliptical and have their longest axes set along the probable courses of underlying lava tubes. In a few cases, smaller sinuous rilles meander along the floors of larger ones, such as Schröter's Valley. Several sinuous rilles have distributaries or re-entrant loops, both of which are common in terrestrial lava channels.

Like normal rilles, sinuous rilles tend to concentrate around the borders of the circular maria or at the junctions of lunabase and lunarite. Exceptionally strong concentrations of sinuous rilles are found in the densely domed region near the crater Marius and also around the crater Aristarchus. Thus, sinuous rilles show a preference to regions that have been assessed from other evidence as showing volcanic characteristics.

Opposing sides of a few stretches in some normal and sinuous rilles are observed to be at different levels. In principle, a rille may form by the collapse of a weakly cohesive regolith into an open fracture. Faulting is initiated when there is relative movement between the two blocks that define the fracture. The displacement of a fault may remain constant, or there may be continuing or intermittent movement. The direction of displacement may be steeply inclined to the horizontal (normal, or dip-slip, fault); steeply inclined to the vertical (thrust fault); or lateral (strike-slip, wrench, or transcurrent fault). Faults on the Earth and Moon may show a combination of these idealized directions of displacement. On the Moon, however, no thrust fault has yet been recog-

Lunar faults

nized. The term wrinkle ridge, a synonym for mare ridge, is suggestive of compression or thrusting, but there is little or no real evidence that any of the mare ridges (Figure 4) are compressional features.

Some rilles are directly associated with probable dip-slip faults. The characteristic *en echelon* pattern of strike-slip faults is reflected in other rilles, in segments of wrinkle ridges, and in lunaritic ridge systems. More than one major strike-slip fault appears to have offset blocks of the lunar Caucasus Mountains; and there are a host of probable minor strike-slip faults on the Moon, one of the most notable being the fault that has displaced the walls of the crater Capella and of another two craters further to the south. Strike-slip faults are perhaps of more importance on the Moon than the better known dip-slip faults, such as the inappropriately named Straight Wall. Major faults, dissecting large areas of lunarite, have been recognized. These "selenofaults" measure hundreds, rather than tens, of kilometres in length.

Bright rays. The bright rays that diverge from craters such as Tycho (Figure 2) are thought by some to be fracture controlled, but the majority of lunar geologists believe the rays to be the result of ejecta of secondary particles from a primary impact site. One of the strongest arguments for the impact origin of rays is that they look like splash marks. The particles that formed the end of the longest ray of Tycho must have been ejected from Tycho at a velocity of at least 1.4 kilometres (0.9 mile) per second if the ejection hypothesis is correct. The velocity of escape of a particle from the lunar surface is 2.4 kilometres (1.5 miles) per second, so potential ray-forming particles would not escape from the Moon. The evidence from closeup photographs is that more than the average number of craters are in unit areas crossed by rays; and evidence gathered by astronauts points to there being a complement of bright-toned rock blocks in a ray-strewn zone.

Mountain height measurements

Lunar mountains. Systematic estimates of the altitudes of lunar mountains were first made in the 18th century. The most comprehensive program of lunar height measurement ever attempted was started in 1959 by the United States Air Force's Aeronautical Chart and Information Center. The results of this concerted program, in which many thousands of lunar photographs were taken at different Earth-based observatories, are incorporated in lunar nearside charts prepared by the Aeronautical Chart and Information Center.

The classical program of heliometer observations of the angular separation of points on the Moon, made in the 19th and early 20th centuries, is of fundamental importance in the present understanding of the lunar physical libration. The time-consuming reductions involved the computation of the distances between Mösting A (a crater near the centre of the Moon's disk) and many control points scattered over the Moon's near side and, finally, solution for constants characterizing the librations.

Another series of classical observations was made to elucidate the motion of the Moon in its orbit. When the Moon passes in front of a star it is said to occult the star. Up to the present time, tens of thousands of occultations have been timed in this continuing study of the Moon's movements and of the shape of the Moon's limb in the librational zone (see also above).

Temporary or transient changes on the Moon. Ever since serious telescopic observation of the Moon began, astronomers have reported mistlike phenomena or temporary obscuration of detail in specific patches of the Moon. In 1966 a significant positive correlation was found between the times of more than 100 observations of transient lunar phenomena made between 1749 and 1963 and the distance of the Moon from the Earth. The majority of transient lunar phenomena occurred close to the time of the Moon's perigee or apogee passages. The indication was that the Earth's tidal forces on the Moon's solid crust had contributed to the cause of the transient lunar phenomena, although the transient lunar phenomena themselves may be manifestations of seismic (moonquake) or seismically triggered volcanic activity or merely caused by dust either blown out from the regolith and dispersed by cold gases escaping from cracks in the Moon or set in motion by seismic activity. Similar periodicities in some types of seismic signal from observing stations planted on the Moon show that lunar seismicity occurs most commonly within a day or so of perigee and of apogee, and this suggests that the majority of the transient lunar phenomena are connected with some kind of seismic activity.

Other kinds of lunar change have been suggested. Perhaps the most frequently discussed case of a possible permanent or long-term change of topography is that of the crater Linné, which may be located on many photographs as a whitish patch in Mare Serenitatis and appears on the best photographs of today as a crater only 1.5 kilometres or so in size, centred in a bright halo. It cannot be concluded from the evidence available that the area has suffered any morphological change.

Observed eruptions

In 1958, a Soviet astronomer, N.A. Kozyrev, claimed to have detected a reddish cloud of volcanic ash, followed by an efflux of gas lasting for at least half an hour, from the vicinity of the central mountain block of the crater Alphonsus. He recorded a lunar emission band having its maximum intensity at 4737 angstroms and gradually fading toward the violet end of the spectrum. This and other bands, he proposed, had their origin in carbon molecules. Some volcanoes on Earth emit carbon dioxide gas. In 1959 Kozyrev again obtained an unusual spectrogram of Alphonsus and maintained that the central block of the crater had given birth to an eruption of lava at a temperature exceeding 1,270° C (2,320° F). Although these observations and interpretations have not been universally accepted, the reports did stimulate interest among other professional astronomers in a Moon long considered to be dead and changed only by impacts.

Notable reddish glows on the crests of ridges in the Aristarchus region were observed in 1963 at the Lowell Observatory in Flagstaff, Arizona. A month later, similar observations of the Aristarchus region were reported at two observatories. At this time, coloured patches persisting for over an hour seem to have been authenticated.

The photometric function. Scientists correctly reasoned, in the early 20th century, that the Moon's photometric function (changes in the intensity of reflected sunlight with different angles of reflection) proved that the lunar surface was far from smooth on a centimetric scale. The respective scattering properties of highland and mare material were deduced in 1956, when it was shown that the lunar surface in both the lunarite and the lunabase was extremely irregular and porous and that both types of terrain displayed essentially similar surface structure. Slight differences were observed in the way light was scattered by lunarite (highland) and lunabase (maria) material, and these differences indicated that, in general, there was a slightly greater roughness (more irregularities, or pores, per unit of surface) in the lunabase. In a more sophisticated analysis, in 1971, it was estimated that the porosity (fractional pore space) of the highland topsoil had an average value of 60 percent and that the mare topsoil averaged 80 percent. The measured values of the Moon's surface porosity at specific sites are not generally in conflict with these overall results.

Porosity of topsoils

The reason for the different structure in the uppermost centimetre or so of the lunarite and lunabase may be found in a study of the differential denudation or of the different histories of outgassing of the two types of terrain. Processes such as mass wastage—that is, downslope migration of material under gravity—may be expected to play a relatively important role in the highlands. Therefore, there may well be a tendency for craters and pores in the highlands to be smoothed over more quickly than corresponding features in the maria. On the other hand, the outgassing of the mare materials is believed to have occurred later than much of that in the highlands; and the initial porosity of the two types of material probably differed as well.

The packing of lunar fines. A special use of photometry is in the determination of the packing of lunar fines (small particles and dust). The acceleration caused by the Earth's gravity is six times that of the Moon at their

respective surfaces, so that fines scooped from the Moon and transported to Earth will undergo an increase in their state of compaction. Agitation, severe during parts of the journey back to Earth, assists the process of compaction. The undisturbed fines and samples returned to Earth will scatter light in different ways, and it is possible, by rearranging the compacted fines into various states on Earth and testing them again, to deduce their approximate surface state before they left the Moon.

Colour contrasts. It is difficult to assess large-scale colour contrasts on the Moon from the Earth by eye. A profitable investigation of lunar colour contrasts may be made from ultraviolet and infrared photographs. The technique is useful for surveying extensive areas of the Moon for differing rock units.

Certain parts of the Moon absorb ultraviolet light strongly. Such an absorption can be produced by traces of the element sulfur, for example. At the other end of the spectrum, lunar rocks display characteristic absorption bands in their infrared reflection spectra. One such prominent band, at a wavelength of about one micron, is due to the presence of iron in certain lunar materials.

Another instructive technique is that of plotting the photometrically determined colours of discrete patches of lunar terrain against their respective albedos and comparing the resulting colour-brightness diagram with others constructed for a wide range of terrestrial rocks prepared in widely different forms. It is found that blocks of terrestrial-type rock, or meteorites, cannot cover more than a small fraction of the lunar surface, although many rocks ground to powders and then irradiated with protons (to simulate the effect of particles from the Sun striking the Moon) have been found to approach the lunar domain of the colour-brightness diagram.

Lunar polarization studies. *The lunar soil.* A much more powerful optical method of studying the nature of the particles of lunar soil is that in which polarization curves are utilized. Polarization is a wave property of light, and different substances have different characteristic polarization curves. At a given lunar phase, the amount by which light from different parts of the Moon is polarized depends on the brightness of those parts: the brightest spots polarize no more than about 5 percent of the incident light, whereas the degree of polarization attains 20 percent or so for the darkest spots. These maxima were recorded at times close to those of the First and Last Quarters of the Moon. Most terrestrial rocks, whether solid or pulverized, polarize much more light than the Moon. The Full Moon polarizes no light, and practically no light is polarized when the Moon offers a very narrow, sunlit crescent. When the light intensity component in the plane Sun–Moon–Earth exceeds the corresponding component at right angles to this plane of diffusion, the maximum polarization in the visible (yellow light) is found to be —1.2 percent, for all parts of the Moon. The independence of the negative part of the polarization curve on the location on the Moon's near side indicates a fairly high degree of textural uniformity of this part of the lunar surface. Extensive laboratory experiments made with visual and photoelectric polarimeters, in attempts to narrow the choice of lunar surface models by careful comparison of laboratory and lunar polarimetric functions, have shown that the best match to the lunar soil at large is in dark, fine-grained basic to intermediate rocks.

Angle of inversion

In changing from positive to negative, the Moon's polarization passes through zero at a phase angle of about 23° called the angle of inversion. The angle of inversion remains constant only when the behaviour of light of a particular wavelength is considered: the angle increases with wavelength (whereas the degree of polarization generally decreases as the light becomes redder). The maximum polarization, at a given wavelength, generally decreases as the particle size decreases. Reducing the grain size of a rock usually has the effect of increasing its albedo, and this, in turn, generally decreases its maximum degree of polarization.

The maxima of the degree of polarization versus wavelength for at least one fines sample returned to Earth from Mare Tranquillitatis are identical to that of Mare Tranquillitatis as a whole, observed telescopically from Earth, suggesting that the polarimetric curves of fines just below the surface are similar to those pertaining to material actually on the surface.

It has been suggested that solar protons not only damage but also darken particles on the lunar surface. It is difficult for an experimenter to simulate all the appropriate aspects of the lunar environment in the laboratory, but it is clear that, if the solar wind were to darken fine particles derived from certain terrestrial rocks, their polarization functions could be made to approach or be rendered identical with those pertaining to the lunar fines.

The lunar rocks. Polarization studies of light-toned rocks brought from the Moon have shown that they either do not occur in large concentrations on the Moon's surface or they are generally covered with the fines responsible for the uniformity of the Moon's nearside polarization.

Infrared (heat) studies. Other evidence of a widely dispersed layer of dustlike material on the Moon is given by measurements of infrared radiation from the Moon. The lag shown by temperature changes of the subsolar point during eclipse shows the very poor conductivity of the lunar surface in the eight- to 14-micron (one micron $= 10^{-6}$ metre) waveband. Highlands and maria behave similarly, so the poorly conducting layer must cover most of the surface.

The poor surface conduction also produces differences in heat curves at different wavelengths. Measured at a microwave wavelength of 1.25 centimetres, the Moon's temperature attains a lower maximum than that determined by the eight- to 14-micron infrared measurements, and this lower maximum temperature occurs about 3.5 days later than the infrared maximum. The eight- to 14-micron radiation is from a surface layer only a millimetre or so thick, whereas the centimetre radiation comes from layers a few tens of centimetres beneath the surface. The Sun's heat generates the highest temperatures on the surface of the Moon, but deeper rocks are also warmed as the thermal wave penetrates and is attenuated in the poorly conducting regolith. Lunar radio emission derives from thermal energy finding its way to different levels in the Moon. Increasingly longer radio wavelengths have been used to observe the Moon at increasingly greater depths; but, although the average depth of the emitted waves increases with wavelength, the radiation at radio frequencies originates over a range of depths. In addition, the limit of angular resolution of a telescope increases with wavelength, so that, whereas the optical heat measurements may refer to a small patch of the Moon, the specific origin of the longer radio waves may be impossible to locate on the disk. At wavelengths above about ten centimetres, no diurnal change in the intensity of received radiation has been observed. In these cases the upper layers of the Moon, which show strong diurnal temperature changes, are contributing a negligible fraction of the total radiation received.

Changes in temperature with depth

In principle, radio observations provide a means of estimating the variation of temperature with depth in the regolith and, thus, of investigating any internal heat source such as one that could be produced by widespread radioactive elements. The thermal conductivity at depth in the Moon, however, is not yet well-known, nor is it in the troublesome regolith, in particular, where the temperature and depth dependence of conductivity is marked and thermal transport by radiation through incompletely specified vacuum pores contributes to the difficulties.

Theoretical models of the Moon's upper layers have been attempted, but it is not possible to derive the conductivity directly: density and specific heat (the amount of heat required to raise the temperature of a particular substance by a given amount) must be determined first. Furthermore, the specific heat of lunar rock depends on its temperature: the specific heats of both a vesicular basalt sample and a sample of regolith from the Moon have been found to change smoothly from 0.06 calorie per gram per °K at 90° K to 0.2 calorie per gram per °K at 350° K (0° K equals —273° C [—460° F]). Such dependence on the prevailing temperature can change the

thermal inertia of lunar surface materials by a factor of up to 2. A representative value of the thermal conductivity of the uppermost part of the regolith is about 5×10^{-6} calorie per centimetre per second per degree.

The so-called hot spots

During optical infrared scans across the eclipsed Moon with a resolution of details of about 20 kilometres, numerous patches of terrain—mostly eumorphic craters—have been found to be significantly warmer than their surroundings. The most easily recognizable thermal anomalies (hot spots) were associated with bright-ray centres such as Tycho, Copernicus, and Aristarchus. These craters remained cooler than their surroundings during the lunar daytime, and the hot spots could be areas of higher than average thermal conductivity permitting heat at depth to flow out during eclipse and be radiated to space more readily than from adjacent areas.

The night spectrum of Tycho, Copernicus, and Aristarchus, observed over the three- to 15-micron waveband, proved that the surface rocks of these craters emitted radiation from areas at widely different temperatures. Parts of the floors of two, Tycho (Figure 2) and Aristarchus, appear to be of ashy or regolith-type material, but other parts are probably volcanic domes apparently not covered by detritus or pyroclastics (substances fragmented by volcanic action). With geologically dissimilar rock units found in and around the craters, including lava flows with contorted surface ridging, such craters must be expected to generate cooling curves that are made up from several different cooling functions.

The hottest craters are invariably the most sharply sculptured, freshest looking features. Large blocks of rock and characteristically rough terrain may be resolved around several of these craters, the hottest 20 of which lie in the diameter range four to 16 kilometres (two to ten miles).

There are relatively few hot spots per unit surface of the highlands compared to the maria; the number density of hot spots changes significantly from one mare to the next. Mare Tranquillitatis, for example, sports an anomalously high number of hot spots per unit of its surface. The reasons are not well understood, though a tentative explanation may be offered in the last case. First, there is a positive correlation between the number of eumorphic craters in the lunabase and the number of hot spots in the same area. Second, a study of the shape parameters of small, concentric craters leads one to believe that at least the southern part of Mare Tranquillitatis has a thinner cover of regolith than most of the maria. It may be imagined that the sharpest eumorphic craters—which are almost certainly explosion craters—would be formed preferentially in areas of thin regolith, where the excavation of coherent bedrock could provide an abundance of ejected rock blocks.

A few cold spots have also been observed. Of the nine cold spots with the highest thermal gradients (those in excess of $\frac{5}{7}°$ C per second of arc), none is associated with a single, eumorphic crater.

Finally, there is the type of thermal anomaly in which a spot is observed to be hot during both eclipse and daytime conditions. Such a spot could be indicative of a source of internal heat.

Analysis of returned radar signals. For better understanding of the nature and origin of lunar thermal anomalies, more widely dispersed and improved estimates of the regolith thickness, layering, and conductivity are required. Analyses of radar returns from the Moon have proved of interest in this connection. The first part of a radar echo from the Moon returned to Earth derives from the central region of the Earth-pointing face. Later parts of the return signal come from rings of progressively increasing radii. Also, the lunar librational motions introduce frequency shifts in the return signals. As these effects are superimposed, it is possible to isolate the radar-reflection characteristics of two small patches on the Moon. Anomalously strong radar reflections were obtained in 1962 from Tycho and the corresponding area in the Moon's northern hemisphere. The latter had no topographic peculiarities, and it was concluded that Tycho was probably responsible for the anomaly: either the terrain in and around Tycho was very much rougher than that in any other equal area of the Moon's near side, or the rocks of Tycho were very much denser than those elsewhere. Since that time, photogeological studies of high-resolution pictures of the Tycho (Figure 2) area have shown that it is indeed rough.

Radar has been used, further, to estimate the porosity of lunar-surface materials. On radar wavelengths of ten to 100 centimetres, the effective dielectric constant (its ability to store electrical potential energy) of the lunar surface lies in the range of 1 to 2.7. To calculate its actual porosity, this can be compared with the assumed dielectric constant of its solid component. Returned fines have been used to estimate that the density of the solid rock is about 3 grams per cubic centimetre and that the corresponding dielectric constant at 450 megahertz is about 6. These figures, with a mean observed lunar dielectric constant of 1.6, show that the average porosity of the lunar surface layers may be over 80 percent. The results compare favourably with those from Earth-based photometry, although the two methods refer to data from different areas and to different effective depths.

Relative reflectivity

Radar studies of the relative reflectivity of small areas of the Moon's surface at 2.2 metres in wavelength involving the circumlunar satellite Explorer 35 show that, on average, the maria reflect approximately 30 percent more power than the highlands; and reflectivity structure was observed in the lunabase, a particularly high reflectivity being associated with a region near to the crater Flamsteed. There appears to be a significant correlation among radar reflectivity, hot spots, and regolith thickness; both the radar reflectivity and the number density of hot spots increase as the thickness of regolith decreases. The effective (mean) dielectric constant of the lunar rocks (lunarite and lunabase together) down to depths of several tens of metres is about 3, slightly more than the mean value of the dielectric constant of layers nearer the surface measured on shorter wavelengths from the Earth. The porosity of the lunar rocks should decrease, on average, with depth as, in a fragmental, or granular, regolith, the weight of the overburden will cause increased packing as the depth increases.

Physical experiments from orbiting spacecraft. Other physical experiments conducted by the Soviets from circumlunar orbits include a gamma-ray-spectroscopy experiment carried aboard the first artificial lunar satellite. Gamma rays are emitted by lunar radioactive elements, particularly potassium, uranium, and thorium, and the character of the emission can indicate whether the Moon has been chemically differentiated. Cosmic rays incident on the Moon induce a very much higher intensity of gamma-ray emission than that deriving from natural radioactive decay in the lunar rocks. Nevertheless, Soviet scientists have deduced that the surface rocks of the Moon were of the basaltic type and that a slightly greater intensity of gamma radiation derived from the maria. The indications were that the Moon was a differentiated body.

In another Soviet study, gamma rays from a cesium source carried by a soft landing craft were backscattered from the Moon as the probe was landing and were received and analyzed to determine the density of the surface rocks. Density was determined using a calibration curve of density against intensity of the scattered radiation and was considered to be 0.8 gram per cubic centimetre in a surface layer about 15 centimetres (six inches) thick. (The form of the calibration curve gave rise to an ambiguity in the estimated density. Of the possible solutions 0.8 and 2.1 grams per cubic centimetre, the former was preferred because of other evidence.)

THEORIES OF ORIGIN OF THE SURFACE FEATURES

In the early 17th century the lunar craters were thought to be endogenic; that is, of internal origin. The first part of the 19th century saw truly under way the argument as to whether most craters were caused by the impacts of external bodies or by volcanism. Theories that could not be classified as either volcanic or meteoric (impact) have also been proposed; but lunar craters are now generally

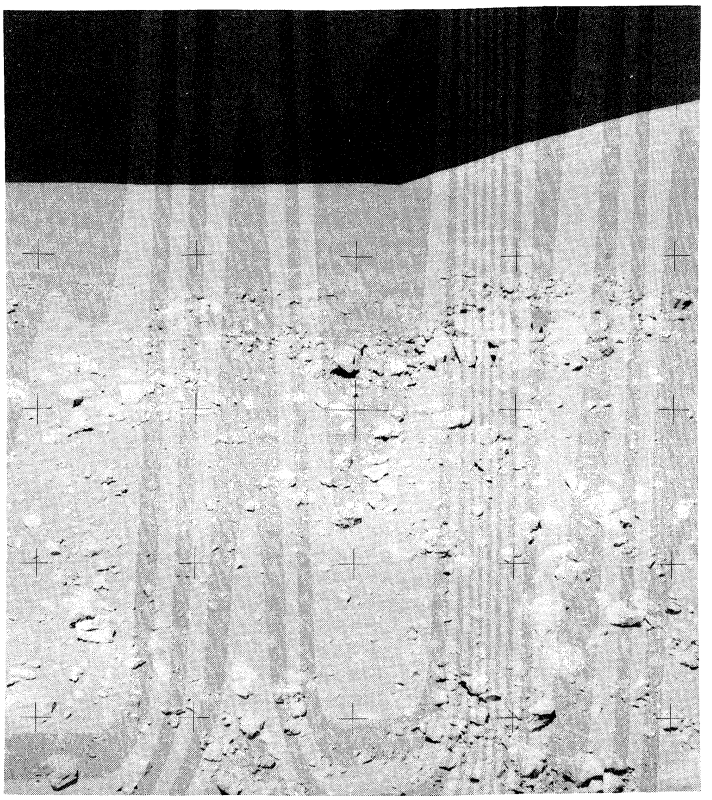

Figure 6: Surface of the moon at the Hadley–Apennine landing site photographed during the third Apollo 15 EVA (extravehicular activity), August 2, 1971.

thought to include both impact craters, of all sizes, and endogenic craters, predominantly in the sub-kilometre-size bracket.

Gas-bubble theory

Volcanic theory. One of the earliest hypotheses of the mode of formation of the lunar craters was the so-called gas-bubble theory of the English physicist Robert Hooke, who proposed in 1655 that they were formed by the collapse of huge bubbles of gas; the discharge of gas is a vital part of the volcanic process. On Earth in fluidized mud, as at La Solfatara, Italy, such bubbles commonly measure centimetres or decimetres in diameter, increasing in size with the viscosity of the containing medium and the gas pressure. In Iceland there are hollow domes of lava measuring metres in diameter; on the Moon the low gravity and lack of atmosphere could lead to significantly larger domes. In a later and more attractive theory, as far as the larger lunar craters were concerned, the starting point was a conventional eruptive centre such as might have given rise to a cone volcano of the Vesuvius type. Volcanic materials were ejected from the central orifice in a symmetrical fountain and landed to construct, layer on layer, a roughly circular ringwall. Sometimes, dying activity built up a central eminence; in other cases, the floor of a crater was flooded by dark lavas.

Comparison of lunar features with terrestrial ones

Volcanoes on Earth generally produce cones rather than ringwalls. In Iceland, however, a ring structure about one kilometre in diameter, called Hverfjall, has been formed by steam eruption. Hrossaborg is a similarly formed crater in Iceland; and there are many tuff or lava and tuff rings of kilometre size in terrestrial volcanic fields; for example, in Hawaii, Arizona, and Mexico, where central collapse or engulfment of materials tends to leave landforms resembling many of the lunar craters.

Both the bubble hypothesis and the volcanic-fountain theory were argued without any appreciation of the physical or geological principles involved. More competent arguments for lunar volcanism and caldera collapse are the similar morphologies of particular Hawaiian structures and certain lunar features. In 1944 a U.S. geologist, Josiah Edward Spurr, developed a theory that the larger lunar craters were volcanic collapse structures (calderas); he developed a classification of craters and described in detail the different modes of origin of different classes of crater. More importantly, he was the first to recognize the uniformity and extent of the overall structural pattern in the Moon's crust and to name it "the lunar grid system." Spurr's analyses were closely tied to his meticulous photogeological analyses of the lunar craters. Calderas may have developed during an intensive phase of lunar outgassing, while many of the low-walled ring formations on the Moon marked the positions of ring fractures from which lavas had been erupted in the precaldera phase of lunar crater formation.

Impact theory. The impact hypothesis was formulated comparatively late. Few people had seen a large meteoroid fall on Earth, though many had witnessed terrestrial volcanic eruptions. There was practically no evidence for live, meteoric cratering events on the face of the Moon. Even the U.S. geologist who had been one of the first to argue convincingly (in 1893) for impact craters had disputed the impact origin of the world's best authenticated meteoritic crater, in Arizona. Until recent years, few craters on Earth had been described as of probable impact origin. Many structures on Earth now regarded as impact craters had been branded cryptovolcanic craters by geologists. The predominantly circular shape of lunar craters was thought to be impossible to produce by impact, except from relatively rare, vertical impacts. It is now believed that a nearly circular crater would be blasted out of the lunar rocks by a large meteorite arriving at a high speed even if the angle of approach to the Moon's surface were far from the vertical.

This, essentially, is the basis of the modern impact theory. A vast array of statistical data on both terrestrial and lunar craters has been collected, compared, and analyzed by the U.S. geologist Ralph Baldwin, who developed a thesis on the assumption that the great majority of the lunar craters were of impact origin, argued for the cataclysmic formation of Mare Imbrium following a major collision between a large object and the Moon that resulted in a gigantic explosion. Later, it was reasoned that the nearly circular maria, all the large craters, and the majority of the small ones were impact scars and that later lavas, flooding impact basins such as that of Mare Imbrium, flowed further afield than the confines of the basins and created the irregular maria. Later impact theories differed considerably from Baldwin's in some details.

Impact velocities

The velocities of interplanetary meteoroids in the vicinity of the Moon are commonly of the order of tens of kilometres per second. Because, in such a meteorite-impact process, the energy is transformed and released very rapidly, little of the initial kinetic energy is converted into heat, and the rocks in the floor of a crater are not likely to be melted to any appreciable extent. A longer period of time for the impact is needed to give the Moon rocks time to absorb more of the heat that would otherwise be dissipated in other ways.

A ring 1,000 kilometres (600 miles) in diameter (such as Mare Imbrium; Figure 1) could be formed by impact of a high-velocity meteorite of less than one-tenth of that diameter or with a larger, lower velocity object. Asteroids, for instance, would collide with the Moon at relative velocities around six kilometres (four miles) per second. Objects circling the Earth in a ring at about the Moon's distance could collide with the Moon at velocities as low as the velocity of escape from the Moon's surface, 2.4 kilometres (1.5 miles) per second.

The Moon was nonspherical. It had a nonequilibrium shape (even allowing for the Earth's tidal effects) and a peculiar mass distribution. The most important irregularity in the Moon's distribution of mass was found in the excess mass in or around the axis directed toward the Earth. Support of the excess mass in the Moon's Earthward-pointing bulge implied considerable mechanical strength. If the Moon had undergone any appreciable melting phase in the past, it would still have had insufficient strength in its deep interior to support the bulge. This is regarded by some scientists as an indication that the Moon could never have been melted to any significant

Evidence against large-scale melting

extent. The mare lavas would have been derived from the impacts themselves, and, hence, the impacting bodies must have been large, low-velocity objects. The observed asymmetric pattern of radial grooves and ridges beyond the periphery of Mare Imbrium could be generated by splashlike ejecta following an oblique, low-velocity collision, whereas a high-velocity collision at a similar angle of impact would produce an ejecta pattern essentially symmetrical about the explosion centre. It is to be pointed out, however, that one prediction of this theory was that the Moon had not undergone widespread igneous differentiation, whereas such differentiation is now known to have occurred.

Modern views on the origin of the craters have been much influenced by Baldwin's statistical work. He showed that the ratio of the depth to the diameter of terrestrial shell, bomb, and meteoritic craters and of the craters of the Moon could all be fitted on smooth curves showing logarithmic plots of the ratio against the diameters of the craters. Terrestrial calderas (collapsed volcanic structures) also fit the depth-to-diameter curves of Baldwin. Further studies extended Baldwin's data, relating the ratios of rim widths of lunar craters to their diameters to that for volcanic craters and calderas on Earth; the six calderas studied had much wider rims than lunar craters of the same diameter (1–10 kilometres), though this may be because of underestimations of the lunar rims.

The shape of plots of the logarithm of cumulative number of craters larger than a certain diameter against the logarithm of that diameter has been said to be evidence for impact origin of the craters; probable amounts of meteoroidal debris in the solar system would collide with the Moon to produce craters giving a similar statistical result; that is, the numbers of lunar craters of various diameters seem to be relative to the numbers of meteoroidal bodies of various sizes, in space, available to produce the craters. Other workers, however, found that a high proportion of sub-kilometre-sized craters were not impact craters and that the proportion varied with position.

There is now no real doubt that both impact and volcanic features exist on the Moon. Many details and some major problems remain to be solved. The origin of the circular maria, as has been suggested, may be that basins were created by impacts and were later flooded by lavas from within the Moon; the same argument may apply to many of the larger craters, but, if true in some cases, there are still exceptions. For Mare Orientale, there is much to be said for an explosive origin, since, for one thing, many characteristics of the surrounding terrain may be so explained. Other maria may be predominantly lava-filled calderas of igneous origin. The maria differ in age and were not all formed in one short-lived catastrophe.

IV. The origin and evolution of the Moon

THE EVOLUTION OF THE MOON'S ORBIT

The sea tides raised on the rotating Earth by the gravitational attraction of the Moon and the Sun make an important contribution to the transfer of the Earth's angular momentum to the Moon. Tidal friction is slowly reducing the Earth's rate of rotation: its day is increasing by about 1.8×10^{-3} second of time per century. Some of the energy of the Earth–Moon system is dissipated as heat. Energy is exchanged with the Earth–Moon system by other bodies, the Sun in particular.

Most of the angular momentum lost by the Earth is transferred, by gravitational interaction, to add to the Moon's orbital angular momentum, and this tends to accelerate the Moon. As a consequence, the Moon is lifted into a slightly higher orbit, farther from the Earth, and appears to slow down relative to the fixed stars. This deceleration may be measured by observing the position of the Moon's mean longitude relative to the stellar background. It is common practice to refer to the secular acceleration of the Moon, preceding the numerical value by a negative sign, and estimates range from −40 arcsec/century^2 (40 seconds per century per century, deduced from observations of solar eclipses) to −10 arcsec/century^2. The difference is actually double rather than quadruple because the astronomical value refers to the coefficient T^2 in the equation for mean longitude; the value −10 is thus exactly one-half the larger determination.

Secular acceleration of the Moon

The classical works of the English scientist George Darwin, as recently refined, show that, if the presently observed motion of the Moon is taken as a basis for examining its past behaviour, the Moon was once very much closer to the Earth and was in an orbit more highly inclined to the ecliptic than is its present orbit (which makes an angle of only a little over 5° with the ecliptic). Some 2×10^9 years ago the Moon would have been at a distance of 2.8 Earth radii, revolving around the Earth—which would then have had a five-hour day—in 6.5 hours in an orbit of inclination of about 46° to the ecliptic.

Such calculations, involving the gravitational interaction of more than two bodies, may now be performed effectively using modern computing techniques, but the results relating to large time intervals in the past or future are critically dependent on the assumptions made before the problem is processed. The older observations of the Moon's motion lack high accuracy. A homogeneous set of modern occultation observations is not sufficiently dispersed in time to discover any variability of the secular acceleration. There is still some uncertainty about the respective roles of shallow and deep seas in the tidal-friction problem and about the role of terms from small-scale irregularities in the Earth's gravitation potential regarding the dissipation of the angular momentum. Although, in some calculations of the past history of the Moon's orbit, the Earth's viscosity and moment of inertia (resistance to change in rotation) were assumed constant, the thermal evolution of the Earth, the progressive separation of materials to form the core and the mantle, and the changing positions and areas of the continents and seas must have changed these important parameters. Most scientists now regard the oceans to be a comparatively late acquisition of the Earth.

For reasons such as these, it is clear that it would be unwise to rely too heavily on extrapolations of the Moon's presently observed orbital behaviour in speculating on the origin of the Moon itself. It may be safe, on the other hand, to say that the Moon seems to be receding from the Earth at the present time and that the Earth–Moon distance may have been considerably less in the distant past. It has been suggested that the Moon, not being a fluid, would not have undergone disruption by the Earth's gravity even if the Moon had come within the Roche limit; that is, the distance within which breakup can occur if the body's binding strength is not enough to prevent it. At such a time the inclination of the lunar orbit would have progressed back through 90°, and thus the orbit would have been a retrograde one. Still further backward extrapolation, if correct, leads to the notion that the Moon has been captured by the Earth.

Changing distance of the Moon

A more cautious view is that the Moon might once have been within several Earth radii of the Earth's centre. Suggestions that the Moon separated from the Earth at a very early stage in the history of the solar system were revived in the 1960s. The weakness of such theories is that they are essentially attempts to explain the mechanics of the hypothetical separation process without regard for the geological evidence against them.

EVIDENCE FROM THE COMPOSITION AND PHYSICAL PROPERTIES OF THE MOON

Chemical analysis of lunar samples. The first orbital measurements of the broad composition of the rocks covering the Moon's surface served to confirm the speculations of photogeologists, who had argued for the presence of basic rocks, such as the mare basalts.

Detailed and more accurate measurements of the compositions of lunar samples were made *in situ*, for the first time, through the use of instruments carried by soft-landing vehicles beginning in 1967. One such craft landed in Mare Tranquillitatis, another in Sinus Medii, and another on the edge of a flow unit in the highlands near Tycho. Their findings indicated compositions close to those of some basalts on Earth, but there were differences between

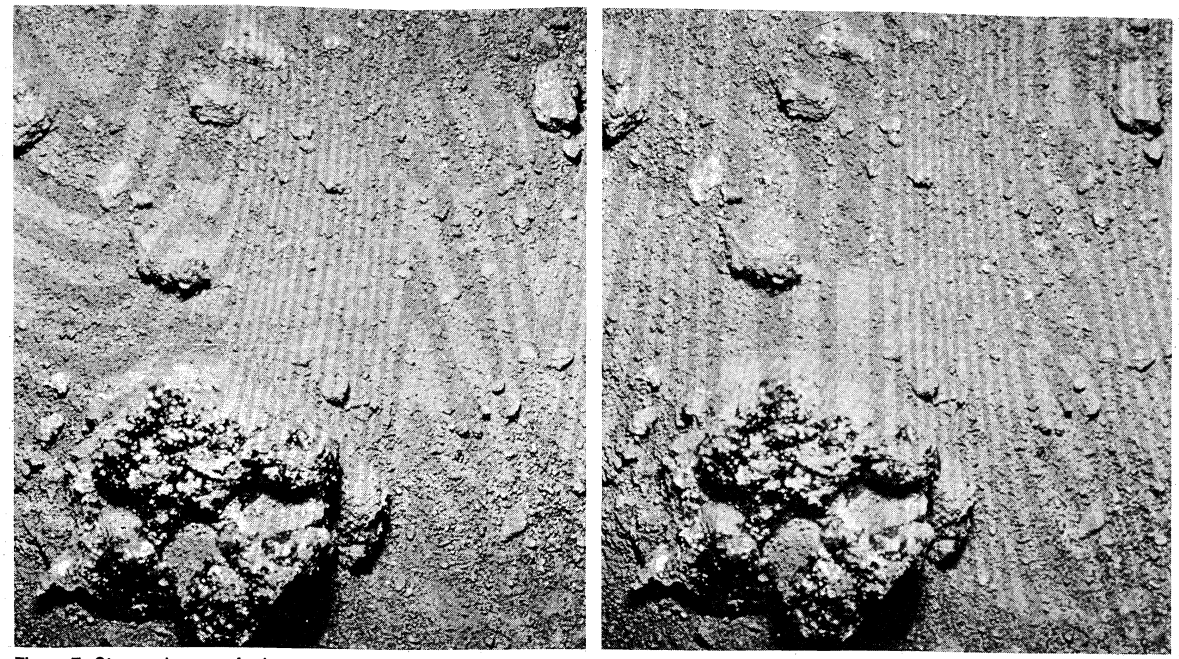

Figure 7: Stereo closeup of a lunar rock taken during the Apollo 12 EVA (extravehicular activity) on the lunar surface. A long handle on the camera permitted the astronaut to position it for surface object photography without stooping. The image scale is half actual size.

the highland analyses, on the one hand, and the earlier analyses in two patches of the lunabase. In the highland site, undisturbed lunar soil, disturbed soil, and a small rock block were analyzed separately. The rock block had a chemical composition that closely paralleled that of the undisturbed soil except for the elements magnesium and iron, which were slightly less abundant in the rock, and aluminum, which was slightly more abundant. Taken as a whole, the results indicate that the Tycho flow unit is compositionally similar to anorthosite, a granular igneous rock on Earth.

The results of the soft-landing program led many authors to suggest that the lunar highlands in general were higher in aluminum and calcium and lower in the iron-group elements (those with mass numbers between about 47 and 65) than the maria. More iron in the maria could contribute to their generally darker tones and could also contribute to the possibly higher rock density of the mare units.

Chemical differentiation

By 1968, scientists were beginning to appreciate the fact that the Moon had more in common with the Earth than many of them had been prepared to accept previously. It appeared that the Moon had suffered some degree of chemical differentiation and that its face presented not only physiographic domains but also true geological domains (the highlands and the lunabase) that differed in density. Furthermore, if these areas were to be established as separate geological domains, it would be clear that the Moon had been differentiated and heated. The evidence for the mare–highland rock contrast, however, was slender. First, it was based on only one analysis in the highlands. Second, the rocks analyzed were not necessarily typical highland material, especially in view of the fact that the vehicle had landed on some sort of flow unit. Third, two independent methods were used to determine the iron content of the soil in three cases, and, in the last, the methods gave discordant results. One method seemed to show that iron at Tycho was present in only half the concentration of that at the two mare-type Surveyor sites, while the other indicated there was essentially no difference in iron concentration among the three sites. One possible reason for this discrepancy is that the two methods were used to examine different samples of Moon rock. Magnetic experiments indicated that the lunar samples were of basalt with little (about 1 percent by volume) or no addition of meteoric nickel–iron. This level of iron is less than would be expected if meteoroids were the only agent responsible for breaking up and gardening the lunar rocks.

The first samples of Moon rock (Figure 7) to be returned to Earth for exhaustive study were collected in Mare Tranquillitatis in July 1969. Since that time, rocks from Oceanus Procellarum, Fra Mauro highlands, and Hadley Rille, in Mare Imbrium, have been returned to Earth and analyzed by scientists of several nations; and rocks collected and returned to Earth automatically from Mare Fecunditatis have been analyzed in the Soviet Union.

All the rocks (Figure 7) are volcanic basalts (a type of rock formed by solidification of magma) except for small meteoric (~1 percent), anorthositic (granular igneous rock), and glassy components in the surface debris. The coherent, basaltic rocks subdivide into those of vesicular, crystalline type and breccias (consisting of compacted regolith materials) formed from the regolith materials, although the breccias and regolith contain fractions of meteoric nickel–iron, anorthosite, and glass, and, among themselves, glass particles show a range of composition which includes that of basalt.

Evidence that meteoroids have been an important factor in shaping the Moon is found in the shocked minerals present in the returned rocks. Many authors consider that the compositional similarity between the anorthosites and the rocks of the Tycho highlands points to the anorthosites and some of the shocked materials found in the mare regions having been ejected from the highlands. The glasses that have undergone selective volatilization and that range widely in overall composition have probably derived from the melting of materials at a variety of impact sites. Certain glass globules of more uniform composition may be volcanic in origin.

Density at different depths

The astronomically determined mean density of the Moon as a whole is 3.34 grams per cubic centimetre, and the mean density of the basalts returned from the Moon's surface has a similar value. Yet the Moon cannot be composed of these mare basalts all the way through, since, at the pressures existing at moderate depths in the Moon, such materials would suffer a phase change and transform to eclogite, which has a density of 3.7 grams per cubic centimetre. One hypothesis is that the lunar highlands are composed of anorthosites of density between 2.8 and 2.9 grams per cubic centimetre, and certainly the bulk of the Moon's outer parts must be of rock with lower density than basalt. Yet, by comparison with

the average chondrite (the most common type of meteorite), the returned lunar basalts are, generally speaking, enriched in silicates and oxides and depleted in iron-group elements, and this is consistent with the theory that the Moon has undergone general magmatic differentiation that might have led to the formation of a nickel–iron core. Dynamical considerations limit the mass of iron in any lunar core to 6 percent of the Moon's mass, so that the core, if it exists, must be very small compared to that of the Earth.

Differences in the abundances of the element are observed at different lunar sites. Some differences could be related to crystal fractionation (crystallization of successive minerals with falling temperature) in near-surface melts, and, if the final products of fractionation had neared the lunar surface, the residual liquid rocks would have crystallized as granites. A few such fragments have been reported. In the rocks from Mare Tranquillitatis, titanium (occurring principally as ilmenite, $FeTiO_3$) was found to be much more abundant than in either chondrites or most terrestrial rocks. Evidently, the lavas in Mare Tranquillitatis contain more titanium because they were extruded at a stage in the fractionation process when certain elements, including titanium, were enriched in the melt.

Origin of mare lavas

Formation of the maria and highlands. The geological evidence for magmatic differentiation, partial melting, and crystal fractionation seems to rule against the theory that the mare lavas were generated by impact; rather, it seems that they came from deep within the Moon. Furthermore, the lavas were extruded at widely different times. Standard rock-dating methods show that the crystalline rocks from Mare Tranquillitatis last solidified 3.7 $\times 10^9$ years ago, whereas those from Oceanus Procellarum crystallized between 2.8 and 3.4 $\times 10^9$ years ago. One piece of rock returned in 1971 from the lunar highlands is reported to be 4.1 $\times 10^9$ years old.

Stratigraphers have attributed a greater age to the lunar highlands, relative to the mare units. Consequently, if this age were correct and representative, the lunar highlands would be very much older than any of the Earth's dated rocks—the oldest meteorites. The crater counts in distinct geological units suggest that parts of Tycho and Aristarchus are considerably younger than the surrounding materials, so there may be a dispersion of ages in highland material as well as in mare material. The highlands were probably formed overall, however, in the first few hundred million years of the solar system; whereas in the case of the mare lavas at least some of them were extruded and flowed across the surface after a further interval of hundreds of millions of years.

The thermal history of the Moon. Certain radioactive isotopes of the elements potassium, uranium, and thorium are, together, the most important source of radioactive heating in the Moon, and more of these elements occur in the lunar rocks than in the chondrites, possibly through fractionation. The Moon, if built out of chondrite material, was probably at least partly melted, over an epoch centring on about 2 $\times 10^9$ years after its formation. The extent of the melting would depend on the initial temperature of the Moon, but the period of maximum melting would appear to approach or coincide with the outpourings of the mare lavas.

The observed concentration of radioactive elements in returned lunar basalts, as well as the geological evidence, establishes the fact that the Moon underwent widespread melting. It has been argued that, because this melting occurred early in the Moon's history, the initial temperature of the Moon was high. The gravitational energy of accumulation of the Moon provides one early source of heating. Another source is the transfer of tidal energy to the solid body of the Moon by the Earth when the two planets were closer together, but it is uncertain whether the highest temperatures produced by such transferral of energy would be at the centre of the Moon or in its outer layers.

Possible sources of melting heat

A more complete picture of the Moon's internal composition and structure is needed to clarify details of the Moon's thermal history and origin. Surface faults and the general tectonic pattern on the Moon's surface demonstrate that the Moon has undergone general adjustments at least in its outer parts. Meteoric impacts and at least one deep-focus moonquake have been deduced from records made by instruments left on the Moon. The records are difficult to interpret, because the maria where the first instruments were landed are good scatterers of seismic (earthquake-like) vibrations that, nevertheless, are damped out much more slowly than seismic signals on Earth. Major structural discontinuities, such as are found in the Earth's interior, have not yet been found in interior of the Moon.

Correlation of physical and chemical data. Remanent magnetization has been found in lunar crystalline-rock samples. Further studies of the specimens may throw some light on the origin of the magnetization, which may be associated with the Moon's core. Evidence drawn from surface instruments has been combined with that derived from other sources to deduce the bulk electrical conductivity and temperature profile of the lunar rocks at different depths. Although the electrical conductivity of rocks has a low value near the surface of the Moon, it increases to a depth of the order of 200 kilometres (120 miles). A mantle with the conductivity of basalts and a core with the conductivity of olivine-like materials would be consistent with these observations. The precise temperature of the core is not yet decided; the core's temperature must be related, for example, to the initial temperature of accumulation of the Moon and to the extent and rate of redistribution of radioactive elements in the upper layers of the Moon.

A picture of the Moon's evolution and origin is now beginning to emerge from the mass of extremely varied data. The elemental abundances of the stony meteorites and of the rocks of the Earth seem to be much the same, but they differ from the overall abundances of elements on the Moon. The Moon may be not a captured body but one formed in the immediate vicinity of the Earth during

an era in which planets were forming by the accumulation of particles.

THE "CIRCUMTERRESTRIAL SWARM" THEORY

The Moon's origin from a "circumterrestrial swarm" was proposed in 1950 and later modified. Bits of dust, meteorites, and larger planetesimals are believed to have come together to form the primitive Earth and a surrounding ring of debris. The metallic iron content of the swarm of material was accumulated by the Earth, whereas silicates tended to evaporate in the Earth's extensive atmosphere. The atmosphere dissipated; the silicate phase precipitated and accumulated to form the Moon. In this way the Moon accreted material of lower mean density than that of the Earth. The bulk of the lunar iron may now be found in a small lunar core. The lunar basalts are depleted, relative to chondrites and terrestrial basalts, in water and volatile elements that might have dispersed prior to accretion or as a result of the general outgassing of the Moon's rocks following intensive phases either of early bombardment or of later volcanism.

Nearly all the gases of the lunar atmosphere soon escaped, even perhaps as the Moon was still accumulating, the exact times depending on such factors as the mass of an atom of gas, the temperature of the upper layers of any temporary atmosphere, and the velocity of escape of a particle from the Moon at that level. Any secondary atmospheric gases (those derived from within the Moon) present on the Moon now or any gases remaining from encounters with comets would be composed of the heaviest gases—such as argon. Rare gases are found to be concentrated in the lunar soils and breccias; these gases are believed to have originated from the solar wind or solar cosmic rays. (G.Fi.)

Moore, Henry

Henry Moore is a British sculptor who represents the continuance of a vital tradition of humanist sculpture into the 20th century. In his early career, before 1940, he seemed to be a revolutionary, introducing new forms and new images into sculpture, deeply involved in the Abstract and Surrealist movements. With World War II, however, the humanism of Moore's sculpture became dominant, and his shelter drawings of Londoners sleeping in the Underground during air raids brought him new popularity and the status of a modern artist who could speak directly and powerfully to ordinary people. In the postwar years Moore was pre-eminent among living sculptors, with an international reputation based on work that seemed to use a new sculptural language to express ideas common to humanity since time immemorial.

Moore in his studio, mid-1960s.

Background and education. Henry Moore was born July 30, 1898, at Castleford, a small coal-mining town near Leeds, Yorkshire, in the north of England. He was the seventh child of Raymond Spencer Moore, a Lincolnshire man of Irish ancestry, and his wife, Mary Baker, who came from Staffordshire, in the English Midlands. Moore's father came from farmworker stock, but for most of his life he was a coal miner. He was a self-educated man and an active Socialist and trade unionist.

A clever child, Moore won a scholarship to the Castleford Grammar School, where he studied from 1909 to 1915. He was helped and much encouraged by the art instructor Alice Gostick, evidently an exceptional teacher who had several gifted pupils. Already ambitious to become a sculptor, the young Moore acceded to his father's wish that he should first train to be a schoolteacher, like his older brother and sisters. For several months he did

practice teaching at his old primary school in Castleford, a necessary preliminary to entering a teachers' training college.

Service in World War I

Because of World War I such plans had to be postponed, and in February 1917 Moore joined the British Army as a private in the 15th London Regiment. He was sent to France in the summer of 1917 and stationed in a quiet sector of the Western Front near Arras. Later in the year he was transferred to the Cambrai section, where the fighting was heavy, and, after an intensive bombardment, Moore suffered from the effects of gas shells. He collapsed and was sent back to England for two months' hospital treatment. After further convalescence he made a complete recovery and became an instructor in physical training until his return to France in November 1918, the month of the Armistice.

Moore left the army in February 1919 and went back to teaching small children. But in September he was given a rehabilitation grant, to which he was entitled as a former serviceman, and he went to the Leeds School of Art, where he studied for two years. In his first year at Leeds, Moore spent most of his time studying drawing. Although he wanted to study sculpture, no teacher was appointed until his second year; and Moore was his first pupil. He was soon joined by a very young student from nearby Wakefield, Barbara Hepworth, who also was to fulfill an early childhood ambition and become a major British sculptor.

As a result of his contact with the flourishing artistic life in Leeds, Moore's intellectual horizons slowly began to broaden. He was excited by the modern paintings that he saw in the private collection of the vice chancellor of the University of Leeds, Sir Michael Sadler, who was responsible for the first English translation (1914) of the classic manifesto of abstract art, *Concerning the Spiritual in Art*, by Wassily Kandinsky, a Russian abstract painter.

At the end of his second year at Leeds School of Art, Moore passed the sculpture examination and was awarded a Royal Exhibition scholarship to study at the Royal College of Art. In September 1921 he moved to London and began three years of advanced study in sculpture; he took his diploma at the Royal College after two years and spent a third doing postgraduate work. Moore found a good friend and lifetime supporter in the director of the Royal College, William Rothenstein, who was not unsympathetic to modern artistic tendencies, although he remained a conservative himself.

Studies at the Royal College of Art

Instruction at the Royal College of Art was less important to Moore than the opportunity of private study in the museums of London—particularly in the British Museum, with its wide-ranging and unrivalled collection of ancient sculpture. There was also close at hand the fine collection of Auguste Rodin sculpture at the Victoria and Albert Museum, but Moore was already reacting against the European sculptural tradition and turning instead to primitive and archaic art. He was discovering for himself the strange power and unusual beauty of Egyptian, Etruscan, and, later, Mexican and African sculpture.

Away from the college, spending vacations in Norfolk (where his parents now lived in retirement), Moore began to carve directly, in wood and especially in stone, making heads and small figures and animals.

Travel and further artistic influences. Upon graduating from the Royal College in 1924, Moore was appointed a part-time instructor in sculpture for a seven-year term. His exceptional gifts and potential stature were already recognized by those who knew him best. He was also awarded a travelling scholarship and spent the first six months of 1925 in France and Italy. He had already made the first of many visits to Paris in 1923, when he was particularly interested in the Paul Cézanne paintings of bathing figures that he saw in the Pellerin Collection. In Italy he stayed in Rome, visiting Florence, Pisa, Siena, Assisi, Ravenna, Padova, and Venice.

Back in England, Moore began work in 1926 on the first of his reclining women. He was also carving in stone: half-length female figures, mother and child groups, masks and heads. Though certain works show his awareness of the Romanian sculptor Constantin Brancusi and the Cubist sculptors, the most important influence on Moore's work at this time was that of ancient Mexican stone carving. In 1925, in the Trocadero Museum in Paris, he had been impressed by a plaster cast of the Chac Mool—a Mayan limestone sculpture of the rain spirit, depicted as a male reclining figure with knees drawn up together, staring head at a right angle to the body, and hands holding on the stomach a flat dish for sacrifices. Moore became fascinated with this sculpture, which seemed to him to have qualities of power, sensitivity, three-dimensional depth, and originality of form that no other stone sculpture possessed. Disdainful of conventional standards of the beautiful, seeking a way of imbuing his own work with such qualities, he changed the Mexican male figure into a female one, the better to express a more human, more earthy, more rhythmic image of his own.

Influence of ancient Mexican stone carving

Guaranteed a small income from part-time teaching, Moore was in no hurry and could absorb influences and work out his own ideas in relative tranquillity. In 1928 he was ready for his first one-man exhibition, at the Warren Gallery in London, and he began his first public commission, a relief carving of the "North Wind" on the new headquarters building for the London Transport Board —part of an ambitious decorative scheme to which Jacob Epstein and Eric Gill also contributed sculptures. In 1929 he married Irina Radetzky, of Russian–Austrian parentage, who was a painting student at the Royal College of Art. The young couple moved into a large studio in Hampstead, one of the northern suburbs of London. He now began a close association with a group of young artists who in 1933 formed Unit One, a deliberate attempt to make the indifferent English public aware of the international modern movement in art and architecture. The driving spirit behind Unit One was the painter Paul Nash, but the leading members were Ben Nicholson and his wife, Barbara Hepworth, who now lived in a neighbouring studio in Hampstead. Another neighbour, close friend, and advocate was the poet and critic Herbert Read, who wrote the first monograph on Moore in 1934.

Formation of Unit One

Achievements in the 1930s. Around this circle of friends the most advanced artistic activity in England in the early 1930s was centred. They were all interested in abstract art at a time when this was considered the ultimate in artistic extremism. In his own work from 1931 onward, Moore moved tentatively away from the human figure to experiment with abstract shapes and, more individually, to combine abstract shapes with references to the figure.

In 1931 Moore had the first of many one-man exhibitions in the Leicester Galleries in London. His work was enthusiastically introduced by Jacob Epstein, but it aroused violent criticism in the press and made Moore a notorious figure. He was urged to resign his position at the Royal College of Art, and, when his contract expired in 1932, he left to start a sculpture department at the Chelsea School of Art. There he taught part-time until the outbreak of war in 1939. Much of his more ambitious work was necessarily done during vacations, when the Moores lived in a country cottage, at Barfreston in Kent from 1931 to 1934, and then at Kingston near Canterbury, where Moore also had a large field that enabled him to work out of doors in the open landscape.

Throughout the 1930s Moore displayed in his work not the slightest inclination to please the public. He was very interested in Pablo Picasso's drawings and paintings of the late 1920s, which have strong sculptural implications, and felt free to distort and break up the forms of the body in a much more radical way than before. Sometimes he seemed to leave the human figure behind altogether. The pages of his sketchbooks of this period show him full of ideas for abstract sculptures that make use of organic and natural forms rather than pure geometrical shapes. He was collecting pebbles, rocks, shells, and bones, making drawings of them, studying them to find what he called "nature's principles of form and rhythm," which he sought to apply to his own sculpture. In particular, this meant opening up the carvings with concavities and even with holes pierced right through the forms—a practice

often found shocking and abhorrent when the sculpture retained a strong suggestion of the human figure.

Surrealist allegiance

The courage to experiment perhaps explains why Moore became a founder member of the Surrealist group in England and shifted his allegiance away from the more dogmatic abstract artists. He was not a polemicist, however, and thus did not engage in the disputes of the 1930s between the rival avant-garde factions of Surrealist and abstract artists. Without contentiousness and with great lucidity, Moore set forth his ideas about sculpture in several articles and reviews written in the 1930s and early 1940s.

Changes wrought by World War II. When the war broke out, Moore's whole pattern of existence changed. The Chelsea School was evacuated from London, and Moore stopped teaching. At first he worked mostly in his cottage in Kent, until its propinquity to the Channel coast, where invasion was hourly expected, forced a return to London. For a time he used one of the Hampstead studios that Barbara Hepworth and Ben Nicholson had evacuated on their move to Cornwall, but in October 1940 this was damaged by bombing, and the Moores took a house at Perry Green, Much Hadham, in Hertfordshire, which became their permanent home. There, in tranquil countryside about 20 miles north of London, he slowly added studios and extra rooms to an ancient farmhouse with wooden beams and low ceilings.

Shortage of materials in the early years of the war forced Moore to concentrate on small sculptures and then exclusively on drawing. Seeing the people of London sheltering at night in the stations of the London Underground in September 1940 led him to begin his shelter drawings. Moore would spend the night observing and making small sketch notes; then, in the next days at the Much Hadham studio, he would work his ideas up into large coloured drawings that expressed in permanent form the resigned but indomitable spirit of Londoners during the bombing of their city. While making the drawings, Moore was appointed an official war artist under a government scheme to employ artists to make a record of the war (not for propaganda purposes but as a historical witness). He also visited the colliery in Castleford, Yorkshire, where his father had worked, and made drawings of the coal miners at work, which have a strength and dignity similar to the shelter drawings.

Moore's wartime experiences led him to reconsider the relationship between the modern artist and his public. Instead of the widespread idea that there is necessarily a conflict, Moore came to believe that the artist should be a leader and that there was a public role for him to play. He agreed to become a trustee of the Tate Gallery in 1941 and has since served on the boards of numerous public institutions, including the Arts Council, the British Council, the National Gallery, the Royal Fine Art Commission, and the National Theatre—all of them state-financed institutions in which decisions are made by independent committees.

Church art

In 1943 Moore accepted a public commission to create a "Madonna and Child" for the church of St. Matthew in Northampton. His willingness to do this, although he was not a Christian himself, is further evidence of his feeling that the modern sculptor must be ready to meet a new audience. Moore has written about his initial uncertainty when asked to carve the "Madonna and Child," but the possibility of reviving the great tradition of religious art appealed to him, and he tried to give his figures for Northampton "an austerity and a nobility, and some touch of grandeur (even hieratic aloofness) which is missing in the everyday 'Mother and Child' idea."

Another commission, for a family group, followed in 1944, and the result was a dramatic change in Moore's style, away from the experimentation of the 1930s and toward a more naturalistic approach that had an immediate popular appeal. Moore had made dozens of studies in clay and terra-cotta when working on the "Madonna and Child" and family-group commissions, and these were cast in bronze and issued in editions of seven or nine copies each. In this way, Moore's work became available to museums and collectors all over the world.

This humanistic work of 1943–46 was the basis of Moore's international reputation, which dates from the large retrospective exhibition held in 1946 at the Museum of Modern Art in New York. On this occasion Moore visited the United States for the first time. American collectors began to buy his work, and henceforward he was at last freed of financial worries and able to work on the scale he felt his sculpture demanded. In Europe, too, Moore's reputation as an outstanding sculptor was confirmed when he won the sculpture prize at the 1948 Venice Biennale; more than 100 retrospective exhibitions followed in various countries.

In Britain, Moore fulfilled several commissions that extended the range and scale of his work: family groups for the new towns of Stevenage, Hertfordshire, in 1948, and Harlow, Essex, in 1954–55; "Three Draped Standing Figures" in stone (1947–48) for Battersea Park, London; a "Madonna" for St. Peter's church in Claydon, Suffolk, in 1949; and a large "Reclining Figure" for the 1951 Festival of Britain. The death of his mother, in 1944, and the birth of his only child, Mary, in 1946, made the theme of the family—particularly the mother and child relationship—a more personal one, expressive of Moore's deepest feelings. Although Moore himself neither encouraged nor endorsed psychological interpretations of his work, it is evident that on its most profound level it is a statement about nature and the qualities of the most basic human relationship—that of mother and child.

Later years. Critics who had begun to think by 1950 that Moore, the revolutionary sculptor, had been tamed, were to be proved wrong by the appearance in that year of the bronze standing figures, with their harsh and angular pierced forms and distinct feeling of menace. When, in the summer of 1953, Moore was ill, his work began to turn inward, showing a willingness to experiment and to follow private concerns. A large marble carving he made in 1957–58 for the headquarters of UNESCO in Paris belongs to a long series of reclining female figures, but the brick sculpture relief made in 1955 for the Bouwcentrum in Rotterdam reintroduces biomorphic forms into his work, and this leads to the series of freestanding totemic upright figures made in 1955–56. Moore also varied his subject matter in the 1950s with such works as the "King and Queen" of 1952–53, and the two warriors, the "Warrior with Shield" of 1953 and the "Fallen Warrior" of 1956–57—rare examples of Moore's use of the male figure. All three works owe something to Moore's visit to Greece in 1951, when he saw Athens, Mycenae, and Delphi for the first time. Most of his sculpture since the war was in bronze, though he had not altogether stopped carving in wood and stone. Furthermore, even when the sculptures were cast in bronze, they were not modelled in clay but built up initially in plaster over a wire and wood armature. Moore always liked to work like a carver, cutting and scraping and chiselling the surfaces with a carver's tools.

Turn toward private concerns

From the time of his 60th birthday in 1958, Moore seemed less concerned with his public role as a modern sculptor and more inclined to pursue his private interests. It is true that he continued to accept commissions, most notably for the Lincoln Center in New York in 1963–65 and for the University of Chicago in 1966; but in both cases, unlike earlier commissions, Moore made no attempt to provide a sculpture peculiarly appropriate for the site: he used the commission to work out on a larger scale than would otherwise have been possible, an idea that had long occupied his imagination. Thus, the Lincoln Center sculpture is the largest of a series of multipart reclining female figures in which Moore makes use of symbolic correspondences between the body and such elements of landscape as cliffs, caves, and hillsides and between the body and organic forms, particularly human and animal bones. Although the University of Chicago's "Atom Piece," with its mushroom-cloud formation at the top, commemorates the splitting of the atom, the sculpture is also closely related to other large abstract sculptures of the 1960s: the "Locking Piece" of 1963–64, the "Three-way Piece No. 1: Points" of 1964, the "Knife-Edge Two-Piece" of 1965, and the "Three-Piece Sculp-

ture No. 3: Vertebrae" of 1968—all of them massive objects that have lost their obvious human connotation as a consequence of their enormous size.

Some of the abstract sculptures from the mid-1960s and after were executed in marble rather than bronze. Beginning in 1965, Moore had a summer cottage at Forte dei Marmi, near the Carrara stone quarries, and, with the assistance of Italian workmen, began to make stone carvings again. At times he used marble of unusual colouring, notably a pinkish stone.

Moore has been much honoured, receiving honorary degrees from numerous universities, including Cambridge, Harvard, and Oxford. He was awarded the Companion of Honour in 1955 and the Order of Merit in 1963—the highest distinction that can be offered to a British subject. Yet he remained a forthright and simple man who never lost touch with his working class origins and continued to be proud of his miner and farm-labourer forebears. He established an unostentatious way of living, his daily routine consisting in working mornings supervising the activities of his small secretarial staff (which arranges sales and exhibitions, supplies information and photographs, and the like) and of the two or three young sculptors who help with the more laborious and time-consuming activities that the making of sculpture entails; in the afternoon, a leisurely lunch and then more supervision in the studios, for every stage is carefully controlled, and Moore's active participation is evident on even the largest sculpture; finally, whenever possible, an hour or more alone, working in a small studio, using pebbles and bones to try out on a minute scale ideas that may lead to nothing or may become the basis of a sculpture of considerable dimension. The only sign of wealth is his art collection, the work of artists whom he most admires—a small "Bathers" composition by Cézanne, figure drawings by Edgar Degas and Pierre Renoir, landscapes by Gustave Courbet, and sculptures by Rodin and the early Italian masters. In later life his taste became less purist than it was when he was a young man, for he came to be more aware of belonging to the sculptural tradition he had persistently reacted against that encompasses Michelangelo and Rodin.

MAJOR WORKS

Sculpture

MARBLE, STONE, WOOD AND LEAD, and WIRE: "Mother and Child" (stone, 1924–25; City Art Gallery, Manchester, England); "North Wind" (stone, 1928–29; St. James's Park, London Transport building, London); "Reclining Figure" (stone, 1929; City Art Gallery, Leeds); "Reclining Women" (stone, 1930; National Gallery of Canada, Ottawa); "Two Forms" (wood, 1934; Museum of Modern Art, New York); "Figure" (marble, 1937; Art Institute of Chicago); "Recumbent Figure" (stone, 1938; Tate Gallery, London); "Mother and Child" (wood, 1938; Museum of Modern Art, New York); "The Bride" (lead and wire, 1939–40; Museum of Modern Art, New York); "Madonna and Child" (stone, 1943; St. Matthew's, Northampton, England); "Memorial Figure" (stone, 1945; Dartington Hall, Devon); "Time-Life Screen" (stone, 1952–53; Time-Life Building, Bond Street, London); "Internal and External Forms" (wood, 1953–54; Albright-Knox Art Gallery, Buffalo, New York).

BRONZE: (most in multiple editions): "Family Group" (1948–49; Tate Gallery); "Helmet Head No. 1" (1950; Tate Gallery); "Reclining Figure" (1951; Musée National d'Art Moderne, Paris); "King and Queen" (1952–53; Tate Gallery); "Reclining Figure External Form" (1953–54; Art Institute of Chicago); "Mother and Child" (1953; Tate Gallery); "Warrior with Shield" (1953–54; Art Gallery of Ontario, Toronto); "Reclining Figure" (1956; Western Australian Art Gallery, Perth); "Falling Warrior" (1956–57; Clare College, Cambridge, Cambridgeshire); "Seated Figure Against Curved Wall" (1956–57; Museum of Fine Arts, Boston); "Reclining Figure" (1957–58; UNESCO, Paris); "Draped Seated Woman" (1957–58; Musées Royaux des Beaux-Arts, Brussels); "Two-Piece Reclining Figure No. 1" (1959; Albright-Knox Art Gallery); "Two-Piece Reclining Figure No. 2" (1960; Tate Gallery); "Standing Figure: Knife Edge" (1961; private collection); "Knife-Edge Two-Piece" (1962; Haags Gemeentemuseum, The Hague); "Locking Piece" (1963–64; Banque Lambert, Brussels); "Atom Piece (1964–66; University of Chicago); "Three-way Piece No. 1: Points" (1964; Columbia University, New York).

BIBLIOGRAPHY. The definitive catalog of Moore's sculptures is *Henry Moore: Sculpture and Drawings*—vol. 1, *Sculpture and Drawings, 1921–1948*, 4th ed. by DAVID SYLVESTER, with an introduction by HERBERT READ (1957); vol. 2, *Sculpture and Drawings, 1944–54*, 2nd ed., with an introduction by HERBERT READ and a catalog of the sculpture by ALAN BOWNESS (1965); vol. 3, *Sculpture, 1955–64*, 1st ed. by ALAN BOWNESS, with an introduction by HERBERT READ (1965). Moore's writings have been collected and published in *Henry Moore on Sculpture*, ed. with an introduction by PHILIP JAMES (1966). Important monographs are: ERICH NEUMANN, *The Archetypal World of Henry Moore* (1959); WILL GROHMANN, *The Art of Henry Moore* (1960); JOHN RUSSELL, *Henry Moore* (1965); and ROBERT MELVILLE, *Henry Moore Sculpture and Drawings: 1921–69* (1970).

Moravian Church

The Moravian Church, a Protestant communion tracing its origin to the Hussite Unitas Fratrum ("Unity of Brethren") in Bohemia and Moravia, is principally a product of German Pietism. Though numerically insignificant, its impact upon modern Protestantism has been significant in the areas of worship, evangelism, missions, and theology. A membership of 353,228 in 1969 included 21,558 in continental Europe (9,650 Czechs), 4,598 in England, and 65,459 in North America (4,074 Eskimos); while 32,987 are in the West Indies, 83,654 in Latin America, 144,842 in Africa, and 130 in Tibet and north India. Devotional cultivation and practical application of individual and communal "Jesus mysticism" is the distinguishing mark of the movement.

HISTORY

Origins. The Unitas Fratrum originated with the Hussite Reformation in 15th-century Bohemia. Jan Hus's teaching had a twofold emphasis: the first, national and ecclesiastical, seeking a distinctly Bohemian church marked by lay reception of cup as well as bread in the Eucharist—this represented by the Utraquist ("two kinds") party; the second emphasis, religious and ethical, aiming at ecclesiastical purification in accordance with primitive practice—this represented by the Taborites and Horebites until their destruction by the Utraquists in 1434 and 1452. The Unitas Fratrum, reaffirming the religious-ethical emphasis, was founded in the Bohemian village of Kunvald under the leadership of Gregory the Tailor, probably in 1458. Influenced by his uncle, Jan Rokycana, archbishop of Prague, Gregory studied the writings of Petr Chelčický, a puritan-primitivist Hussite. To Chelčický's Wycliffite Biblicism, Donatist conception of the ministry (*i.e.*, moral requirements for ministerial validity), and commitment to political noninvolvement, Gregory added a desire to experiment with a type of primitive Christian community. This emphasis upon common life continues to mark the Moravian Church.

Jan Hus

Composed of clergy and nobles, as well as laymen like Gregory, this congregation was bound together by acceptance of the Bible as the single rule of life. Suspension of their pastor Michael Bradacius, a Utraquist priest of the village, in 1460 prefaced the first persecution of the movement. Efforts to gain a hearing from the authorities led to the first official theological statements of the Unitas, which emphasized the imitation of Christ in gentleness, poverty, patience, and in the love of enemies.

More basic than theological concerns was the experiment taking place in disciplined communal life patterned on primitive Christianity. Supervised by "elders" with Catholic clerical standing, the Unitas at first remained within the Roman Catholic Church and was served by sympathetic Roman priests. Difficulty with this arrangement led to selection of their first priests in 1467. To assure a "pure" priesthood, ordination by Stephen, a Waldensian "bishop," was obtained.

Early popular success confronted this ascetic movement with the necessity to relate with "this world," particularly to review strictures against exercise of political authority. By 1500 the movement in Bohemia and Moravia numbered 100,000 members, including barons and scholars as well as peasants. By the end of the 15th century the formerly withdrawn ascetic community participated fully

in society. Accompanied by heated controversy and temporary schism, a more formal constitution replaced the earlier charismatic structures. Externally this success led from a generalized and rather sporadic persecution to the Edict of St. James (1508), under which the Unitas in Bohemia was to suffer for a century.

The Reformation. Immediately before the impact of the 16th-century Reformation, the Unitas, led by Luke of Prague (1460–1528), enjoyed a literary and theological revival. Yet initial contacts between Luther and the Unitas (1522–23) were marred by mistrust, misunderstanding, and divergent preoccupations leading not to bitterness but to indifference. Only under the leadership of Jan Augusta (1500–72), the "Bohemian Luther," did the 16th-century Reformation reach the Unitas as a religious impulse. The Habsburg goal of eradicating Protestantism and Bohemian nationalism, coupled with the impact of Luther in Bohemia, led directly to a vision shared by Augusta with the Evangelical Party of the Utraquists to create a Bohemian Protestant National Church. After 1532 cordial relations existed between the Unitas and Luther, and the Unitas Confession of 1535, introduced by Luther, was published in Wittenberg in 1538 as a sign of agreement. Under Lutheran influence the Unitas abandoned the observance of seven sacraments, rebaptism of converts, and mandatory clerical celibacy.

Luther

The Bohemian nobility was embroiled in the disastrous collapse of the Schmalkaldic League (coalition of German Protestant states) at Mühlberg in 1547, and, despite only marginal involvement, the Unitas and Augusta were singled out for royal retribution. The resulting persecution led to migration ending in Poland and contacts with Calvinism. In 1575, three years after Augusta's death, his unionist policies bore fruit in the Bohemian Confession, creating a National Czech Evangelical Church. With the Letter of Majesty (1609) this union finally gained toleration.

The period of religious peace in Bohemia was to be short. The Counter-Reformation, particularly that aspect led by Jesuit educators, made impressive gains against the Protestants; and demise of the Unitas in the lands of its origin came quickly with the early events of the Thirty Years' War. Support of Frederick V of the Palatine ("the Winter King") by the Protestant barons, and their common defeat at the Battle of the White Mountain in 1620, sealed the doom of Protestantism in Habsburg lands. In 1624 non-Roman Catholic groups were outlawed in Bohemia and Moravia, and by 1628 the last of the Unitas ministers were exiles. Among these was John Amos Comenius (1592–1670), last great bishop of the movement and grandfather of Daniel Ernst Jablonski (1660–1741), Prussian court preacher who in 1735 consecrated the first bishop of the Revised or Renewed Unitas Fratrum, better known as the Moravian Church.

The Counter-Reformation

The Moravian Church. Revival of the Unitas resulted from the German Pietist awakening. Stirred by Pietism, Kristián David (1690–1751) undertook missionary journeys into his native Moravia to contact families still identified with the Unitas. In 1722 a group of these Moravians under his leadership settled on the estate of Berthelsdorf at a place later called Herrnhut (from which Moravians derived the name "Herrnhuters"). Their encounter with Nikolaus Ludwig, Graf von Zinzendorf (1700–60), was to set the historical course of the renewed Moravians. Zinzendorf, trained under A.H. Francke at Halle, developed a communal piety centring in encounter and identification with the historical Jesus. The various religious groups settled in Herrnhut occasioned disorder until Zinzendorf took personal leadership of the colony, bringing it under a disciplinary structure patterned on the Unitas. A spiritual awakening during the eucharistic celebration of August 13, 1727, marks the birth and unification of the congregation around Zinzendorf's religious genius. Zinzendorf shaped the prosperous colonies of artisans gathered at Herrnhut and numerous other settlements into near-monastic communities with lives completely organized for glorification and service of God through a veritable maze of liturgical functions, communal organizations, and daily vocational activities. No art escaped mobilization by the creative Zinzendorf, but the key to all was the unique application of music and hymnody in worship.

Zinzendorf

Exercise of inner piety was not, however, the raison d'etre of these communities. Although driven at every turn toward a sectarian identity, Zinzendorf's ambitions were ecumenical. Awakening of all denominations in Christendom and extension of Christianity to the ends of the earth were the goals of Herrnhut. By 1732 mission work had begun both at home (so-called Diaspora) and abroad (Greenland and West Indies). Episcopal consecration from the Unitas Fratrum (1735) was obtained to facilitate foreign missions rather than to introduce a new denomination in Germany. Although large mission congregations were developed overseas, the tendency of the Diaspora policy was to hold people in their own churches and avoid development of a large membership in the Moravian settlements.

Ecumenism

Zinzendorf's time was a period of religious, theological, and organizational formation; but it was also an era marked by religious excesses and financial irresponsibility. The sensual aberrations of the Sifting Time (1740s), with its idealization of childlike behaviour and preoccupation with a sensual participation in the dying, burial, and bodily corruption of Jesus, were short lived but badly damaged the public image of the Moravians. Still further difficulties were occasioned by their leader's unrealistic fiscal policies. The second generation, under the leadership of August Gottlieb Spangenberg (1704–92), witnessed consolidation both in structure and public acceptance. The instability of one-man dominance was replaced by a representative constitution. Though still bearing its distinctive stamp, the church was freed of religious excess, both real and reputed. The movement was now generally accepted in both intellectual and ecclesiastical circles.

Influence. The primary influence of the Moravians was religious. John Wesley, the founder of Methodism, owed them much, both in his religious development and in the formation of his movement. Much less noted than this influence on Wesley is the impact of Moravian work in Europe on the 19th-century Protestant revivals. Aside from shock at the outcome of the French Revolution, a major factor in the religious awakenings that spread over Europe from the Baltic States to the Netherlands and from Switzerland to Scandinavia was the Diaspora activities of the Moravians. Reports from the far-flung missionary fields of the Moravians played a major role in influencing, instituting, and spreading Protestant missions.

The intellectual and theological contributions of the Moravians are also significant. Friedrich Schleiermacher (1768–1834), a father of modern Protestant theology, brought the heritage of Pietism to bear in theology. Reared under Moravian influence, he gained an enduring conviction of the "empirical" reality of religion and a highly developed taste and skill in its practice. His later claim to be a "Herrnhuter . . . of a higher order" recognized the biographical basis of his highly experiential theology. The Moravians made other significant contributions to the formation of Romanticism. J. Wolfgang Goethe (1749–1832), though not attached to the movement, was impressed in his Romantic inclinations by it. Also, the classic German Romantic Novalis (1772–1801) had been reared in a Moravian Diaspora congregation and was deeply marked by their approach to reality. Nor does the theological contribution of the Moravians end with Schleiermacher. Led by Spangenberg in response to the victories of rationalism, a theological synthesis of the centuries-old enemies—Pietism and Orthodoxy—took place, which spread through the Pietist revivals as the historic foundation for modern Fundamentalism.

Moravians since the 18th century. In North America the Movarians had difficulty implementing Zinzendorf's inner churchly ideals. Operating within a free-church context, they were pressed toward separate denominational identity. Missionary activity among American Indians was from the start a central and successful concern. After removal from Georgia to Pennsylvania (1740), the entire membership in North America was mobilized for this work. Under the so-called Economy (1748–62) centred in Bethlehem, Pennsylvania, all production was held in com-

mon and directed toward the missionary task. In 1753 a second Moravian centre in North America was established in Winston-Salem, North Carolina.

The Moravian Church at present operates in five continents. Still small in membership, it continues to wield great influence on Protestantism in Europe. The work in East Germany has been greatly impaired as a result of partition; but Herrnhut, located there, remains a chief European centre. Early and continually involved in missionary efforts at home and abroad, as well as in ecumenical aspirations, its role in the modern ecumenical movement is obvious. Beyond active membership in various national confederations of churches and in the World Council of Churches, the Moravians—particularly in Europe—have been promoters and leaders in such ecumenical endeavours as the *Kirchentag* ("church day," on which clerics and laity meet to discuss religious and social issues) and Evangelical Academy movements.

BELIEFS, PRACTICES, AND INSTITUTIONS

Despite some rather unusual theological statements, Zinzendorf's intention was to maintain the Moravian movement's Lutheran identity in respect to Scripture and creed. His "Christocratic" keynote never attained creedal formulation, expressing itself rather in hymnody and liturgy. Influenced by the theological movements associated with Schleiermacher, Albrecht Ritschl (1822–89), and finally the "Theology of Crisis" of Karl Barth (1886–1968) and Emil Brunner (1889–1966), there has been a revival of Zinzendorfian thinking in recent decades.

Since the middle of the 19th century Moravian polity has been extremely loose. Provinces (jurisdictional units) are virtually autonomous, representing the common interests of individual congregations. The Moravian episcopacy is spiritual, not administrative. Bishops elected by periodic synods on the basis of spiritual merit are pastoral, even prophetic, not presidential.

Moravian uniqueness lies in its liturgy. A body of hymns and anthems emphasizing the life and passion of Christ is utilized to illustrate, supplement, and even replace spoken discourse and prayer. This idiom completely dominates eucharistic and Love Feast celebrations, where only a few words are spoken.

More, Sir Thomas

Thomas More, the English saint and humanist, prolific writer of anti-heretical works, and statesman, was martyred for refusing to accept the Act of Supremacy establishing the king as supreme head of the Church of England. More, however, is best remembered as the author of *Utopia,* a speculative political essay contrasting an ideal society with the evils of the existing one.

Education

Thomas More was born in London on February 7, 1477, the eldest son of John More, a lawyer who was later knighted and made a judge of the King's Bench. More was educated at the City's best school, St. Anthony's in Threadneedle Street, and in the household of John Morton, archbishop of Canterbury and chancellor of England. The future cardinal, a shrewd judge of character, predicted that the bright and winsome page would prove a "marvellous man." His interest sent the boy to Oxford, where More seems to have spent two years, developing his command of Latin and undergoing a thorough drilling in formal logic.

Sir Thomas More, oil painting by Hans Holbein the Younger, 1527. In the Frick Collection, New York.

About 1494 his father brought More back to London to study the common law. In February 1496 he was admitted to Lincoln's Inn, one of the four legal societies preparing for admission to the bar. Grinding at law probably toughened More's delicate intellectual fibre and fostered the healthy realism that struck the readers of *Utopia.*

Marriage and early career. In 1501 More became an "utter barrister," a full member of the profession. Thanks to his boundless curiosity and a prodigious capacity for work, he managed, along with his study and practice of the law, to keep up his literary pursuits. He read avidly from Holy Scripture, the Church Fathers, and the pagan classics. He tried his hand at all literary genres, including drama and poetry, to acquire ease and fluency of pen and tongue.

Although bowing to his father's decision that he should become a lawyer, More was prepared to be disowned rather than disobey God's will. To test his vocation to the priesthood, he resided for about four years in the Carthusian monastery adjoining Lincoln's Inn and shared as much of the monks' way of life as was practicable. Although attracted especially to the Franciscan order, More decided that he would best serve God and his fellowmen as a lay Christian.

Toward the end of 1504 or in early 1505, More married Jane Colt, the eldest daughter of an Essex gentleman farmer. Quite young and with little formal schooling, she received instruction in music and enough Latin from her husband to make her a competent hostess for non-English visitors, such as the Dutch humanist Erasmus, who was eventually given permanent rooms in the Old Barge on the Thames side in Bucklersbury in the city of London, More's home for the first two decades of his married life. More never discarded the habits of early rising, prolonged prayer, fasting, and wearing the hair shirt. God remained the centre of his life.

Friendship with Erasmus. Erasmus first went to England in the summer of 1499, as the guest of William Blount (later Lord Mountjoy), whom he had tutored in Paris. His first extant letter to More, written in October 1499, implies weeks of acquaintance and shows the Dutch priest as the more eager of the two friends.

During his second stay in England (1505–06), Erasmus was More's houseguest. To increase their proficiency in both Latin and Greek, and to learn the art of ironic

dialogue and of persuasive oratory, the two friends vied in translating several pieces from Lucian, the 2nd-century Greek satirist. The fruit of these labours, published in Paris in 1506, was often reprinted.

More's only extant English book of this decade is a *Life of John Picus*—the Italian humanist Giovanni Pico della Mirandola—translated from the Latin, with a devotional anthology from Pico's *Opera*.

Henry VIII's accession, in April 1509, brought Erasmus back to England for his longest stay. In More's house he wrote his *Praise of Folie*. The very title, *Encomium moriae*, plays on the name of More, who was among the very few to relish the full flavour of the sophisticated satire, rich in Lucianic echoes and even biblical undertones.

In the face of the encroachment of legal and commercial business, More needed to do some tightrope walking to maintain his family life, a large dose of prayer, and his humanistic pursuits. The important negotiations he conducted in 1509 on behalf of a number of London companies with the representative of the Antwerp merchants confirmed his competence in trade matters and his gifts as an interpreter and spokesman. From September 1510 to July 1518, when he resigned to be fully in the king's service, More was one of the two undersheriffs of London, "the pack-horses of the City government." He endeared himself to the Londoners—as an impartial judge, a disinterested consultant, and "the general patron of the poor."

More's domestic idyll came to a brutal end in the summer of 1511 with the death, perhaps in childbirth, of "More's little wife": *uxorcula Thomae Mori*, to quote her epitaph. He was left a widower with four children: Margaret, Elizabeth, Cecily, and John. Within weeks of his first wife's death, he married Alice Middleton, the widow of a London mercer. She was several years his senior and had a son and a daughter of her own; she did not bear More any children. He taught her music, though not Latin. A shrewd housewife, she also proved an affectionate mother to a family that was to include a foster-daughter and several wards. The More home was a Christian academy of "virtue and learning," where tutors taught all kinds of subjects and the younger ones were expected both to learn and to teach.

Second marriage

More's *History of King Richard III*, written in Latin and in English between about 1513 and 1518, is the first masterpiece of English historiography. Though never finished, it influenced succeeding historians. Shakespeare is indebted to More for his portrait of the tyrant.

The "Utopia." In May 1515 More was appointed to a delegation to revise an Anglo-Flemish commercial treaty. The conference was held at Bruges, with long intervals that More used to visit other Belgian cities: his favourite friends were men who, like him, combined cultural pursuits with political responsibilities. Begun in the Low Countries and completed after his return to London, the "golden little book" was published at Louvain in December 1516. It was an immediate success with the audience for which More wrote it: the humanists and an elite group of public officials.

Book 1 is a keen analysis and passionate indictment of the economic and social conditions prevailing in Europe, particularly in England. In book 2 the narrator depicts the best state of society, as he has seen it flourishing on an island off the shore of the New World. The Utopians are immune to Europe's evils, thanks to their basic communism. All citizens participate with full equality in activities related to food, clothing, housing, education, philosophy, government, war, and all else, even religion. There is one exception to this universal sharing: monogamy is safeguarded by stricter laws than in Christendom. A common denominator for full citizenship is belief in a good and just God who rules this world and metes out reward or punishment in an afterlife of immortality.

Utopia is a Greek name of More's coining, from *ou-topos* ("no place"); a pun on *eu-topos* ("good place") is suggested in a prefatory poem. As was inevitable with an ironic dialogue, More's fiction has been subjected to the most diverse interpretation. The German Socialist theoretician Karl Kautsky took its communism seriously, thus causing More to be hailed as a father of the Russian Revolution; historians have read into it a blueprint for British imperialism; literary critics have viewed it merely or mainly as the *jeu d'esprit* of a noncommitted intellectual; Humanists have proclaimed it a manifesto of total reform for the Christian renaissance. The endeavour of recent scholarship has been to decipher the witty travelogue in the light of its author's later and larger writing, to ponder the circumstances of its genesis and publication, and to place it firmly in its historical context, including More's personal misgivings about entrance into his king's service. Among the "sources whence flow all social evils," the chief is pride or ambition, the same "pestilent serpent" embodied by More in the hideous figure of the usurper Richard III.

Interpretations of Utopia

The island of Nowhere is a vision to be contemplated (like Plato's *Republic*), rather than a practical goal to be achieved; the narrator's "idle tales" are, as the French humanist and Greek scholar Budé remarked in 1517, a nursery (*seminarium*) of intellectual seeds to be selected and tested: some of them may be transplantable onto the stubborn soil of Europe. More's own household had a few Utopian traits: no gaming, dicing, idleness, or "idle business"; all did some gardening; education was a lifelong affair for both sexes; and there was something patriarchal about the meals and the evening prayers. But folly had been praised under his roof too eloquently for "nature and reason" to hold an undisputed sway over his life and that of his charges.

While *Utopia* made its impact as soon as it was published, its status as a classic is attested by its having remained "a commentary on the morning paper": penology, eugenics, euthanasia, divorce, the gold standard, women's rights, continued and state-controlled education, religious pluralism, and even ecology, More has a word to say on all these topics. When does he speak his mind? Even in the more serious *Dyaloge Concerning Herecies* (1529), the messenger says: "Ye use to look so sadly when ye mean merrily." No one looks more "sadly"—that is, more in earnest—than the humourless, doctrinaire narrator of the *Utopia*, yet even he perhaps means merrily at times.

Career as king's servant. On May 1, 1517, a mob of Londoners rose against the alien residents: More's role in quenching this Evil-Mayday riot inspired a scene, attributed to Shakespeare, in *The Book of Sir Thomas More*, a composite Elizabethan play. More's success in the thorny negotiations with the French at Calais and Boulogne (September to December 1517) over suits born of the recent war made it harder for him to dodge royal service. While yielding to pressure, he embraced the chance of furthering peace and reform. The lord chancellor, Thomas Wolsey, now looked ready to implement some of the political ideas of the Christian humanists.

Between 1515 and 1520 More campaigned spiritedly for Erasmus' religious and cultural program—Greek studies as the key to a theology renewed by a return to the Bible and the Church Fathers—in poems commending Erasmus' *Novum instrumentum*, a new Latin version of the New Testament, and open letters to his various personalities. More's Latin poems were published in 1518 under one cover between his *Utopia* and Erasmus' *Epigrammata*: they are extremely varied in metre and matter, their main topics being government, women, and death.

Erasmus offered his London friend as a model for the intelligentsia of Europe in letters to the German humanist Ulrich von Hutten, the Paris scholar Germain De Brie (1520)—with whom More had just engaged in a polemic and Guillaume Budé, whom More had met in June 1520 at the Field of the Cloth of Gold, the meeting ground, near Calais, between Henry VIII and Francis I. According to Erasmus, More was of medium stature, his complexion was fair, and his eyes were bluish gray. Simplicity was his mark in food and dress. He shrank from nothing that imparted an innocent pleasure, even of a bodily kind. He had a speaker's voice and a memory that served him well for extempore rejoinders. "Born for friendship," he could extract delight from the dullest people or things. His family affections were warm yet unobtrusive. He gave

Erasmus' description of More

freely and gladly, expecting no thanks. Exotic objects and curious animals graced his house and garden. Amid his intense professional activity, he found hours for prayer and for supervising his domestic school. Most of his charges were girls, to whom he provided the most refined classical and Christian education.

In 1520 and 1521 More took part in talks, at Calais and Bruges, with the emperor Charles V and with the Hansa merchants. In 1521 he was made undertreasurer and knighted. His daughter Margaret married William Roper, a lawyer. For Henry VIII's *Defense of the Seven Sacraments*, he acted as "a sorter out and placer of the principal matters." When Martin Luther hit back, More vindicated the King, under the pseudonym of Gulielmus Rosseus, in a learned, though scurrilous, *Responsio ad Lutherum* (1523). In 1526 he attacked all the major dogmas of Luther in an *Epistola ad Pomeranum*, first printed in 1568.

About 1522 More wrote a meditation that he never finished on *The Four Last Things*—death, doom, pain, and joy. In addition to his routine duties at the Exchequer, More served throughout these years as "Henry's intellectual courtier, his tame humanist." He welcomed foreign envoys, delivered official speeches, drafted treaties, read the dispatches exchanged between the King and Wolsey, and answered in the King's name. Often he rode posthaste between the Cardinal's headquarters at Westminster and Henry's various hunting residences. In April 1523 he was elected speaker of the House of Commons: while loyally striving to secure the government's ends, he made a plea for truer freedom of speech in Parliament. The universities—Oxford in 1524, Cambridge in 1525—made him their high steward.

By 1524 More had moved to Chelsea. The Great House he built there bore the stamp of his philosophy, its gallery, chapel, and library all geared toward studious and prayerful seculsion. In 1525 he was promoted to chancellor of the duchy of Lancaster, which put a large portion of northern England under his judiciary and administrative control. Before the end of 1526, the Dutch painter Hans Holbein arrived at Chelsea from Basel recommended by Erasmus and set to work on portraits of his hosts.

On More's return from an embassy to France with Wolsey in the summer of 1527, Henry VIII "laid the Bible open before him" as proof that his marriage to Catherine of Aragon, who had failed to produce a male heir, was void, even incestuous, because of her previous marriage to Henry's late brother. More tried in vain to share the King's scruples, but "diligent search and long study" confirmed his view that Catherine was the King's true wife. After being commissioned in March 1528 by Bishop Tunstall of London to read all heretical writings in the English language in order to refute them for the sake of the unlearned, he published seven books of polemics between 1529 and 1533—the first and best being *A Dialogue Concerning Herecies.*

Years as chancellor of England. In 1529 Tunstall and More assuaged the rancour provoked by Wolsey's duplicity; thus England was included in the Peace of Cambrai, proclaimed that August, between France and Emperor Charles V. The Cardinal parted with the great seal on October 19, and six days later More became chancellor. On November 3, he opened the Parliament that was to forge the legal instruments for his death. As the King's mouthpiece, More indicted Wolsey in his opening speech and, in 1531, proclaimed the opinions of universities favourable to the divorce; but he did not sign the letter of 1530 in which England's nobles and prelates, including Wolsey, pressured the Pope to declare the first marriage void, and he tried to resign in 1531, when the clergy acknowledged the king as their supreme head, albeit with the clause "as far as the law of Christ allows." More was never Henry VIII's chief adviser; he thus discharged his legal duties with the greater energy: his regularity and promptitude became legendary.

His longest book, *The Cōfutacyon of Tyndals Answere*, in two volumes (1532 and 1533) centres on "what the church is." To the stress of stooping for hours over his manuscript More ascribed the sharp pain in his chest, perhaps angina, which he invoked when begging Henry to free him from the yoke of office. This was on May 16, 1532, the day when the convocation of the archdiocese of Canterbury delivered to the crown the document by which they promised never to legislate or convene without royal assent, thus placing a lay person at the head of the spiritual order.

While enjoying the privacy of his home, although in relative poverty, and resting by doctor's order, More prepared a tomb for himself and his wives. Its Latin epitaph underlines the fact that his resignation had been no dismissal and proclaims that he had "been grievous to thieves, manquellers [murderers], and heretics," a duly thought-out crescendo occurring elsewhere in his works.

He continued his campaign for the old faith, defending England's anti-heresy laws and his own handling of heretics, both as magistrate and as writer, in two books of 1533: the *Apology* and the *Debellacyon*. He also laughs away the accusation of greed levelled by William Tyndale, translator of parts of the first printed English Bible. More's poverty was so notorious that the hierarchy collected £5,000 to recoup his polemical costs, but he refused this grant lest it be construed as a bribe.

Anti-heretical writings

Indictment, trial, and execution. His refusal to attend the coronation of Anne Boleyn, whom the King married after his divorce from Catherine in 1533, marked him out for vengeance. Several charges of accepting bribes recoiled on the heads of his accusers. In February 1534 More was included in a bill of attainder for alleged complicity with Elizabeth Barton, who had uttered prophecies against Henry's divorce, but he produced a letter in which he had warned the nun against meddling in affairs of state. The House of Lords passed the bill only after More's name had been struck off the list. Summoned to appear before royal commissioners on April 13 to assent under oath to the Act of Succession, he said he "would not deny to swear to the succession"—that is, to give priority to Anne's issue over Catherine's—but he could not in conscience swear to the whole document. His main objection was the sentence in the preamble repudiating the authority of any "foreign potentate," which implied rejection of papal supremacy. Led to the Tower on April 17, More welcomed prison life. But for his family responsibilities, he would have chosen for himself "as strait a room and straiter too," as he said to his daughter Margaret, who after some time took the oath and was then allowed to visit him.

At the time of his arrest, More was writing a *History of the Passion*, which ends with the institution of the Eucharist. In prison, More gave up such works, which required accurate references. Instead, he wrote *A dialoge of comfort against tribulacion*, a masterpiece of Christian wisdom and of literature, studded with biblical texts and flavoured with humorous anecdotes, some of them autobiographical.

His trial took place on July 1, 1535. Richard Rich, the solicitor general, a creature of Thomas Cromwell, the unacknowledged head of the government, testified that the prisoner had, in his presence, denied the King's title as supreme head of the Church of England. Despite More's scathing denial of this perjured evidence, the jury's unanimous verdict was "guilty." Before the sentence was pronounced, More spoke "in discharge of his conscience." The unity of the church was the main motive of his martyrdom. His second objection was that "no temporal man may be head of the spirituality." Henry's marriage to Anne Boleyn, to which he also referred as the cause for which they "sought his blood," had been the occasion for the assaults on the church: among his judges were the new queen's father, brother, and uncle.

More's defense

More was sentenced to the traitor's death—"to be drawn, hanged, and quartered"—which the King changed to beheading. During five days of suspense, he prepared his soul to meet "the great spouse" and wrote a beautiful prayer and several letters of farewell. On July 6, he walked to the scaffold on Tower Hill. "See me safe up," he said to the lieutenant, "and for my coming down let me shift for myself." He told the onlookers to witness that he was dying "in the faith and for the faith of the

Catholic Church, the king's good servant and God's first." He altered the ritual by blindfolding himself, playing "a part of his own" even on this awful stage.

The news of More's death shocked Europe. Erasmus mourned the man he had so often praised, "whose soul was more pure than any snow, whose genius was such that England never had and never again will have its like." The official image of More as a traitor did not gain credence even in Protestant lands.

Assessment. Margaret Roper, More's favourite child and his confidante for years, the washer of his hair shirt and rescuer of his unpublished writings, died in 1544. Her husband's recollections of More as "a mirror of virtue in worldly greatness" first appeared in 1626. Editions of some of More's works appeared all over Europe. The folio *English Works* (1557) was dedicated to Queen Mary. His Latin works appeared at Basel (1563), Louvain (1565), and Frankfurt (1689).

Cresacre More, a grandson of John, Thomas More's only son, wrote a *Life of More* (Paris, *c.* 1631), which belongs to hagiography. Nicholas Harpsfield, archdeacon of Canterbury in Queen Mary's reign, wrote a full life of More, first printed in 1932, using Roper's notes. Thomas Stapleton, a theology professor in Douai, published a *Thomae Mori vita* in 1588, as part of a trilogy—*Tres Thomae*, the other Thomases being the apostle and Becket.

The triumph of Anglicanism brought about a certain eclipse of Thomas More. Foxe's *Book of Martyrs* (1563) caricatured him as a cruel foe of the gospel. The publication of the state papers restored a fuller and truer picture of More, preparing public opinion for his beatification (1886). He was canonized by Pius XI in May 1935. His name is given to boys, schools, clubs, family clinics, and parishes, where his panegyric is preached ritually every year.

Though the man is greater than the writer, and though nothing in his life "became him like the leaving of it," his "golden little book" has earned him greater fame than the crown of martyrdom or the million words of his English works. His name is listed among the heroes of the Revolution on a stela in the Red Square in Moscow.

Erasmus' phrase describing More as *omnium horarum homo* was rendered later as "a man for all seasons" and was given currency by Robert Bolt's play *A Man For All Seasons* (1960) and Fred Zinnemann's film (1966). Monuments to him have recently been placed in Westminster Hall and the Tower in London. In the words of the English Catholic apologist G.K. Chesterton, More "may come to be counted the greatest Englishman, or at least the greatest historical character in English History."

BIBLIOGRAPHY. R.W. GIBSON and J.M. PATRICK, *St. Thomas More: A Preliminary Bibliography of His Works and of Moreana to the Year 1750* (1961); FRANK and M.P. SULLIVAN, *Moreana: Materials for the Study of Saint Thomas More*, 5 vol. (1964–71).

Editions: The Yale University edition of the *Complete Works* is in progress with 4 of 18 volumes completed to date: *The History of King Richard III*, ed. by R.S. SYLVESTER (1963); *Utopia*, ed. by E. SURTZ and J.H. HEXTER (1965); *Responsio ad Lutherum*, ed. by JOHN HEADLEY (1969); *Confutation*, ed. by R.J. SCHOECK *et al.* (1973). The first English version of *Utopia*, by RALPH ROBINSON (1551), a classic for centuries, has been superseded as a standard by the Yale edition. See also H.W. DONNER, *Introduction to Utopia* (1945); and the paperbound Yale *Utopia*, ed. by E. SURTZ (1964).

Correspondence and studies: The letters exchanged between More and Erasmus are in P.S. ALLEN (ed.), *Opus epistolarum Des. Erasmi Roterodami*, 12 vol. (1905–58). For the rest, see E.F. ROGERS, *The Correspondence of Sir Thomas More* (1947) and *Selected Letters* (1961). *The Latin Epigrams of Thomas More*, ed. by L. BRADNER and C.A. LYNCH (1953), provide the text and an English rendering. Useful monographs are STANLEY MORISON, *The Likeness of Thomas More: An Iconographical Survey of Three Centuries*, ed. by NICOLAS BARKER (1963); and GERMAIN MARC'HADOUR, *The Bible in the Works of Thomas More*, 5 vol. (1969–72).

Biography: The first standard modern life, R.W. CHAMBERS, *Thomas More* (1935), has come under fire recently, because it tones down the starkness of More's asceticism, the radicalism of his Utopian vision, his hatred of schism and heresy, and the dogmatic motives of his martyrdom. E.E. REYNOLDS, *The Field Is Won: The Life and Death of Saint Thomas More* (1968), is the work of a professional biographer, who had prepared for his task by writing six other books on More and his circle. Less literary, less allusive than Chambers, Reynolds is balanced and up-to-date.

(G.P.Ma.)

Morgan, Thomas Hunt

Thomas Hunt Morgan, geneticist and embryologist, is particularly noted for his experimental research with the fruit fly, *Drosophila melanogaster*, by which he established the chromosome theory of heredity. He showed that genes are linked in a series on chromosomes and are responsible for identifiable, hereditary traits. His research in embryology and genetics helped to move biology away from its former emphasis on descriptive morphology to its present experimental and quantitative character.

By courtesy of the California Institute of Technology, Pasadena

Morgan.

Morgan was born in Lexington, Kentucky, on September 25, 1866, into a prominent Southern family. His father, Charlton Hunt Morgan, was the American consul in Messina, Sicily, in 1860, and his uncle was a Confederate Army colonel. His maternal great-grandfather was Francis Scott Key, author of the national anthem.

Early in life, Morgan showed an interest in natural history during his frequent excursions into the Kentucky and western Maryland countrysides, where he spent many summers. In 1886 he received the B.S. degree from the State College of Kentucky, later the University of Kentucky, in zoology and then immediately entered Johns Hopkins University for graduate work in biology.

Criticism of descriptive biology

At Hopkins, Morgan studied under the morphologist and embryologist William Keith Brooks, who led him to see the important interrelationships among apparently disparate disciplines of biology, such as anatomy, embryology, and cytology, and to see heredity and variation as appropriate problems for investigation. Morgan also learned the value of marine organisms—the oldest and most basic forms of life—for understanding general principles. Brooks's descriptive and sometimes highly speculative methods contributed to Morgan's growing dissatisfaction with the morphological tradition and its nonrigorous, nonexperimental approach. In addition, he felt that morphologists subjugated embryology to evolution, thus neglecting the value of the discipline for its own sake.

After being awarded the Ph.D. in 1890, Morgan accepted a teaching post at Bryn Mawr College, near Philadelphia, where he came under the influence of the German-born physiologist Jacques Loeb, who was an outstanding advocate of the experimental and mechanistic approach to biology.

Experimental embryology

Morgan's growing preference for experimental work, particularly in embryology, was strengthened by his visits to the Zoological Station at Naples, Italy, in 1890, 1894, 1895, and 1900. There he made contact with an interna-

tional group of researchers, many of whom strongly favoured experimental as opposed to descriptive methods. He worked closely in 1894–95 with the German embryologist Hans Driesch, who, as an enthusiastic proponent of the experimental approach to embryology, called *Entwicklungsmechanik*, had performed some highly controversial experiments on the sea urchin egg.

During the period 1893–1910, Morgan applied experimental techniques to fundamental problems of embryology. In order to identify causally related events during development, he analyzed such problems as the formation of embryos from separated blastomeres (early embryonic cells) and fertilization in nucleated and nonnucleated egg fragments. As examples of the effects of physical factors, he analyzed the way in which the spatial orientation of eggs affects their future development and the action of salt concentration on the development of fertilized and unfertilized eggs. In 1904 he married one of his graduate students at Bryn Mawr, Lillian V. Sampson, a cytologist of considerable skill. The same year he accepted an invitation to assume the professorship of experimental zoology at Columbia University, where, during the next 24 years, he conducted most of his important research in heredity.

Morgan favoured the development of marine-research laboratories where biologists from different specialities could work together and exchange ideas. He contributed to the development of this approach at the Marine Biological Laboratory in Woods Hole, Massachusetts, where he worked nearly every summer during his Bryn Mawr and Columbia years and served as a trustee from 1897 until his death.

Objections to Darwin's theory of natural selection

Like most embryologists and many biologists at the turn of the century, Morgan found the Darwinian theory lacking in plausibility. It was difficult to conceive of the development of complex adaptations simply by an accumulation of chance variations. Moreover, Darwin had provided no mechanism of heredity to account for the origin or transmission of variations, except his early and hypothetical theory of pangenesis. Although Morgan believed that evolution itself was a fact, the mechanism of natural selection proposed by Darwin seemed incomplete because it could not be put to an experimental test.

Morgan had quite different objections to the Mendelian and chromosome theories. Both theories attempted to explain biological phenomena by postulating units or material entities in the cell that somehow control developmental events. To Morgan this was too reminiscent of the preformation theory—the idea that the fully formed adult is present in the egg or sperm—that had dominated embryology in the 18th and early 19th centuries. Although Morgan admitted that the chromosomes might have something to do with heredity, he argued in 1909 and 1910 that no single chromosome could carry specific hereditary traits. He also claimed that Mendelian theory was purely hypothetical: although it could account for and even predict breeding results, it could not describe the true processes of heredity. The fact that each pair of chromosomes separates, with the individual chromosomes then going into different sperm or egg cells in exactly the same manner as Mendelian factors, did not seem to be sufficient proof to Morgan for claiming that the two processes had anything to do with each other. In 1909, Morgan delivered a particularly vehement attack on Mendelian theory and the seemingly unrigorous approach of many Mendelians.

The work on *Drosophila*

Morgan apparently began breeding *Drosophila* in 1908. Surprisingly, he was not as interested in heredity itself as in determining whether macromutations, observed in plants, also occurred in animals. In 1909 he observed a small but discrete variation known as white-eye in a single male fly in one of his culture bottles. Aroused by curiosity, he bred the fly with normal (red-eyed) females. All of the offspring (F_1) were red-eyed. Brother–sister matings among the F_1 generation produced a second generation (F_2) with some white-eyed flies, all of which were males. To explain this curious phenomenon, Morgan developed the hypothesis of sex-limited—today called sex-linked—characters, which he postulated were part of the X-chromosome of females. Other genetic variations arose in Morgan's stock, many of which were also found to be sex-linked. Because all of the sex-linked characters were usually inherited together, Morgan became convinced that the X-chromosome carried a number of discrete hereditary units, or factors. He adopted the term gene, which was introduced by the Danish botanist Wilhelm Johannsen in 1909, and concluded that genes were possibly arranged in a linear fashion on chromosomes. Much to his credit, Morgan rejected his skepticism about both the Mendelian and chromosome theories when he saw from two independent lines of evidence—breeding experiments and cytology—that one could be treated in terms of the other.

In collaboration with A.H. Sturtevant, C.B. Bridges, and H.J. Muller, who were undergraduates at Columbia, Morgan quickly developed the *Drosophila* work into a large-scale theory of heredity. Particularly important in this work was the demonstration that each Mendelian gene could be assigned a specific position along a linear chromosome "map." Further cytological work showed that these map positions could be identified with precise chromosome regions, thus providing definitive proof that Mendel's factors had a physical basis in chromosome structure. A summary and presentation of the early phases of this work was published by Morgan, Sturtevant, Bridges, and Muller in 1915 as the influential book *The Mechanism of Mendelian Heredity*. To varying degrees Morgan also accepted the Darwinian theory by 1916.

After the last of the Morgans' four children entered school, Mrs. Morgan returned to the laboratory and added considerably to cytological aspects of the *Drosophila* work. She was responsible for discovering and analyzing the attached-X *Drosophila* strain, which became widely used to maintain sex-linked mutants, in which the females are usually weak or sterile.

In 1928 Morgan was invited to organize the division of biology of the California Institute of Technology, an offer he could not refuse because of the opportunity it provided to establish a model department along modern—that is, experimental and quantitative—lines. He was also instrumental in establishing the Marine Laboratory on Corona del Mar as an integral part of Caltech's biology training program.

In subsequent years, Morgan and co-workers, including a number of postdoctoral and graduate students, continued to elaborate on the many features of the chromosome theory of heredity. Toward the end of his stay at Columbia and more so after moving to California, Morgan himself slipped away from the technical *Drosophila* work and began to return to his earlier interest in experimental embryology. Although aware of the theoretical links between genetics and development, he found it difficult at that time to draw the connection explicitly and to support it with experimental evidence.

Assessment

According to Morgan, biology had been dominated for too long by purely descriptive methods. In both research and writing, he sought to demonstrate the importance of the quantitative and experimental approach—including the methods of physics and chemistry—to the study of biology. Only by experiments, he maintained, could biological processes be identified. Although not a strict mechanist or physico-chemical reductionist, Morgan felt that life sciences could progress only by applying the methods of the exact sciences. This emphasis was well reflected in Morgan's lifelong interest in the Marine Biological Laboratory in Woods Hole, Massachusetts, and in his early visits to the Zoological Station at Naples, Italy.

Morgan's career encompassed studies on a wide range of organisms and a large number of topics. He had an active and imaginative mind, which moved easily from one special field to another, while always maintaining awareness of the connecting links between them. His persistent interest in marine biology emphasized his commitment to biology as a whole, as opposed to narrowly specialized disciplines. Even in his most technical work—for example, on the chromosome theory of heredity—Morgan saw the broad implications for other areas, such as embryology and evolution.

In 1924 Morgan received the Darwin Medal; in 1933 he was awarded the Nobel Prize for Medicine or Physiology for his discovery of "hereditary transmission mechanisms in *Drosophila*"; and in 1939 he was awarded the Copley Medal by the Royal Society of London, of which he was a foreign member. In 1927–31 he served as president of the National Academy of Sciences; in 1930 of the American Association for the Advancement of Science; and in 1932 of the Sixth International Congress of Genetics. He remained on the faculty at Caltech until he died, in Pasadena, on December 4, 1945.

BIBLIOGRAPHY. A.H. STURTEVANT, "Thomas Hunt Morgan, 1866–1945," *Biog. Mem. Natn. Acad. Sci.*, 33:283–325 (1959), is a reasonably complete biographical sketch with complete bibliography. Discussions of Morgan's work, and the work of the "Morgan school" of *Drosophila* geneticists may be found in A.H. STURTEVANT, *A History of Genetics* (1965); L.C. DUNN, *A Short History of Genetics* (1965); and E.A. CARLSON, *The Gene: A Critical History* (1966). Specific aspects of the development of Morgan's scientific work are: G.E. ALLEN, "Thomas Hunt Morgan and the Problem of Sex Determination, 1903–1910," *Proc. Am. Phil. Soc.*, 10:48–57 (1966); "Thomas Hunt Morgan and the Problem of Natural Selection," *J. Hist. Biol.*, 1:113–139 (1968); and "T.H. Morgan and the Emergence of a New American Biology," *Q. Rev. Biol.*, 44:168–188 (1969).

Among Morgan's most important books are those dealing with (1) evolution: *Evolution and Adaptation* (1903), in which he strongly criticizes Darwinian theory; and *A Critique of the Theory of Evolution*, 2nd ed. (1925), a more favourable view of the selection process; (2) heredity: *Heredity and Sex* (1913), his first major exposition of the Mendelian system in relation to *Drosophila;* and with A.H. STURTEVANT, H.J. MULLER, and C.B. BRIDGES, *The Mechanism of Mendelian Heredity* (1915); and *The Theory of the Gene* (1926); the latter two works firmly established the Mendelian theory as it applied to heredity in all multicellular (and many unicellular) organisms; and (3) embryology: *The Development of the Frog's Egg: An Introduction to Experimental Embryology* (1897), a detailed outline of the developmental stages of frogs' eggs; *Regeneration* (1901), a discussion of experimental approaches to regeneration; *Experimental Zoology* (1907), a strong statement on the value of experimentation in biology; *Experimental Embryology* (1927), Morgan's statement on the value of experimentation in embryology; and *Embryology and Genetics* (1934), an attempt to relate the theory of the gene to the problem of embryological differentiation and development.

(G.E.Al.)

Mormonism

Mormonism is a religion founded in the United States in 1830. The church's membership is principally concentrated in Utah and in neighbouring states. This article surveys the origins, history, teachings, social ethic, and church structures of Mormonism.

ORIGIN AND CHARACTERISTICS

Distribution

The Church of Jesus Christ of Latter-day Saints, the principal formal body embracing Mormonism, has about 3,600,000 members, nearly 80 percent of whom are in the United States; the majority of the remainder are in Latin America (especially Mexico), Canada, Europe (especially England), and parts of Oceania (especially New Zealand). From headquarters in Salt Lake City, Mormons are organized through a lay priesthood in local units that regulate religious practice and important welfare activities. The church was founded in New York State by Joseph Smith, Jr. (1805–44), after, according to his account, he had translated by revelation the *Book of Mormon*, which recounted the history of tribes of Israel that migrated to America centuries before Christ and that underwent experiences closely similar to those recounted in the Bible. Smith described American Indians as descendants of these tribes.

Smith instituted a new ecclesiology and theology. Mormonism proclaimed a new dispensation and the restoration of the two orders of priesthood and rituals of the "true church." Deity was pronounced to be an attainment of spiritual evolution for which all Mormons were eligible, and the unregenerate were also promised a measure of eternal glory. Mormonism combined universalism with contemporary millennialism but gave millennialism the goal of building up Zion in the American West under a prophet to whom was revealed not only theological truth but day-to-day practical guidance (see MILLENNIALISM).

New secular institutions were proclaimed, including collective ownership (later changed to a system of tithing) and plural marriage, which was practiced by Smith himself (although the schismatic Reorganized Church of Jesus Christ of Latter Day Saints disputes this point) and by most leading Mormons until, under pressure from the federal government, the practice was given up.

Collectivism, persecution, conflict, successive migrations, and self-identification as a chosen people under the control of an inspired religious authority produced a distinctive Mormon way of life characterized by order, activism, in-group orientation, and vigorous proselytism, all of which were sanctioned by continuing revelation.

HISTORY

In 1827 Joseph Smith, Jr., son of an impoverished New England farmer, living in that part of upstate New York now known, because of recurrent revivalistic enthusiasms, as "the burned-over district," claimed to have received from an angel, Moroni, golden plates from which, with the use of special stones set in silver bows, he translated the *Book of Mormon*. Three associates solemnly testified that they, too, saw both the plates and the angel Moroni, and thereafter they and other converts frequently claimed visions and revelations.

Smith's followers soon moved to Kirtland, Ohio, where a prominent Campbellite preacher, Sidney Rigdon, and his following had embraced Mormonism. Authorized by revelation, and under Rigdon's influence, Smith established at Kirtland and in Missouri (where some Mormons had migrated) the communistic United Order of Enoch. Strife with non-Mormons led to the prophet's being tarred and feathered, to killings, and to the burning of Mormon property. Despite persecution, the apostasy of some early converts, occasional quarrels among Smith's brothers, the failure of specific prophecies, and the collapse of the bank that Smith had founded in Kirtland, Mormonism grew. Armed skirmishes led several thousand Mormons to leave Missouri in 1839, even though Smith had designated it as Zion. In Illinois, Smith built a new city, Nauvoo, of which he became mayor and lieutenant general of militia. Mormon self-assurance, commercial advantage, and political power provoked renewed hostility from the "Gentiles," while Smith's secret teaching and practice of plural marriage and his trade in land caused dissension among his ablest converts. Smith was arrested and murdered by Illinois militiamen in June 1844.

Early growth

The move to Utah. Despite rivalry in the Mormon hierarchy, the majority chose to follow Brigham Young, president of the Council of Twelve Apostles, to Utah in 1846–47. Young dominated his people, decided on their place of settlement, built Salt Lake City, and promoted further missionary work in Britain and Scandinavia. The Mormon migrations from Europe were admirably organized, and Mormons were highly praised for their discipline, orderliness, and moral probity by the captains of the ships that conveyed them to America. The overland journey to Utah was itself a rigorous test of the converts' faith, especially after the disastrous trek in 1856 when the converts were organized to cross from Iowa City to Utah pulling handcarts.

Young became territorial governor in 1851 and instituted polygyny in 1852. His subsequent defiance of federal authority (under Pres. James Buchanan's administration) led to his deposition and the "Utah War," in which a Mormon militia was mobilized. Mormon settlers fled from northern Utah, burning the crops at Ft. Supply and Ft. Bridger and the grass on the route of the advancing United States federal troops. In 1857 occurred the Mountain Meadows massacre, by uncontrolled Mormon enthusiasts, of non-Mormon settlers bound for California. Although the whole military episode became known as "Buchanan's blunder," it proved to be the end of direct Mormon political control of Utah. Polygyny was relinquished by the church in 1890.

Splinter groups. An important minority of Mormons rejected Young and remained in Iowa and Illinois, where, with the adherence of Emma Smith, the prophet's (first) wife, and their son, Joseph Smith III, the Reorganized Church of Jesus Christ of Latter Day Saints was formed (1852–60). That church eventually set up its headquarters at Independence, Missouri, which Smith had designated as Zion in 1831. Splinter groups also arose after Smith's death. Rigdon led one; another went to Texas with Lyman Wight, who had been an apostle. David Whitmer and Martin Harris, two witnesses of the golden plates, eventually set up a church in Kirtland. James Jesse Strang, a recent convert, was joined by John C. Bennett (second in command of the Nauvoo militia until expelled by Smith for licentious conduct) and established a polygynous community of about 3,000, eventually proclaiming himself "King in Zion."

SCRIPTURES

Mormons accept the Bible "as far as it is translated correctly." Smith did not finish his inspired translation of the Bible, which incorporates prophecies of his own coming and of the *Book of Mormon*, which is more central to Mormon belief. The *Book of Mormon* is largely similar in style and themes to the Old Testament. It recounts the history of the virtuous, industrious, fair-skinned Nephites, who were eventually exterminated by the sinful, red-skinned Lamanites. A familiar moral cycle is discernible: the virtue of God's people leads to prosperity; then to pride, iniquity, decadence, and sin; and so to God's chastisement and the people's repentance. Smith's other revealed scriptures were later incorporated into the *Pearl of Great Price*, together with his inspired translation of papyri that he declared to be the *Book of Abraham* and the *Book of Moses*. Facsimiles published by Smith as part of the *Book of Abraham* were later declared by experts to be parts of common Egyptian funerary texts—an opinion reinforced by examination of what were claimed to be the original papyri, rediscovered in the Metropolitan Museum of Art, New York City, in 1966. Smith's translation referred to gods (in the plural), affirmed that the stars were peopled with spirits, and held that persons with black skins were cursed "as pertaining to the priesthood." In consequence, Negroes have not been admitted to office in the Mormon church. *Doctrines and Covenants* is a selection of revelations to Smith and one given to Young and includes the manifesto of Pres. Wilford Woodruff abolishing plural marriage. The version of the Reorganized Church includes fewer revelations from the last decade of Smith's life.

DOCTRINES

Mormon doctrine diverges from the orthodoxy of established Christianity, particularly in its polytheism, in affirming that God has evolved from man and that men might evolve into gods, that the Persons of the Trinity are distinct beings, and that men's souls have pre-existed. Mormons accept that Christ came to earth so that all might be saved and raised from the dead but maintain that a person's future is determined by his or her own actions. Justification is by faith and obedience to the ordinances of the church, repentance, Baptism by immersion, and laying on of hands for the Spirit gifts (including prophecy, revelation, and speaking in tongues).

The *Book of Mormon* describes conventional hellfire for the unregenerate, but in 1833 Smith had a revelation of three post-resurrectional kingdoms: the celestial, the terrestrial, and—for the unclean liars and adulterers—the "telestial" kingdom on another earth. Faithful members of the church would inherit eternal life as gods, and even those who had rejected God's law would live in glory. Mormons believe that the return of Christ to earth will lead to the first resurrection and the millennium, the main activity of which will be "temple work," especially Baptism on behalf of the dead. After the millennium and second resurrection, the earth will become a celestial sphere and men will be assigned to the eternal kingdoms.

Mormons regard the Christian churches as apostate; lacking revelations, miracles, and Spirit gifts; and maintaining corrupt rituals, priesthoods, and teachings. Smith came to restore the institutions of the church and God's law in society. Although calling people to repent, Smith's creed reflected contemporary optimism in emphasizing man's inherent goodness and limitless potential for progress. Smith tempered millennialism by calling the faithful to gather and labour to build Zion as a new social order. He curbed revivalistic excess and controlled the claims to revelation of his followers. Successive church presidents have claimed divine inspiration, and private persons may expect inspiration that is helpful to their church duties.

INSTITUTIONS AND PRACTICES

The restored priesthood eliminates distinctions of priest and layman. At the age of 12, all worthy males become deacons and later teachers in the Aaronic priesthood; before they are 20 they become priests. At that age a man becomes an elder in the Melchizedek priesthood; in later life, he may become a "seventy" (a member of a larger priesthood quorum composed of 70 members) and a high priest. Each rank is organized into a quorum and has its own activities. Thus deacons and teachers accompany elders on the extensive house visiting undertaken among Mormons. Those called abroad as missionaries (at their own or their families' expense) are usually elders.

Adult Baptism, signifying repentance and obedience, has acquired additional importance as a ritual that may be undertaken by a proxy for the salvation of those who died without knowledge of the truth. Mormon interest in genealogy proceeds from concern to save dead ancestors. Baptism for the dead, endowment, and sealing (which may also be undertaken by proxy for the dead) are secret but essential ceremonies that take place in the temple. At endowment, the person is ritually washed, anointed with oil, and dressed in temple garments (underwear that good Mormons continue to wear as protection against evil and as a symbol of faithfulness). Initiates witness a dramatic performance of the story of creation, learn secret passwords and grips, and receive a secret name. The sealing ceremony, which was of special importance in the period when Mormons practiced plural marriage, seals men and women in marriage for time and eternity. Smith, who became a Mason in 1842, borrowed Masonic ritual for Mormon ceremonies, eliminating what he regarded as corruptions of the original Hebrew forms.

Persecution and segregation reinforced Mormon community identity. The patriarchal priesthoods, four decades of polygyny, and Baptism for dead ancestors have consolidated kinship allegiances. Church direction of private and public affairs reveals a persisting sectarian strain, but Mormonism is less opposed to secular culture than most sects and Mormons, although committed to millennialism and Spirit gifts, engage in worldly pursuits, business, and politics. Despite prohibitions (on alcohol, tobacco, tea, and coffee) and a vigorous work ethic, Mormonism is not ascetic. Recreation, sport, and education are positive values. Smith danced, wrestled, and, despite his "Word of Wisdom," sometimes drank. He wrote, "Men are that they might have joy." The positive attitude toward recreation, together with the emphasis on order and moral integrity, has been of great importance.

STRUCTURE OF THE CHURCH

Church polity embraces both hierarchic and egalitarian tendencies. Status is widely diffused, but authority is clearly structured. The church president and two councillors, a Council of Twelve Apostles, the First Council of Seventy (concerned especially with missions), and the presiding bishop and two councillors (who control the Aaronic priesthood) constitute, together with the patriarch (a ceremonial office), the "General Authorities" of the church. They are "sustained in office" by the regular and now ritualized vote of confidence of the General Conference, which is open to all Mormons.

At the local level, Mormons are divided into "stakes" of, on the average, 4,000 to 5,000 members under stake presidents; and wards, each of a few hundred members, under a bishop. The life of the individual Mormon is closely regulated by these local units, through which the

religious, economic, and social activities, tithing, and the operation of the church's elaborate welfare plan are organized. Ancillary organizations, Sunday school, mutual improvement associations for young people, a women's relief society, and the two-year missionary work undertaken by many young men ensure a wide distribution of responsibility and involvement.

The Reorganized Church. The Reorganized Church of Jesus Christ of Latter Day Saints holds firmly to the *Book of Mormon* but rejects the evolutionary conceptions of deity and the polytheism implicit in it, the new covenant of celestial marriage, Baptism on behalf of the dead, plural marriage, and tithing. Secret ceremonies are not performed in the Kirtland temple, to which the Reorganized Church gained legal title in 1890. The *Book of Abraham* is not accepted as of divine origin. The church's presidents, descendants of the prophet, have been appointed by revelation.

Other churches. Some Mormon splinter groups adopted communistic practices. The followers of Granville Hedrick took as their mission the building of Smith's projected temple in Missouri and acquired part of the "Temple Lot." After the Mormon church renounced plural marriage in 1890, some groups in Arizona continued the practice, but they remained secret.

BIBLIOGRAPHY. In addition to the basic scriptures cited in the text, the following commentaries on theology and ecclesiology written by Mormons in good standing are useful: J.E. TALMAGE, *A Study of the Articles of Faith* (1901); J.A. WIDTSOE, *Rational Theology* (1915), *Priesthood and Church Government* (1939), and, with L.D. WIDTSOE, *The Word of Wisdom: A Modern Interpretation*, 4th ed. (1938). For an excellent sociological treatment of Mormonism, see THOMAS O'DEA, *The Mormons* (1957). The well-documented history of Mormonism is best studied in works that deal with specific periods. Two early official histories are JOSEPH SMITH, JR., *History of the Church of Jesus Christ of Latter-day Saints*, ed. by B.H. ROBERTS, 6 vol. (1902–12); and B.H. ROBERTS, *A Comprehensive History of the Church of Jesus Christ of Latter-day Saints*, 6 vol. (1930). A popular history from the Mormon point of view is J.B. ALLEN and G.M. LEONARD, *The Story of the Latter-day Saints* (1976). For the origins and history of Mormonism to the death of Joseph Smith, Jr., see F.M. BRODIE, *No Man Knows My History: The Life of Joseph Smith, the Mormon Prophet*, 2nd ed., rev. and enl. (1971); the author, a Mormon who was excommunicated after the publication of her book, is very thorough on the details of Smith's life. Mormon accounts include PRESTON NIBLEY, *Joseph Smith, the Prophet* (1944); and J.A. WIDTSOE, *Joseph Smith: Seeker after Truth, Prophet of God* (1951). On the period in Illinois, see ROBERT FLANDERS, *Nauvoo: Kingdom on the Mississippi* (1965). On the migration from Nauvoo to Utah, see BERNARD A. DE VOTO, *Year of Decision: 1846* (1943); and W.E. STEGNER, *The Gathering of Zion: The Story of the Mormon Trail* (1964). For Mormon recruitment abroad, emigration to the United States, and the journey to Utah, see L.R. and A.W. HAFEN, *Handcarts to Zion: The Story of a Unique Western Migration, 1856–1860* (1960); WILLIAM MULDER, *Homeward to Zion: The Mormon Migration from Scandinavia* (1957); and P.A.M. TAYLOR, *Expectations Westward* (1965). For the life, views, and times of Brigham Young, see the Mormon account by one of his daughters, SUSA YOUNG GATES, written with L.D. WIDTSOE, *The Life Story of Brigham Young* (n.d.); M.R. WERNER, *Brigham Young* (1925); S.P. HIRSHSON, *The Lion of the Lord: A Biography of Brigham Young* (1969). For the period of the "Utah War", see O.G. HAMMOND (ed.), *The Utah Expedition, 1857–1858: Letters of Capt. Jesse A. Gove* (1928); JUANITA BROOKS, *The Mountain Meadows Massacre* (1950); N.F. FURNISS, *The Mormon Conflict, 1850–1859* (1960). More generally, see K.J. HANSEN, *Quest for Empire: The Political Kingdom of God and the Council of 50 in Mormon History* (1967). Useful essays on early Mormonism and on some Mormon schisms are contained in F.M. MCKIERNAN, A.R. BLAIR, and P.M. EDWARDS (eds.), *The Restoration Movement: Essays in Mormon History* (1973). For life in Salt Lake City in the 19th century, see R.F. BURTON, *The City of the Saints*, new ed. by F.M. BRODIE (1963); and WILLIAM MULDER and A.R. MORTENSEN (eds.), *Among the Mormons: Historical Accounts by Contemporary Observers* (1958). Also of importance for Mormon relations of church and state are NELS ANDERSON, *Desert Saints: The Mormon Frontier in Utah* (1942); and R.J. DWYER, *The Gentile Comes to Utah* (1941). On Mormon economic and social organization, see L.J. ARRINGTON, *Great Basin Kingdom: An Economic History of the Latter-day Saints, 1830–1900* (1958). For a sociological study of Mormon polygyny, see KIMBALL YOUNG, *Isn't One Wife Enough?* (1954). For an interpretation of church history from the perspective of the Reorganized Church, and for its own early development, see JOSEPH SMITH and H.C. SMITH, *History of the Church of Jesus Christ of Latter Day Saints*, 3 vol. (1897–1908). Summary statements of the theological and social perspective of the Reorganized Church may be found in R.A. CHEVILLE, *The Latter Day Saints and Their Changing Relationship to the Social Order* (1942); and E.A. SMITH, *Differences That Persist Between the Reorganized Church of Jesus Christ of Latter Day Saints and the Utah Mormon Church* (1943). (B.R.W.)

Morocco

Morocco, which has been an independent nation only since 1956 and a constitutional monarchy since 1962, is situated in northwestern Africa, where it looks northward across the Strait of Gibraltar to the continent of Europe, westward to the Atlantic Ocean, and northeastward to the Mediterranean Sea. To the east, as well as across a long reach of disputed territory in the southeast, lies Algeria, with which Morocco shares much—existence within the overlapping influences of the Arab and the Islāmic worlds; within the community of the Maghrib; and, in a wider sense, within the community of African and Mediterranean nations. In 1970 Spain ceded its Atlantic enclave Ifni to Morocco, but two more Spanish enclaves on the Mediterranean coast, containing Ceuta and Melilla, still remain under Spanish control. In April 1976 Moroccan territory was further enlarged when Morocco and Mauritania agreed to a boundary dividing the former Spanish Sahara between them; the *de facto* annexations resulting were not recognized in international law. Excluding these territories, Morocco had in 1976 an area of 177,117 square miles (458,730 square kilometres). Rabat is the political capital, but Marrakech, Fès, and Meknès are traditional capitals; Tangier is the summer capital.

Territorial boundaries

In spite of the modern European aspect of large parts of such cities as Casablanca, Morocco must yet be considered an underdeveloped country from a socio-economic point of view. With some 70 percent of Morocco's estimated population of 17,300,000 dependent on traditional agriculture (farming and herding), and nearly 50 percent of it under 15 years of age, the country has a soaring

population and an almost stagnant economy—a combination that threatens to pull its standards of living still further behind those of the industrialized nations. The economic development of Morocco is also complicated by its ethnic and linguistic diversity; in addition to Berber and Arab peoples, there are also relatively small but significant European, Jewish, Algerian, and Negro communities. (See CASABLANCA; for associated physical features, see ATLAS MOUNTAINS and SAHARA DESERT; for historical aspects, see NORTH AFRICA, HISTORY OF; for Moroccan arts, see ISLAMIC PEOPLES, ARTS OF.)

THE NATURAL AND HUMAN LANDSCAPE

The natural environment. *Surface features.* Most of Morocco lies at a high altitude; the average height above sea level is about 2,600 feet. Two chains of mountains, the Rif along the northern coast and the Atlas in the centre, divide eastern Morocco (which physically is much like neighbouring Algeria) from Atlantic Morocco, which the mountains cut off from the rest of northwestern Africa. Eastern Morocco and Atlantic Morocco are connected only by the narrow Taza Pass in the northeast. These systems of mountains were formed during the Tertiary Period—from 2,500,000 to 65,000,000 years ago—by the folding and uplift to sediment that had accumulated in the ancient sea that at that time edged the northern coast of the old continent of Africa.

The Rif, a complex structure, is geologically part of the cordilleras (mountain chains) reaching southward from the Iberian Peninsula of Europe, from which Africa was separated only after the Tertiary Period. Crescent-shaped, almost entirely over 4,900 feet and rising to 8,058 feet (2,458 metres) in Jebel Tidirhine, the limestone peaks of the Rif rise abruptly from the narrow Mediterranean shore.

The Atlas Mountains

The Atlas comprise three quite distinct chains. The Haut Atlas (High Atlas), 460 miles long, begins as small hills at the edge of the Atlantic, rises rapidly to over 6,500 feet, and reaches its highest point in Jebel Toubkal, which is 13,665 feet (4,165 metres) high. The Moyen Atlas (Middle Atlas) slopes away from the Haut Atlas in a northerly direction, rising to 10,794 feet (3,290 metres). The Anti-Atlas extends southwestward from the Haut Atlas to the Atlantic.

To the east of the Atlas, are the flat Hauts Plateaux (High Plateaus) of eastern Morocco, which are between about 3,900 and 4,250 feet in altitude, and which were formed by depressions which became filled with rubble. Atlantic Morocco comprises plains formed of sediment, and plateaus consisting of rubble.

The vast plain of the Rharb, at the foot of the Rif, is an old pass, which has been narrowed by the upheaval of the Rif and has then gradually been silted up by alluvial deposits from the Oued Sebou (a *oued*, or wadi, is a seasonal watercourse). Inland, the plains of Fès, Oujda, and the Angad become progressively smaller. The vast region lying between the Rharb, the Atlantic, and the Atlas, is named the Moroccan *meseta* ("plateau"); it is covered with a thin layer of sediments, thus forming a coastal plateau about 700 feet high running from Rabat to the coastal range of the Haut Atlas.

The coastline is regular, but, before modern ports were built, a strong sandbar made navigation difficult. To the south, the Sous plain separates the Haut Atlas from the Anti-Atlas, south of which begins the great expanse of the Sahara.

The rivers

Drainage. The Saharan area of eastern Morocco is drained by the Dadès, Rheris, Ziz, and Guir rivers, all of which originate in the Haut Atlas and lose themselves in the desert after cutting impressive chasms through the mountains. The northern region is drained by the Moulouya, which begins in the Moyen Atlas and empties into the Mediterranean after flowing for 320 miles. The Rif is drained by small torrential rivers such as the Laou, the Rhis, and the Nekor. Among the rivers flowing into the Atlantic are the Loukkos, which has its source in the western Rif and enters the ocean at Larache; the Sebou, the most strongly flowing river in Morocco, which is 280 miles long, and reaches the ocean at Mehdiya after much meandering; and the Oum er-Rbia, somewhat longer than the Sebou, and the most regular of Morocco's rivers.

All Moroccan rivers are torrential in nature: the Moulouya's flow ranges from 35,000 cubic feet per second to 175 cubic feet per second in the course of the summer.

Climate. In the coastal regions, the Moroccan climate is temperate within a narrow climatic range. Because of its latitude, climate is influenced by the proximity of the Azores anticyclone (a system of winds that rotates in a clockwise direction about a centre of high atmospheric pressure). The west winds that blow for most of the year result in changeable weather and irregular rainfall in the autumn and winter months. During the summer months, this anticyclone moves north, resulting in calmer weather. The cold ocean current, which flows to Morocco from the Canary Islands to the southwest, also helps to produce a milder climate.

In contrast to the coastal pattern, the inland climate assumes an increasingly continental character as the Atlas and the eastern inland plains are approached. Sometimes, but very rarely, the desert wind known as the chergui ("that which blows from the east") can cause the temperature to rise to 95° to 104° F (35° to 40° C) in the mountains and even the coast. Tangier has an average temperature of about 54° F (12° C) in January, and 75° F (24° C) in August; Casablanca's temperature averages 54° F (12° C) and 73° F (23° C) for the same months, while Essaouira has temperatures of 59° F (15° C) and 68° F (20° C). Inland the range is greater: the average at Meknès ranges between 50° and 77° F (10° and 25° C), and at Taza between 52° and 82° F (11° and 28° C). In the mountains the thermometer may plunge to −4° F (−20° C) at the summits or soar to 104° F (40° C) when the chergui is blowing.

Temperatures and rainfall

Rainfall depends on altitude and latitude; the Rif and the Moyen Atlas in the north receive an annual precipitation of over 47 inches; the northern Atlantic plains receive between 16 and 32 inches, which is just enough to cultivate corn without irrigation. To the south, and up to the Atlas, the rainfall average is steady at between eight and ten inches. To the east it ranges from six to 14 inches, whereas in the Sous it is less than eight inches. The rainy season usually lasts from November to January and sometimes continues into March. Rainfall is often irregular and unevenly distributed. Torrential downpours sometimes cause catastrophic floods, particularly in the Rharb, and in the Sous and Tafilalt regions, just north of the Sahara. Snow falls above about 6,500 feet and melts in the spring, by June or July at the latest.

Vegetation and animal life. The vegetation of Morocco is typical of that of the western Mediterranean region and similar to that of the Iberian Peninsula. In the mountain regions are stands of cedars, firs, and junipers. South of Essaouira, the tropical argan tree, which has an olive-like fruit that produces oil, covers 300,000 acres. The commonest trees are the cork oak, which covers 740,000 acres in the Rif and in the Rharb; the evergreen oak, which covers a third of the wooded areas; and the thuja, a pine, which covers 2,000,000 acres in the lower Moulouya Valley and in the high areas of the Sous. The wild olive and the mastic tree are found on high plateaus where there is little rainfall; the dwarf palm grows on the arid inland plains; the fruit-bearing jujube tree is common in the Tadla and the Haouz regions. Tough esparto grass (often used for making cordage and clothing) sometimes mixed in with wormwood covers a vast area. Unless they are grown under artificial conditions, as in the Marrakech area, date palms mark the northernmost limit of the desert, south of the Oued Drâa and east of the Atlas, at Boudenib and Figuig. Such species as the Barbary fig and the eucalyptus are imports; the former was introduced from the Americas via Spain in the 16th century, the latter by the French early in the 20th century.

The animal life is also Mediterranean: camels and horses were introduced at the dawn of history. Lions have disappeared, as the elephants did before them; mouflon (a wild sheep), gazelle, fennec (a kind of fox), and macaco (a kind of monkey) are still common in the Atlas region.

Human imprints on Morocco. *Traditional regions.* Morocco has five great regional units—the Rif, the Rharb, the Haouz, the Sous, and eastern Morocco. The Rif, a mountainous country, is well watered and inhabited by settled farmers, mostly tree cultivators, who have a strong sense of clannish loyalty. The Rharb, in the wider sense of the term, is centred on Fès and Meknès and comprises a unit in which the economy of the Berber-speaking shepherds of the Moyen Atlas, who practice transhumance (the seasonal migration of herds to mountain pastures), mingles with that of the settled Arabic-speaking grain producers of the Atlantic coastal region and that of the seminomadic cattle breeders from the central mountain ranges.

The five main regions

The south–central region, or Haouz, now looks to Casablanca as its urban centre, but its capital was once Marrakech. This region brings together peasants long settled on the soil of the Doukkala and the Abda plains, seminomadic cattle breeders of the central plateaus and the inland Tadla plains, and settled farmers of the Dir area (dirs are conical deposits left by seasonal streams) and the valleys of the Haut Atlas.

The Sous in the historic sense includes the Haut Atlas, the Sous plain, and the Anti-Atlas. This is the land of the Shleuh (Chleuh) who are a Berber people; its high population density has brought about extremely complex community organization. The region is traditionally associated with the production of herbaceous oils, saffron, and the exquisite metalwork traditional to Morocco.

Finally, eastern Morocco covers the region known historically as Tafilalt, in which the desert's influence is strongly felt. Settled inhabitants of the irrigated oases, including a strong proportion of people of mixed negroid descent, or Ḥarāṭīn, live alongside nomadic sheep breeders; they earn their living as agricultural labourers. The great nomads, the camel drivers such as the Regeibat and the Tekna tribes, live only temporarily within the territorial limits of Morocco.

Modes of life. In Morocco, settled mountain people living in villages, with architecture adapted to local conditions, have always lived alongside the nomadic or seminomadic peoples of the plateaus and of the Moyen Atlas, who live in black tents (*khaymah*). Other more or less settled farmers, who are tied to the soil, live together in thatched-roofed dwellings called *noualas*. Nomadism currently is declining rapidly, and the *khaymah* and the *nouala* are being replaced with solid houses, particularly in the irrigated Triffa, Rharb, Tadla, and Haouz plains. The precarious valley economy of the Atlas and the Rif is hard hit by the migration of mountain people to the coast, and the villages are becoming empty of men of working age. As a result, vast areas may become desert as

already has happened in eastern Morocco and the Haouz, which now are haunted only by shepherds, the last people to use *khaymahs*.

Towns have traditionally been divided into three groups —port towns, royal towns, and market towns—each with its distinctive style of life. Recent developments have tended to increase the prosperity of port towns throughout the country. Towns in which economic life has declined, such as Ouarzazate and Tiznit in the south, Chechaouene and Tétouan in the north, or Essaouira or Asilah on the coast, maintain the rhythms of the traditional way of life and hide great poverty with dignity.

Rural and urban settlement

Towns experiencing a certain degree of expansion, however, whether they are old like Meknès and Oujda or rebuilt like Casablanca and Safi, have not yet established their new balance and possess a characteristically unfinished quality. These towns are composed of five distinct parts that exist side by side without integrating with one another. The old centre, the *madīnah*, is surrounded by ramparts, which still exist almost everywhere. Overcrowded by immigrants from outlying areas, it usually has fallen into decline, despite efforts by local authorities to prevent it from total decay. The business and entertainment centre, the modern town inhabited mostly by foreigners, is very busy by day but empties rapidly at night. The constantly expanding residential area indicates the rapid rise of the local middle class. Flower-bedecked, lighted, and clean, it consists of a succession of separate houses, each surrounded by a large garden.

The new *madīnah*, a tangle of narrow alleys with tiny houses built on the same model and with little planning or sense of style, is packed with low-ranking officials, small shopkeepers, workers, and pensioners. It unceasingly attempts to check the growth of the shanty towns, or *bidonvilles*, which expand constantly despite all efforts to resettle their inhabitants, who comprise newcomers to the town, the unemployed, and casual labourers who remain on the fringes of urban life. *Bidonvilles* and the newer quarters of the new *madīnah* often partly overlap, depending on the whims of financial speculators. This pattern of separation, common to most Moroccan cities, brings about an atmosphere that lacks the extroversion and tumult usually characteristic of a large city.

THE PEOPLE OF MOROCCO

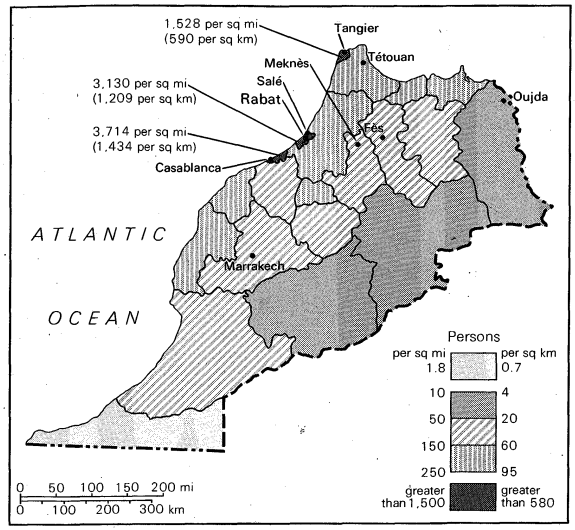
Arabs and Berbers

Linguistic and ethnic groups. The population of Morocco is Arab and Berber in origin, though the difference between the two groups today is more linguistic than racial. The Berber language, although greatly influenced by Arabic, has been preserved in the mountainous regions, which have long been areas of refuge. Berber-speaking inhabitants are divided into three dialect groups: Rifian in the Rif, Amazigh in the Moyen Atlas, and Shleuh in the Haut Atlas and the Sous. With improved communications and the exodus to the towns, Arabic-Berber bilingualism has become common, and the proportion of monolingual Berbers does not exceed 25 percent. The remainder of the Moroccan population speaks Arabic and is composed mainly of Arabized Berbers from the plains and the plateaus, and a small number of Bedouin Arabs who moved to Morocco with the armies of Islām in the 7th century or with the invading Hilāl tribe in the 11th and 12th centuries.

Immigrants from Spain, who travelled to Morocco at various stages of the Christian reconquest of the Iberian Peninsula, which culminated in 1492, were themselves a mixture of Arab, Berber, and Iberian; today they live chiefly in Rabat, Salé, Fès, and Tétouan.

Trade and cultural relations with black Africa since the Middle Ages have resulted in the gradual growth of a significant Negro minority, living chiefly in the southern oases or in the royal towns, particularly Marrakech and Meknès. The Jewish minority—a considerable community until emigration to Israel began in 1948—consists of small Berber-speaking groups whose origins are obscure and of Arabic-speaking groups who arrived from Spain and other Mediterranean countries at various periods of history.

European colonization brought a French and a Spanish minority whose numbers had reached some 500,000 on the eve of independence in 1956. The French and Spanish languages, which spread among the urban population during the preceding protectorate period, are still spoken. With the exception of the rapidly declining gallicized Jewish minority, however, the majority of the Moroccan population has a common culture and religion. Most Moroccans are Sunnī Muslims of the Mālikite rite, who, until recently, had a marked inclination to join religious confraternities of varying degrees of orthodoxy.



Population density of Morocco.

Contemporary demography. The 1971 census put Morocco's Islāmic population at about 15,250,000. The Jewish population, which in 1960 numbered about 160,000, had dropped to 31,000, while foreigners of all nationalities, who previously numbered nearly 400,000, dropped to only 112,000. The Islāmic population had one of the highest rates of increase in the world, estimated at 3.2 percent per year. The birth rate was close to 50 per 1,000 inhabitants per year, whereas the death rate stood at about 16.5 per 1,000; infant mortality reached 15 percent. These figures explain the extreme youth of the population, more than 45 percent of which is under 15 years of age, and more than 55 percent, under 20; as a result, the productive portion of the population amounts to only about 28 percent.

In the early 1970s, some 5,000,000 Moroccans lived in towns whose populations were growing at an annual rate of about 6 percent. Casablanca had a population of 1,500,000 and 9 other towns—Fès, Kenitra, Marrakech, Meknès, Oujda, Rabat, Safi, Tangier, and Tétouan —had populations of more than 100,000. Population density varies outside urban areas: the Doukkala and western Rif regions have an average of 180 inhabitants per square mile; the Anti-Atlas and the Marrakech area, about 50 to 150; and the eastern and southern steppe regions, about 13. The present trend is toward a massive concentration of people in the coastal area between Kenitra and Casablanca.

The population increase

The government has launched a family-planning campaign that the population does not seem to oppose, although the youthful composition of the population suggests that rapid results cannot be expected. Population figures projected for 1985 range from 23,000,000 to 26,000,000, depending on the program's success or failure; it is estimated that by that time about 10,000,000 people will live in the towns, 7,000,000 to 8,000,000 will be of school age; and 8,000,000 jobs will be needed, 4,000,000 of them in the towns. Such projections are alarming, considering the slow rate of economic growth in the 1960s.

Large-scale emigration to Europe remains a continuing phenomenon. After France—the traditional labour market—Belgium, The Netherlands, and West Germany are using increasing amounts of Moroccan manpower. Training centres, jointly financed by the state and by European

employers, are open to those wishing to emigrate. In the early 1970s, 240,000 Moroccans were working in Europe, most of whom were originally from the overpopulated Atlas, Rif, and Tafilalt regions.

THE NATION'S ECONOMY

Economists were optimistic after World War II about Morocco's future. The subsequent population explosion and indecisiveness concerning economic policies in the decade that followed independence, have made them more cautious. From the point of view of area, population, resources, and geographic location, Morocco is a medium-sized country that might be expected to play a significant role in a regional framework. Stagnation of the national product, small individual incomes, and poor development indices threaten Morocco with increasing poverty as the years go by.

Components of the economy. In spite of such gloomy economic prognostications, Morocco's mineral, agricultural, and hydroelectric resources are far from negligible. It has about 40 percent of the world's known phosphate reserves and is the world's second-largest producer. Mining is under the direction of the Office Chérifien des Phosphates, a public body founded in 1921, and exports are nearly all in the form of unrefined ores. The discovery of more easily exploited deposits in the Spanish Sahara, however, is providing increasing competition for the Moroccan mines. Other mineral products include iron, lead, manganese, zinc, cobalt, and copper. A pocket of natural gas was discovered near Essaouira in 1961.

Mining, agriculture, and industry

Petroleum resources in the Rharb are being rapidly depleted, necessitating the importation of most of the crude oil processed by Morocco's two refineries. Domestic coal is a major source of fuel for the nation's power plants; in the early 1970s only about one-half of the hydroelectric potentiality of the rivers was being utilized.

Some 38,300,000 acres of land are under cultivation, but irregular harvests and poor yields force Morocco to import a large percentage of its foodstuffs. To help offset this trade imbalance, the government is pinning its hopes on increasing production of edible beans, cereals, cotton, and sugar from cane and beet. Vines are cultivated, mainly by Frenchmen, for the export wine trade. Citrus fruits, tomatoes, vegetables, and canned fish comprise the largest portion of exports. Other export products include olive oil, cork, oak timber, esparto grass, and sardine and tuna from the rich coastal fishing grounds. Income from livestock—sheep, cattle, goats, and camels—represents one-third of all agricultural income.

About 600,000 Moroccans either work in industry, mines, or handicrafts. Automobile assembly, textile spinning and weaving, and food processing are among the more modern industrial processes; textiles and processed foods provide surpluses for export. The ancient Moroccan handicraft products, which include carpets, hand-tooled leather, and intricate metalwork, are also produced in sufficient quantity for export.

In the early 1970s Morocco continued to have a balance of trade deficit, but this was offset by aid from various Western nations and from international organizations. Most of the nation's trade—about 50 percent of imports, and 60 percent of exports—was with members of the European Economic Community, or the Common Market.

Economic management. The private sector of the Moroccan economy is dominated by the European minority, mainly French, which controls production of a large proportion of the nation's wine, paper, metals, and processed foods. The new class of Moroccan entrepreneurs controls only the textile and hotel trades. In 1969 the state introduced a policy of accelerating the Moroccanization of banks and insurance agencies, and service agencies—by encouraging the conclusion of agreements between Moroccan nationals and foreigners, rather than by nationalization. Private interests are protected by a French chamber of commerce, a French–Moroccan young businessmen's association, and an American–Moroccan chamber of commerce.

While state activity in the economy continues to expand, its role is primarily to stimulate the private sector. In order to encourage and guarantee investment of foreign currency in the economy, liberal benefits, mainly to foreign private investors, have been available since 1958; Moroccan ministerial committees meet regularly with their counterparts from West Germany, France, and Spain to study aid proposals within the framework of current development plans.

Among such plans, one for rapid industrialization in the early 1960s was abandoned in order to concentrate on developing irrigation for agriculture, so as to stimulate exports; on promoting tourism as a national industry; and on the training of administrators and technicians to decrease the degree of extensive foreign assistance still needed in these areas. Morocco's alliance with the Common Market has resulted in more secure markets, as well as in more secure jobs for its surplus manpower; it has also helped to attract tourists and capital.

Within the framework of current policies, annual growth rates in the gross national product of from 3.5 to 5 percent are forecast for the 1970s. Given this rate, however, unemployment would probably remain at more than 1,000,000 persons, and the surplus agrarian population, at about 40 percent, while education would be available to only 30 percent of the school-age population. Meanwhile, a heavy burden on the economy is the employment of about 350,000 persons—five times as many as before independence—as government functionaries of various kinds.

Wages are negotiated directly between management and the trade unions. In keeping with its guarantees of monetary stability, the government has in effect kept wages frozen since 1960; this policy is made easier by the great surplus of labour. The major trade union is the Union Marocaine du Travail (Casablanca); its membership, estimated at more than 350,000, is mainly in the mining, textile, and food-processing industries.

Transportation. The transportation network radiates outward from the regional capitals—Oujda, Fès, Marrakech, Agadir, and Tangier—to focus on Casablanca, Morocco's economic and commercial capital. Casablanca handles four-fifths of Moroccan imports, but the free port of Tangier is the main landing place for tourists.

The ports

Mineral products from eastern Morocco are shipped through the Algerian port of Ghazaouet (formerly Nemours); products from the Rharb region, stockpiled at Fès and Meknès, are exported through Casablanca and Kenitra; the phosphate is refined through Safi; the Sous region ships its products through the port of Agadir; and the port of Tangier serves the Rif region. Because the two ports of Ceuta and Melilla are still in Spanish hands, the Moroccan government is planning to build a new Mediterranean port at Nador. Mohammedia is the principal port handling petroleum imports. The national shipping company, Comanav, owns seven ships.

The railway system, which is nationalized, has about 1,632 miles of track, of which about 472 miles—which includes the Marrakech–Casablanca–Fès section—are electrified. The system includes part of the main line from Algiers to Marrakech, via Oujda, Taza, Fès, Meknès, Rabat, and Casablanca; there are extensions northward to Tangier and southward to the phosphate mines of Khouribga, as well as an extension to Safi. The eastern Moroccan line serves mining areas in that region.

Air traffic is being rapidly expanded; services provided by the national airline are supplemented by those of a second company, which provides flights on inland routes. There are international airports at Nouasser near Casablanca, and at Rabat-Salé; those at Agadir and Tangier are being enlarged to accommodate all categories of commercial aircraft. Smaller but well-equipped airports are at Marrakech, Fès, Oujda, and al-Hoceima.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. *Constitutional framework.* Morocco has been a constitutional monarchy since 1962. It experimented with a parliamentary type of government between 1963 and 1965, but after a period of five years during which full power devolved upon the king, the

constitution of 1970 (a new one was approved by a referendum in 1972) replaced the previous bicameral legislature with a single chamber having limited powers. This chamber comprises members elected by universal suffrage (men and women citizens 21 years of age or older); two-thirds of its members are elected by the municipal councils and committees, and one-third by organizations of professional people and wage earners. The chamber shares with the king the right to initiate legislation; it can, however, be dissolved at a moment's notice. The king, whose person is sacred and inviolable, has the right to submit laws directly to a popular referendum and can send back any law that has been adopted after a second reading in the chamber.

The centralization of local government

Administration in Morocco is highly centralized, and strictly speaking no local government exists. *Qā'īd*s (caids), the heads of local administrative units in rural areas, and pashas, administrators in the towns, are appointed by the Minister of the Interior, Town Planning and Housing; governors of the 19 provinces and of the prefectures of Casablanca and Rabat-Salé are appointed by royal decree. These representatives of the central government exercise tight control over the municipal and communal councils, and over the 21 prefectoral and provincial assemblies, and over the seven regional assemblies that have a consultative role in economic and social matters.

Political life. This centralization and the influence traditionally wielded by government on public life in an underdeveloped country that has widespread illiteracy and no long history of democratic rule has tended to alienate many factions within Moroccan society, including the intellectual and political elite, the trade unions, and youth. These groups feel that, in spite of legal guarantees, severe limitations exist on the citizens' freedom of choice. Supporters of the system of "guided democracy" and "electoral apprenticeship" suggest that the sociocultural backwardness of the country would make any freedom of choice illusory. There was widespread withdrawal from participation in the political process in the early 1970s, and unsuccessful coups d'etat in 1971 underlined instabilities in the nation's political life.

Of the four political parties, the oldest is the nationalist Istiqlāl Party, founded in 1944; it has a bent toward bold social reform in spite of its middle-class membership. The Union Nationale des Forces Populaires was formed in 1959 by left-wing secessionists; it has been the object of severe governmental repression. Two other parties are much in the minority. Campuses in such university cities as Rabat and Fès have tended to become increasingly politicized and antigovernment.

Justice. Although in theory the Qur'ān is the source of law, and the king is the spiritual head of the community, in effect the Qur'ānic jurisdiction, exercised by the *qāḍī*s or cadis (Muslim judges who interpret and administer the religious law of Islām), is limited to matters relating to the personal status of Muslims; whereas rabbinical justice exists for Jews. All other matters, whether they concern Muslims, Jews, or others, are in the hands of the "modern" courts, which apply a code of laws inspired by the French. The various regional and local courts are beneath the three courts of appeal and the supreme court, which sits in Casablanca. All are supervised by the Ministry of Justice. A Franco-Moroccan judicial convention allows Morocco to use the services of 100 French magistrates. French and Spanish lawyers may in principle practice at the Moroccan bar. The Ministry of Justice has conducted its affairs in Arabic since 1965.

Military and police. The Moroccan Army is made up of contingents that previously served under the French or Spanish flags or that formed part of the guerrilla forces that fought against the French before independence was obtained in 1956. The 55,000-man army, divided into five brigades, is equipped with French and Russian tanks. Some 20,000 supplementary soldiers under the Ministry of the Interior, Town Planning and Housing form a militia, which is responsible for maintaining order in the interior. The air force is equipped with French, American, and Soviet fighters, and the navy has several light warships. The royal gendarmerie is made up of 3,500 well-trained men; and the police force, which receives technical assistance from France, numbers 12,000.

Standards of living

The social milieu. Morocco's low standard of living is characterized by great inequalities in the distribution of wealth. One-half of the national product is derived from the modern sector of the economy, which involves only 10 percent of the population. At the same time, 10,000,000 peasants contributed only 20 percent of the product. The average annual income of the great majority is about $80, although workers in private industry earn considerably more. Rising prices of dietary staples threaten to lower standards of living further. The hill peoples fare less well in most areas of social services.

Education. Although about one-fifth of Morocco's budget is spent on education, barely 50 percent of the nation's school-age population receives an education. The system of primary and secondary schools, in which boys greatly outnumber girls, is supplemented by traditional Islāmic Arabic schools, as well as by private schools, both Moroccan and foreign.

The French Cultural Mission, the most important foreign institution in the country, provides schooling to 10,000 Moroccan pupils at the primary and the secondary levels. French and Arab bilingualism at all levels constitutes a problem resulting in extra expense and waste of energy. Only about 40 percent of the teachers in the secondary schools and barely 15 percent in the scientific disciplines at the higher level are Moroccan. Programs promoting unification, Moroccanization, and Arabization of the educational system, long accepted in principle by the government, had not yet been put into effect in the early 1970s.

Health and welfare. Social services are the responsibility of the ministries of Public Health, Work and Social Affairs, and Youth and Sports. These services largely benefit the urban population, especially the civil servants and other middle-class groups. Neither craftsmen, members of the liberal professions, nor agricultural workers benefit from medical insurance or family allowances.

Public health receives about 6 percent of the Moroccan budget, but the entire country has only about 1,150 doctors and fewer than 1,000 nurses. Health centres and dispensaries are located throughout the country to supplement the work of 76 general and specialized hospitals. The faculty of medicine at Rabat (a second one is planned for Casablanca) produces only a small number of doctors in a country in which some 2,000,000 children suffer from the disease of malnutrition, which takes the form of rickets (a childhood disease characterized by faulty ossification of the bones).

Housing. The Ministry of the Interior, Town Planning and Housing is responsible for housing, often acting as trustee for communities whose large real-estate holdings are owned in common. The number of persons inadequately housed—in shantytowns or in the *madīnah*s—is estimated at 2,000,000; governmental policy is to leave the problem of urban housing to the private sector. The state parcels out public land and arranges easy terms of payment; in the early 1970s it was concentrating on improving rural housing in an effort to stop the exodus to the towns. Within the framework of the 1968 to 1972 plan, and with help from the United Nations, 30,000 dwellings were improved in the south and 60,000 built in irrigated areas. It was considered, however, that this relative indifference to urban housing problems on the part of the government would only be temporary.

CULTURAL LIFE AND INSTITUTIONS

Illiteracy and biculturalism are the major facts of Morocco's cultural life. More than three-quarters of young people between 15 and 19 years of age are illiterate. Divisions between town and country and between linguistic and dialectal areas persist. Arabic is the national and official language of Morocco, but in many areas, French is the working language. A heritage from the colonial past, biculturalism is reinforced by the presence of a strong and dominant foreign minority in the modern sector of the economy.

Duality of literary traditions

The arts. Two literatures—Arabic and French—exist side by side in Morocco. The future of literary works in French cannot be predicted with any degree of certainty, though many young Moroccans are following in the footsteps of older writers who used French. A modern Arabic literature is, however, also developing in spite of publishing and distribution difficulties. These works either have to be published abroad, generally in Beirut or Lebanon, or at the author's expense; editions rarely exceed 3,000 copies.

Painting and sculpture have experienced a veritable blossoming since independence.

Both primitive and abstract artists have found encouragement in foreign cultural centres and are exploiting an almost untouched market in the growing Moroccan middle class. The École Municipale des Beaux Arts (Municipal School of Fine Art) in Casablanca is striving to save Morocco's artistic tradition by reviving it. At the same time, the government, in an effort to safeguard a folklore that is rich and varied, organizes every spring a national folklore festival at Marrakech which attracts thousands of tourists. The theatre is subsidized, either by the local authorities as in Casablanca and el-Jadida, or by the Ministry of Youth, Sports, and Social Affairs. Conservatories of music are located in Casablanca, Rabat, and Tétouan; their dual purposes are both to preserve the Andalusian musical tradition and to spread a taste for modern Western music, as well as a knowledge of its techniques.

Cultural organization. The Department of Culture is responsible for libraries and archives; it classifies and restores historic monuments, sponsors art exhibitions, and awards the Prix du Maroc for literature, the social sciences, and the exact sciences. The association of Moroccan writers, which has branches in the main cities, attempts to disseminate the new Moroccan literature in collaboration with similar associations in the Maghrib and in other Arab countries.

Communications media. The bilingual Moroccan press has a small circulation: between 15,000 and 45,000 copies for the largest dailies. Among Arabic newspapers are *al-ʿAlam*, the Istiqlāl organ; *al-Anbāʾ*, the official government paper; and *ash-Shaʿb* (*al-Chaʿn*), which is government inspired. Among the French-language newspapers are *L'Opinion* (Istiqlāl); *La Dépêche* (independent; suppressed in 1971); and *Le Petit Marocain* and *La Vigie Marocaine*, which date from the protectorate period and were Moroccanized under new names, *Le Matin* and *Maroc-Soir*. Morocco has an independent press agency, the Maghreb Arabe Presse (MAP).

As in all countries with widespread illiteracy, the radio plays an important role. According to official figures, there is one receiver for every 16 Moroccans, but since the advent of transistorized receivers, it is probable that nearly every family owns a radio. A powerful station, Voice of America, broadcasts from Tangier, a medium-powered one from Rabat. Moroccan radio broadcasts for 12 hours daily in Arabic, Berber, French, Spanish, and English. The state television network in Rabat, inaugurated in 1962, broadcasts for four and a half hours daily in Arabic and in French; entertainment outweighs education in its programming.

PROSPECTS

Ongoing economic and social instabilities

The 1970s will be decisive for Morocco's future. If the nation contrives to take advantage of its geographical situation, its climate, its countryside, and its cultural patrimony to attract the capital it lacks, if it provides its young people with the adequate education and the work that they require, and if it is able to process its mineral and agricultural resources instead of simply exporting them as raw materials, then observers believe that Morocco might yet achieve a major economic and social turnabout. If it does not, illiteracy, unemployment, and underemployment could lead Morocco into poverty and decline.

These problems have not yet reached catastrophic proportions; between 1960 and 1970 the royal government tried to resolve them within a traditionalist, relatively liberal, and moderate framework. In this way it has been able to win the confidence of international organizations and to receive aid from the industrialized countries of the West; however, because of the concentration of power, administrative centralization, and the growing part played by the army in public affairs, those areas in which the political and intellectual elite could participate shrank just at a time when the problem required nationwide cooperation by all elements of Moroccan society.

Social stability is also called into question by deficiencies in economic growth. Should the birth-control campaign fail, which it is likely to do, the situation would then become aggravated. Most impartial observers felt that the government would then be forced either to stress its authoritarian character or to open the way to new forces.

BIBLIOGRAPHY. No complete, up-to-date monograph on all aspects of Moroccan life exists, although V. MONTEIL, *Le Maroc*, new ed. (1972) and N. BARBOUR, *Morocco* (1965), provide perspectives. Worthwhile sociological studies are regional rather than national in content; CARLETON S. COON, *Tribes of the Rif* (1927), is a major pioneer study. The point of view of the colonial administration is well documented in R. MONTAGNE, *Les Berbères et le Makhzen dans le Sud du Maroc* (1930). More methodical and liberal in inclination is JACQUES BERQUE, *Structures sociales du Haut Atlas* (1955). E. GELLNER, *Saints of the Atlas* (1969), is a remarkable study of a segmental society. A good general survey of the changes introduced by colonization is found in CHARLES F. STEWART, *The Economy of Morocco, 1912–1962* (1964). The INTERNATIONAL BANK FOR RECONSTRUCTION AND DEVELOPMENT, *The Economic Development of Morocco* (1966), is a report by international experts on the problems and perspectives of the Moroccan economy. The fundamental analysis of the subject, however, is found in SAMIR AMIN, *L'économie du Maghreb*, 2 vol. (1966), summarized in *Le Maghreb moderne* (1970; Eng. trans., *The Maghreb in the Modern World*, 1970). The sociopolitical situation under the protectorate is discussed with great finesse in JACQUES BERQUE, *Le Maghreb entre deux guerres* (1962; Eng. trans., *French North Africa: The Maghrib Between Two World Wars*, 1967). The history of the nationalist movement is traced faithfully by JOHN P. HALSTEAD in *Rebirth of A Nation: The Origins and Rise of the Moroccan Nationalism, 1912–1944* (1967). Two complementary points of view concerning the transformations and the problems following independence are found in DOUGLAS E. ASHFORD, *Political Change in Morocco* (1961); and WILLIAM I. ZARTMAN, *Morocco: Problems of New Power* (1964). The mechanisms of power are analyzed in great detail in CLEMENT H. MOORE, *Politics in North Africa* (1970); and JOHN WATERBURY, *Commander of the Faithful: The Moroccan Elite* (1970).

(A.La.)

Morphology

Morphology is a term used in biology for the study not only of shape and structure in plants, animals, and micro-organisms but also of the size, shape, structure, and relationships of the parts comprising them. The term morphology connotes the general aspects of biological form and arrangement of the parts of a plant or an animal. The term anatomy also refers to the study of biological structure but usually connotes study of the details of either gross or microscopic structure. In practice, however, the two terms are used almost synonymously.

Typically, morphology is contrasted with physiology, which deals with studies of the functions of organisms and their parts; function and structure are so closely interrelated, however, that their separation is somewhat artificial. Morphologists were originally concerned with the bones, muscles, blood vessels, and nerves comprising the bodies of animals and the roots, stems, leaves, and flower parts comprising the bodies of higher plants. The development of the light microscope made possible the examination of some structural details of individual tissues and single cells; the development of the electron microscope and of methods for preparing ultrathin sections of tissues created an entirely new aspect of morphology—that involving the detailed structure of cells. Electron microscopy has gradually revealed the amazing complexity of the many structures comprising the cells of plants and animals. Other physical techniques have per-

mitted biologists to investigate the morphology of complex molecules such as hemoglobin, the gas-carrying protein of blood, and deoxyribonucleic acid (DNA), of which most genes are composed. Thus, morphology encompasses the study of biological structures over a tremendous range of sizes, from the macroscopic to the molecular.

A thorough knowledge of structure (morphology) is of fundamental importance to the physician, to the veterinarian, and to the plant pathologist, all of whom are concerned with the kinds and causes of the structural changes that result from specific diseases.

HISTORICAL BACKGROUND

Significant events. Evidence that prehistoric man appreciated the form and structure of his contemporary animals has survived in the form of paintings on the walls of caves in France, Spain, and elsewhere. During the early civilizations of China, Egypt, and the Near East, as man learned to domesticate certain animals and to cultivate many fruits and grains, he also acquired knowledge about the structures of various plants and animals.

Aristotle was interested in biological form and structure, and his *Historia Animalium* contains excellent descriptions, clearly recognizable in extant species, of the animals of Greece and Asia Minor. He was also interested in developmental morphology and studied the development of chicks before hatching and the breeding methods of sharks and bees. The Greek physician Galen was among the first to dissect animals and to make careful records of his observations of internal structures. His descriptions of the human body, although they remained the unquestioned authority for more than 1,000 years, contained some remarkable errors, for they were based on dissections of pigs and monkeys rather than of humans.

Emergence of modern morphology

Although it is difficult to pinpoint the emergence of modern morphology as a science, one of the early landmarks was the publication in 1543 of *De Humani Corporis Fabrica* by the Belgian Andreas Vesalius, a professor at the University of Padua, in Italy, whose careful dissections of human bodies and accurate drawings of his observations revealed many of the inaccuracies in Galen's earlier descriptions of the human body. Leonardo da Vinci was a morphologist as well as a painter, engineer, and inventor, even though many of his original observations in biology were discovered only after his notebooks were deciphered.

In 1661 an Italian physiologist, Marcello Malpighi, the founder of microscopic anatomy, demonstrated the presence of the small blood vessels called capillaries, which connect arteries and veins. The existence of capillaries had been postulated 30 years earlier by the English physician William Harvey, whose classic experiments on the direction of blood flow in arteries and veins indicated that minute connections must exist between them. Between 1668 and 1680, the Dutch microscopist Antonie van Leeuwenhoek used the recently invented microscope to describe red blood cells, human sperm cells, bacteria, protozoans, and various other structures.

Cellular components—the nucleus and nucleolus of plant cells and the chromosomes within the nucleus—and the complex sequence of nuclear events (mitosis) that occur during cell division were described by various scientists throughout the 19th century. *Organographie der Pflanzen* (1898–1901, "Organography of Plants"), the great work of a German botanist, Karl von Goebel, who was associated with morphology in all its aspects, remains a classic in the field. The Scot John Hunter and the Frenchman Georges Cuvier were early 19th-century pioneers in the study of similar structures in different animals—*i.e.*, comparative morphology. Cuvier in particular was among the first to study the structures of both fossils and living organisms and is credited with founding the science of paleontology. A British biologist, Sir Richard Owen, developed two concepts of basic importance in comparative morphology—homology, which refers to intrinsic structural similarity, and analogy, which refers to superficial functional similarity.

Prospect: direction and trends. One of the major thrusts in contemporary morphology has been the elucidation of the molecular basis of cellular structure. Techniques such as electron microscopy have revealed the complex details of cell structure, provided a basis for relating structural details to the particular functions of the cell, and shown that certain cellular components occur in a variety of tissues. Studies of the smallest components of cells have clarified the structural basis not only for the contraction of muscle cells but also for the motility of the tail of the sperm cell and the hairlike projections (cilia and flagella) found on protozoans and other cells. Studies involving the structural details of plant cells, although begun somewhat later than those concerned with animal cells, have revealed fascinating facts about such important structures as the chloroplasts, which contain chlorophyll that functions in photosynthesis. Attention has also been focussed on the plant tissues composed of cells that retain their power to divide (meristems), particularly at the tips of stems, and their relationship with the new parts to which they give rise. The structural details of bacteria and blue-green algae, which are similar to each other in many respects but markedly different from both higher plants and animals, have been studied in an attempt to determine their origin.

Morphology continues to be of importance in taxonomy because morphological features characteristic of a particular species are used to identify it. As biologists have begun to devote more attention to ecology, the identification of plant and animal species present in an area and perhaps changing in numbers in response to environmental changes has become increasingly significant.

THE SCOPE OF CONTEMPORARY MORPHOLOGY

Fundamental concepts. *Homology and analogy.* Homologous structures develop from similar embryonic substances and thus have similar basic structural and developmental patterns, reflecting common genetic endowments and evolutionary relationships. In marked contrast, analogous structures are superficially similar and serve similar functions but have quite different structural and developmental patterns. The arm of a man, the wing of a bird, and the pectoral fins of a whale are homologous structures in that all have similar patterns of bones, muscles, nerves, blood vessels, and similar embryonic origins; each, however, has a different function. The wings of birds and those of butterflies, in contrast, are analogous structures—*i.e.*, both allow flight but have no developmental processes in common.

Application to molecular structure

The terms homology and analogy are also applied to the molecular structures of cellular constituents. Because the hemoglobin molecules from different vertebrate species contain remarkably similar sequences of amino acids, they may be termed homologous molecules. In contrast, hemoglobin and hemocyanin, the latter of which is present in crab blood, are termed analogous molecules because they have a similar function (oxygen transport) but differ considerably in molecular structure. Corresponding similarities occur in the structures of other proteins from different species—*e.g.*, cytochrome c and other enzymes (biological catalysts) such as the lactic dehydrogenases in birds and mammals.

Body plan and symmetry. The bodies of most animals and plants are organized according to one of three types of symmetry: spherical, radial, or bilateral. A spherically symmetrical body is similar throughout and can be cut in any plane through the centre to yield two equal halves. A few of the simplest plants and animals are spherically symmetrical—*e.g.*, protozoans such as radiolaria and heliozoa. Radially symmetrical bodies, such as those of starfishes and mushrooms, have a distinguishable top and bottom and usually have a cylindrical shape, with the body parts radiating from the central axis. A starfish can be cut into two equal halves by any plane that includes the line, or axis, running through its centre from top to bottom. The anterior, or oral, end usually contains the mouth; a posterior, or aboral, end may have an anus. In the bilaterally symmetrical body of higher animals including man, only a cut from head to foot exactly in the centre divides the body into equivalent halves. An anterior, or head, end and a posterior, or tail, end can be

distinguished; and the dorsal, or back, side can be distinguished from the ventral, or belly, side. But because some internal organs of man are not symmetrical (*e.g.*, the heart), even the right and left halves of the human body are not exactly equivalent. A few organisms—amoebas, slime molds, and certain sponges—with an irregular form, or one that changes as the organism moves, have no plane of symmetry.

Morphological basis of classification. The features that distinguish closely related species of plants and animals are usually superficial differences such as colour, size, and proportion. In contrast, the major divisions, or phyla, of the plant and animal kingdoms are distinguished by characteristics that, although usually not unique to a single division or phylum, occur in unique combinations in each.

One morphological feature useful in classifying animals and in determining their evolutionary relationships is the presence or absence of cellular differentiation—*i.e.*, animals may be either single celled or composed of many kinds of cells specialized to perform particular functions. Some multicellular animals have only two embryonic cell, or germ, layers: an outer ectoderm and an inner endoderm, which lines the digestive tract. Other animals have these, in addition to a mesoderm, which lies between the ectoderm and endoderm. Animals may have one of two types of body cavity. The bodies of the Coelenterata (invertebrates such as the jellyfish) and other primitive many-celled animals consist of a double-walled sac surrounding a single cavity with a mouth. Higher animals have two cavities, and their bodies are constructed on a so-called tube-within-a-tube plan. An inner tube, or digestive tract, is lined with endoderm and opens at each end to form the mouth and the anus. An outer tube, or body wall, is covered with ectoderm. Between the two tubes a second cavity, or coelom, lies within the mesoderm and is lined by it. Another major distinguishing morphological feature of animal phyla is the presence or absence of segmentation. The members of several phyla have bodies characterized by the presence of a row of segments, or body units, of the same fundamental structure. Segmented animals include the vertebrates, the annelids (invertebrates such as the earthworm), and the arthropods (invertebrates such as insects); in some segmented animals such as man and most vertebrates, however, the segmental character of the body is obscured. An evolutionary tendency in many animal phyla has been the progressive differentiation of the anterior end to form a head with conspicuous sense organs and an accumulation of nervous tissues, a brain; the tendency is termed cephalization. Some morphological structures are found only in one phylum; for example, only the Coelenterata have stinging cells (nematocysts); the Echinodermata (invertebrates such as starfishes) have a peculiar water vascular system, and only the Chordates (*e.g.*, reptiles, birds) have a dorsally located, hollow nerve cord.

Segmentation and cephalization

Like animals, plants may be either single celled or composed of many kinds of specialized cells. The bodies of most of the lower plants, such as algae and fungi, are comprised of the least differentiated and least specialized type of plant cells, parenchyma cells. The embryonic tissues of higher plants, unlike those of animals, remain extremely active throughout the life of the plant. In addition, the different types of cells characteristic of the body of higher plants arise from meristems, specific regions in the plant body where cells divide and enlarge. In all but the simplest forms, the plant body is composed of various types of cells associated in more or less definite ways to form systems of units called tissue systems—*e.g.*, the vascular system consisting of conductive tissues. The arrangement of the components of the vascular system is a distinguishing morphological feature of various plant groups. The character and relative extent of the two phases in the life history of a plant—the sexual phase, or gametophyte, and the sporophyte—vary considerably among the plant groups and are useful in distinguishing them.

Anatomy. The best known aspect of morphology, usually called anatomy, is the study of gross structure, or form, of organs and organisms. It should not be inferred however, that even the human body, which has been extensively studied, has been so completely explored that nothing remains to be discovered. It was found only in 1965, for example, that the nerve to the pineal gland, which lies on the upper surface of the brain of mammals, is a branch from the sympathetic nerves; the sympathetic nerves receive nerve impulses from a small branch of the nerves that transmit impulses from the eye to the brain (optic nerves). Thus the pineal gland responds by a very indirect route to quantitative changes in the environmental lighting and secretes appropriate amounts of the substance it forms, the hormone melatonin.

Animal structure. Detailed comparisons of the morphological features of different animals, termed comparative anatomy, provide strong arguments for the evolutionary relationships among different species. In the course of evolution, animals and plants tend to undergo adaptive morphological changes that enable them to survive under certain environmental conditions. As a result, animals only remotely related evolutionarily may come to resemble each other superficially because of common adaptations to similar environments, a phenomenon known as convergent evolution. Structural similarities—streamlined shape, dorsal fins, tail fins, and flipper-like forelimbs and hindlimbs—for example, have evolved in such varied animal groups as the dolphins and porpoises, both of which are mammals; the extinct ichthyosaurs, which were reptiles; and both the bony and cartilaginous fishes. In a like manner, the mole, an insectivore, and the gopher, a rodent, have both evolved shovellike forelimbs, an adaptation for digging.

An opposite phenomenon, divergent evolution, occurs when animals originally closely related adapt to different environments and come to be superficially quite different. Although sea lions and seals, for example, are carnivores and thus closely related to bears, cats, and dogs, their adaptations to an aquatic existence have resulted in morphological characteristics distinct from those of the terrestrial carnivores. In the course of mammalian evolution, many features have changed to permit specific animal groups to adapt to particular environments—*e.g.*, the number and shape of the teeth, the length and number of bones in the limbs, the number and attachment sites of muscles, the thickness and colour of the hair or fur, and the length and shape of the tail.

Relationship of morphological phenomena to evolution

Careful study of adaptive morphological aspects has permitted inferences about the course of the evolutionary history of various animals and of their successive adaptations to changing environments. The present-day Australian tree-climbing kangaroos, for example, are the descendents of a ground-dwelling marsupial, from whom evolved forms that began to live in trees and eventually developed limbs adapted to tree climbing. But the events may have occurred in the reverse sequence; that is, specialized limbs may have evolved before the animal adopted an arboreal mode of life. In any event, some of the tree-dwelling kangaroos subsequently left the trees, became readapted to life on the ground (*i.e.*, their hindlegs became adapted for leaping), and then went back to the trees but with legs so highly specialized for leaping as to be useless in grasping a tree trunk; consequently, present-day tree kangaroos climb by bracing their feet against a tree trunk, as do bears. Careful comparisons of the feet of the many kinds of living Australian marsupials reveal the stages in this complicated process of adaptation and re-adaptation.

Changes in genes (mutations) constantly occur and may cause a decrease in size and function of an organ; on the other hand, a change in the environment or in the mode of life of a species may make an organ unnecessary for survival. As a result, many plants and animals contain organs or parts of organs that are useless, degenerate, undersized, or lacking some essential part when compared to homologous structures in related organisms. The human body, for instance, has more than 100 such organs —*e.g.*, the appendix, the fused tail vertebrae (coccyx), the wisdom teeth, the muscles that wiggle the ears, and the hair on the body.

Plant structure. The parts of a seed plant include roots, stems, leaves, and reproductive organs in the flowers. The evolution of specialized conducting tissues called xylem and phloem has enabled seed plants to survive on land and to attain large sizes. Roots anchor the plant; enable it to maintain an upright position; and absorb water, minerals, and other nutrients from the soil. The roots of plants such as carrots, beets, and yams serve as sites for food storage. The stem links the roots with the leaves, where photosynthesis occurs, and its xylem and phloem are continuous with those of root and leaf. The stem supports leaves, flowers, and fruits. Each year, the stems of woody plants add a layer of xylem and phloem, the annual ring, the width of which varies with climatic conditions. A leaf consists of a petiole (stalk), by which it is attached to the stem, and a blade, typically broad and flat, that contains bundles, or veins, of xylem and phloem on the undersurface. The flower contains pollen-producing anthers and egg-producing ovules. After fertilization the base of the flower, or ovary, enlarges and forms the fruit, which is a mature ovary containing seeds, or mature ovules. The bodies of ferns and mosses also are composed of roots, stems, and leaves, but those of lower plants such as mushrooms and kelps are much more simple and lack true roots, stems, and leaves.

Histology. A major trend in the evolution of both plants and animals has resulted in the specialization of cells and a division of labour among them. The cells comprising a tree or a man are quite different; each is specialized to carry out certain functions. Although specialization may permit a cell to function efficiently, it also increases the interdependence of body parts; an injury to or the destruction of one part, therefore, may result in death of the whole organism. The study of the structure and the arrangement of tissues, which are defined as groups or layers of similarly specialized cells that together perform certain special functions, is termed histology. Each kind of tissue is composed of cells with characteristic features such as size, shape, and relationship to adjacent cells and may also contain noncellular material—connective tissue fibres or a bony material.

Types of tissues and their roles

Animal tissues. Morphologists usually separate animal tissues into six groups: epithelial, connective, muscular, blood, nervous, and reproductive tissues. The cells composing epithelial tissues form a continuous layer or sheet that either covers the surface of the body or lines some cavity within the body, thus protecting the underlying cells from mechanical and chemical injury or from invasion by micro-organisms. Epithelial tissues absorb nutrients and water, secrete a wide variety of substances, and may play a role in the reception of sensory stimuli. The connective tissues—bone, cartilage, ligaments, and fibrous connective tissue—support and hold together the other cells of the body. The cells of the connective tissues secrete large quantities of nonliving material (matrix), the characteristics of which largely determine the nature and the function of the specific types of connective tissue; the matrix secreted by fibrous connective tissue cells, for example, is a thick matted network of microscopic fibres surrounding the connective tissue cells. Connective tissue holds skin to muscle, keeps glands in position, makes up the tough outer walls of the blood vessels, and forms a sheath around nerve fibres and muscle cells. Tendons are flexible, cable-like cords of specialized fibrous connective tissue that join muscles to each other or muscle to bone. Ligaments are somewhat elastic cords of specialized fibrous connective tissue that join one bone to another.

Muscular tissues are composed of elongated, cylindrical, or spindle-shaped cells, each of which contains many small fibres called myofibrils. Muscle cells perform mechanical work by contracting—that is, by becoming shorter and thicker. The three types of vertebrate muscles include cardiac muscle, which is found only in the walls of the heart; smooth muscles, which are found in the walls of the digestive tract and in other internal organs; and skeletal muscles, which make up the bulk of the muscle masses attached to the bones of the body. Skeletal and cardiac muscles have alternating light and dark stripes the relative sizes of which change during the contraction process. Evidence from electron microscopy indicates that two types of filaments occur in muscle; during contraction, one type of filament slides past the other.

Nerve tissue is made of cells, called neurons, which are specialized to conduct nerve impulses. Two or more thin hairlike fibres, called axons and dendrites, extend from the enlarged cell body containing the nucleus. The neurons extending from the spinal cord to the end of an appendage (*e.g.*, arm, leg) may be a metre (about three feet) or more long in man and up to several metres long in an elephant or a whale.

Egg cells in the female and sperm cells in the male are reproductive tissues adapted for the production of offspring. The egg cell is modified by the accumulation of considerable amounts of yolk and other food reserves. The highly specialized spermatozoon contains a tail, the beating of which propels it to the egg. Blood is composed of red cells, which are specialized for the transport of oxygen and carbon dioxide, and white cells, which engulf bacteria and produce antibodies (proteins formed in response to foreign substances called antigens). Blood also contains platelets, small fragments of cells from the bone marrow that play a key role in initiating the clotting of blood.

Types of plant tissues

Plant tissues. The cells of higher plants may be differentiated into meristematic, protective, fundamental, and conductive tissues. Meristematic tissues, which are composed of small, thin-walled cells with few or no vacuoles (cavities), differentiate into the other types of plant tissue and are found in the rapidly growing parts of the plant—*e.g.*, at the tips of roots and stems. Protective tissues are composed of thick-walled cells that protect the underlying thin-walled cells from mechanical abrasion and dehydration; examples of protective tissues include the epidermis of leaves and the cork layers of stems and roots. The fundamental tissues comprising the body of a plant include the soft parts of the leaf, the components of the pith and the cortex of stems, the roots, and the soft parts of flowers and fruits. These tissues function in the production and storage of food. Two types of conductive tissues occur in higher plants: xylem conducts water and dissolved salts, and phloem conducts dissolved organic materials such as sugars. Both types are composed of elongated cells that fuse end to end with other cells to form the sieve tubes through which substances are transported in phloem and xylem vessels.

Cytology. The living material of most organisms is organized into discrete units termed cells; the study of their features is known as cytology. The cellular contents, when viewed through a microscope at low magnification, usually appear to consist of granules or fibrils of dense material, droplets of fatty substances, and fluid-filled vacuoles suspended in a clear, continuous, semifluid substance called cytoplasm. The remarkable structural complexity of the cell is more fully revealed at the higher magnifications attainable with the electron microscope; structural details of various cellular components, or organelles, as revealed by the technique known as X-ray diffraction analysis, have provided information concerning the relationships between the structures of the cellular components and of the molecules comprising them. Although most cells have certain features in common, the kinds and amounts of components vary considerably. Cellular components include structures such as mitochondria, chloroplasts, endoplasmic reticulum, Golgi complex, lysosomes, oil droplets, granules, and fibrils. The membrane around the cell is a three-layered structure called a unit membrane; similar membranes surround many cellular components—*e.g.*, the mitochondria.

Nuclear components. A small spherical or oval organelle, the nucleus, is typically found near the centre of a cell. The genes within the nucleus control the development of the various traits of the cell by controlling the synthesis of specific proteins. The nuclear components are separated from those of the cytoplasm by the nuclear membrane. The structure of the nucleolus, a spherical body within the nucleus, is extremely variable in most cells. Although more than one nucleolus may occur in a nucleus, each cell of an animal or plant species has a fixed

number of nucleoli. The nucleoli apparently play a role in the synthesis of the ribonucleic acid (RNA) constituent of the cellular components called ribosomes, which function in protein synthesis. Adjacent to the nucleus in the cells of animals and certain lower plants are two small, cylindrical bodies, the centrioles, which, during cell division, separate, migrate to opposite sides of the cell, and organize a structure called a spindle between them.

Cytoplasmic components. Within the cytoplasm of both plant and animal cells are components called mitochondria, which may be shaped like spheres, rods, or threads. Each mitochondrion is bounded by a double membrane, the outer layer of which forms the smooth outer boundary of the mitochondrion; the inner layer, folded repeatedly into shelflike folds called cristae, contains enzymes that play an essential role in the conversion of the energy of foodstuffs into the energy used for cellular activities. The cells of most plants contain plastids, small bodies involved in the synthesis and storage of foodstuffs. The most important plastids, the chloroplasts, function in trapping the energy of sunlight during photosynthesis. They are disk-shaped structures with a platelike arrangement of tightly stacked membranes.

The cytoplasmic components important in protein synthesis, the ribosomes, are composed of nucleic acid and protein. Clusters of five or more ribosomes, termed polysomes, appear to be the functional unit in protein synthesis.

Lysosomes are membrane-bound structures containing a variety of enzymes that can break down the large molecular constituents of the cell. The membrane surrounding lysosomes presumably prevents the enzymes from digesting the cell contents before the cell dies.

Embryology. The structures and the relationships among the various parts of a mature plant or animal are usually better understood if the successive developmental stages are studied. Thus, morphologists have traditionally been interested in the study of embryos and their developmental patterns—*i.e.*, the science of embryology.

Animal development. Development typically begins in animals with the cleavage, or division, of the fertilized egg (zygote) to form a hollow ball of cells called the blastula; the blastula then develops into a hollow cuplike body of two layers of cells, the gastrula, from which the embryo ultimately is formed. At one time, the techniques available to embryologists enabled them to study only whole embryos at different developmental stages. The science of experimental embryology began during the first half of the 20th century, when microsurgical techniques became available either for the removal and study of certain structures from tiny embryos or for their transplantation to other regions of the embryo. Advances in understanding the mechanism by which biological information is transferred in DNA and the means by which this information results in the production of specific proteins have led to efforts to describe development in biochemical terms. Although hypotheses regarding the reasons for the appearance of a specific enzyme or some other protein at a specific time during development have been formulated and tested, the biochemical basis of morphogenesis itself—that is, the development of particular structures—has not yet been established.

Development of microsurgical techniques

Plant development. The development of the seed plant is basically different from that of an animal. The egg cell of a seed plant is retained within the enlarged lower part, or ovary, of the seed-bearing organ (pistil) of a flower; two sperm nuclei pass through a structure called a pollen tube to reach the egg. One sperm nucleus unites with the egg nucleus to form the zygote from which the new plant will develop; the second sperm nucleus unites with two nuclei, called polar nuclei, to form a body called a triploid endosperm, the cells of which divide to form a nutritive mass within the seed. The zygote undergoes several cell divisions to form the embryo, which is surrounded by the endosperm. The embryo develops one or two seed leaves, or cotyledons, which may become thick and fleshy with stored foodstuffs. The epicotyl, which consists of a growing point enclosed by a pair of folded miniature leaves, develops above the point of attachment of the seed leaves. Below the seed leaves extends the hypocotyl, the tip, or radicle, of which forms the primary root of the embryonic plant. The factors involved in initiating and controlling morphogenesis in plants have been studied by growing cells, tissues, and organs derived from plants. Indeed, an entire carrot plant has been grown from one cell of a mature carrot; this provides striking evidence that the cell from the adult plant contains all of the genetic information needed to produce an entire plant, including roots, stems, and leaves. The technique of growing plants from isolated plant parts has been useful in studies involving the characteristics of embryonic growth, the correlated growth of plant parts, and the nature of differentiation and regeneration (the replacement of lost parts).

METHODS IN MORPHOLOGY

Chemical techniques. The methods of investigating gross structure depend on careful dissection, or cutting apart, of an organism and on accurate descriptions of the parts. The study of the structure of tissues and cells has been extended by the techniques of autoradiography and histochemistry. In the former, a tissue is supplied with a radioactive substance and allowed to utilize it for an appropriate period of time, after which the tissue is prepared and placed in contact with a special photographic emulsion. Silver grains in the emulsion in contact with radioactive substances darken; thus, the location of the dark spots indicates the position at which the radioactive substance was concentrated in the tissue. Histochemistry involves the differential staining of cells (*i.e.*, using dyes that stain specific structural and molecular components) to reflect the chemical differences of the constituents. By choosing appropriate dyes, the histochemist is able, for example, to determine the acidity or alkalinity of the chemical compounds comprising cell components. In addition, dyes that stain specific molecular constituents such as glycogen, DNA, RNA, and protein also are used. The histochemist is able to locate a specific enzyme in a thin slice of tissue, to provide the specific substance with which the enzyme reacts to form a product, and to add a compound that reacts with the product to form an insoluble coloured compound the location of which is relatively easy to determine. In this way, information has been obtained about the specific location of enzymes within the cell.

Dissection and description

Microscopic techniques. Histologists and cytologists utilize microscopic techniques—light microscopy, phase contrast microscopy, interference microscopy, polarization microscopy, fluorescent microscopy, and electron microscopy—to investigate certain aspects of cell structure. Phase contrast microscopy is widely used to study the structure of living cells because, with such apparatus, internal structures can be observed without killing and staining the cell. In addition, motion pictures of dividing cells or moving cells can be made using phase contrast microscopy.

The interference microscope involves passing two separate beams of light through the specimen. With the appropriate instrument, the mass of material per unit area of the specimen can be determined, and contour mapping of small objects is possible.

Crystalline or fibrous elements, both of which are characterized by an orderly or layered molecular structure, are studied with a polarizing microscope; the polarizing microscope has been particularly useful in studying the detailed structure of bone.

In fluorescence microscopy, the images seen are molecules of fluorescent dyes added to cells that attach to specific cellular components. Appropriate filters are required to insure that only the light of longer wavelength contributes to the image. Fluorescent antibodies have been used to locate specific kinds of proteins and other materials in certain cells of a tissue or in certain regions of a cell. The antibodies are prepared by injecting into a rabbit an antigen (*e.g.*, the protein myosin), which stimulates white blood cells called lymphocytes to synthesize antibodies that react specifically with the antigen. After the antibodies are isolated and purified, the fluorescent dye, fluorescein, becomes attached to them by a chemical

Fluorescence microscopy

reaction. If the fluorescent antibodies are spread over a tissue, they attach specifically to the molecules that stimulated their formation (myosin). The fluorescence microscope reveals the sites containing the antigen–antibody complex as bright luminescent areas in a dark background.

In the scanning electron microscope, a moving spot of electrons (negatively charged particles) is used to scan an object and to produce an image similar to that which appears on a television screen. In this manner, photographs with a three-dimensional appearance can be produced. With the transmission electron microscope, a beam of electrons passes through an object, such as a cell, and is focussed on the other side onto a fluorescent screen or a photographic plate. The beam of electrons in the scanning electron microscope is focussed and then scanned across the specimen. The electrons that leave the specimen, which are not necessarily the same electrons that strike it, are then used to control the beam of a cathode-ray picture tube. Scanning electron microscopes allow photographs to be taken not only of large molecules such as DNA but of very small objects—individual atoms of elements such as uranium or thorium.

MORPHOLOGICAL SOCIETIES AND PUBLICATIONS

The major morphological society in the United States is the American Association of Anatomists, which publishes the *Anatomical Record*. The American Society of Zoologists encompasses a broad group of biologists that includes morphologists, physiologists, and ecologists; similarly, the Botanical Society of America, which publishes the *American Journal of Botany*, includes plant biologists with a wide range of interests in both structure and function. Major biological societies with strong interests in morphology also include the Société de Biologie (France), Linnean Society of London, the Zoological Society of Japan, and Scandinavian Biological Society.

Specific societies are concerned with the study of one major group of animals or plants; *e.g.*, the societies of mammalogists, of ornithologists, of entomologists, of ichthyologists, of parasitologists, of cryptogamic botanists, and of mycologists are concerned with the various groups after which they are named. A primary interest of each society is the structure of the organisms and the range of variation in such structure.

Studies concerning detailed structures of cells are published in various journals throughout the world. These include *The Journal of Cell Biology* (U.S.), *The Journal of Cell Science* (U.K.), and *Experimental Cell Research* (Sweden). Other major morphological journals include *American Journal of Anatomy*, *Journal of Morphology* (U.S.); *Canadian Journal of Zoology; Acta Morphologica* (Hungary); *Acta Anatomica* (Switzerland); *Acta Morphologica Neerlando-Scandinavica* (The Netherlands); *Compte rendu hebdomadaire des séances et mémoires*, Société de Biologie (Paris); *Zoological Journal*, Linnean Society (U.K.); *Zoologicheski Zhurnal* (U.S.S.R.); *Zoologischer Anzeiger* (Germany); *Zoologica Africana* (Union of South Africa); and *Zeitschrift für Anatomie und Entwicklungsgeschichte* ("Journal of Anatomy and Developmental Science").

BIBLIOGRAPHY. B.I. BALINSKY, *An Introduction to Embryology*, 3rd ed. (1970), an excellent general college-level text that includes details of organogenesis in each of the vertebrate types, plus a synthesis of the experimental analysis of cellular differentiation; R.D. BARNES, *Invertebrate Zoology*, 2nd ed. (1968), an excellent modern treatment of invertebrate morphology; E.D.P. DE ROBERTIS, W.W. NOWINSKI, and F.A. SAEZ, *Cell Biology*, 5th ed. (1970), an excellent text describing the cytological features of animal and plant cells; KATHERINE ESAU, *Plant Anatomy*, 2nd ed. (1965), a beautifully illustrated text with an excellent treatment of plant anatomy; DON FAWCETT, *The Cell* (1966), a collection of superb electron micrographs of several kinds of cells and cell organelles, with a brief description of each; LIBBIE H. HYMAN, *The Invertebrates*, 6 vol. (1940–67), the definitive treatise of the invertebrates, covering morphology, development, and evolution; A.S. ROMER, *The Vertebrate Body*, 4th ed. (1969), a standard college-level text of comparative anatomy of the vertebrates; C.A. VILLEE, W.F. WALKER, and R.D. BARNES, *General Zoology*, 4th ed. (1973), a standard college-level text of vertebrate and invertebrate morphology and its relation to function.

(C.A.V.)

Morris, William

Poet, designer, craftsman, and pioneer Socialist, William Morris is now regarded as one of the great men of the 19th century, though he turned away from what he called "the dull squalor of civilization" to romance, myth, and epic. Following his contemporary the art critic John Ruskin, Morris defined beauty in art as the result of man's pleasure in his work and asked, "Unless people care about carrying on their business without making the world hideous, how can they care about Art?" To Morris, art included the whole man-made environment.

The Mansell Collection

William Morris, drawing by C.M. Watts.

In his own time William Morris was most widely known as the author of *The Earthly Paradise*, a series of narrative poems based on classical and medieval sources in the manner of Chaucer's *Canterbury Tales*, and for his designs for wallpapers, textiles, and carpets. Since the mid-20th century it is as a designer and craftsman, rather than as poet or politician, that Morris is valued most, though future generations may esteem him more as a social and moral critic, a pioneer of the society of equality.

Education and early career. Morris was born on March 24, 1834, at Walthamstow (in those days an Essex village on the southern edge of Epping Forest), a member of a large and well-to-do family. From his preparatory school, he went at the age of 13 to Marlborough College. A schoolfellow describes him at this time as "a thick-set, strong-looking boy, with a high colour and black curly hair, good-natured and kind, but with a fearful temper." At Marlborough, Morris said that he learned "next to nothing . . . for indeed next to nothing was taught." As in later life, he learned only what he wanted to learn. In 1853 Morris went to Exeter College at Oxford, where he met Edward Jones (later the painter and designer Burne-Jones), who was to become his lifelong friend.

Friendship with Edward Burne-Jones

Both Morris and Jones became deeply affected by the High Church (Anglo-Catholic) movement of the Church of England, and it was assumed that they would become clergymen. Nevertheless, it was the writings of John Ruskin on the social and moral basis of architecture (particularly the chapter "On the Nature of Gothic" in *The Stones of Venice*) that came to Morris "with the force of a revelation." After taking his degree in 1856, he entered the Oxford office of the Gothic Revivalist architect G.E. Street. In the same year he financed the first 12 monthly issues of *The Oxford and Cambridge Magazine*, where many of those poems appeared that, two years later, were reprinted in his remarkable first published work, *The Defence of Guenevere and Other Poems*. Visits with Street and Burne-Jones to Belgium and northern France, where he first saw the 15th-century paintings of Hans Memling and the Van Eyck brothers and the cathedrals of Amiens, Chartres, and Rouen, confirmed Morris in his

love of medieval art. It was at this time that he came under the powerful influence of the Pre-Raphaelite painter and poet Dante Gabriel Rossetti, who persuaded him to give up architecture for painting and enrolled him among the band of friends who were decorating the walls of the Oxford Union with scenes from Arthurian legend based on the *Morte d'Arthur* by the 15th-century English writer Sir Thomas Malory. Only one oil painting by Morris survives: "Queen Guinevere" (Tate Gallery, London). His model was Jane Burden, the beautiful, enigmatic daughter of an Oxford groom. He married her in 1859, but the marriage was to prove a source of unhappiness to both. Morris appears at this time, in the memoirs of the painter Val Prinsep, as "a short square man with spectacles and a vast mop of dark hair." It was observed "how decisive he was: how accurate, without any effort or formality: what an extraordinary power of observation lay at the base of many of his casual or incidental remarks." From 1856 to 1859 Morris shared a studio with Burne-Jones in Red Lion Square, London, for which he designed, according to Rossetti, "some intensely medieval furniture."

Morris, Marshall, Faulkner & Company

After his marriage, Morris commissioned his friend the architect Philip Webb, whom he had originally met in Street's office, to build the famous Red House at Bexleyheath (so called because it was built of red brick when the fashion was for stucco villas). It was during the furnishing and decorating of this house by Morris and his friends that the idea came to them of founding an association of "fine art workmen," which in April 1861 became the firm of Morris, Marshall, Faulkner & Company with premises in Red Lion Square. The other members of the firm were Ford Madox Brown, D.G. Rossetti, Webb, and Burne-Jones. At the International Exhibition of 1862 at South Kensington they exhibited stained glass, furniture, and embroideries. This led to commissions to decorate the new churches then being built by G.F. Bodley, notably St. Martin's-on-the-Hill at Scarborough. The apogee of the firm's decorative work is the magnificent series of stained-glass windows designed during the next decade by Burne-Jones for Jesus College Chapel, Cambridge, the roof being painted by Morris and Webb. The designs for these windows came to Morris uncoloured, and it was he who chose the colours and put in the lead lines. He also designed many other windows himself, for both domestic and ecclesiastical use.

Two daughters, Jenny and May, were born in 1861 and 1862, and altogether the five years spent at Red House were the happiest of Morris' life. After a serious attack of rheumatic fever, brought on by overwork, he moved in 1865 to Bloomsbury in London. The greater part of his new house was given over to the firm's workshops—an arrangement that, combined with her husband's boisterous manners and Rossetti's infatuation with her, reduced Jane to a state of neurotic invalidism. Morris' first wallpaper designs, "Trellis," "Daisy," and "Fruit," or "Pomegranate," belong to 1862–64; he did not arrive at his mature style until ten years later, with the "Jasmine" and "Marigold" papers.

Success as a poet

Iceland and Socialism. As a poet, he first achieved fame and success with the romantic narrative *The Life and Death of Jason* (1867). In the 20th century, *Jason*, with its lax, easily flowing couplets, appears diffuse to the point of tenuity. Just as in the seemingly endless stories of *The Earthly Paradise* (1868–70), all painful emotion is carefully avoided or smothered in prettiness. The best parts of *The Earthly Paradise* are the introductory poems on the months, in which Morris reveals his personal unhappiness. A sterner spirit informs his principal poetic achievement, the epic *Story of Sigurd the Volsung and the Fall of the Niblungs* (1876), written after a prolonged study of the sagas (medieval prose narratives) read by Morris in the original Old Norse. The exquisitely illuminated *Book of Verse*, telling once more of hopeless love and dedicated to Georgiana Burne-Jones, belongs to 1870.

In 1871 Morris and Rossetti took the Elizabethan manor house of Kelmscott in Oxfordshire. In the same year Morris paid his first visit to Iceland, and the journal he kept of his travels contains some of his most vigorous descriptive writing. He returned to Iceland in 1873. The joint tenancy of Kelmscott, however, was never a success, and, after the final breakdown of his health in 1874, Rossetti left the house for good, to Morris' great relief. At the same time, the firm was reorganized under his sole proprietorship as Morris & Company. In 1875 Morris began his revolutionary experiments with vegetable dyes, which, after the removal in 1881 of the firm to larger premises at Merton Abbey in Surrey, resulted in their finest printed and woven fabrics, carpets, and tapestries.

In 1877 Morris gave his first public lecture, "The Decorative Arts" (later called "The Lesser Arts"), and his first collection of lectures, *Hopes and Fears for Art*, appeared in 1882. In 1877 he also founded the Society for the Protection of Ancient Buildings in an attempt to combat the drastic methods of restoration then being carried out on the cathedrals and parish churches of Great Britain.

The Morris family moved into Kelmscott House (named after their country house in Oxfordshire), at Hammersmith, in 1878. Five years later Morris joined Henry Mayers Hyndman's Democratic (later Social Democratic) Federation and began his tireless tours of industrial areas to spread the gospel of Socialism. But he was considerately treated by the authorities, even when leading a banned demonstration to London's Trafalgar Square on "Bloody Sunday" (November 13, 1887), when the police, supported by troops, cleared the square of demonstrators. On this occasion he marched with the playwright George Bernard Shaw at his side. But by this time Morris had quarrelled with the autocratic Hyndman Federation and formed the Socialist League, with its own publication, *The Commonweal*, in which his two finest romances, *A Dream of John Ball* (1886–87) and *News from Nowhere* (1890), an idyllic vision of a Socialist rural utopia, appeared. Subsequently, he founded the Hammersmith Socialist Society, which held weekly lectures in the coach house next door to Kelmscott House as well as open-air meetings in different parts of London.

The Kelmscott Press

The Kelmscott Press was started in 1891, with the printer and type designer Emery Walker as typographical adviser, and between that year and 1898 produced 53 titles in 66 volumes. Morris designed three type styles for his press: Golden type, modelled on that of Nicolas Jenson, the 15th-century French printer; Troy type, a gothic font on the model of the early German printers of the 15th century; and Chaucer type, a smaller variant of Troy, in which *The Works of Geoffrey Chaucer* was printed during the last years of his life. One of the greatest examples of the art of the printed book, *Chaucer* is the most highly decorated of the Kelmscott publications. Most of the Kelmscott books were plain and simple, for Morris observed that 15th-century books were "always beautiful by force of the mere typography."

A sea voyage to Norway in the summer of 1896 failed to revive Morris' flagging energies, and he died at Hammersmith on October 3, 1896, worn out by the multiplicity of his activities. He was buried at Kelmscott beneath a simple gravestone designed by Philip Webb.

Morse, Samuel F.B.

Samuel Morse was one of the most respected American painters of his day and also famous as the inventor of the electric telegraph. Born on April 27, 1791, in Charlestown, Massachusetts, Morse was the son of Jedidiah Morse, a distinguished geographer and Calvinist clergyman. From Phillips Academy, Andover, where he had been an unsteady and eccentric student, his parents sent him to Yale College. Although an indifferent scholar, his interest was aroused by lectures on the then-little-understood subject of electricity. To the distress of his austere parents, he also enjoyed painting miniature portraits.

By courtesy of the Addison Gallery of American Art, Phillips Academy, Andover, Mass.

Morse, self-portrait in oils, *c.* 1814.

After graduating from Yale in 1810, Morse became a clerk for a Boston book publisher. But painting continued to be his main interest, and in 1811 his parents helped him to go to England to study painting. During the war of 1812, between Great Britain and the United States, Morse reacted to the English contempt for Americans by becoming passionately pro-American. Yet, like most Americans of his time, he accepted English artistic standards, including the "historical" style of painting—the romantic portrayal of legends and historical events with personalities gracing the foreground in grand poses and brilliant colours.

But when, on his return home in 1815, Morse found that Americans did not appreciate his historical canvases, he reluctantly took up portraiture again to earn a living. He began as an itinerant painter in New England, New York, and South Carolina; after 1825, on settling in New York City, he painted some of the finest portraits ever done by an American artist. He combined technical competence and a bold rendering of his subjects' character with a touch of the Romanticism he had imbibed in England.

Work as a portrait artist

Although often poor during those early years, Morse was sociable and at home with intellectuals, the wealthy, the religiously orthodox, and the politically conservative. In addition, he possessed the gift of friendship. Among his friends in his middle years were the French hero of the American Revolution, the Marquis de Lafayette, whose attempts to promote liberal reform in Europe Morse ardently endorsed, and the novelist James Fenimore Cooper. Morse and Cooper shared several traits: both were ardent American republicans, though both had aristocratic social tastes, and both suffered from American preference for European art.

Morse also had the gift of leadership. As part of a campaign against the licentiousness of the theatre, he helped launch, in 1827, the New York *Journal of Commerce*, which refused theatre advertisements. He also was a founder of the National Academy of Design, organized to increase American respect for painters, and was its first president from 1826 to 1845.

In 1832, while returning by ship from studying art in Europe, Morse conceived the idea of an electric telegraph as the result of hearing a conversation about the newly discovered electromagnet. Although the idea of an electric telegraph had been put forward before 1800, Morse believed that his was the first proposal. He probably made his first working model by 1835. Meanwhile, he was still devoting most of his time to painting, teaching art at the University of the City of New York (later New York University), and to politics. But, by 1837, he turned his full attention to the new invention. A colleague at the university showed him a detailed description of an alternative model proposed in 1831, and a friend offered to provide materials and labour to build models in his family's ironworks. These two became partners in Morse's telegraph rights. By 1838 he had developed the system of dots and dashes that became known throughout the world as the Morse Code. In 1838, while unsuccessfully attempting to interest Congress in building a telegraph line, he acquired a congressman as an additional partner. After failing to organize the construction of a Morse line in Europe, Morse was finally able to obtain, without his partners' cooperation, financial support from Congress for the first telegraph line in the United States, from Baltimore to Washington. The next year he sent the first message, "What hath God wrought!"

Morse was immediately involved in legal claims by his partners and by rival inventors. He fought vigorously in this dispute as he had in controversies about art, religion, politics, and even over the new invention of the daguerreotype, an early photographic process, of which he had been one of the first practitioners in America. A series of legal battles culminating in a United States Supreme Court decision established his patent rights in 1854. As telegraph lines lengthened on both sides of the Atlantic, his wealth and fame increased. By 1847, Morse bought Locust Grove, an estate overlooking the Hudson River near Poughkeepsie, New York, where, early in the 1850s, he built an Italian-villa-style mansion. Morse spent his summers there with his large family of children and grandchildren, returning each winter season to his brownstone home in New York City.

In his old age, a patriarch with a flowing beard, Morse became a philanthropist. He gave generously to Vassar College, of which he was a founder and trustee; to his alma mater, Yale College; and to churches, theological seminaries, Bible societies, mission societies, temperance societies, as well as to poor artists.

Assessment

Even during Morse's own lifetime, the world was much changed by the telegraph. After his death, his fame as the inventor of the telegraph was obscured by the invention of the telephone, radio, and television, while his reputation as an artist has grown. At one time he did not wish to be remembered as a portrait painter, but his powerful and sensitive portraits, among them those of Lafayette, the American writer William Cullen Bryant, and other prominent men, have been represented in special exhibitions at museums in many parts of the country. The number of Morse telegraphic operators has decreased sharply, but his memory is perpetuated by the Morse Telegraph Club, which was organized in 1942 as an American and Canadian association of former telegraphers. His 1837 telegraph instrument is preserved by the United States National Museum of History and Technology in Washington, D.C., while his estate, Locust Grove, now designated as a historic landmark, has been willed to the federal government as a Morse memorial. Morse died on April 2, 1872, in New York City.

Mortgages, Law of

As used in modern law, a mortgage is a transfer of a property interest by a debtor (mortgagor) to his creditor (mortgagee) to be held as security for the performance of an obligation. Usually, the obligation is to pay a debt created or evidenced by the debtor's bond or promissory note. The property interest is commonly in land and buildings but may be in tangible goods or intangible assets, such as life insurance policies, corporate stock, government bonds, or other investment securities. Mortgages on land and buildings are known as real estate mortgages; those on movable goods, tangible or intangible, are known as chattel mortgages. So defined, the mortgage differs from the pawn of tangible goods, the pledge of documents representing intangible assets, and the medieval gage (pledge) of land, in that the mortgagee's security interest is not dependent upon his having possession of the land, goods, or documents involved. The mortgage also differs from the long-term contract for sale of land, in which the seller retains title until the price has been paid, and from hire-purchase agreements and conditional sale contracts for sale of movable goods on credit, in that the property is owned by the debtor immediately before the transaction. In the case of the purchase-money mortgage, the debtor's prior ownership is momentary and theoretical. Nevertheless, there are often substantial differences in the relative rights of seller, purchaser, and third parties when the unpaid portion of the purchase price is secured by mortgage rather than retention by the seller of his original ownership.

CIVIL-LAW DEVELOPMENT

Horoi, the inscribed mortgage stones that were removed by Solon when he became the archon of Athens in 594 BC (but soon reappeared), are perhaps the most famous examples from antiquity. Most of them probably represented a type of mortgage known as sale with right of redemption, under which the creditor acquired ownership of the land but left it in the possession of the debtor, who paid interest (12 percent per annum was common) or rent in lieu of interest. If the loan contract specified no due date it would seem that the creditor could take possession on default in payment of interest but the debtor retained a perpetual right of redemption. If a date for payment of the principal was specified it is probable that, on default, the creditor's ownership became absolute. Presumably, the debtor could not transfer his interest or give a second mortgage without the cooperation of the creditor. Some of the later stones may have evidenced the type of mortgage known as *hypotheke*, under which the creditor had only a lien or charge until default, when he could take possession and vest absolute ownership in himself. It is not at all likely that any of these stones would evidence a third type of mortgage known as *antichresis*, under which the creditor took possession of the land and kept the rents and profits in lieu of interest. The detailed effects of these transactions are disputed and may have depended on the terms of particular contracts: some may have permitted the debtor to transfer his interest and give a second, junior, mortgage and may have required the creditor to sell the land on default and account to the debtor for the amount by which the sale price exceeded the debt.

Roman law of mortgage

Roman law produced three forms of mortgage, *fiducia cum creditore*, *pignus*, and *hypotheca*, which developed in that order. *Fiducia cum creditore* involved a transfer of ownership from the debtor to the creditor, effected by a formal ceremony before witnesses or a public officer, accompanied by a *pactum fiduciae* binding the creditor to reconvey on payment. When land was involved the debtor might be allowed to retain possession by way of *precarium* (tenancy at will). The debtor had no property interest in the subject matter and no protection against third parties who dealt with the creditor as owner. *Pignus*, used mainly for movables but sometimes, in the form known as *antichresis*, for land, involved delivery of possession to the creditor and retention of ownership by the debtor. *Hypotheca* gave the creditor only a lien or charge. The debtor retained ownership and, commonly, possession until default and so could give a second or junior mortgage. The terms of these transactions usually empowered the creditor to sell on default and such a power was implied by AD 200. Until forbidden by Constantine, the terms could include the *lex commissoria*, a provision for strict foreclosure giving the creditor absolute ownership on default; after AD 200 it also gave him the right to acquire absolute ownership by a judicial proceeding, which afforded the debtor a year's time for redemption and provided for payment of the amount by which the value of the property exceeded the debt. Sixth-century legislation gave the debtor two years in which to redeem after notice of default and the creditor a clear right to foreclose by sale, accounting to the debtor for any excess of the sale price over the debt. Strict foreclosure by judicial decree was possible if a purchaser could not be found.

Development of German and French law

Medieval German law provided for three types of land gage, all involving possession by the creditor. Ownership could be conveyed to the creditor with a condition allowing for subsequent re-entry or a proviso for reconveyance on payment. Possession could be delivered to the creditor with a conveyance of ownership to become effective upon the condition precedent of default. Possession could be delivered to the creditor, to be retained until payment of the principal, without any transfer of ownership, present or future. As under equivalent English types of gage, the creditor might be bound to apply the rents and profits to reduce the debt or he might be entitled to keep them without accountability. These possessory gages were superseded by the *jüngere Satzung* or execution gage, which resembled the English statute staple. The debtor entered into a recognizance before an official. This was registered in a public office and gave the creditor a lien or charge. The debtor retained ownership and possession until default, when the creditor could secure judicial foreclosure, usually by sale. If the sale proceeds exceeded the debt, the surplus was paid to the debtor. With the reception of Roman law in northern Europe, the *jüngere Satzung* was replaced by the Roman *hypotheca*. This was, in fact, a regressive development because no provision was made for recording. Legislation beginning in Prussia early in the 18th century and culminating in the German Civil Code of 1900 required registration of mortgages in public offices and recognized two types, the *Hypothek*, which entails personal liability of the debtor as well as a lien on the land, and the *Grundschuld* (ground-debt), which is solely a charge on the land. Foreclosure is by judicially ordered sale.

The French development paralleled the German. The possessory gages were superseded by the *obligation*, the equivalent of the *jüngere Satzung*. This in turn was superseded by the *hypothèque*, which had to be acknowledged before a judge or a notary and, after 1771, had to be by notarial deed. The inconvenience caused by the lack of recording was partially overcome by the clearance, a judicial proceeding whereby a purchaser of land could compel all persons claiming to be mortgagees, known or unknown, to present their claims or be barred. The Law of the 11th Brumaire, year VII (as the French Revolution styled November 1, 1798) required every mortgage to describe the land bound by it and to be registered in a public office. The German *Grundschuld*, which is a charge on land but not a personal liability of a debtor, is unknown in France. Chattel mortgages under which the debtor retains possession of the goods are virtually unknown in both countries, except as to ships and aircraft, for which there are registration systems. French law does permit nonpossessory liens on automobiles, farm products, hotel furnishings, shares in the Bank of France, and equipment and stock of manufacturers and oil refiners.

COMMON-LAW DEVELOPMENT

The development of the mortgage in England is somewhat obscured by the papal prohibition of interest on debts, enforced by the secular law until 1545. The Christian lender tended to conceal what was essentially a loan at interest in the guise of some other transaction, commonly a purchase for a lump sum of a beneficial lease of land for a term of years.

From a time before the Norman Conquest of 1066 until

1925, English law permitted a type of gage of land as security for a debt that corresponded in form, although not at all times in effect, to the real-estate mortgage now common in the United States. This was an outright conveyance of the fee simple (perpetual ownership) by the debtor to the creditor accompanied by a proviso that, if the debt was paid by the due date, the debtor might terminate the creditor's ownership by re-entry. After 1500 the proviso usually required the creditor to reconvey the land to the debtor upon timely payment of the debt. Both types of proviso were interpreted as conditions subsequent on the creditor's fee simple; that is, the creditor would obtain the complete legal title only if the debtor did not perform. Before the Conquest the conveyance was made by delivery of the landbook; from the Conquest until 1536 it was usually by "feoffment with livery of seisin," a formal transfer of possession of the land in the presence of witnesses, accompanied by oral words of conveyance that might be accompanied by a written charter. After 1535 the conveyance was usually by delivery of a deed operating under the so-called Statute of Uses of that year, which gave legal titles and the right to possession to those who before were entitled only to the use of the land under an equitable title. Under the gage in fee simple, both the creditor and the debtor had property interests in the land enforceable against third parties. That of the debtor was known as a right of entry. It descended to his heirs at death but could not be transferred *inter vivos* (between living persons) or by will before the 17th century.

By the 12th century another form of gage was also being used. This was an informal delivery of possession of the land to the creditor, accompanied by an understanding that he could retain possession until the debt was paid. The understanding might include a provision that, if the debt was not paid by a stipulated date, the creditor could keep the land forever. In the absence of such a provision and of any provision showing that the creditor's interest was limited to rents and profits, the creditor could bring suit to obtain a decree that if the debt was not paid by a specified date the latter would own the land in fee simple. This form of gage, which left ownership of the land with the debtor until default, proved to be unsatisfactory for the creditor because the courts would not protect his possession against either the debtor or third parties. To remedy this defect, it became common in the 13th century for the debtor to give the creditor a formal lease for a definite term of years with a proviso that, if the debt was not paid by the end of the term, the creditor would have a fee simple. This device gave the creditor an estate for years in the land, which the courts would protect against the debtor and third parties. By the 15th century, however, the device was abandoned because the courts would not enforce the proviso for a fee simple to spring up in the future. This leasehold device was the basis of a type of mortgage prescribed by English statute in 1925.

Vif gage and mortgage

All three types of gage contemplated retention of possession of the land and collection of the rents and profits by the creditor. If the terms of the transaction called for the creditor to credit the rents and profits against the principal of the debt, the transaction was a vif gage (*vivum vadium*). If the creditor was permitted to keep the rents and profits without accountability the transaction was a mortgage (*mortuum vadium*), and in this case the creditor could be suspected of evading the ban on interest. This, coupled with a situation in which unwritten conveyances were possible and there was no system of recording written conveyances in a public office, made it unsafe for the creditor to permit the debtor to occupy the land. Moreover, a lease by the creditor to the debtor, reserving rent that was not to be applied on the principal of the debt, would also have violated the rule forbidding Christians to charge interest.

Irrespective of these prohibitions, it was seen as commonly advantageous to both parties to permit the mortgagor to retain possession of the land until default. This solution had been made feasible for Jewish gagees (those who held the gage, or pledge) in 1194 by an edict establishing public offices for recording conveyances to Jews. As Jews were exempt from the ban on receiving interest, a Jewish gagee could require a Christian gagor in possession to pay interest or rent in lieu of interest. On default the Jewish creditor could secure a court order authorizing him to take possession of the land and sell it after a year and a day or hold it until the debt was paid by application of the rents and profits. These privileges were withdrawn and the Jews expelled from England late in the 13th century, but the convenience of mortgages permitting the mortgagor to retain possession until default had been discovered. Legislation of 1285, amplified in 1353, provided that when a debtor acknowledged a debt by formal recognizance (obligation of record requiring performance of an act) in certain courts and public offices, the creditor would immediately have a security interest in lands then owned by the debtor. In the event of default, the creditor was entitled to take possession of half the lands of the debtor (all in the case of certain mercantile debts) and retain them until the debt was paid by application of the rents and profits. An ordinary creditor holding land under this legislation was called a tenant by elegit; a mercantile creditor was called a tenant by statute merchant or, after 1353, tenant by statute staple. Legislation of 1531 made the statute staple, which bound all lands of the debtor, available to noncommercial creditors.

The common-law mortgage

When a statutory recognizance was used as a substitute for a mortgage, the creditor had, until default, only a lien or charge on the land; the debtor remained the owner, entitled to possession and to convey his interest. On the other hand, the gage by feoffment (the granting of a fee) in fee simple with proviso for reconveyance on payment of the debt, which became the standard form of mortgage in the 15th century and is usually referred to as the common-law mortgage, made the mortgagee the owner, entitled to possession. The mortgagor retained only a right of entry, which was inalienable and gave him no right to possession until he paid the debt. Legislation in 1535 eliminated, for all practical purposes, oral conveyances of land, and a statute of 1545 abolished the ban on interest. These changes made it safe for the mortgagee of land to permit the mortgagor to retain possession until default. The mortgagee could protect himself against third parties by retaining the title deeds, and a provision requiring the mortgagor to pay interest, or rent in lieu of interest, was no longer invalid. By the 17th century most mortgagors of land were permitted, by express proviso or tacit understanding, to retain possession of the mortgaged land until default. In the absence of other agreement, such a mortgagor was not bound to pay rent or to account to the mortgagee for the rents and profits. It remained unsafe for a mortgagee of movable goods to leave them in the possession of the mortgagor until the 19th century, when legislation was enacted providing for the recording of chattel mortgages in public offices and protecting the mortgagee who had made such a recording against purchasers from and creditors of the mortgagor in possession.

The common-law mortgage protected both the mortgagor and the mortgagee against third parties but was unsatisfactory to the mortgagor because his interest in the land was not transferable and was forfeited if full payment of the debt was not made on the due date stated, even if the amount due was only a small fraction of the value of the land. Nontransferability meant that the mortgagor could not give a second or junior mortgage. The harshness of the forfeiture was aggravated in the 15th century as a result of a relaxation in the papal ban on interest that permitted a creditor to charge interest on a debt while it remained unpaid after the due date. To take advantage of this, lenders drew up mortgages with nominal due dates, which were long before payment was actually anticipated. The common-law courts of King's Bench, Common Pleas, and Exchequer would give no relief against such forfeitures, but the Court of Chancery, which could apply equitable principles, began to do so in the 16th century. The mortgagor who had defaulted in payment and so had lost all his rights in the land at common law was then permitted to sue in equity for redemption. Upon payment of the debt, with interest to the time of payment, the mortgagee would be compelled to reconvey the land to the mortgagor. The Court of Chancery did not, however, interfere

with the mortgagee's right to possession pending full redemption. If the mortgage entitled him to possession from its date, he retained that right. If it entitled him to take possession on default, he could still do so, and could keep possession until redemption. The "equity of redemption" created by the Court of Chancery was only a right of the mortgagor to pay the debt and recover the land after the due date of the mortgage.

The Court of Chancery and equity redemption

Although at common law, the interest of the mortgagor was inalienable and could not be transferred, by the 17th century the Court of Chancery had converted his equity of redemption into an equitable estate in land, equivalent to the legal estate in fee simple that he held before giving the mortgage. It was as freely transferable *inter vivos* and devisable by will as like legal estates. Hence the mortgagor could give a second or junior mortgage. The Court of Chancery would not give effect to any provision of a mortgage that would do away with or hinder the equity of redemption. The mortgagor, moreover, could assert his equity of redemption for at least 20 years after default, so the mortgagee, despite the fact that he was the absolute owner at common law, did not have a secure title during this period. He could, however, clear the title at any time after default by a suit in equity for foreclosure of the equity of redemption; that is, for a decree requiring the mortgagor to pay by a date specified in the decree or lose his equity of redemption. Such a decree of "strict foreclosure" gave the mortgagee an indefeasible title on the date specified. A statute of 1881 empowered the court, as an alternative to strict foreclosure, to order foreclosure by sale of the land to satisfy the debt. If the proceeds of the foreclosure sale exceeded the debt and the interest due on it, the excess was paid to the mortgagor. For purposes of redemption and foreclosure, the Court of Chancery treated deposit of the title deeds with a creditor as a mortgage. A suit for foreclosure, however, was likely to be slow and expensive. The net effect of the development of the equity of redemption by the Court of Chancery was that, whereas at common law the mortgagee was the owner of the land and the mortgagor had only a right of entry, in equity the mortgagor was the owner and the mortgagee had only a lien or charge on the land.

Once it was established that, despite the provisions of the mortgage, the mortgagee's title would be encumbered by the equity of redemption for at least 20 years after default unless he secured a judicial decree of foreclosure, efforts were made to put terms in the mortgage that would give the mortgagee a power to override the equity of redemption by sale. The first case involving this device, decided in 1738, was interpreted as holding that a purchaser from the mortgagee was also subject to the equity of redemption. As a result of this decision, use of the common-law mortgage was abandoned by some conveyancers in favour of a substitute known as the deed of trust. The deed of trust is a conveyance by the debtor to a third party trustee who is to allow the debtor to occupy the land until default. If the debt is paid, the trustee is to reconvey the land to the debtor. If it is not paid, the trustee, after the default, is to sell the land and, from the proceeds, to pay the amount due to the creditor and account for the balance to the debtor. Both debtor and creditor are beneficiaries of the trust so each has an interest in the land good against third parties and freely alienable and devisable. The debtor can mortgage his equitable interest by a second or junior deed of trust.

Early in the 19th century it was held in England that the terms of a mortgage could confer on the mortgagee power to sell the land after default, free of the equity of redemption. English and some American conveyancers then returned to the use of the common-law mortgage, but the deed of trust is the usual form of security transaction in land in a number of U.S. jurisdictions, notably California, Colorado, the District of Columbia, Delaware, Illinois, Missouri, Mississippi, North Carolina, Tennessee, Texas, Virginia, and West Virginia. Its effects and enforcement in part tend to be regulated by statute in the jurisdictions where it is commonly used. The debtor is ordinarily entitled to some notice of the trustee's intent to sell and an opportunity to redeem for at least a short time after default.

Modern law of mortgage in England and the United States

English legislation of 1925 permits two types of mortgage of land. The first is a lease from the debtor to the creditor for a term of years, usually 3,000 years, with a provision that the term shall cease on timely payment of the debt. The other is by deed from the debtor to the creditor imposing a "charge by way of legal mortgage." The first type resembles the form of gage used in the 13th century; the second resembles the statute staple of the 14th century. In either case the mortgagor retains the legal fee simple, which is transferable *inter vivos* and devisable by will and may be subjected to a second or junior mortgage. A mortgagor in possession has statutory power to grant leases for terms of up to 50 years, which will bind the mortgagee if an adequate rent is reserved. After default the mortgagee has statutory power to sell the fee simple after three months written notice to the mortgagor. He is accountable to the mortgagor for proceeds of the sale in excess of the amount of the debt. Alternatively, the mortgagee may sue for a decree of foreclosure providing that, if the debt is not paid within six months, the mortgagee will own the fee simple. The court may, in lieu of the strict foreclosure sought, direct foreclosure by sale. In any of these cases the proceedings remove the mortgagor's equity of redemption.

In most of the United States the common-law mortgage, in form a conveyance in fee simple on condition subsequent made by the mortgagor to the mortgagee, is still the usual type of land security. In many, however, it does not have the precise effects that it had in England before 1925. It is usually held that, at law as well as in equity, the mortgagor, at least until default, remains the owner and the mortgagee, despite the form of the transaction, has only a lien or charge on the land. This is called the lien theory of mortgage, which stands in opposition to the older common-law title theory. Where the lien theory has been adopted, the mortgagor is entitled to possession, at least until default, and the mortgagee is not. In some states an express provision of the mortgage giving the mortgagee the right to possession is void, and in most states strict foreclosure by judicial decree vesting indefeasible title in the mortgagee is no longer permitted. It has been replaced by foreclosure through judicially ordered sale, as under the English statute of 1881. A provision in a mortgage empowering the mortgagee to foreclose by sale, without judicial proceedings, is valid in most states, but the mortgagee who sells under such a power is accountable to the mortgagor for any amount by which the proceeds of sale exceed the amount of the debt. Statutes in some states give the mortgagor a period of redemption after a sale under judicial decree or under a power conferred by the mortgage. In states where the mortgagor is entitled to possession of the land until the expiration of the period of redemption he may be able to retain possession for more than a year after the institution of foreclosure proceedings.

As in the case of real estate mortgages, a number of U.S. states apply the lien theory to chattel mortgages. Even in them, however, a chattel mortgagor has fewer of the attributes of ownership than a real estate mortgagor. He may be entitled to possession of the mortgaged goods until default, but statutes tend to make it a criminal offense for a chattel mortgagor to sell the goods or remove them from the county in which the chattel mortgage is recorded without the permission of the mortgagee. Moreover, his equity of redemption is commonly more readily and quickly extinguished, usually by sale under a power conferred by the chattel mortgage or under a summary statutory procedure.

SOCIAL IMPORTANCE OF MORTGAGES

Given the fact that the chief finite resources of any society are men and land, it is of maximum importance that each parcel of land be devoted to the use for which it is most fit. The socialist countries attempt to achieve these ends by government planning and regulation. A society that relies upon private ownership as the incentive for the best development and fullest use of its resources must provide a

system for the ready transferability of land and a means by which men without available cash can finance the purchase and improvement of land. The real estate mortgage is what performs this function.

A typical mortgage problem

By way of simple illustration, suppose the following rural problem: An elderly farmer who is anxious to retire owns a quantity of arable land in need of ditching, agricultural buildings, and other improvements, which would double its productivity. The local bank has money available for investment, while a vigorous young man is eager to buy and improve the land but has no money. If the land is not transferable because of legal restrictions, the owner can neither finance improvements by mortgaging to the bank nor sell to the younger man. At best, he could lease the land for a limited term, in which case the potential buyer in this example would have neither the means nor the motive to make the needed improvements. Given a situation in which, however, the land is freely transferable and a type of mortgage that is fair to both debtor and creditor exists, the buyer can borrow enough from the bank on first mortgage to pay for the improvements and make a down payment to the seller. In addition, he can give the seller a second mortgage to secure payment of the balance of the purchase price in annual installments over an extended period. The down payment here would enable the retiring owner to purchase another home and the installment payments would provide support in his declining years. Neither the bank nor the elderly farmer could safely extend this much credit to the young buyer without effective security interests in the land since there are always risks; he could, for example, be conscripted, lose his health, or die prematurely. Urban home and industrial sites produce similar problems which only mortgages can solve.

PARTICULAR ASPECTS OF MORTGAGES

The mortgage device performs its social function well only if it is fair to both creditor and debtor. The potential lender will demand excessive interest or invest his money in some other way unless the mortgage gives him adequate security, is readily transferable, and can be foreclosed without undue delay and difficulty. A device unfair to the debtor, on the other hand, generates social unrest and discourages persons who, like the young farmer of the illustration, can devote their full talents to productive enterprise only by borrowing. If, for example, the mortgagee can acquire absolute title to the land by strict foreclosure when a small installment payment is delayed in the mail for a day beyond the due date, the mortgagor will lose his land without fault on his part even though it is worth much more than the total amount of the mortgage debt. Similarly, if a mortgagee who has led the mortgagor to believe that he does not want payment on the due date can foreclose without giving the mortgagor notice and a reasonable time in which to redeem, the mortgagor may lose his land although, with notice and time, he could easily have raised the amount due. All modern systems offer mortgagors some protection against such harsh treatment.

Most land is mortgaged; hence transferability of the interests of mortgagors is necessary if land is to be kept in the hands of people able to use it efficiently. The able-bodied farmer of today may be a conscript, an invalid, or dead tomorrow, and the stable and contented homeowner of today may be moved by his employer to a distant city tomorrow. Such transferability may impair the mortgagee's security to some extent. Some U.S. courts do, in fact, uphold provisions in a mortgage giving the mortgagee a right of pre-emption or a right to accelerate the due date if the mortgagor transfers his interest, but the trend of all modern systems to the lien theory of mortgages encourages free transferability. English and French legislation empowering a mortgagor in possession to give leases that override the mortgage permit him to transfer even more than his interest.

The lien theory

The hypothecary or lien theory of mortgage, to which all modern legal systems have moved, is unquestionably superior to the types that involve ownership or possession by the mortgagee. The *hypotheca* of Roman law had, however, a serious weakness in the lack of a recording system. This made it possible for a mortgagor in possession to sell or mortgage to a person who did not know of the outstanding mortgage. The Greek *horoi* and the English deposit of title deeds with the first mortgagee were crude efforts to deal with this problem. Only a compulsory system of recording deeds and mortgages, which gives priority to those recorded first, eliminates the weakness. Such systems have been in effect on the European Continent since the 18th century and in North America and Australasia since the 19th. Compulsory recording was instituted in Yorkshire and Middlesex in the 18th century and an English statute of 1897 empowered the queen in council to extend it to other areas. All areas in England are expected to be subject to it by 1980. Unfortunately, no system of recording chattel mortgages provides adequate protection. The purchaser of a steak in New York, for example, cannot ascertain whether the animal from which it was cut was subject to a chattel mortgage duly recorded in Montana, and so for most items that are readily transported and not easily identified.

If interest rates decline after a mortgage is given, the mortgagor has a motive for terminating the transaction; if they rise, the mortgagee has such an interest. Therefore, in the absence of provision in the mortgage itself, neither party to the standard Anglo-American mortgage may compel termination before the due date; when that arrives the mortgagor may terminate by payment, the mortgagee by foreclosure. Provisions for earlier termination by the mortgagor, often on payment of a penalty to compensate the mortgagee for loss of interest, are common. Termination by mutual agreement is always possible. The rarely used Welsh mortgage, which corresponds to the Graeco-Roman *antichresis* and the early medieval Anglo-German possessory gage without a due date, may be paid off by the mortgagor at any time but may not be foreclosed by the mortgagee. French and Italian law empower a purchaser of mortgaged land who is not personally liable for the mortgage debt to compel the mortgagee to accept payment of the principal although the due date has not arrived. This right of "purge" or clearance has public policy advantages when the mortgage has no due date or has a very remote one, such as 3,000 years, but in the case of a mortgage with a five- or ten-year due date, it may be unfair to the mortgagee to deprive him of the interest that he was promised.

BIBLIOGRAPHY. The leading contemporary treatises on this subject are W.R. FISHER and J.M. LIGHTWOOD, *Law of Mortgage*, 8th ed. by E.L.G. TYLER (1969), for England; and G.E. OSBORNE, *Handbook on the Law of Mortgages*, 2nd ed. (1970), for the United States. The current law of mortgages in civil-law countries is described in M.S. AMOS and F.P. WALTON, *Introduction to French Law*, 3rd ed. by F.H. LAWSON, A.E. ANTON, and L.N. BROWN (1967); and K.W. RYAN, *An Introduction to the Civil Law* (1962). English historical development is discussed in H.D. HAZELTINE, "The Gage of Land in Mediaeval England," *Select Essays in Anglo-American Legal History*, vol. 3 (1909); and R.W. TURNER, *The Equity of Redemption* (1931), with an introduction by H.D. Hazeltine comparing the Roman *fiducia cum creditore* with the English mortgage. Information on the historical development in the Greek and civil-law systems may be found in A.R.W. HARRISON, *The Law of Athens*, vol. 1, *The Family and Property* (1968); W.W. BUCKLAND, *Text-Book of Roman Law from Augustus to Justinian*, 3rd ed. by P. STEIN (1964); J.B. BRISSAUD, *History of French Private Law* (1912; Eng. trans. by R. HOWELL from the 2nd French ed., 1898–1904); and R. HUBNER, *History of Germanic Private Law* (1918; Eng. trans. by F.S. PHILBRICK from the German, 1908).

Mosaic

Mosaic is the art of decorating a surface with designs made up of closely set, usually variously coloured, small pieces of material such as stone, mineral, glass, tile, or shell. Unlike inlay, in which the pieces to be applied are set into a surface, which has been hollowed out to receive the design, mosaic pieces are applied onto a surface, which has been prepared with an adhesive. Mosaic also differs from inlay in the size of its components. Mosaic pieces are anonymous fractions of the design and rarely

have the dimensions of pieces for intarsia work (fitted inlay usually of wood), whose function is often the rendering of a whole portion of a figure or pattern. Once disassembled, a mosaic cannot be reassembled on the basis of the form of its individual pieces.

Technical insight is the key to both the creation and the appreciation of mosaic, and the technical aspects of the art therefore require special emphasis in the present article, both in the sections devoted to materials and methods and in the historical survey of the major periods and centres of mosaic activity. Stylistic, religious, and cultural aspects of mosaic, its role in Western art, and its appearance in other cultures are also dealt with in order to complete the picture of an art form that appears in widely separated places and at different times in history, but only in one place—Byzantium—and at one time—4th to 14th centuries—rose to become the leading pictorial art.

PRINCIPLES OF DESIGN

Interaction of painting and mosaic

Between mosaic and painting, the art with which it has most in common, there has been a reciprocal influence of varying intensity. In colour and style the earliest known Greek figurative mosaics with representational motifs, which date from the end of the 5th century BC, resemble contemporary vase painting, especially in their outline drawing and use of very dark backgrounds. The mosaics of the 4th century tended to copy the style of wall paintings, as is seen in the introduction of a strip of ground below the figures, of shading, and of other manifestations of a preoccupation with pictorial space. In late Hellenistic times there evolved a type of mosaic whose colour gradations and delicate shading techniques suggest an attempt at exact reproduction of qualities typical of the art of painting.

In Roman imperial times, however, an important change occurred when mosaic gradually developed its own aesthetic laws. Still basically a medium used for floors, its new rules of composition were governed by a conception of perspective and choice of viewpoint different from those of wall decoration. Equally important was a simplification of form brought about by the demand for more expeditious production methods. In the same period, the increasing use of more strongly coloured materials also stimulated the growing autonomy of mosaic from painting. As a means of covering walls and vaults, mosaic finally realized its full potentialities for striking and suggestive distance effects, which surpass those of painting.

The general trend towards stylization—that is, reduction to two-dimensionality—in late antique Roman painting (3rd and 4th centuries AD) may have been stimulated by experimentation with colour in mosaic and particularly by the elimination of many middle tones for the sake of greater brilliance. The central role played at that time by mosaic in church decoration, for which it is particularly well suited, encourages the assumption that the roles had shifted and painting had come under its influence. The strong, sinuous outlines and the absence of shading that came to characterize painting during certain periods of Byzantine and western European art of the Middle Ages may have originated in mosaic technique and use of materials. It is notable, however, that from the Renaissance to the 20th century, mosaic was again wholly dependent on painting and its particular forms of illusionism.

In modern mosaic practice, the main tendency is to build on the unique and inimitable qualities of the medium. Although not a few of the works created in the 20th century reveal the influence of painting, figurative or abstract, the art has gone a long way towards self-realization. By and large the modern mosaic maker shares with his medieval predecessor the conviction that there are functions to which the materials of mosaic lend themselves with particular appropriateness.

MATERIALS

In antiquity, mosaics first were made of uncut pebbles of uniform size. The Greeks, who elevated the pebble mosaic to an art of great refinement, also invented the so-called tessera technique. Tesserae (Latin for "cubes" or "dice") are pieces that have been cut to a triangular, square, or other regular shape so that they will fit closely into the grid of cubes that make up the mosaic surface. The invention of tesserae must have been motivated by a desire to obtain densely set mosaic pictures which could match, in pavements, the splendour of contemporary achievements in painting.

Invention of the tessera technique

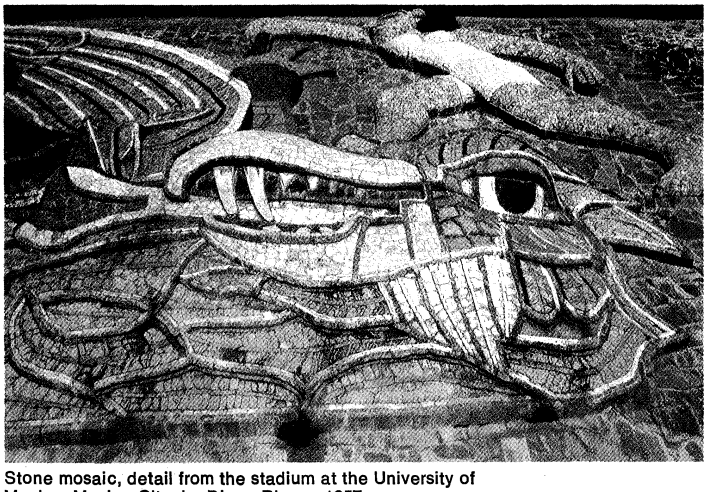
Tesserae vary considerably in size. The finest mosaics of antiquity were made of tesserae cut from glass threads or splinters of stone; ordinary floor decorations consisted of cubes about one centimetre square. Medieval works often display a differentiation in tessera size based on function: areas requiring a wealth of details, faces and hands, for instance, are sometimes set with tesserae smaller than average, while dress and jewelery are occasionally set with very large, single pieces.

As long as mosaic was a technique for the making of floors, the main requisite of its materials, besides their colour, was their resistance to wear.

Stone. Stone, therefore, was long dominant, and throughout antiquity the natural colours of stone provided the basic range of tints at the artist's disposal; they put their mark not only on the earliest Greek works but continued to determine colour schemes far into Roman times. Stone continued to be used in Christian monumental decorations but on a more limited scale and for special effects. In Byzantine mosaics, faces, hands and feet, for example, were set with stone, while cubes of marble, often of coarse crystals, were used to depict woollen garments. Stone was also used for background details (rocks, buildings), probably to bring about particular illusions. Though marble and limestone were ordinarily preferred, in a period when Roman mosaic cultivated a black and white technique, black basalt was widely employed. Marble cubes painted red, probably to substitute for red glass, have been found in many Byzantine mosaics, in 9th-century works at Istanbul, for example.

Because its granular, nonpolished surface is often preferred to the hard brilliance of other materials, stone is also widely used in modern mosaics. At the University of Mexico in Mexico City, for example, the mosaics covering the exterior of the library by Juan O'Gorman (1951–53) and the exterior of the stadium by Diego Rivera (1957) are made with natural stone.

Harrison Forman



Stone mosaic, detail from the stadium at the University of Mexico, Mexico City; by Diego Rivera, 1957.

Glass. Glass, which first appeared among the materials of mosaic in the Hellenistic period (3rd–1st century BC), brought unlimited colour possibilities to the art. In floors, however, it had to be used sparingly because of its brittleness. In floors, glass tesserae were used for the strongest hues of red, green, and blue, while softer tints were rendered with coloured stone. With the development of wall mosaic, glass largely took over the functions of stone, producing tints of unsurpassed intensity and leading to a continuing search for new coloristic effects.

Use of gold tesserae, detail from the Early Christian vault mosaics of Sta. Constanza, Rome, *c.* 337–354 AD.
SCALA, New York

Gold and silver tesserae

With little knowledge of the laws of optics but with immense practical experience, mosaic makers of the Early Christian period gave the art a completely new direction with the exploitation of gold and silver glass tesserae. Like a mirror, the glass from which this kind of tesserae was made had a metal foil applied or, better, encased in it. The metal was gold leaf or, for the "silver," probably tin. These pieces of mirror glass gave golden or white reflections of high intensity and could be used to depict objects of precious metal or to heighten the effect of other colours; but, above all, it was used as a means of rendering the light emanating from God.

Gold tesserae were first used by the Romans, in both floor and vault decoration of late antiquity. Initially, their role was simply to give a golden effect. Gold tesserae, for example, were employed to depict a golden wreath in a floor mosaic at Antioch (*c.* AD 300) and gold vessels in some of the vault mosaics in Sta. Constanza in Rome (*c.* AD 337–354). Later, when this use of gold for imitation purposes had become more refined, some spectacular effects were produced in the depiction of garments. The Good Shepherd in the Mausoleum of Galla Placidia at Ravenna (*c.* AD 450) is dressed in golden robes of densely set gold cubes shaded with stripes of light-yellow tesserae. The female saints in S. Apollinare Nuovo (*c.* AD 550–570) in the same town wear costumes set with green glass cubes among which appear both patterns and large fields of gold tesserae, producing a striking similarity to rich silk brocade. Silver was used in a similar way. Christ scenes in S. Apollinare Nuovo (AD 500–526) employ silver tesserae in the drawn sword of Peter in the betrayal, no doubt an imitation of steel. Silver tesserae are also found in the silver jug and basin in the scene of Pilate washing his hands.

Gold cubes were distributed among the ordinary tesserae to add to the shimmer of light in ornaments and background details. To avoid an uneven gleam in the surface, the mirror effect was often moderated by setting the gold tesserae in reverse, so that the visible part of the cube is the side with the thickest sheet of glass covering the gold leaf. In the now-lost mosaics of the Church of the Dormition in Nicaea, a scholar observed another exquisite effect, which he called dark gold, created by cubes from which some of the gold leaf had been chipped off, for example, in the frontal part of Mary's golden footstool (7th or 8th century AD).

An early instance of the use of gold for depicting light emanating from God is in a representation of Christ-Helios (Christ as the Sun God) in a 3rd-century mausoleum under St. Peter's at Rome. Here, a few gold tesserae are seen in the rays coming from Christ's head. The halo of gold, a feature so common in Christian art that religious pictures without it can hardly be imagined, developed in mosaic art in the 4th century AD. The gold background, signifying divine light, probably originated in Roman mosaic art, but the first preserved instances date from the advanced 4th century. The cupola mosaic of Hagios Georgios at Thessaloníki (*c.* 400), for example, has a background of gold. In Italian mosaics of the 5th century, other types of background, such as a dark-blue ground or a more naturalistic landscape setting, were dominant. Only at the beginning of the 6th century did the gold background become the rule.

In addition to this massive predilection for gold, the Christian East began to use silver to depict the symbolic light emanating from Christ. First, it was used for the entire disc of his halo, later only for the cross arms. The archangels were the only figures besides Christ for whom the silver halo was used. The light of God, appearing as rays from above in scenes of the Annunciation, Nativity, Baptism, and Transfiguration, was also depicted with silver tesserae. Finally, silver and gold were used together in Byzantine representations of the infant Jesus whose golden robes are highlighted with silver cubes (the apse and south vestibule of Hagia Sophia, Istanbul; both 9th century).

Other materials. In Christian mosaics, tesserae of mother-of-pearl or coarse-grained marble cut to round or oblong shapes were used to depict pearl. Though pieces of semiprecious stones were among the mosaic materials of antiquity, their use was rarely dictated by the wish for particular sumptuous effects. Reduced to common tessera size, bits of this strongly coloured material served as part of the general colour scheme of the mosaic pictures. Objects like those of the pre-Columbian American Indian cultures, in which, because of its exquisite materials, such as turquoise and garnet, mosaic attained the status of jewelry have not been found in Western art.

Ceramic tesserae

Among the materials that have played and continued to play a role in the production of mosaic, ceramic is the most versatile. Terra-cotta "threads" were used in Greek mosaics as contours, and tesserae of the same material were frequently used by the Byzantines for the depiction of red objects and garments. Today, glazed or unglazed ceramic is used and is one of the strongest competitors with glass and stone. Ceramic tesserae are cut from tiles or, like much modern glass mosaic material such as pressed glass, come prefabricated. Prefabricated tesserae have the advantage of a very uniform and smooth surface which harmonizes with glass, steel, and other new building materials.

TECHNIQUES

The most commonly used adhesive for mosaics was mortar, the function of which in the 20th century has been largely taken over by modern, tougher kinds of cements or glue. In Roman floors, two to three layers of mortar preceded the setting bed that was to carry a tesserae facing. The first layer rested on a thick foundation of stone that prevented settling of the mortar bed and the formation of cracks. For wall mosaics the preparation was equally painstaking, and in many cases an application of a waterproofing of resin or tar preceded the laying of the mortar. There then followed two layers of coarse, roughened mortar, the stability of which was often improved by large nails that had been driven into the joints of the wall before the work of laying started. A third and final layer was of fine consistency and frequently, like the mortar for floor mosaics, contained powdered marble and binding elements such as pounded brick.

As in fresco painting (technique of using water suspended pigments in a moist plaster surface), the setting bed was applied in patches never larger than were needed for one day's work. In a frescoed surface, the breaks between the different stages of the work can easily be detected; they are harder to discover in mosaic.

Sketches and underpainting

Numerous underpaintings discovered in wall mosaics indicate that sketches, often detailed and with the main colours suggested, were executed on the setting bed to serve as guides for the disposition of the tesserae. Similar procedures are thought to have been part of the technique of floor mosaic. In church mosaics, rough preliminary sketches have been found on layers underneath the setting bed and, in a few instances, even on the brick wall itself. This kind of preparatory sketch, for which there are parallels in wall painting, suggests that the artist was trying out the overall scheme of the decoration before making a more detailed sketch on the setting bed.

Instead of laying the tesserae one by one directly onto the mortar, another method was sometimes used. In Pompeii many of the so-called *emblēmata* (central panels of floors), which were made up of smaller than average tesserae and were often of very high artistic quality, appear to have been preset on trays of stone or terra-cotta which were then embedded in the mortar of the floor. The surrounding mosaic area was then set according to the ordinary, direct method. Although the direct method was used for wall mosaics during the Middle Ages, there are signs in at least one medieval monument of a partial use of the prefabrication—or "indirect"—method: in the cupola mosaic of the church of Hagios Georgios, Thessaloníki (late 4th century), the heads of the saints seem to have been inserted in the mortar in one piece. The indirect method is the one most used in the 20th century. In the workshop, the mosaic is first set in reverse with glue on paper or cloth and then applied to the floor or wall. The technique permits preassembling of mosaics intended even for curved surfaces, cupolas, or apses. It has been hypothesized that behind the enormous output of floor mosaics in the Roman era lay similar production methods which had developed out of the tray procedure described above. The introduction of wall mosaics led to experimentation with the spacing and angling of tesserae. The solidity of floor mosaics depended on a close-set texture, but in wall mosaics, in which the element of wear was no longer relevant, the organization of the surface could become looser. For several centuries, a very wide spacing of the tesserae was cultivated, and the placing of cubes at irregular angles was regarded as important to the over-all effect of wall mosaics. These tendencies reached the extreme in the 7th and 8th centuries, in mosaics of the chapel of S. Venanzio in the Lateran Baptistery, Rome

SCALA, New York

Wide-spaced tesserae set at irregular angles in the head of a saint, detail from mosaics in the Chapel of S. Venanzio, Lateran Baptistery, Rome, *c.* 640 AD.

(*c.* AD 640–49), and in the fragments of the decoration of Pope John VII (AD 705–07) in the old St. Peter's in the Vatican. Later periods preferred a somewhat closer setting, but the irregular surface continued to be in fashion for most of the Middle Ages.

Tilting of tesserae

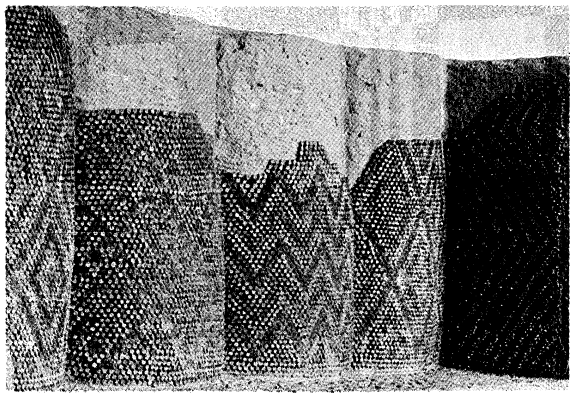
The tilting of tesserae became an art in itself. In 6th-century Byzantine mosaics, there evolved a new technique whereby gold and silver tesserae were set at extremely sharp angles to enhance reflection. By pointing their mirror ends downward in the direction of the onlooker it was possible to secure maximum light effect. In Hagia Sophia at Istanbul, the enormous gold areas in the wall mosaics of the emperor Justinian are set with cubes tilted this way. In one particularly dark corner, the tesserae are not only tilted downward but are also turned slightly sideways to catch the light from a nearby window. A similar technique, based on a high degree of tilting of the gold tesserae in unlit areas, can be observed in the mosaics of the Dome of the Rock in Jerusalem (*c.* AD 690).

Haloes set with tilted cubes that bring out the circle of light surrounding the heads of holy figures became common in Byzantine mosaics of the 6th to 7th centuries, as is seen in the mosaic panels dating from this period in the church of Hagios Demetrios, Thessaloníki. Striking examples of such haloes are also found among mosaics that were put up in Hagia Sophia in Istanbul in the 9th century, above all in a panel with the kneeling emperor (Leo VI?).

Effects such as those described above are unthinkable without the accumulated experience of the craftsman-artist. In the 20th century, mosaic increasingly has become an art divided between the inventor who furnishes the design and the worker who executes it. It may be that the dry character of many modern mosaics can be ascribed to the fact that the artist no longer puts his thumb on every tessera.

PERIODS AND CENTRES OF ACTIVITY

Ancient Near Eastern mosaics. Among the cultures of the ancient Near East there is one remarkable occurrence of a mosaic-like technique: the exteriors of some large



Columns decorated by the Sumerians in a mosaic-like technique with polychrome terra-cotta cones, from Uruk, Mesopotamia, early 3rd millennium BC. In the Staatliche Museen zu Berlin.

Terra-cotta cone mosaics

architectural structures, dating from the 3rd millennium BC, at Uruk (Erech) in Mesopotamia, are decorated with long terra-cotta cones imbedded in the wall surface. The blunt, outer ends of the cones, coloured in red, black, and white, form patterns consisting of zigzag lines, lozenges, and other geometrical motifs. This revetment was decorative as well as functional, for the cones shielded the core of sun-dried bricks from rain and wind. The technique, however, died out and seems to have had no influence on the later development of mosaic.

In western Asia Minor are preserved the earliest examples of the surface-covering technique that lead to mosaic in the present sense of the word. In the town of Gordion near modern Ankara in Turkey, houses have been uncovered with floors made of pebbles set in a primitive mortar. In some of these floors (dated to the 8th century BC), rows of light pebbles form awkward geometrical figures against a background of darker stones. These rudimentary elements of decoration introduced into a crude form of pavement laying spurred artistic imagination and set in motion a process that was to bring spectacular results.

Ancient Greek mosaics. Three main phases can be determined in the development of mosaic art in antiquity. The first, chiefly a Greek matter, involved the gradual perfecting of the pebble medium. The second, which saw the invention and spreading of the tessera technique, took place partly in the Hellenistic Greek world and partly on Roman soil. The third, largely a Roman phenomenon, was characterized by the popularization of mosaic and the application of the medium to new functions. By a process of diffusion, the taste in floor decoration documented at Gordion spread through the Greek-speaking world of the Mediterranean. Its first full flourishing seems to have occurred in late Classical times. Pebble mosaics are found as far west as Sicily (Motya, Morgantina) and, in the east, in the Greek colonies on the Crimea (Cherson). They are preserved in large number at only two sites, Olinthos and Pella, in Macedonian northern Greece.

In the town of Olinthos there are floor mosaics, with elaborate figures and complicated patterns, which were part of the new city culture that developed in the 5th century BC. The Olinthos mosaics also reveal that picture making with light and dark pebbles had by then evolved into an intricate art. Against a ground set with black or blue-black stones stand figures or patterns set with white or slightly tinted ones. Pebble size had become fairly uniform, with diameters from one to two centimetres, but particularly intricate areas, like faces, are set with smaller stones. Very small black pebbles serve as outlines. Although the mortar between them is visible, the pebbles are set close enough so that the pictures appear with regular, not too broken outlines and with some emphasis on detail.

Floors in houses at Pella, dating from the 4th century BC, demonstrate a significant later development of the pebble technique. Floor mosaics then openly vied with wall painting in the rendering of space and realistic detail. This was made possible by the introduction of new materials that eliminated the shortcomings of the ordinary pebble medium. Among the basic changes was an increase in the range of colours. When the demand for particular tints could not be met with pebbles of natural colours, "artificial pebbles" were made and are found in several of the floors at Pella. These "pebbles" have been painted in the required tones—mostly strong green and red—and, to protect the film of paint, have a depression sunk in the middle. The new trend also called for smaller pebbles to permit pictures to be set more closely. To obtain precise delineation of limbs and features, outlines made not with pebbles but with long strips of terra-cotta or lead wire were employed. Pictures made in this technique reflect a taste for heroic hunt scenes and fights with wild animals, themes inspired from court art glorifying the ruler.

Hellenistic mosaics. The next innovation came at the end of the 4th or the beginning of the 3rd century BC, when the introduction of new principles led to the abandonment of the pebble technique. Cut mosaic pieces permitted the nearly complete elimination of the disturbing effects of visible mortar patches, and new materials, above all glass, offered a vast new range of colours. The acceptance of the new methods and materials seems, however, to have come about slowly. In Alexandria (Greco-Roman Museum) there is a mosaic (depicting Erotes fighting a stag and, in the outer border, a frieze of animals) in which cut, triangular tesserae are used together with both pebbles and lead wire. In somewhat later Alexandrian mosaics made with tesserae (late 3rd/early 2nd century BC) lead threads are still in use; for example, in a panel signed by the artist Sophilos and depicting a personification of Alexandria, that is the earliest known example of miniature mosaic work (called *opus vermiculatum*, meaning "wormlike work" because of the close-set, undulating rows of small tesserae).

The Pergamum School

Pergamum, another centre of the Hellenistic world, was particularly famous for its school of mosaics. According to the ancient Roman historian Pliny the Younger, Sosos, one of the most renowned mosaic artists of antiquity, worked in this city. None of his works survives but, thanks to Roman copies, the intentions that underlay his

art can be judged. Pliny listed as his most celebrated works a representation of drinking doves and a clever imitation of the "unswept floor" of a banquet room (*asarōtos oikos*). The copies tell of Sosos' phenomenal ability to create trompe l'oeil ("fool-the-eye") effects through a shading and colouring that seems to bring the objects out in full plasticity on the ground on which they are depicted. To call the work merely an imitation of painting may be incorrect. The intense colours and the smooth texture permitted by the new setting technique paved the way for illusionistic effects that went beyond those achieved by painting.

Roman mosaics. Eager to adopt the artistic culture of the Hellenized eastern Mediterranean, the Romans introduced mosaic in this exquisite form in both their domestic architecture and their places of worship. Pompeii has yielded a host of *opus vermiculatum* works datable to the 2nd/1st century BC. Among these the most famous is the Battle of Issus, found in the Casa del Fauno in 1831 (now in the Museo Archeologico Nazionale, Naples). This is the largest of all known works, measuring about 11.22 by 19.42 feet (3.42 by 5.92 metres), in the miniature mosaic technique. This mosaic (which probably copies a work of painting, perhaps a famous picture by Philoxenus of Eretria) and other Pompeiian panels of similar quality are supposed to have been executed by Greek artists, who carried on in the tradition established at Alexandria and Pergamum.

The Romans transformed mosaic from an exclusive art to a common decorative medium. Some of the earliest examples of this new type of floor are in the late republican (2nd century BC) houses at Delos. For rooms of secondary importance and often for floors surrounding the finely designed and executed central *emblēmata* (a featured picture or ornamental motif) in the most important rooms, the Romans developed a simpler, less artistic kind of mosaic. The floors are set with fairly large tesserae with a limited range of colours, some tending toward monochrome (black-and-white). The decorative designs and motifs are also simple and uncomplicated.

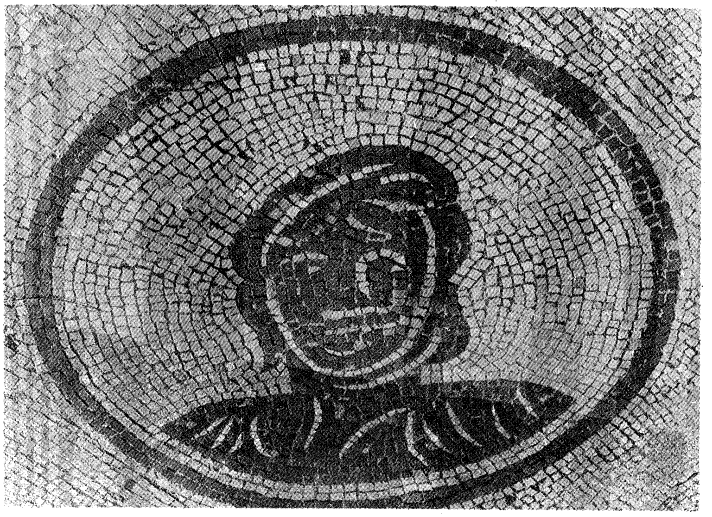
Roman floor mosaics

This new trend in mosaic floors was probably stimulated by new and functional ways of thinking about the role of floors in architecture. To the practical Romans it may have seemed illogical that floors destined for rough wear should bear delicate pictures. Moreover, the demand for large-scale mosaic making brought about by the colossal urban expansion in the 1st century AD made the development of quicker and simpler techniques imperative. The aim of the Romans seems to have been to create a style, technique, and form of composition that would be simple and functional. Competition with painting in illusionistic and coloristic refinement was therefore abandoned; *emblēmata* gave way to decorative elements distributed over the floor in one large overall pattern or to figure compositions taking the full floor plane; and polychrome gave way to monochrome mosaics (which may have been easier to produce). Enormous floors in the baths and in the courtyards of warehouses (1st to 3rd century AD) at Ostia, Rome's port at the mouth of the Tiber, are the best preserved examples of the monochrome style.

The expressionist Roman style, which flourished in Italy, penetrated into the former Greek cities in the eastern part of the empire, but polychromy and types of composition based on the framed picture persisted with especial tenacity due to strong local Hellenistic traditions. A splendid series of *emblēmata* (2nd century) with mythological representations, allegories, and scenes from the theatre have been uncovered at Antioch in southern Turkey. They prove the existence of a school there of mosaicists of particular brilliance. Recent research has pointed to the African provinces as the site of another, highly active school with a taste for larger, dramatic compositions. Influence from these areas may have been responsible for the renewed opulence, represented by a vivid polychrome pictorial mosaic, which reappeared in Roman art in late antiquity. Outstanding examples of this renewal are the mosaics in the Roman villa of Casale (*c.* AD 300) near Piazza Armerina, Sicily. The mosaic decoration of this vast palace complex culminates in the gallery of the Large Hunt, which contains a scene of animal hunting and fighting covering an area of 3,200 square feet (300 square metres).

It is generally agreed that in the course of the 3rd century the status of mosaic was radically altered. Already in Hellenistic times the medium had been employed for other ends than floor covering and had become part of the embellishment of the fantastic garden architecture of which the rulers of the period seem to have been particularly fond. Reflections of this tradition in the 1st century AD are the mosaic-covered fountains in the mansions at Pompeii and Herculaneum and mosaic panels and niches in rustic banquet halls and artificial grottoes at The Golden House of Nero in Rome and his villa at Anzio. Mosaic fragments and imprints of tesserae in the vaults of baths and buildings of similar size demonstrate that mosaic gradually was introducd into new fields. Equally important is the evidence that mosaic was used to depict sacred images. On some of the monochrome floors at Ostia are

SCALA, New York



Roman monochrome floor mosaic in the Portico delle Corporazioni, Ostia, Italy, 3rd century AD.

Cultic mosaics

scenes pertaining to animal sacrifice and to the cult of the dead. Three monuments of the 3rd century inform of another new practice introduced at this time, that of putting mosaic pictures of religious importance on walls: a niche mosaic with the god Silvanus from a temple of Mithra at Ostia; a Christian wall and vault mosaic depicting Christ as Helios, the Sun God, in a mausoleum under St. Peter's, Rome; and a decoration, now lost but recorded in a 17th-century drawing, of a chapel for the Lupercalian worship at Rome. It has been pointed out by modern scholarship that the new role gradually assumed by mosaic must be related to the corresponding decline in interest in three-dimensional representation. The cultic mosaic took over the function of the cult statue, mosaic being that two-dimensional medium which was considered most capable of convincingly expressing religious ideas in visual form.

Early Christian mosaics. Present-day insight into the crucial, early phase of this part of the history of mosaic is limited because of the loss of nearly everything that was made in the field during the first half of the 4th century. Nevertheless, as indicated above, it seems certain that wall mosaics had come into use in Roman art well before Emperor Constantine's edict of toleration of the Christian faith in AD 313. Considered to be among the earliest Christian wall mosaics in Rome are those in the church of Sta. Constanza built about AD 320–330 as a mausoleum for Constantine's daughter. The content of the pictures is almost completely Dionysiac and pagan, but a series of small format scenes from the Old and New Testaments were included among the non-Christian pictorial elements of the decoration. Obviously an independent Christian pictorial program for buildings of Sta. Constanza's size and complexity had not yet been developed; and, probably in lieu of that, a Dionysiac program had been chosen because its many allusions to the symbolism of wine lent themselves to a Christian interpretation.

Other monuments of the 4th century bear similar marks of transition. Floor mosaics in the cathedral complex at Aquileia demonstrate that the church before and immediately after Constantine's edict of tolerance of the Christian faith in AD 313 adhered to the late antique tradition of placing religious pictures in pavements. In the earliest group of Aquileia mosaics (*c.* AD 300) objects and animals symbolize the Good Shepherd, while the later group (second decade of 4th century) contains scenes from the story of Jonah, symbolic animals, such as the deer and the lamb, and a representation of the bread and the wine. Before long, pictures of this character were banished from floors, and simpler and more general symbols took their place.

The latest of the preserved transitional works, a decorated cupola in a mausoleum, possibly imperial, at Centcelles (now Constantí, Tarragona), Spain, seems to have been made not long after AD 350. This very fragmentary decoration has yielded important information about a stage of increasing mastery in the handling of the medium. The scenes from the Old and the New Testament are presented with greater self-confidence and occupy a full, broad zone in the lower part of the cupola. Yet, below it is a stag hunt, rich in symbolic content but adhering closely to the patterns of profane floor mosaics. Stone tesserae dominate in the lower zones, but glass cubes are found in large quantities in the upper. Glass, with its stronger colours, was doubtlessly concentrated in this area intentionally. The zenith of the cupola, weak in lighting and distant from the spectator, needed tesserae of strong reflecting power to make it possible to read its decoration.

A series of large, in part well-preserved mosaics make it possible to follow the progress of the art in 5th-century Italy. Ravenna and Rome have several important works, while Naples and Milan have preserved enough to suggest that workshops of high artistic standard must have existed in many of the large cities of the peninsula. In these works, the tendency to clarify and even underline the content of religious pictures with the help of colour is brought to its full peak. The swing towards a greater employment of glass reached a point at which the mosaics are almost entirely made of this material. In what must be regarded as a late but vigorous revival of the painterly illusionism of antiquity, there is an audacious blending of colours. Among the high points of this trend are the flaming visages of angels in Sta. Maria Maggiore, Rome (*c.* AD 432–440) and the spiritualized physiognomies of St. Bartholomew and his fellow apostles in the Baptistery of the Orthodox, Ravenna (*c.* 450). But the designer's mastery and sophistication are nowhere more overwhelmingly illustrated than in the glowing interior of the Mausoleum of Galla Placidia (*c.* 450) at Ravenna, with its blue star-filled mosaic dome, and in the decoration of the Naples Baptistery of S. Giovanni in Fonte (5th century), with its hypnotizing glimmer.

Development of an iconographic tradition

A Christian language of pictures (iconography) was now developed, and its grammar worked out. In cupolas, the centre tended to be reserved for depictions of Christ or the cross. In apses there was a trend toward static and symbolical representation of holy figures and a reduction of detail. On the walls of the nave of basilicas were scenes from the Old or the New Testament or both. The largely intact decoration of the church of Sta. Maria Maggiore, Rome, throws some light on the principles involved.

Old Testament scenes are distributed on the side walls of the nave in panels measuring about six by six feet (1.9 by 1.9 metres). There is one panel below each of the basilica's large windows. The pilasters (columns projecting shallowly from the surface of the wall) between the windows (restored but repeating the original disposition) serve as outer frames for these panels. Before the restoration of the church in the 16th century there were also inner frames, made of stucco; in addition, each panel was adorned with a small pediment (triangular gable) of the same material and thus appeared as if enshrined by a small aedicula (a pedimented niche). The classical rules governing the relation between the architecture of a building and its decoration may be expected to leave their mark on Christian mosaic art for a long time.

Early Byzantine mosaics. Mosaics made in Ravenna for the Ostrogoth king Theodoric (AD 493–526) are the first full manifestations of Byzantine art in the West. As seen in two of the foremost works from his time, the Baptistery of the Arians and the church of S. Apollinare Nuovo, the gold background now dominates. Accompanying it was silver, a novelty among the mosaics of Italy. In S. Apollinare Nuovo, the faces and hands in several of the Christ scenes are set not with glass tesserae but with cubes of stone. Stylistically, these mosaics are characterized by more static figures and less depth and plasticity than in those of the 5th century.

Developed integration of architecture and mosaic decoration

Another remarkable element is the movement, now fully developed, toward an integration of architecture and mosaic decoration. This is most clearly seen in the basilica. In the church of S. Apollinare Nuovo, the mosaics are no longer inserted panels but form a continuous "skin" that covers every inch of the wall. The size of the windows and even their number have been reduced, apparently to provide more wall space for pictures. Figures have grown in size, to match the dimensions of architectural components, and they seem to have taken the place of pilasters in the articulation of the room. This trend is given truly monumental expression in the choir of the church of S. Vitale at Ravenna, dating from *c.* AD 526–548. A profusion of decorative elements is spread like tapestry over the walls and vault, the panels of the emperor Justinian and his consort Theodora near the apse embodying the new spirit in their colour-laden pageantry.

In the East, the circular church of Hagios Georgios at Thessaloníki, Greece, shows Byzantine mosaic at its earliest flourishing (*c.* AD 400). Its partly preserved mosaics display a disposition related to that of the Baptistery of the Orthodox at Ravenna, with a lower zone containing Paradisiac architecture; above this a zone with standing and walking figures and in the centre of the cupola a medallion with a figure of Christ. A uniform gold background dominates the two lower zones, at a time well before it had come into general use in the West. Silver is

found in profusion, used for the background in the central medallion as well as a means to enhance the radiation of light from all parts of the mosaic. In Hagios Georgios another feature emerges fully developed: in the figures of saints the material for faces and hands is chiefly natural stone, its gentle gradations contrasting spectacularly with the violent juxapositions of coloured glass tesserae of the hair and the garments.

Effects of this kind, which are the hallmark of Byzantine mosaic technique, seem to derive from intentions wholly dissimilar to those which had determined the development of early Christian mosaic art in the West, where the illusionism of Greco-Roman art persisted for a long time. In the great Ravenna mosaics of the 5th century, pictures illustrating the narrative of the Bible or expounding the dogmas of religion were still done in the painterly style of Roman mosaics and wall painting. During the same period, mosaic art of the Eastern Empire, having abandoned conventional illustration, was boldly exploring the way that lay open, in mosaic art, toward a new kind of imagery.

In the mosaics of the 6th century are found the earliest refinement introduced by the Byzantines to enhance the brilliance of gold tesserae. This refinement, already described, involved setting gold cubes at oblique angles to direct their reflections toward the viewer. Used in haloes, the tesserae, obliquely set, convey to the holy figures a miraculous aura of light. The visages of the saints, with their dull stone surfaces and hues reminiscent of actual human skin, add a touch of mysterious reality to this theatre of effects.

Splendid mosaics from many parts of the eastern Mediterranean testify to the continuous cultivation and improvement of these effects. In the city of Thessaloníki the mosaics in the churches of Hosios David (5th century AD) and Hagios Demetrios (6th and 7th centuries) ex-

Rene Percheron—J.P. Ziolo

Gold tesserae reflecting light to the viewer; from the Byzantine votive mosaic showing St. Demetrios between two donors, from Hagios Demetrios, Thessaloníki, Greece, 7th century.

emplify the trend, which is also expressed in apse decorations preserved at Cyprus (church of the Panagia Angeloktistos, at Kiti, and of the Panagia Kanakaria near Lithrankomé; both 6th century) and in the Monastery of St. Catherine, Sinai Desert, founded by Justinian.

Apart from the gold ground, which had considerable impact, the technical subtleties essential to these mosaics met very little response outside Byzantium. When Byzantine artisans operated in foreign territory, they brought their particular techniques with them. Again and again the impact of this tradition was felt in the West, though, at its purest, mostly as short-lived episodes. To judge from a few surviving fragments, mosaics executed under Pope John VII (AD 705–707) in a chapel in St. Peter's, Rome, might have been the work of artisans summoned from Byzantium. Technical and stylistical features demonstrate that the mosaics executed under the earliest Muslim rulers, in the Dome of the Rock at Jerusalem (*c.* AD 690) and in the Great Mosque at Damascus (*c.* AD 715), are certainly the work of specialists called from Byzantium. Sources testify that even the mosaics in the mosque at Cordova, Spain (AD 965), were made by Greek craftsmen.

The floor mosaics in the great palace of the Byzantine emperors at Istanbul—with their pastoral scenes, fights with wild animals, and figure groups taken from pagan mythology—testify to an undercurrent of classical taste in Constantinople. The date, which according to archaeological evidence must be placed as late as around the year AD 600, demonstrates the tenacity of that taste in the midst of the Christian milieu of the Byzantine metropolis.

Middle Byzantine mosaics. Scholars have been concerned to discover how Iconoclasm, the dispute concerning images during the 8th and 9th centuries, may have influenced the course of Byzantine art. In some respects, at least, mosaic reflects very little change. The main source of knowledge about the state of mosaic in the time shortly after the end of Iconoclasm is Hagia Sophia at Istanbul. Parts of the redecoration that the church underwent in the last half of the 9th century have been uncovered in recent times. In their colour and technique these show a continuation of the early Byzantine tradition: the preference for rather strong, clear tints, and the effects created by such techniques as the tilting of tesserae and the turning of gold cubes. The preoccupation with light seems stronger than ever: in badly lit places in the vestibule and gallery, the gold ground displays a high percentage of silver cubes among the gold ones to add to the sparkle. Stylistically, new ground had been broken. Particularly in faces, the tesserae are set in wavy lines which break up the modelling in bandlike configurations. Linearism (the expression of form in terms of line rather than colour and tone) had taken a great step forward.

Mosaics of Hagia Sophia

In the arrangement and distribution of pictures new features are visible. In the apse of Hagia Sophia, the Virgin with the Child sits surrounded by a vast expanse of gold. She is one of the first of a family of similar majestic madonnas, the most striking of which is in the Cathedral of Torcello near Venice (12th century). The tendency to depict icon-like, motionless mosaic figures isolated on a gold background has pre-Iconoclastic precedents, but from the 9th century onward it became a leading decorative principle.

Nineteenth-century drawings show that the decoration of Hagia Sophia also included comprehensive series of saints. Of these saints, which stood in rows on the nave walls above the galleries, only a few have survived. According to the drawings, those of the middle zone represented prophets, those of the lower, holy bishops. Higher up there may have been a guard of angels and in the centre of the cupola, probably a mosaic of Christ. The disposition of the pictures, in other words, may have corresponded to that which at this time was being tried out especially for the new church architecture and which was to become the accepted system of decoration in the middle Byzantine churches.

Interplay of architecture and mosaic at Daphni

The monastery church at Daphni, near Athens, contains one of the best preserved decorations of this type (11th century). The building belongs to a category of central-plan structures that had come into fashion and was to dominate for centuries both in Byzantium and in other areas under the influence of the Orthodox Church. The interior of the church at Daphni displays a layout which, compared with the wealth of detail of the early Christian

period, appears single-minded and concentrated. In the centre of the dome is a medallion containing a colossal bust of Christ as Pantokrator, the All-ruler. In the lowest part of the dome, separated from the medallion by a broad zone of gold, stand prophets with their scrolls. Further down, there may originally have been medallions with portraits of the Evangelists. In the four arches that carry the drum of the cupola are scenes from the life of Christ which, with eight more Christological scenes in the transepts, formed a cycle devoted to the central feasts of the church. The Virgin is represented in the apse, her guard of archangels on the side walls of the sanctuary. About thirty saints, depicted either as busts or as full-length figures, fill the remaining wall space. In the vestibules are more scenes from the life of Christ and the remains of a cycle devoted to the life of the Virgin. Golden frames with floral ornaments surround the panels, and gold once covered every inch of wall between them.

Rene Percheron—J.P. Ziolo

Interplay between architecture and mosaics in the monastery church at Daphni, Greece, 11th century, crowned with a Byzantine dome mosaic Christ Pantokrator.

The ensemble represents a visualization of the Christian cosmos, its effect created by an intricately conceived interplay of pictures and architecture. The worshipper who moves within this golden shell finds its world of pictures thoroughly involved with space. Space in fact fuses the decoration into one giant image, in which the ruler, hailed by the prophets surrounding him, presides in his sphere above the host of saints that people the lower part of the room.

Subtle spatial devices animate the individual pictures; figures of saints, their two-dimensionality emphasized by their outlines, appear in niches sunk in the wall or lean forward in the interior curves of arches. The 20th-century Austrian scholar Otto Demus, in studies on the aesthetics of middle Byzantine mosaic art, has coined the term space icons for this kind of imagery, in which the forms of architecture collaborate to make the solemnly stylized figures appear with unexpected tactility. As shown by Demus, the spatial element contributes to the narrative scenes also. In the four arches, for example, the hollow plane on which the scenes from the life of Christ unfold adds a dimension of spatial realism to the total image. This is most clearly to be observed in the Annunciation scene, where Mary and the Angel face each other across a stretch of real space. The figures share or are made to appear to share the room with the beholder.

The "classical system"

The "classical system," as this close interrelation of architecture and mosaic has been called, was probably perfected in the course of the 9th to 10th centuries, but the earliest fully preserved examples are from the 11th to 12th. Besides Daphni, Greece owns two more monuments of this kind, the monastery church of Hosios Loukas in Phocis and the Nea Moni on Chios (both 11th century). Similar churches are found in such widely distant places as Kiev (Hagia Sophia, 11th century) and Palermo (Martorana, *c.* 1150), both the products of strong Byzantine influence. The system, however, is not identical in any of these. The churches belong to the same general type, but their plans and elevations vary and thus require variations in this disposition of pictures as well.

The classical system with its emphasis on totality may have led to the gradual toning down of the many splendid effects of the earlier tradition for the sake of the equilibrium and clarity of the whole. At Daphni, for example, the rich, tapestry-like character of earlier mosaic has given way to a controlled, less sparkling range of tints. The reds and yellows are restricted, their function in the all-over scheme taken over by the gold of the background. Sombre, often hard blues, greens, and violets are preferred to the lighter ones. Compared with the Hosios Loukas and the Nea Moni mosaics, which retain more of the older colour scheme (the latter almost to the point of brutality), the Daphni mosaics appear cool and intellectual, an impression further conveyed by their elegant style. Actually they belong to a new phase of Byzantine art which took its name from the dynasty of the Comnenus (AD 1081–1185). This style appears at its most refined in Hagia Sophia, Istanbul, in a panel depicting the Virgin flanked by the emperor John Comnenus II and his wife Irene. The practice of tilting the gold tesserae also seems to have been abandoned, for it is not found at Daphni nor in any of the mosaics that are examples of the fully developed classical system. Silver was reduced to the single role of depicting the light emanating from God and Christ. This drying out of the effects of light and colour was partly compensated for by a perfectionist setting and spacing of the tesserae.

Medieval mosaics in western Europe. The prestige, both cultural and political, enjoyed by Byzantium in the Middles Ages led to a widespread imitation of its arts. Art objects in great number were imported to the West from Constantinople and other Greek centres. Individuals or communities outside the realm of Byzantium, however, were able to secure Byzantine artisans for the execution of monumental mosaics. Abbott Desiderius of the abbey of Montecassino in Italy, for example, called specialists in many crafts from Constantinople to decorate his new basilica (dedicated AD 1071). Among these were mosaic workers. Of particular importance is the fact that he took care to see that young local artists were trained by the foreigners. This was the pattern that was followed where Byzantine experts were temporarily called in.

Sicilo-Byzantine mosaics

The Norman rulers of Sicily, who vied with the Byzantines for control of the Mediterranean, molded their representational arts largely on those of the great Eastern power. The existence, at Palermo, of a central-plan church (Martorana) embellished according to the classical system has already been noted. In other 12th-century churches in Sicily, the Byzantine element is blended with western Mediterranean traits. Cappella Palatina, the palace chapel of the royal residence at Palermo (*c.* 1143 and later), for example, is a synthesis of a centralized middle Byzantine church and a basilica. The building therefore called for a hybrid program. According to Western custom, the mosaics of the basilical parts depict narrative cycles: scenes from the Old Testament and from the lives of SS. Peter and Paul. In the centralized part of the church most of the features belonging to the classical system are at hand. There is a bust of the Pantokrator in the dome, surrounded by angels, but as a con-

cession to the longitudinal disposition of the church, the Pantokrator reappears in the apse.

Martorana and Cappella Palatina were decorated by Byzantine artists, a fact borne out by the brilliant technique, the purity of the Comnenian style, and the adherence to Eastern iconographical prototypes. Two large basilicas are among the highpoints of this Sicilo-Byzantine flowering: the cathedral of Cefalù (*c.* 1148) and the church of Monreale, the last of the mosaic churches of Sicily (*c.* 1180–90). Demus has pointed out the extraordinary homogeneity of style and technique in the Monreale mosaics, which constitute the largest decoration of this kind in Italy. He has also shown that the Monreale mosaics are not executed in the refined and softly curved style that dominates in Cappella Palatina and at Cefalù. Monreale is infused with a more agitated and expressive style which, however, has nothing local or provincial about it. It was the late Comnenian style of Constantinople which had then reached Sicily—a testimony to the unbroken artistic contact that existed at this time between the Norman court and Byzantium.

Italo-Byzantine mosaics in Venice

Venice, for a long time commercially active in the eastern Mediterranean, enjoyed similar but more long-lasting artistic connections with Constantinople. A church that in the 11th century must have looked exotic as well as old-fashioned, St. Mark's was copied after the venerable Church of the Holy Apostles at Constantinople, an early Byzantine, many-domed type that had long since gone out of favour.

The mosaic work undertaken at St. Mark's lasted more than two centuries, from the end of the 11th to the middle of the 14th century. The many and marked stylistic disparities can be ascribed in part to the changes that affected Byzantine art during this period; but they may even have been caused by the freer, Western organization of the Venetian workshop, which allowed artists to develop and cultivate their own personal styles. Among the variety of styles, the Byzantine element is dominant, but it is modified by local tendencies and particularly by strong Romanesque impulses.

The workshops established in Sicily and Venice were active in the neighbouring areas. Mosaics in the cathedral at Salerno (*c.* 1190) and in the monastery at Grottaferrata near Rome (*c.* 1200) are regarded as products of the Sicilo-Byzantine school. The apse decoration of the cathedral at Ravenna (early 12th century), of which fragments survive, seems to have been the work of mosaicists from Venice and, in Florence, Venetian artists decorated the dome of the Baptistry (1225–1330). The much later mosaics on the facade of the cathedral at Prague (14th century) are also Venetian.

The Roman school

In the early Middle Ages, Rome had been able to maintain and defend a mosaic tradition of its own despite the Byzantine hegemony in the arts. At a period when Iconoclasm had loosened the ties between Byzantium and the West, at the end of the 8th century and the beginning of the 9th, the influence of the Roman school extended even into the Carolingian Empire. The apse mosaic of Germigny-des-Prés, France (between 799 and 818), is a product of this influence. In Rome, the pontificate of Paschal I (817–824) left three monumental decorations which constitute the best sources concerning the artistic intentions of this time: the sanctuary mosaics of the churches of Sta. Cecilia in Trastevere, Sta. Maria in Domnica, and Sta. Prassede (attached to the latter is the domed chapel of S. Zeno, also fully decorated with mosaics). The iconographic schemes of these 9th-century churches largely reflect local 5th- and 6th-century church decorations. Also remarkable is the return of many of the technical idiosyncrasies of the early Christian period, including the employment of large tesserae for faces and dress and the use of glass for all parts of the composition. The setting of the tesserae is, however, loose and disorganized; and their varying shapes suggest that they are reused cubes taken from older monuments. Stylistically, the mosaics of the Paschal period, with their extreme two-dimensionality, are related to Byzantine mosaics of the 9th century (the cupola of Hagia Sophia, Thessaloníki), but technically the differences could not be greater.

Little is known of the art in 10th and 11th century Rome. But from the 12th century, a group of works testify to continued inbreeding. The apse decoration of S. Clemente (the 1st half of the 12th century), for example, contains a scroll pattern (rinceaux) reproduced from a 4th-century decoration in a technique that in many respects resembles that of the Paschal mosaics. This isolation, or resistance to foreign influence, seems to have been broken in the 13th century. In 1218, Pope Honorius III asked the doge to send craftsmen for the decoration of S. Paolo Furori le Mura (1218). Several important mosaics from the later part of the same century reflect the trends current at that time in Byzantine and Italo-Byzantine mosaics. The mosaics by Jacopo Torriti in the apse of the basilica of Sta. Maria Maggiore (*c.* 1290–1305) are among the finest of these. They show a mingling of Western medieval and Early Christian iconographical features, such as a scene of the crowning of the Virgin surrounded by the scrolls of a fleshy, classicizing rinceaux; but the lower zone with scenes pertaining to Mary reflects Byzantine influence, an influence also seen in the technique and colour scheme of the mosaics.

Floor mosaics had a renaissance in the West that was unmatched in the Eastern Empire. In the early Middle Ages, the Byzantines developed their particular form of floor covering consisting of a geometrical mosaic made up of pieces of marble of various sizes and shapes (*opus sectile*) usually with some tessera work added for special coloristic touches. This art, called Cosmati work, spread to the West, in which, however, there was also a revival of the tesselated pavement. This pavement, which had survived the Dark Ages in a very primitive form, reemerged in Italy in the 11th century in greater splendour. There are impressive remains of such floors in many of the larger Italian churches. The fashion spread to other parts of Italy and even to France and Germany. In France, where large floors were produced in quantity in the 12th century, fragments of outstanding quality are found; for example, in Saint-Nicolas' at Reims (last half of 12th century). Cologne seems to have been a leading centre for this art in Germany. The style of the floors is usually one of simple outlines and light colours, though in some cases figures and ornaments appear against dark ground. The programs draw their inspiration from many sources, such as textiles, early floor mosaics, and the sculptural ornamentation of churches. An exceptionally well-preserved example is found in Otranto in the Italian province of Apulia, now Puglia (1163–66), where vast floors depict scenes from the Old Testament and mythology (the ascension of Alexander), representations of the Zodiac, and of the labours of the month. A profusion of monsters and fantastic animals fills out the picture of a decoration cast in the Romanesque iconographic tradition.

Cosmati work

Late Byzantine mosaics. The phenomenon called the Palaeologian renaissance (from the dynasty of the Palaeologians, 1261–1453) led to a renewal of Byzantine mosaic art. The stylistic innovations that made themselves felt both in painting and mosaics of the late 13th and beginning 14th century bear witness to one of the most startling changes that ever took place within the framework of Byzantine culture. Bred by a vital humanism, which penetrated westward and laid the foundations for the Italian Renaissance, painting showed a predilection for perspective and three-dimensionalism. A peculiar vivacity invaded religious art, together with a sense of pathos and of the tragic. The results, as expressed in mosaics, were extraordinary.

To respond to the new trend, mosaicists recast their technique. The tessera size generally became smaller than it had been in earlier epochs; and contours lost their rigidity, became thinner, and were occasionally abolished. Colour was reintroduced in a manner that gives the Palaeologian works a striking likeness to the mosaics of the Early Christian period, which, one must suppose, in many cases served the artists as models. An interest in the optical effects of gold apparently returned but rarely, it seems, in the form of the tilting technique. On flat walls, the gold ground was sometimes set in a shell pattern,

probably to enhance the play of light on the surface and to avoid a too-uniform brilliance. For domes, a densely ribbed form of cupola construction, which, when covered with mosaics, produces reflections of light that expand like rays from the central medallion toward the figures surrounding it, was preferred. Such domes are preserved in Kariye Cami, the former church of the Chora, at Istanbul, which was reconstructed and decorated as an act of piety by the logothete, or controller, Theodore Metochites in the second decade of the 14th century. Another superb example is found in Fetiye Cami (Church of the Virgin Pammakaristos) in the same city.

The feeling for colour, which is at its most refined in fragments from the decoration of the Church of the Holy Apostles in Thessaloníki (*c.* 1315) and at its most intense in the partly well-preserved cycles in the Kariye Cami, informs one of the greatest mosaic works of art, the Deësis panel in the south gallery of Hagia Sophia in Istanbul (*c.* 1300). In this same panel, the tilting technique reappears (in the cross arms of Christ's halo)—another indication of the retrospection inherent in late Byzantine art.

No mosaic in the true Palaeologian style has survived outside Byzantium. Reflections of it are found, however, in some of the 13th- and 14th-century works at Venice and in the mosaics executed by Pietro Cavallini in the apse of Sta. Maria in Trastevere in Rome (*c.* 1290–1300). Some of the characteristics of the style may have been brought to the attention of the Italian artists through

Portable mosaics

portable mosaics, which despite their small size (generally about two by four to eight by ten inches [five by ten to 20 by 25 centimetres]) are imbued with many of the coloristic and technical features typical of monumental mosaics. Byzantine mosaic icons, the production of which was stimulated during the early Palaeologian era, were manufactured for personal devotion more than for the embellishment of churches and were exported in considerable numbers to the West or found their way there as gifts or booty in the politically troubled 14th and 15th centuries. In works whose quality can be compared with the most splendid of the Hellenistic *emblēmata*, extremely small tesserae, some measuring less than 0.04 inch (one millimetre) square, were assembled in wax or mastic on a board of fine wood. The tesserae material is often exquisite: silver, gold, and lapis lazuli and other semiprecious stones. The icons depict single figures such as saints, Christ, or the Virgin; single Christian scenes such as the Annunciation (Victoria and Albert Museum, London) and the Crucifixion (Staatliche Museen zu Berlin); or even the full Greek Festival Cycle (Museo dell'Opera del Duomo, Florence).

Renaissance to modern mosaics. With the downfall of Byzantium in the 15th century, there perished that milieu in which mosaic had been constantly cultivated and had undergone continuous renewal in response to changing patterns of religious and cultural life. The art lost another foothold in Italy at the beginning of the same century, when changing attitudes about the world and about the function of art eliminated the very bases upon which mosaic had been built. One of the conventions against which the artists of the Renaissance, who were striving for pictorial realism, most strongly rebelled was the use of gold, the other-worldly element most typical of mosaic art.

The decline of mosaics

Although mosaic continued to be used to a certain extent as church decoration, it was a changed art. Some of its traditional glitter was retained, but essentially mosaics became imitations of painting. These imitative intentions were disastrous and led to the loss of knowledge of how to blend colours and handle materials. In earlier mosaics, there undoubtedly had been a distinction between the leading artist of the project, who drew the composition and oversaw the execution, and the ordinary setters of the tesserae. The leading artist, however, almost certainly took a hand in the setting of special parts and was thoroughly trained in the technical side of the production. Now the preparatory work was divorced from the execution: the artist submitted his cartoon and left its transposition into mosaic to artisans. This drew the lifeblood from the art and caused its degradation.

In Italy, many of the great painters of the 15th and 16th centuries delivered designs for decorations in mosaic. Best known among these decorations are the works of the Venetian Luigi da Pace after Raphael's cartoon, in the

dome of the Chigi Chapel in Sta. Maria del Popolo in Rome (1516), and the mosaics made after the cartoons of Titian, Tintoretto, Giuseppe Salviati, and Paolo Veronese to complete the decoration of St. Mark's in Venice. Among the greatest single undertakings of this kind was the decoration of the dome of St. Peter's in Rome, executed in the last quarter of the 16th century from the cartoons of Cavalier d'Arpino. St. Peter's also displays some of the most technically striking mosaic reproductions of paintings ever executed—the much admired altar pictures after originals by 16th- and 17th-century masters. Created for the completion and care of the large mosaics of the two great churches, the workshops attached to St. Peter's and to St. Mark's gradually became centres for the manufacture of mosaics. From them, artists were summoned for decorative work in all parts of Europe. The school of mosaics in the Vatican and the workshops in Venice still have a considerable share in the field, together with the school more recently set up for the restoration of the mosaics at Ravenna.

Nineteenth-century historicism and the breaking down of Neoclassicism's contempt for Byzantine art led to an increasing interest in and demand for mosaics. Improvements in the technique of prefabrication according to the indirect method and in the manufacture of tessera material led to a veritable mass production, which has put its mark on countless churches, town halls and opera houses. Shrill colours and a gleaming, metal-like surface characterize many of these works.

The modern revival of mosaics had several causes. Scholarship and tourism made the monuments of ancient and medieval mosaics available to an art-loving public. Painting, since the last third of the 19th century engaged in the exploitation of colour, at the turn of the century focussed on the problems of colour as the expression of psychological qualities rather than of the external world. Expressionism, which opened the eyes of artists to the art and artifacts of foreign and distant cultures, also turned their interest towards medieval mosaics. The abstract element which these mosaics contain and which springs from the latent conflict between the design and the tessera pattern made them particularly attractive to artists of the earliest decades of this century such as Marc Chagall and Giovanni Serverini. The texture of mosaic was also an attraction. An American mosaicist, Jeanne Reynal, for example, created abstract compositions in which texture is emphasized by a combination of granulated, pebble-sized, and normal tesserae, sparsely spread over a coloured base of portland cement. Many of these mosaics are small and are hung on the wall like paintings.

Renaissance of the mosaic art in Mexico

Mosaic's smooth yet faceted surface is ideal for decorating the large, unbroken surfaces of modern architecture. The greatest modern use of mosaic as architectural decoration is in Mexico, a country with a long tradition of folk mural painting. Realizing the potential of the medium for public enjoyment and education, the government in the 1930s and 1940s commissioned many murals with historical and political themes for public buildings. Later, it became desirable to decorate the exterior walls of buildings, and mosaic was the logical alternative to the less durable murals. Often mosaics were designed by mural painters such as Diego Rivera who, in 1953, designed the immense mosaic on the facade of the Teatro de los Insurgentes. Francisco Eppens also used historical themes in his mosaic decorations of the schools of medicine and dentistry at the National Autonomous University of Mexico (1957), as did Xavier Guerro in the Cine Ermita in Mexico City. Carlos Mérida, however, created abstract mosaic designs in the Reaseguras Alianza in Mexico City. Among the most prolific Mexican mosaicists was the architect-muralist Juan O'Gorman. Of his many mosaic works, the most important is on the exterior walls of the library of the National Autonomous University of Mexico (1951–53), which exemplifies the monumentality of which mosaics are capable. Other works executed by O'Gorman include mosaics on the SCOP, or Secretaría de Communicaciones y Obras Públicas (1952), and a stone mosaic on the facade of the Posada de la Misión Hotel in Taxco. In 1950, O'Gorman began to decorate his own house in Mexico City with phantasmagoric images and symbols from Aztec mythology.

Mosaic in the strict sense of the word is an art in transition. The conventional tessera mosaic is still largely in use, mainly because of the efficient production methods of modern mosaic firms; yet the distinction between this kind of mosaic and other, mosaic-like techniques is slowly being dissolved. A mixture of cubes and larger pieces of glass, ceramics, or stone is one of the variants that occurs, cubes and *objets trouvés* ("found objects") another. After World War II, experiments seem to have moved in the direction of an employment of larger, less regularly cut units. Today, mosaic is just one out of a very wide range of techniques that have as common principle the piecing together of a surface covering with the use of different durable or nondurable materials. (P.J.N.)

Pre-Columbian mosaics. The art of mosaic in pre-Columbian Central America was marked by a combination of great technical skill and widespread use. The representation of a mosaic mask on a stela at Seibal (an upright, freestanding stone slab functioning as a commemorative monument), Guatemala (AD 590), established the early use of the technique in Maya territory, but it became best known from the few specimens surviving from the time of the Aztec empire (*c.* 1376–1519) and from descriptions of others left by the Spanish conquerors. The Mexican lapidaries worked with obsidian, garnet, quartz, beryl, malachite, jadeite, marcasite, gold, mother-of-pearl, and shell, but turquoise above all constituted their favourite material; the excessive richness of the religious ceremonial gave wide range to its employment in ritual paraphernalia of all sorts. The incrustation was laid upon wood, stone, gold, shell, pottery, and possibly leather and native paper and was held in place by a tenacious vegetal pitch or gum or a kind of cement.

Masks, shields, helmets, knife handles, staffs, collars, medallions, ear plugs, leggings, mirrors, animal figures, and cult statues received a covering, in whole or part, of small and irregularly shaped pieces of highly polished turquoise, cut to fit tightly together so as to form a brilliant green surface, varied at times with cabochons (a gem cut in convex form, highly polished but not faceted) of turquoise or other material. Most striking and best preserved of the surviving two dozen major specimens of this art are a mask in the British Museum, London, and a shield in the Museum of the America Indian, Heye Foundation, New York City. Minute pieces of turquoise, stud-

Mask of Quetzalcoatl, turquoise tesserae on wood with mother-of-pearl, Mixtec, from Mexico, 14th–15th century. In the British Museum.
By courtesy of the trustees of the British Museum

ded with cabochon turquoises, completely cover the cedar mask and are laid in symmetrical lines around the eyes and mouth and on the nose; eyes and teeth are of shell inlay. Over the wood of the shield, one panelled and three circular borders of mosaic frame a scene that may relate to the worship of the planet Venus; it is estimated that nearly 14,000 pieces of turquoise make up the decoration. A Nahuatl story of a hall at the Toltec city of Tula, the walls of which were covered with fine mosaic, may belong to legend, but a monumental use of the technique was achieved in the mosaic-like treatment of the exterior wall casing of certain buildings. Those at Mitla in the state of Oaxaca are outstanding; bands and panels of simple but striking geometric ornamentation were produced by fitting together small stones of different shapes and sizes, tenoned back into the rubble mass of the wall. Each stone was cut for the spot it occupied, and some were more deeply imbedded than others so that the designs stand out in sharp relief. The effective simplicity of design and precision of workmanship at Mitla are not matched on the elaborate Maya facades—at Uxmal and Chichén-Itzá in Yucatán, for example—where, along with geometrical designs, animal forms also occur. (F.O.Wa.)

Moscow

One of the world's great cities, Moscow (Moskva in Russian) is the capital of the Soviet Union and also of the Russian Soviet Federated Socialist Republic, its largest constituent unit. As capital of the largest and one of the most powerful countries in the world, Moscow is a city of outstanding international significance. Since it was first mentioned in chronicles dating from 1147, Moscow has played a vital role in Russian history; indeed, the history of the city and of the state are closely interlinked. For more than 600 years Moscow has also been the spiritual centre of the Orthodox Church of Russia. Today it is not only the political focus of the Soviet Union but the country's leading city in population size, in industrial output, and in cultural, scientific, and educational importance, and the name of the Kremlin, the seat of government in Moscow, has become a synonym worldwide for Soviet authority.

Greater Moscow

Greater Moscow, formed in 1960, covers an area of 339 square miles (879 square kilometres), its outer limit being delineated by the Moscow Circular Motorway. Beyond the motorway, an outer zone has been designated as a Forest-Park Zone, or green belt. Occupying 666 square miles (1,725 square kilometres), this is intended as an amenity area, with severely restricted urban development and industry. In 1976 the population of Greater Moscow was 7,734,000, of whom 7,563,000 lived in the city itself.

For information on related subjects, see RUSSIA AND THE SOVIET UNION, HISTORY OF; RUSSIAN SOVIET FEDERATED SOCIALIST REPUBLIC; and SOVIET UNION.

THE PHYSICAL ENVIRONMENT

Setting and relief. Moscow stands on the Moskva River, a tributary of the Oka and thus of the Volga, in the centre of the vast plain of European Russia. This focal region, as a consequence of the developments of the last 100 years, is known as the Central Industrial Region and is one of the most highly developed and densely populated parts of the Soviet Union. The city lies in the broad, extremely shallow valley of the Moskva and its tributaries. The valley itself overlies a deep downfold of the Russian Platform of very ancient crystalline rocks, a granitic basement some 5,740 feet (1,750 metres) below the present-day surface. The trough in the platform has been

Novosti Press Agency

filled through long geological time by sedimentary rocks, mostly of Devonian and Carboniferous age, with Jurassic series and some Cretaceous rocks nearest the surface. Hardly anywhere is the bedrock exposed on the surface.

The advances of the glaciers in the Ice Age deposited a thick mantle of boulder clays and morainic sands and gravels into which the sinuous Moskva River cut its wide valley in successive stages, marked by four corresponding levels. Recent alluvial deposits cover their surfaces. Beside the river itself is the narrow belt of floodplain; a few feet above this is the first terrace, which yields to the successively higher second and third terrace levels. The last of these, rising up to 100–115 feet (30–35 metres) above the river, is the most extensive, and much of Moscow is built on it. Northward the third terrace merges imperceptibly with a morainic plain of clays and sands, which slopes up very gradually to the Klin-Dmitrov morainic ridge some 40 miles (64 kilometres) north of the city. Eastward and southeastward the surface equally gradually merges into the vast, almost completely flat and very swampy clay plain of the Meshchera Lowland, which extends far beyond the city limits.

Almost everywhere surface relief is minor; only in the southwest of the city is there an upland area on Cretaceous rocks, covered by glacial morainic material. This is the Teplostanskaya Upland, which rises more than 400 feet above the Moskva River and on which is the highest point within Moscow's limits, 830 feet (253 metres) above sea level. One of the sweeping bends of the Moskva has cut into the edge of the Teplostanskaya Upland a steep cliff, the Lenin Hills (formerly the Sparrow Hills), from the top of which there are fine panoramic views of the city. Today the Lenin Hills are crowned by the buildings of Moscow State University.

The human imprint. Long occupation by man has extensively altered the natural setting. The "cultural layer," consisting of debris of buildings demolished long ago and of other materials deposited by man, is up to 50 feet deep in some parts of central Moscow. Almost all the small rivers and streams that once flowed into the Moskva through the city area have now been put into underground conduits or filled in. The only tributaries still visible are the Yauza on the northern (left) bank and, on the southern bank, the Gorodnya, Kotlovka, and Setun, with its tributary the Ramenka. The Yauza, largest of these, and the Moskva itself are controlled by stone embankments for most of their winding courses through the city. The Moskva has been diverted in places, with cuts made through the necks of its loops, and it has also been both widened and deepened; in places it is 800 feet wide. The Yauza now receives additional water from the Volga, by way of the Moscow Canal and its branch, the Likhobory Canal. Two dams on its lower course have raised the level of the Yauza and made the lower reaches navigable.

Rivers

Some of Moscow's water supply comes from some 1,000 deep bores in the city, tapping the artesian water of the underlying Carboniferous beds. Overuse has greatly lowered the levels of these underground waters (90–115 feet during 1900–58), and today most water needs are met by surface sources, from the reservoirs north of the city built in connection with the Moscow Canal, in particular the Ucha Reservoir. Water is also drawn from the Moskva River and pumped into underground storage reservoirs. Up to the early 1960s, the discharge of untreated sewage and industrial effluent had brought about extremely severe pollution of the Moskva, together with increasing pollution of underground waters. So serious was the problem that in the mid-1960s a major effort was made to correct it by heavy investment in anti-pollution and water purification measures. Although the work was not complete by the mid-1970s, a great improvement was discernible. The oxygen content of the Moskva had doubled, fish reappeared in its waters, and bathing was permitted at the foot of the Lenin Hills. Slow but steady progress is being made in controlling the discharge of industrial effluent into the river and into bore wells, and the discharge of untreated sewage will end.

Water pollution

Climate. The climate of Moscow is of continental type, modified by the temperate influence of westerly winds of Atlantic origin. Precipitation is moderate, 22.9 inches (582 millimetres) a year, with a marked summer maximum that reaches a peak in July. A considerable part of the precipitation falls as snow, usually beginning about mid-October though permanent snow cover is not normally established before the beginning of November; it lasts on average 146 days, until mid-April. Winters are thus long, dark, and gloomy, although southerly airstreams not uncommonly bring thaw days, with temperatures above freezing. Conversely, northerly airstreams

from the Arctic bring very sharp drops in temperature, often accompanied by clear, brisk weather with a low relative humidity. December, January, and February are in fact the driest months. Thus, although the January average temperature is 13.6° F (—10.2° C), there can be considerable variation; the minimum recorded temperature is —44° F (—42° C). Moscow employs a large number of workers and a fleet of mechanical devices to keep its streets clear of snow throughout the winter. Spring is relatively brief, and the temperature rises rapidly during late April. Summers are warm, and July is the warmest month, with an average temperature of 64.6° F (18.1° C); a maximum temperature of 99° F (37° C), however, has been recorded in August. Rainy days are not uncommon, but the summer rainfall often comes in brief, heavy downpours and thunderstorms. Autumn, like spring, is short, with rapidly falling temperatures.

Urban climate

Human activity has modified the climatic conditions as well as the relief and hydrology. The vast number of buildings creates the so-called urban heat island effect, causing the average annual temperature in the central city to be up to 2.5° F (1.4° C) higher than the temperature in open country outside the city. Plants in central parks and gardens blossom a week or more earlier than those in the outer suburbs. The temperature differential is most marked on clear winter nights as the buildings radiate heat, but foggy weather also traps heat by preventing radiation.

As with the water, up to the late 1950s there was increasing pollution of Moscow's atmosphere. Smogs were common, and often heavy concentrations of sulfur dioxide occurred. Again a major campaign to control noxious emissions was launched, assisted greatly by a changeover from coal to natural gas as the principal fuel. Some seriously polluting factories were moved out of the city. The resulting improvement in the air of the city has been very marked, though further improvements are still necessary. Monthly deposits of dust and ash per square metre vary from 135 grams (0.38 ounces per square foot) in industrial sectors to as little as 15 grams (0.05 ounces per square foot) on the Lenin Hills. The growing number of motor vehicles—though they are far fewer than in comparable North American cities, and low octane gasoline is used—is increasing concentrations of carbon monoxide in certain parts of Moscow.

HISTORY

Foundation and early growth. First documentary reference to Moscow is found in the early monastic chronicles under the year 1147, when on April 4 Yury Vladimirovich Dolgoruky, prince of Suzdal, was host at a "great banquet" for his ally the Prince of Novgorod-Seversky "in Moscow." This is traditionally taken as the date of Moscow's foundation, although archaeological evidence shows that a settlement had existed on the site since Neolithic times. Archaeological work has revealed the remains of corduroy roads and evidence of iron and leather working dating from the 11th century. The disturbed times made defense essential, and in 1156 Prince Dolgoruky built the first fortifications—ditches and earthen ramparts topped by a wooden wall with blockhouses. This was the Kremlin, or Citadel. The origin of the word *kremlin* is disputed; some authorities suggest Greek words for "citadel" or "steepness," others the early Russian word *krem*, meaning a conifer providing timber suitable for building. The Kremlin was sited on the relatively high spit of land between the Moskva River and a small tributary, the Neglinnaya. The triangular piece of land between the rivers was protected on the eastern side by a moat joining them. The Neglinnaya today flows through an underground conduit, but part of its course is traced by a street of the same name. This Kremlin site was the core of the young town, and it still is.

First fortifications

Moscow soon developed as one of the more important towns of the principality of Vladimir-Suzdal. A trading settlement, or *posad*, grew up to the east of the Kremlin, along the Moskva in the area known as Zaradye. Like most other Russian towns, Moscow was captured and burned by the Mongols in their great invasion of 1236–40, and its princes had to accept Mongol suzerainty. It soon recovered, though the Mongols sacked it once again in 1293. Three years later the Kremlin was strengthened with a new earthen wall and oak palisade. Thereafter Moscow grew in importance, in trading and artisan activity, and in size, overtaking the older and previously more important centres of Suzdal and Vladimir. The town was fairly centrally placed in the system of rivers and portages that formed the trade routes across European Russia. The area east of Moscow between the Oka and Volga moreover enjoyed rather better soils than most of northern Russia and formed a region of more developed agriculture and prosperous towns. Moscow's authority was greatly enhanced when in 1326 the metropolitan of the Russian Orthodox Church transferred his seat from Vladimir to Moscow. Thereafter the town was to remain the centre of Russian Orthodoxy, and after the fall of Constantinople to the Turks (1453) it claimed the title of the Third Rome. Under Ivan I Kalita (1325–41) the principality of Vladimir was incorporated into that of Moscow. Gradually the princes of Moscow extended their rule over the other surrounding Russian princedoms, and the town became the leader in the long struggle against Mongol hegemony.

Seat of the metropolitan

The struggle at first fluctuated. In 1378 a Muscovite army repulsed a Mongol attack on the Vozha River south of the town, and in 1380 Prince Dmitry of Moscow inflicted a crushing defeat on the Mongols under the great khan Mamai at Kulikovo on the Don, for which victory he was thereafter known as Dmitry Donskoy ("of the Don"). The Kremlin had been enlarged and given walls and towers of white limestone in 1367, but the new fortifications were unable to withstand a renewed Mongol attack in 1382, when, despite a heroic defense, the khan Tokhtamysh captured and plundered Moscow. Yet another attack in 1408 under Khan Yedigei, however, was beaten off. Steadily Moscow grew in size and importance, as it continued to absorb the surrounding princedoms. Within the Kremlin the first stone cathedral, the Assumption (Uspensky), was built in 1326. Palaces for the prince and leading boyars, monasteries, and churches

were erected. Outside the Kremlin walls, the trading and artisan quarter to the east grew in size and became known as the Kitay-gorod; this name, which originated in the 16th century, probably derives from the word *kita*, a binding of poles used in the fortifications before stone walls were built, and does not mean "Chinese City" as it is sometimes translated.

The rise of Moscow as capital. By the second half of the 15th century, especially after the annexation of Novgorod in 1478, Moscow had become the undisputed centre of a unified Russian state. During the reign of the grand prince of Moscow Ivan III the Great (1462–1505), the Kremlin was again enlarged and given fire-resisting brick walls more than a mile in length and in places up to 60 feet high, with 19 brick towers (1485–95). From this period also date the rebuilt Cathedral of the Assumption (Uspensky Sobor) and the equally beautiful Annunciation (Blagoveshchensky) and (also rebuilt) Archangel cathedrals, the Palace of Facets (Granovitaya Palata), and the soaring white bell tower of Ivan III the Great. In 1534–38 the Kitay-gorod, previously protected only by earth banks and palisades, was also surrounded by a brick wall, with 12 towers. The town continued to grow and spread outside the walls to form what became known as the Bely-gorod (White City) in a semicircle around the Kremlin and Kitay-gorod.

Despite its new fortifications, Moscow remained subject to disaster and attack. In 1547 two great fires destroyed the greater part of the town. In the mid-16th century Ivan IV the Terrible conquered the Tatar (Mongol) khanates of Kazan (1552) and Astrakhan (1556), but the Crimean Tatars succeeded once more in 1571 in capturing Moscow and burned it, except for the Kremlin. The annals record that only 30,000 of 200,000 inhabitants survived. A further attack was launched by the Crimean Tatars in 1591, but they failed to overcome Moscow's stubborn resistance. The defense was helped by the new walls, built between 1584 and 1591 to protect the Bely-gorod, made of stone and some five miles long, with 29 towers and 11 gates. The line of these fortifications is marked today by the broad, tree-lined Boulevard Ring (Bulvarny koltso) of streets. In 1592 an outer earth rampart with 50 towers was thrown up all round the city, including an area on the southern (right) bank of the Moskva. This encompassed a further extension of Moscow that had grown up beyond the Bely-gorod; known at first as Skorodom, this outer sector came to be called the Zemlyanoy-gorod, or Earthen City. The line of its fortifications is also traced today by a ring of very wide avenues, the Garden Ring (Sadovoye koltso). As an outermost line of defense, a chain of strongly fortified monasteries was established beyond the ramparts to the south and east, principally the Novodevichy Convent and Donskoy (Don), Danilovsky, Simonov, Novospassky, and Andronikov monasteries, most of which survive today as museums.

Zemlyanoy-gorod

With much improved security, trade and craft manufacture flourished. Distinct quarters were occupied by particular trades; for example, the suburbs of Bronnaya by armour makers, Kuznetskaya by blacksmiths, and Kotelniki by kettle makers. Across the Moskva was the weavers' suburb. These artisan sectors are commonly commemorated today by street or quarter names. State workshops cast cannon and made weapons and gunpowder. The tsar's court and its attendant nobility provided patronage for luxury crafts. Increasingly the boyars took over the Kitay-gorod, with artisans and traders moving to the outer parts; the Kremlin became solely the seat of temporal and ecclesiastical authority. The centre of commercial activity was the market in Red Square between the Kremlin and the Kitay-gorod, where were rows of stalls, each handling a specific variety of goods; the name Red Square derives from the old Russian word for "beautiful." Trade with western Europe (especially England and Holland), as well as with Central Asia, Transcaucasia, Persia, and the Black Sea coast, was brisk, furs forming a major staple in this international commerce. Foreign merchants lived in the Nemetskaya (German) suburb. Many churches were built in the Kitay-gorod and Bely-gorod. Flourishing cultural life was marked by the growth of the book trade and the founding in 1553 of the first printing house.

The opening of the 17th century saw Moscow, like the rest of Russia, suffer severely during the Time of Troubles. In the reign of Boris Godunov there were severe famines from 1601 to 1603. After Boris' death in 1605, the False Dmitry seized Moscow with Polish help, and though he was killed in 1606 and the Poles were driven out, they reoccupied Moscow with a second False Dmitry in 1608–10. In May 1611 the Muscovites attacked the Poles, and the invaders retreated into the Kremlin. Under the energetic leadership of a boyar, Prince Dmitry Mikhaylovich Pozharsky, and a merchant, Kuzma Minin, the Russians forced the Poles to surrender in October 1612.

With the establishment in 1613 of the Romanov dynasty under Michael, relative peace returned to Moscow and with it further economic advance. Nevertheless the conditions of the poor of the town often led to riots and uprisings; such events were nothing new, having occurred also in 1382, 1445, and 1547. In 1648, as a result of an increase in the salt tax, and again in 1662 (the so-called Copper Riots) there were disturbances by artisans, labourers, and tradesmen. The great revolt of Stenka Razin in southern Russia (1667–71) was echoed by unrest in the capital, and in 1671 Razin was executed in Moscow as a warning to its inhabitants. The revolts were put down by the hereditary militia, the *streltsy*, who in 1698, early in the reign of Peter I the Great, themselves revolted and were suppressed only with great slaughter.

Riots and uprisings

Despite the frequent upheavals, however, culture could flourish. Russia's first higher educational institution, the Slavonic-Greek-Latin Academy attached to the Zaikonospassky Monastery in the Kitay-gorod, dates from 1687. In 1701 Peter founded a School of Mathematics and Navigation. The first newspaper in Russia began publication in Moscow in 1703.

The 18th and 19th centuries. The year 1703 saw Peter I the Great begin construction of St. Petersburg (now Leningrad) on the Gulf of Finland, and in 1712 he transferred the capital to his new, "westernized," and outward-looking city. Members of the nobility were compelled to move to St. Petersburg; many merchants and artisans also moved. Both population growth and new building in Moscow languished for a time, but even during Peter's reign the city began to recover from the loss of capital status. Peter himself stimulated economic growth by establishing new factory industries, and private entrepreneurs followed suit. By 1725 there were 32 new factories employing 5,500 workers; 23 of the factories were textile mills, including a crown enterprise making sailcloth. At the same period there were about 8,500 craft workers.

During the 18th century Moscow retained its major role in the cultural life of Russia. In 1755, on the initiative of the great man of letters and science M.V. Lomonosov, Moscow University (now Moscow M.V. Lomonosov State University) was founded, the first university in Russia; a medical and surgical college was opened in 1786. Although serious fires did much damage in 1737, 1748, and 1752, many splendid new buildings appeared, designed by such architects as Giacomo Quarenghi, Vasily Bazhenov, Matvey Kazakov, and Vasily Stasov. Among many outstanding buildings were the beautiful Pashkov House (now part of the Lenin State Library), the old university buildings, the former Senate in the Kremlin, and the former assembly of nobles (now the House of Trade Unions) famous for its Hall of Columns. In 1741 Moscow was surrounded by a barricade 25 miles (40 kilometres) long, the Kamer-Kollezhsky barrier, at whose 16 gates customs tolls were collected; its line is traced today by a number of streets called *val* (rampart, or wall) and by place-names such as Kaluga Zastava (Customs Gate). Industry flourished, and by the end of the 18th century there were about 300 factories in Moscow, more than half of them textile mills. The population grew to 275,000 in 1811.

Moscow University

In 1812 Napoleon invaded Russia; after a bitter 15-hour battle on September 7 at Borodino on the approaches to Moscow, the Russian commander in chief, Gen. M.I.

Kutuzov, evacuated troops and civilians from the city, which was occupied by the French a week later. A fire broke out and spread rapidly, eventually destroying more than two-thirds of all the buildings. Looting was rife. The lack of supplies and shelter and continual harassment by Russian skirmishing forces made it impossible for Napoleon to winter in Moscow, however, and on October 19 the French troops began their catastrophic retreat.

Rebuilding

In 1813 a Commission for the Construction of the City of Moscow was set up, under the direction of the architect Osip Bove. It launched a great program of rebuilding, which included a partial replanning of the city centre. Among many buildings constructed or reconstructed at this time were the Kremlin Great and Armoury (Oruzheynaya) palaces in the Kremlin, the university, the Manezh (Riding School), and the Bolshoi Theatre. Industry also recovered rapidly and continued to develop through the 19th century. In 1837 the Moscow stock exchange was established. The emancipation of serfs in 1861 and the beginning of the railway era with the opening of the line to St. Petersburg in 1851 greatly increased labour mobility, and large numbers of peasants from the villages began moving into Moscow. The population, which had reached 336,000 in 1835, had almost doubled, to 602,000, in 1871 and by 1897 had reached 978,000. Moscow became the hub of Russia's railways, with trunk lines to all parts of European Russia. A ring of main line termini was built, mostly on or near the Kamer-Kollezhsky barrier at the limits of the built-up area. Outside the barrier many new factories, particularly those concerned with textiles, began operation. In the 1890s heavy engineering and metalworking industries also developed. Between 1897 and 1915 Moscow yet again doubled in size, to a population of 1,983,700.

The later 19th century was a period of ostentatious building by public bodies and wealthy private persons, in various imitative "old Russian" styles and the so-called modern style. From this period date the old Town Hall (meeting place of the Gorodskaya Duma, now the Central Lenin Museum), the State Historical Museum, and the Upper Trading Rows (now the State Department Store, GUM).

The growth of an industrial proletariat in Moscow, together with the generally low living standards of the workers, brought growing unrest and strikes. Various revolutionary groups were active. In the Revolution of 1905 a small-scale insurrection took place in Moscow, and an attempt was made to seize the Nikolayev (now Leningrad) station; the revolt was ruthlessly crushed. In 1917, although a Council of Workers' and Soldiers' Deputies was set up in Moscow, the city remained relatively quiet until after the Bolshevik seizure of power in Petrograd (formerly St. Petersburg) on October 25 (November 7, new style), which was immediately followed by fighting in Moscow. Military cadets held out for a time in the Kremlin, but by November 3 (16, N.S.) they were overcome and Soviet power was firmly established.

The Bolshevik Revolution

Moscow in the Soviet period. In March 1918 Lenin and the Soviet government moved to Moscow, which thereby resumed its former status as capital. This status was formally ratified on December 30, 1922, when the first All-Union Congress of Soviets met in the Bolshoi Theatre and passed the legislation setting up the Union of Soviet Socialist Republics. In the civil war period Moscow, like other Soviet cities, suffered greatly, with grave food shortages, loss of population (falling to 1,027,300 in 1920), and reduction of industry. In the years following the final establishment of Soviet power and peace, recovery was swift, and the beginning of the series of five-year plans in 1928 brought great industrial progress. The city's existing plant and labour force formed one of the main springboards for industrialization elsewhere in the Soviet Union. Between the censuses of 1926 and 1939, Moscow once more doubled its population, from 2,029,425 to 4,182,916 (within the 1959 boundaries). Priorities in investment went to industry, and housing construction was very limited; in consequence, exceptional overcrowding of existing housing developed, with extremely high population densities. Living standards in all respects were low.

During World War II, the Germans in late 1941 reached the outskirts of Moscow, less than 25 miles from the Kremlin. Many factories were evacuated, together with much of the government. From October 20 the city was declared to be in a state of siege. Its remaining inhabitants built and manned anti-tank defenses, while the city was bombarded from the air. A desperate counterattack on December 6 threw the German forces back from the outskirts and saved Moscow. The end of the war once more saw a rapid recovery and further growth of the city's economy. By the mid-1950s the housing shortage had reached grave proportions. Within the Garden Ring, population densities in 1959 surpassed 132,000 persons per square mile. Under N.S. Khrushchev a major program of construction was begun. Although some old housing, sometimes single-storied and made of wood, still remains, much has been cleared in renewal schemes, and extensive new suburbs of large apartment buildings have sprung up all round the historic core of the city. In central areas much urban renewal has taken place, and high-rise buildings now dominate the skyline. In 1960 Greater Moscow was created, incorporating into the city a group of adjacent satellite towns. There have been several development plans for Moscow, the first dating from 1935; the General Plan for the Development of Moscow was adopted in 1971. In accordance with Soviet practice of making awards to cities, Moscow has been given the title of Hero City for its part in World War II, two Orders of Lenin, and the Order of the October Revolution.

LAYOUT AND ARCHITECTURE

The pattern of rings and radials that marked the historical stages of Moscow's growth remains evident in its layout today. Successive epochs of Moscow's development are traced by the Boulevard Ring and the Garden Ring (both following the line of former fortifications), the Greater Moscow Ring Railway, and the Moscow Circular Motorway, which is the administrative limit of Greater Moscow. Each concentric zone carries its own particular stamp of function and architectural style.

The Kremlin. The hub of the layout, and today as throughout its history the heart of Moscow, is the fortified enclosure of the Kremlin, the symbol of first Russian and later Soviet power and authority. Its present crenellated red brick walls and 19 towers were built at the end of the 15th century. Of the most important towers, the Spasskaya (Saviour's) Gate Tower leading to Red Square was built in 1491 by Pietro Solario, who designed most of the main towers; its belfry was added in 1624–25 by an Englishman, Christopher Galloway. The chimes of its clock, dating from 1852, are broadcast by radio as a time signal to the whole Soviet Union. Also on the Red Square front is the Nikolskaya Tower, built originally in 1491 and rebuilt in 1780. The two other principal gate towers lie on the western wall, the Troitskaya (Trinity) Gate, with a bridge and outer barbican (the Kutafya Tower), and the Borovitskaya Gate.

Kremlin gate towers

Within the walls is one of the most striking and beautiful architectural ensembles in the world. Around the central Cathedral Square are grouped three magnificent cathedrals, superb examples of Russian church architecture at its height in the late 15th and early 16th centuries. The white stone Cathedral of the Assumption (Uspensky Sobor) is the oldest, built in 1475–79 by the Italian Aristotele Fioravanti in the Italianate-Byzantine style and modelled on the Cathedral of the Assumption in Vladimir. Its pure, simple, and beautifully proportioned lines and elegant arches are crowned by five golden domes. The interior frescoes and paintings of the iconostasis date from the 17th century. The Orthodox metropolitans and patriarchs of the 14th to 18th century are buried here. Across the square is the Cathedral of the Annunciation (Blagoveshchensky Sobor) built in 1484–89 by craftsmen from Pskov; although burned in 1547, it was rebuilt in 1562–64. Its cluster of chapels is topped by golden roofs and domes. Inside are a number of early 15th-century icons attributed to Theophanes the Greek and to Andrey Rublyov, the greatest of all Russian icon painters. The third cathedral, the Archangel (Arkhangel-

sky), was rebuilt by Alevisio Novyi in 1505–09; in it are buried the tsars of Russia up to the founding of St. Petersburg.

Just off the square stands the splendid, soaring, white bell tower of Ivan III the Great; built in the 16th century and destroyed in 1812, it was rebuilt a few years later. At its foot is the 200-metric ton Tsar Bell (Tsar Kolokol), cast in 1733–35 but never rung; in the fire of 1737 it fell from its scaffolding and a fragment weighing 11.5 tons broke off. It is 20 feet (6.1 metres) high and 22 feet (6.6 metres) in diameter. Nearby is the Tsar Cannon (Tsar Pushka), cast in 1737 but never fired for fear of explosion; intended to project one-ton cannonballs, it has a calibre of 35 inches (89 centimetres) and weighs 40 tons. Beside the gun is the Cathedral of the Twelve Apostles (Dvenadtsati apostolov), built in 1653–56, and the adjoining Patriarch Palace.

On the west of Cathedral Square is a group of palaces of various periods; the Palace of Facets (Granovitaya Palata)—so called from the exterior finish of facetted, white stone squares—was built in 1487–91. Beside it is the Terem Palace of 1635–36, which incorporates the Church of the Nativity of Our Lady, dating from 1393.

Kremlin Great Palace

Both abut on the Kremlin Great Palace, built as a royal residence in 1838–49 by Konstantin Thon and today used for sessions of the Supreme Soviet of the U.S.S.R.; its long, yellow-washed facade dominates the river front. It is connected to the Armoury (Oruzheynaya) Palace, built by the same architect in 1844–51 and now the Armoury Museum, housing a spectacular collection of treasures of the tsars. Along the northeast wall of the Kremlin is another group of buildings, including the Arsenal (1702–36) and the former Senate building (1776–88), designed by M.F. Kazakov and now housing meetings of the Council of Ministers. The one modern building within the Kremlin is the Palace of Congresses (1960–61), with a vast auditorium, seating 6,000, used for Communist Party congresses and as a theatre.

The Kitay-gorod. Along the east wall of the Kremlin lies Red Square, the ceremonial centre of the capital and scene of the May Day and October Revolution parades. Beneath the walls stands the squat bulk of the Lenin Mausoleum. At the southern end of Red Square is the Intercession (Pokrovsky) Cathedral, or Cathedral of St. Basil the Blessed. Built by the architects Barma and Posnik Yakovlev in 1554–60 to commemorate the defeat of the Tatars (Mongols) of Kazan and Astrakhan by Ivan IV the Terrible, it is a unique and magnificent architectural fantasy, each of its 10 domes differing in design and colour. Along Red Square facing the Kremlin is the State Department Store, GUM, in the revivalist imitation "old Russian" style; in the same style is the slightly earlier State Historical Museum (1875–83) closing off the northern end of the square.

Many old churches survive along the narrow streets of the Kitay-gorod. Of particular note are the Church of the Trinity (1628–34) in Nikitniki, the 15th-century Church of St. Anne of the Conception, and the cathedral (1812) of the former Epiphany Monastery (1693–96) in the so-called Moscow Baroque style. Much of the Kitay-gorod near the river was demolished in the 1960s to make room for the huge square block of the Rossiya Hotel, with its accommodations for 6,000 guests. Along the northern front of the hotel is a row of preserved ancient buildings, including the Church of St. Barbara (1794) and the 16th-century house of the Romanov boyars. East of the hotel is a surviving section of the Kitay-gorod wall; another section with a tower can still be seen in the northeast corner of the Kitay-gorod, near Marx Prospekt.

The inner city. In the remainder of the central part of Moscow, within the Garden Ring, are buildings representative of every period of Moscow's development from the 15th century to the present day. Scattered through the inner city are several fine examples of 17th-century church architecture, notably the Church of All Saints of Kulishki, built in the 1670s and '80s to replace a 14th-century edifice, and the Church of the Nativity of Putniki (1649–52). This was the period of development of the Moscow Baroque style, well represented in the Church of the Trinity in the former Sheremetyev estate, which dates from the end of the 18th century. Buildings of the Classical period, beginning about the middle of the 18th century and covering the rebuilding of Moscow after the fire of 1812, abound within the Garden Ring. Notable examples are the old university and the former assembly of nobles with its Hall of Columns (now the House of Trade Unions), both built by Kazakov in the 1780s; Bazhenov's elegant Pashkov House (1785–86); the former Merchants' Court (Gostiny Dvor), designed by Quarenghi and built in 1790–1805; the State Pushkin Museum of Fine Arts (1814); the Manezh (1817), which is now used as an exhibition hall; and the magnificent Bolshoi Theatre (1821–24), rebuilt by A. Cavos in 1856 after a fire. Toward the end of the 19th century and continuing into the early 20th century, buildings in the revivalist "Old Russian" style, often more quaint than beautiful, were built, including the State Department Store and State Historical Museum on Red Square, the State Tretyakov Gallery (1906), and the former Morozov mansion, now the House of Friendship (1894).

In the Soviet period much of the old, dilapidated part of the inner city has been swept away and replaced by large office and apartment buildings. Side by side with the old appeared new buildings in the modern, functional style of the 1920s and '30s, in the ponderous, often over-ornate style of the later Stalin period, and in the high-rise concrete and glass of the 1960s and '70s. Cheek by jowl with the Pashkov House stands the severe main building of the Lenin State Library (1927–29). Among more interesting and imaginative examples of later architecture is the Rossiya Cinema (1960–61) in Pushkin Square.

In general, however, the Soviet period has added little of outstanding architectural merit to the central areas of Moscow, but it has created far more space, with wide, new squares such as the Square of the 50th Anniversary of October (formerly Manezhnaya Square) permitting the older buildings to be seen far more effectively. Many streets have been widened, in particular Gorky Street, now one of Moscow's principal radial roads, lined with large shops, hotels, and offices. The Garden Ring itself has been widened to form a broad inner ring motorway, with up to four lanes in each direction and with overpasses where it is intersected by the main radial routes. In the 1960s a new radial street, Kalinin Avenue, was driven through an area of poorer housing westward from the Kremlin to the Moskva River. The showpiece of the modern city, it is lined by high-rise office and apartment buildings, linked at street and second-floor levels by a shopping mall. At its outer end rises the lofty, three-winged Comecon (Council for Mutual Economic Assistance) building overlooking the river. Beside it a new Council of Ministers building was under construction in the mid-1970s. Although most of the historic buildings of central Moscow have been preserved, and the 1960s and '70s in particular have seen much careful restoration and repair, some architectural monuments disappeared in the early Soviet period. Where before the Revolution the Cathedral of the Saviour stood, near the river just above the Kremlin, there is now a vast open-air swimming pool.

Kalinin Avenue

Inner Moscow has the functions typical of a central business district. Here are concentrated most of the government offices and central administrations of state bodies, most of the hotels and larger shops, and the principal theatres, museums, and art galleries. But the function of residence has not been squeezed out; the many very large apartment buildings of modern times have ensured a large population continuing to live in the centre. Moscow has no dead heart, empty of people at night. Also, a number of industries remain within the Garden Ring.

The middle zone. Beyond the Garden Ring and approximately as far as the Ring Railway lies a zone mostly of late 18th- and 19th-century development. Within it are many factories and the principal railway stations and freight yards. The Likhachyov automobile works, with its associated housing, occupies much of the southeast sector. Enveloped within this zone are further examples of the

Kalinin Avenue in Moscow, with administrative offices (left), apartment houses (right), and the Ukraina Hotel in the background.
V. Yegorov—Tass from Sovfoto

best of Classical Moscow, such as the 18th-century palace that now houses the Presidium of the Academy of Sciences of the U.S.S.R. on Lenin Avenue. Also to the southwest, on the banks of the Moskva, are the most important of the fortified monasteries, the 16th-century Novodevichy Convent, with its beautiful Smolensk Cathedral, whose tall bell tower (1690) dominates the churches and buildings within the crenellated walls and towers of the convent. The cathedral now houses the Novodevichy Convent Museum, and the complex includes a cemetery where, among other prominent Soviet citizens, Khrushchev is buried. Just beyond Novodevichy, within the large loop of the Moskva and facing the Lenin Hills, is the sports complex known as Luzhniki Park, dominated by the huge Central Lenin Stadium (1955–56), built to accommodate 103,000 spectators.

Novodevichy Convent

The middle zone has seen the most urban renewal in Soviet times. Among the features of the present Moscow skyline are the ornate "wedding cake" skyscrapers along the Garden Ring, built in the late 1940s and early 1950s. In the same Stalin period style are the Ukraina Hotel across the river and the gigantic new building in the Moscow State University complex on the Lenin Hills. Most of the renewal has taken place since 1960 in extensive neighbourhoods of wide streets and rather monotonous apartment buildings. A number of areas still await redevelopment, with narrow streets of 19th-century housing, many smaller factories, and air pollution higher than average.

Outer Moscow. This is the zone of modern factory development and of extensive housing construction in the 1960s and '70s. Closer to the centre are the micro-regions, or neighbourhood housing units, of the Khrushchev period, built predominantly of yellowish brick and in five- to nine-story apartment buildings. Farther out, the 1970s neighbourhoods are characterized by high-rise buildings (up to 20 or more stories), made of standardized, prefabricated concrete sections. Commonly the street levels of the buildings are occupied by shops. Streets are broad and tree-lined. Between the densely populated micro-regions are "green wedges" of open land, notably the extensive Izmaylovsky Park in the east, Sokolniki Park and large forest tracts to the northeast, and on the north, in Dzerzhinsky Park, the grounds of the permanent Exhibition of National Economic Achievements. Nearby, at Ostankino, is the television tower of the 1960s, 1,758 feet (536 metres) tall.

In the sea of new building, individual monuments of the past, such as the Church of the Intercession in Fili, built in 1693, survive. Moscow has engulfed a number of former country estates, with mansions mostly dating from the period of Classical architecture. On the east side of Moscow is Kuskovo, once the estate of the Sheremetyev family, with a palace built in the 1770s, a church, hermitage, and Baroque grotto. To the south is the Znamenskoye-Sadki mansion, formerly of the Trubetskoy family; to the north are the Petrovsky Palace (built by Kazakov in 1775–82) and, best known of all, the Ostankino Palace (1790–98). In the southeastern suburbs is the former village of Kolomenskoye, once a summer residence of the princes of Moscow. Its most remarkable architectural ensemble of buildings is dominated by the Church of the Ascension (1532). The Kazan Church and the gatehouse both date from the later 17th century. The surrounding park has a collection of examples of early Russian wooden architecture, brought from various parts of the country. In the nearby village of Dyakovo is the ornate Church of St. John the Baptist, built in 1557.

Beyond the most recent suburbs are remaining areas of open land and forest within the Circular Motorway, together with satellite industrial towns and dormitory suburbs, which were included within the extended boundaries of Greater Moscow in 1960. The principal satellites are Babushkin to the north, with textile mills and a large number of commuters, Perovo to the east, with major marshalling yards and engineering and chemical factories, Lyublino to the southeast, Kuntsevo to the west, and Tushino to the northwest. One part of Moscow lies beyond the Circular Motorway; this is the overspill town of Zelenograd, a new town of the 1960s modelled on the lines of the British New Towns built around London after World War II. Population and industry from the capital were moved north to Zelenograd; in 1975 it had 117,000 inhabitants.

Satellite towns

POPULATION

The program of housing construction since the late 1950s has greatly reduced the excessive population densities of central Moscow, but densities are nevertheless still high, largely as a consequence of the construction of high-rise apartment buildings. Within the Garden Ring the average density in the early 1970s was more than 76,000 persons per square mile (29,000 per square kilometre). This was higher than the overall density for Manhattan (about 69,000 per square mile). Even Greater Moscow, including large areas of park, forest, and other open land, has an overall density exceeding 20,000 persons per square mile (7,700 per square kilometre), lower than the overall density of New York City (about 26,000 per square mile). Moreover, the constant influx of people into the capital steadily, if slowly, increases these figures. A considerable proportion of the inhabitants are first-generation Muscovites, born outside the city. For most of the Soviet period there has been a deliberate attempt to check the growth of Moscow's population by rigid restrictions on the number of police residence permits granted. This policy has not been altogether successful. On the one hand, it has caused a recurrent labour shortage in the city, by no means made good by developments in automation; on the other hand, it has only checked, but not stopped, inmigration. During the 1970s Moscow's population was growing by more than 100,000 persons each year; of this number, less than 20,000 came from natural increase (*i.e.*, the excess of births over deaths), leaving an excess of arrivals over departures totalling some 80,000–90,000 annually. In addition, there is an unknown number of illegal, unregistered arrivals. This increment puts additional demand on housing.

Population imbalance

The population, in common with that of the Soviet Union as a whole, displays a marked imbalance of males and females. In 1976 there were 774,000 more females than males in Moscow, males constituting 45 percent and women 55 percent of the total. In large measure the imbalance is one of the long-term consequences of losses of men in World War II and other periods of population decimation. In terms of age groups, the able-bodied groups (age 20–60) and more particularly the fertile age groups (20–40) form a larger share of Moscow's population than in the Soviet Union as a whole. Yet the birth rate in the city (12.5 per thousand during 1971–75) is one of the lowest in the country; in 1967 it was only 10.5. At the same time the death rate is slowly and steadily rising, from 8.5 per thousand in the mid-1960s to 10 in 1975, a figure higher than the national average. In consequence, the rate of natural increase is extremely low, 2.5 per thousand in 1975, the lowest figure for any major city in the Soviet Union. At the same time the proportion of the population over retirement age is slowly growing, while the proportion of young people (under 20 years old) is far below the national average (24.8 percent for Moscow, as against 38 percent for the nation). This disparity is widening and is most marked in the under-10 age group.

The inhabitants are overwhelmingly Russian, 89.2 percent in 1970. Jews then formed 3.6 percent, Ukrainians 2.6, and Tatars 1.6. No other group formed more than 1 percent, but, as expected in the capital of a multinational state, the remainder include representatives of the more than 100 nationalities within the country.

ADMINISTRATION AND GOVERNMENT

In the period after the Revolution, Moscow was divided into 11 administrative districts, or wards. With the creation of Greater Moscow in 1960 the number of administrative units was increased to 17 *rayony* (districts; singular *rayon*). The subsequent huge building program and redistribution of population from central areas to the suburbs necessitated a new division in 1968 into 29 *rayony*. The *rayony* tend to be wedge-shaped, pointing in toward the city centre, with an inner ring of 13 *rayony* and an outer ring of 16. The *rayony* vary in population from some 140,000 to 340,000, the inner *rayony* usually being somewhat smaller in population and much smaller in area than the outer. Zelenograd forms a separate, 30th *rayon* of the city. The *rayony* elect a total of 1,160 delegates to the Moscow City Soviet of Workers' Deputies (Mossovet), which has its headquarters on Gorky Street. The council handles the city's annual budget, which is chiefly derived from central government funds. Since Moscow is a "city of republic subordination," the City Council is responsible to the government of the Russian S.F.S.R. rather than to a smaller administrative unit.

Twofold capital

Moscow is a twofold capital, of the U.S.S.R. as a whole, and of the Russian S.F.S.R., which comprises about three-fourths of the area of the Soviet Union. Although the centre of national government is the Kremlin, which houses the meetings of the Presidium of the Supreme Soviet and party congresses, the buildings of various ministries and government departments are scattered fairly widely over the inner city. The Ministry of Foreign Affairs is in a skyscraper of the Stalin period on Smolensk Square on the Garden Ring. Several ministries are housed in the new tower buildings on Kalinin Avenue. The new Comecon and Council of Ministers buildings (at the latter of which the council's Secretariat meets) at the outer end of Kalinin Avenue still further disperse the functions of government. A number of foreign embassies have been transferred to the southwestern suburbs on the Lenin Hills, far from the city centre. Naturally, Moscow as capital has the headquarters of most national bodies and organizations. The Central Committee of the Communist Party has its headquarters on the east side of the Kitaygorod, facing Staraya (Old) Square.

ECONOMY

Employment. Although Moscow's role in the administration of the Soviet Union is of prime importance, administration as a source of employment in the city is relatively minor, if steadily growing, both absolutely and relatively. In 1960 3.2 percent of the employed population was engaged in administration; by 1975 the figure had risen to 5.0. A further 5 percent in 1975 was employed in matters relating to housing (other than construction) and ancillary services and another 5 percent in the various social services such as health. Education and cultural activities, including entertainment, accounted for 6 percent. For a major city, a notably small proportion of the working population is engaged in retailing and catering, 7.9 percent in 1975. Conversely an unusually large proportion (19 percent) was engaged in science and research. The building trade employed 10 percent, transport and communications 9.5 percent. Industry remains the dominant source of livelihood for Muscovites, although its share of total employment is gradually falling, from 36.4 percent in 1960 to 27.8 percent in 1975.

The imbalance between males and females in the population is reflected in the preponderant role of women in the city's labour force. Overall, women form 56 percent of the total number employed, but in certain occupations their share is far greater—in education and culture 72 percent, in retailing and catering 80, and in health and social services 86. Even in industry, more than half the employees (52 percent) are female. Only in transport and the building trade is their role less important, with in each case slightly more than 30 percent of the labour force.

Industry. Moscow is the largest industrial centre of the Soviet Union. The contribution to the national budget made by deductions from the profits of Moscow's enterprises makes up a fifth of all such deductions in the Soviet Union. In addition, Moscow provides to the national budget a tenth of the total turnover tax. The city is the focus of an extensive area of industrial development, which includes not only Moscow and its satellites but also many other textile and engineering towns that have linkages with the capital. This Central Industrial Region stretches east and northeast to the Volga between Yaroslavl and Gorky. Moscow's own industries are mainly of the kind that require a skilled and educated labour force but relatively limited raw materials and that are nonpollutant.

Central Industrial Region

At the time of the Revolution, Moscow's industry was dominated by textiles, but nowadays engineering and metalworking are by far the most important, employing 56.6 percent of the industrial work force. Pride of place is taken by the production of automobiles and trucks.

Mass housing and woods in southwest suburban Moscow.
I. Denisenko—Novosti Press Agency

The largest plant in the city is the Likhachyov Auto Works. The second automobile works is the Lenin Komsomol Automobile Plant, making some 200,000 small cars of the Moskvich type each year and employing about 17,000 workers. Closely linked with these two plants are a number of factories producing component parts, both elsewhere in Moscow (carburetors, shafts, and bodies) and in other towns of the Central Industrial Region, together with some as far away as the Urals. Ball bearings, both for the vehicle industry and for other purposes, are a product of prime importance; more than 3,000 varieties of bearings are made, the largest weighing six tons. The manufacture of machine tools is another major branch of engineering, particularly grinding lathes at the Red Proletariat Plant, precision cutting tools at the Stankoliniya Plant, and machinery for the textile industry. Precision engineering is highly developed and is Moscow's fastest growing industry; it is noted for measuring and other instruments (especially at the Kalibr and Frezer factories), watches, and platinum needles. Other products include pumps, compressors, ventilators, pressure gauges, and hydraulic units for tractors. Moscow is a large centre of electrical, electronic, and radio engineering; the wide range of items made includes transformers, computers, radio and television sets, refrigerators, vacuum cleaners, and electric motors. Aviation engineering and the manufacture of bicycles are also carried on.

Precision engineering

Some of the specialized, high-grade steels required by this formidable array of engineering industries are made in the city at the Hammer and Sickle Steel Works; specialized steels also come from electric hearths in the satellite town of Elektrostal, 36 miles east of Moscow. More steel comes great distances from the heavy industrial regions of the Donets Basin (Donbass) and the Urals.

Second place in terms of employment is taken by the numerous branches of the textile industry, for which Moscow is the largest centre in the country. This includes the manufacture of all types of cloth, worsted (Krasnokholmsky Kamvolny Complex), cotton (Trekhgornaya Mill), and linen and silk (Red Rose Factory). Nowadays artificial fibres are also made. There is considerable finishing of fabrics at specialized enterprises, as well as production of clothing.

Moscow's large chemical industry, employing some 3.1 percent of industrial workers, was originally geared to the textile industry, producing dyestuffs. To this has been added the making of synthetic industrial rubber and rubber tires, paints, plastics, pharmaceutical goods, and perfumes. Many of its chemical products are derived from Moscow's oil refinery, which processes petroleum piped from the Volga–Urals oil field; the automobile industry is a major consumer of the petrochemical products.

Chemical industry

There is a wide range of consumer goods industries, serving primarily the Moscow region but also a wider hinterland. These include foodstuffs, especially confectionery and processed dairy and meat products. Footwear and pianos are specialties of Moscow. Furniture making is part of a varied timber-processing industry, which also makes pulp and paper. Wood processing employs 3.1 percent of the city's workers. Some of the timber is used in the vast construction industry, workers in which include not only the large numbers actually employed in building but also those engaged in making building components, such as reinforced concrete sections, glass, and bricks. An industry of particular note is printing and publishing. Three-quarters of all books and journals and more than half the newspapers in the Soviet Union are printed in Moscow.

Under Moscow's general plan for development, a number of factories were scheduled to be relocated out of the central areas of the city, especially those factories that cause the most harm to the urban environment. At the same time the location of new industries in Moscow was prohibited. The pressures on industrial ministries to keep up and indeed to increase production year by year, however, have operated against the aims of the plan. By the later 1970s there was only limited evidence of any significant move of industries out of Moscow; exceptions were the manufacture of dump trucks, which moved to Mytishchi, just beyond the Circular Motorway, and of buses,

which shifted to Likino-Dulevo, east of Moscow. Established factories were expanded and new industries brought in, among them the Khromotron Works, making colour television tubes. During the 1970s more than 10,000,000 square feet (930,000 square metres) of production space were brought into operation annually. The majority of Moscow's factories are not large; in 1974, 51 percent of them employed fewer than 500 workers. Many of these smaller works are long established, and many make highly specialized items. The 6.8 percent of factories with more than 3,000 workers account for nearly two-fifths of the city's industrial output by value.

Small factories

Power. Moscow draws on a very wide area for its power supply. Electrical generating stations in the city are now based on natural gas, which is piped from Saratov on the Volga and Gazli in Central Asia, from Stavropol in the North Caucasus, from the Volga–Urals region, and from Shebelinka and Dashava in the Ukraine. Large gas storage facilities have been constructed near Moscow, and a linking ring pipeline surrounds the city. The changeover from coal to natural gas as the principal fuel source has been a major factor in the improvement of the city's atmosphere. To the east of Moscow the large peat resources of the Meshchera Lowland are converted to electricity in stations near Shatura. High-voltage transmission lines (500 kilovolts) supply power from the hydroelectric stations on the Volga at Uglich, Rybinsk, Gorky, Kuybyshev, and Volgograd. Other sources are the very large thermal stations at Konakovo to the northwest and Kashira to the south of Moscow. A by-product of the power industry is hot water, which is piped from the 22 district central stations to apartment buildings for heating and domestic supplies.

Transport. *Rail.* The Soviet Union is heavily dependent for the transport of freight on its railways, which in 1975 carried 62 percent of the total national freight turnover. The hub of this network is the capital, which handles about a tenth of total freight. The large marshalling yards cope with some 450 freight trains daily and about 71,000,000 metric tons of freight each year, of which 54,000,000 tons are incoming. Eleven trunk lines radiate out from the city: the Leningrad line, first to be opened (1851); the Savyolovo line (1902), running north to the Volga and on as a secondary route to Leningrad; the Yaroslav line (1862), which continues on to Kirov, Perm, the Urals, and, by the Trans-Siberian route, to Vladivostok; the Gorky line (1861), also linking to Kirov; the Kazan line (1912), the most direct route to the Urals and Siberia; the Ryazan line (1862), leading to the southern Urals, Central Asia, the lower Volga, and the Caucasus; the Pavelets line (1900), a secondary route to the European south and the Caucasus; the Kursk line (1866), the main route south to Kharkov, the Donbass, and the Crimea; the Kiev line (1898) to the southwest; the Smolensk line (1870) to Minsk, Warsaw, and Berlin; and the Riga line (1911) to the Baltic. The most heavily used of these lines are now electrified—notably those to Leningrad, Kiev, the Donbass, and the Trans-Siberian—and all lines in the suburban zone are electrified to carry the heavy commuter traffic. To link the radial lines the inner Circle Railway was built in 1908 within the city; this has been supplemented by the Greater Moscow Ring Railway at a distance of some 25 to 40 miles from the city.

Passenger trains connect to destinations throughout the Soviet Union and Europe; through coaches run to Berlin, Vienna, Paris, and the Hook of Holland. Several hundred long-distance passenger trains each day move some 170,000 people, and the 1,500 suburban trains carry a further 850,000 persons daily. The period since World War II has seen a marked growth of commuting into Moscow from satellite towns, and by the early 1970s daily commuters numbered about 500,000.

Waterways. Moscow is a major river port. The canalized Moskva can take only smaller craft, but the Moscow Canal, built by forced labour in 1932–37, can take ships of seagoing size. The canal runs from the Moskva, upstream of the city, northward to the Khimki and Ucha reservoirs (the latter linking to the Klyazma Reservoir and the navigable Klyazma River) and thence north through the Klin-Dmitrov Ridge to the Volga at Ivankovo, in all 80 miles (128 kilometres). The Volga's various canal links open up Moscow to all the seas surrounding European Russia. Minimum depth on the Moscow Canal is 18 feet (5.5 metres), and lock dimensions are 950 by 100 feet (290 by 30 metres). The capital has three river ports, the Southern River Station on the Moskva downstream, the Kiev Station upstream, and the Northern River Station on the Khimki Reservoir. River freight turnover is about 29,000,000 metric tons annually. Passengers are catered for by short- and long-distance cruises.

Moscow Canal

Air. Moscow is similarly the hub of the Soviet Union's airline network, and the number of passengers carried is rising steadily year by year. The original Tushino Airport has long been abandoned, but Moscow now has four airports. Sheremetyevo to the north is the main airport for international flights, with direct links to most European capitals, to Cuba, New York City, Montreal, Tokyo, and other foreign cities. Internal flights are handled at Vnukovo, 15 miles to the southwest; at Bykovo, 20 miles to the southeast; and at Domodedovo, the newest and largest, to the south.

Intracity transport. Compared with other large cities in most developed countries, Moscow has very few privately owned cars, though their number is slowly and steadily rising. On the one hand, this means relative freedom from serious traffic problems, while, on the other, it necessitates heavy reliance on public transport. In this respect Moscow is in general well served. In 1975 nearly 5,300,000,000 people were transported, an increase of 25 percent in a decade. The most important element in Moscow's city transport is the Metropolitan (Metro) subway, with 103 stations and some 295 miles of line. It carried 1,966,000,000 passengers in 1975, or almost 5,400,000 each day. The system, begun in 1935, is renowned for the elaborate architecture of its stations, more especially the older ones, which are highly decorated with marble, stained glass, statuary, and chandeliers. One of the stations built later, Lenin Hills, forms the glass-sided lower level of a two-tier bridge over the Moskva. Train service throughout the day is frequent. The network copies the city street pattern, with a series of radial lines linked by a single ring subway.

Subway system

Next in importance are the motor bus services, carrying 1,781,000,000 people in 1975 in more than 5,000 buses on 200 routes. Moscow still relies heavily on streetcars (trams) and trolleybuses, which in 1975 moved 637,000,000 and 910,000,000 passengers, respectively, in some 1,500 streetcars and 2,000 trolleybuses. The inflexibility of these fixed-line forms of transport poses a potential problem as traffic gradually increases.

Although Moscow has for the most part a dense network of surface transport, new routes sometimes tend to lag behind housing construction, so that certain new suburbs are rather poorly served for some time after their completion. On the credit side, fares on all forms of transport are very low and are standard regardless of distance.

Commercial functions. As capital and as the largest city, Moscow not surprisingly is the largest commercial centre of the Soviet Union. The headquarters of nationwide state insurance and state banking organizations are there. Its retailing facilities are heavily used, not only by the inhabitants of Moscow itself and its surrounding satellite towns but also by people from all over the Soviet Union. Its shops are better stocked with a wider range of goods than those of any other city and are always crowded with customers. Yet in comparison with major cities of western Europe and North America, Moscow is poorly provided with retail outlets. In 1976 there were about 10,500 retail outlets in all Greater Moscow (compared with 37,500 in New York City), employing more than 65,000 people (1970). Of these, 5,370 were stalls or kiosks and only 5,150 were shops; the figure 5,370 represented an increase of only 330 over 1966. Many of the stores are fairly large, including some of the central food shops (*gastronomy*) and department stores (*univermagy*). The most important of the 66 department stores are Children's World, the Central Department Store (TsUM), and, best

known and most heavily patronized, the State Department Store (GUM) on Red Square. GUM, the direct descendant of the medieval trading rows, is alone responsible for about 10 percent of Moscow's total retail trade in goods other than foodstuffs. Moscow does not have shopping centres with local concentrations of retailing; the usual practice is for shops to be widely dispersed on the ground-floor levels of apartment buildings, which tends to add to the time taken up by shopping. A very important part of Moscow's retail trade is carried on at the "collective markets," where collective farms and individual members of such farms bring fruit, vegetables, and meat for direct sale to the populace; although often more expensive than the state shops, they tend to excel in quality and availability of produce.

There are almost 7,800 eating places in Moscow, but most are canteens in places of work, as are most of the 2,300 cafés, buffets, and snack bars; there are 355 restaurants, including those in hotels. As the capital and as the principal focus for foreign tourists, Moscow has always a number of transient inhabitants, but hotel accommodation is rather limited for so large and important a city. In 1975 there were 25 public hotels with places for 33,361 people, with accommodation for another 14,000 in hotels run by the armed services and other bodies for their own personnel. Leading hotels include the huge, modern Rossiya, the Ukraina (one of the Stalin period skyscrapers), and the pre-Revolutionary National and Metropole. In the late 1970s plans were being put into effect for a considerable increase in hotel accommodation to meet the expected influx of visitors for the Olympic Games in 1980; the plans include a very large hotel at Ostankino in the north.

Hotels

EDUCATION, CULTURAL LIFE, AND SOCIAL SERVICES

Education. Moscow has an exceptionally large concentration of educational establishments. At the lowest level, serving the city's own population, are more than 1,050 schools with more than 850,000 pupils (1975–76). Of these, 65 are for handicapped children, some 75 are special foreign language schools, and 36 are boarding schools. For children below school age (seven years old in the Soviet Union) there are about 1,300 nurseries and kindergartens accommodating 156,000 children; many are attached to individual places of work. Moscow's 76 higher educational institutions draw students from all over the Soviet Union, totalling 635,200 in 1975–76. Nearly 44 percent of the students were registered for correspondence courses. Although six out of every seven were Russians, the total included representatives of almost every nationality in the Soviet Union, together with a number of overseas students.

Leading place is taken by the Moscow M.V. Lomonosov State University, founded in 1755 and in 1975–76 having more than 26,000 students, of whom approximately a tenth are from foreign countries. Of its 17 departments, some of the humanities are still housed in the old university buildings facing the Square of the 50th Anniversary of October, near the Kremlin. Science departments are located in the complex of buildings on the Lenin Hills, which date from the early 1950s and are dominated by a huge 34-story Stalinesque skyscraper; this building houses the central administration, three departments, the Museum of Earth Science, and accommodation for thousands of students. In 1970 a new humanities building was constructed on the Lenin Hills site. From 1960, students from African, Asian, and Latin-American countries were segregated in Moscow's newly founded second university, the Patrice Lumumba People's Friendship University, which now has about 7,500 students, including Russians.

Of the many specialist higher educational foundations, outstanding importance attaches to the Moscow Timiryazev Academy of Agriculture in the north of Moscow and the world-famous Moscow P.I. Tchaikovsky State Conservatoire, where many of the world's finest musicians received their training. Also important are the Moscow D.I. Mendeleyev Institute of Chemical Technology, the Moscow N.E. Bauman Higher Technical School, and the State A.V. Lunacharsky Institute of Dramatic Art. Many institutes, among them the Moscow Institute of Aviation Technology and the All-Union Extra-Mural Institute of Railway Engineers, produce specialists for particular industries.

Heading Moscow's libraries is the State V.I. Lenin Library of the U.S.S.R., the principal copyright library of the Soviet Union and one of the world's largest. Some 40,000 different books are published annually in the city (in all, nearly 1,200,000 copies), together with nearly 3,600 journals.

Lenin Library

Scientific research. In addition to the large volume of research undertaken in the university and in other teaching establishments, there is a formidable array of scientific research institutions. Between them they constitute the second largest employer in Moscow after industry, with 17.6 percent of the total employed population and including some 234,000 scientists. More than a third of all Soviet citizens holding the doctor of science degree are employed in Moscow. The main focus of research is the Academy of Sciences of the U.S.S.R., the Presidium of which is located on Lenin Avenue. There are also national academies of arts and medical, pedagogic, and agricultural sciences.

Many scientific institutes, such as the Experimental Research Institute of Metal-Cutting Machine Tools, are concerned with highly specialized industrial research. These are often connected closely with Moscow's own industries, as in the case of the Central Research Institute of Automobile Engineering. Linked to the research bodies are the many design bureaus, such as the All-Union Planning, Surveying, and Scientific Research Institute, which designs hydroelectric power projects, and the State All-Union Institute for the Planning of Metallurgical Plants.

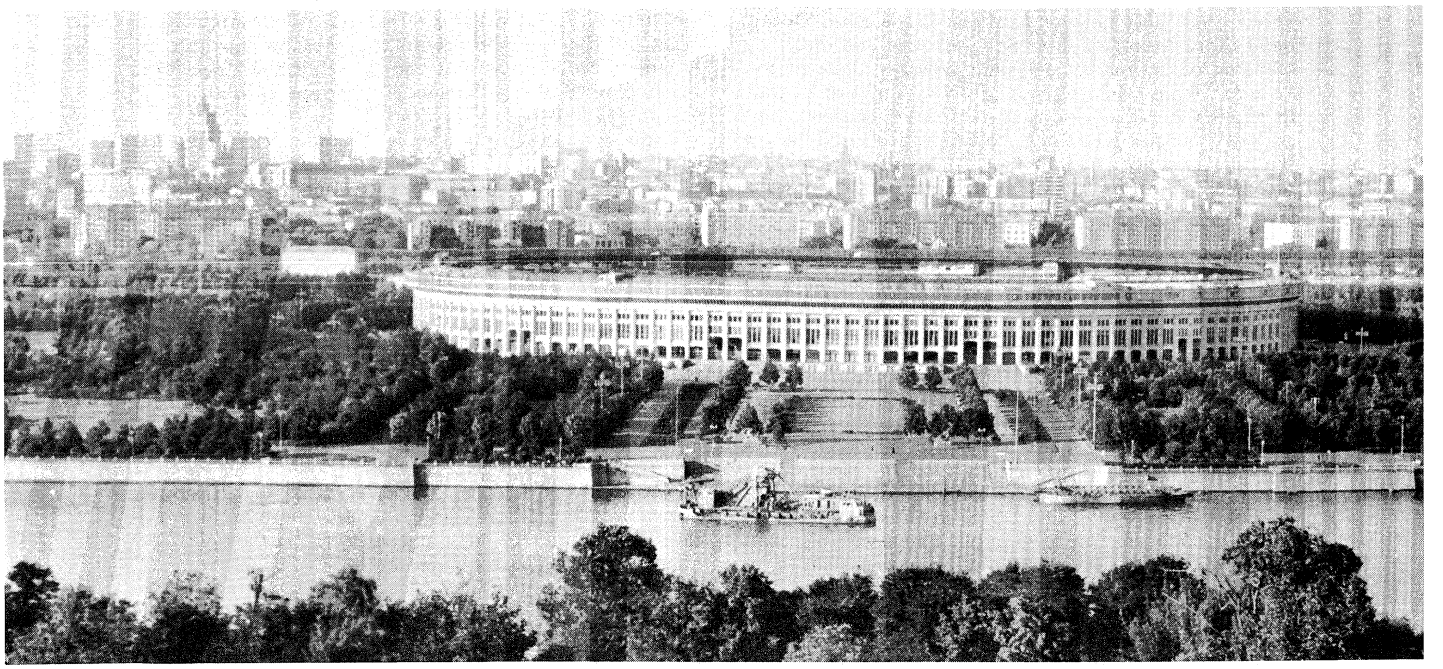
Entertainment. Moscow has 28 theatres, headed by the justly renowned State Academic Bolshoi (Great) Theatre, which was founded in 1825, though its present splendid building facing Sverdlov Square dates from 1856. Also on Sverdlov Square is the Maly (Little) Theatre. The city's principal drama theatre, the Moscow Art Theatre, is particularly noted for its productions of Chekhov and other classical playwrights; founded in 1898, it is especially associated with the name of K.S. Stanislavsky. Also of worldwide fame are the State Central Puppet Theatre and the Moscow State Circus, which in 1971 acquired new quarters on the Lenin Hills. The resident companies of all these theatres are frequently on tour, both in the Soviet Union and abroad. There are several concert halls, notably the Tchaikovsky Concert Hall and the two halls of the Conservatoire. The U.S.S.R. State Philharmonic Orchestra has won international repute, as have a number of Moscow-based folk dance and choral ensembles.

Moscow has 119 cinemas, with further facilities for showing films in several hundred clubs and houses of culture. The October and Rossiya cinemas are the largest in the Soviet Union, both with seating for more than 2,800. There are three studios producing motion pictures in the city. Four television channels are available, the main studios being at Ostankino near the soaring television tower. Moscow radio broadcasts not only in Russian but also in many of the other languages of the Soviet Union and in more than 60 foreign languages. There are 34 newspapers, headed by the two principal national newspapers, the morning *Pravda* and evening *Izvestiya*.

Cinema

Museums and galleries. The 65 museums and art galleries in the capital include several of international rank. In first place are the State Pushkin Museum of Fine Arts, with a very fine international collection, and the State Tretyakov Gallery. The latter, which began in 1856 as the private collection of a connoisseur, Pavel Tretyakov, is noteworthy for its superb collection of icons, including several by Rublyov. Other notable museums are the Armoury Museum in the Kremlin, the State Historical Museum on Red Square, and the nearby Central Lenin Museum on Revolution Square.

Recreation and health facilities. The Luzhniki Park complex heads Moscow's provision for sports and is intended to form one of the main arenas for the 1980 Olympic Games. The Central Lenin Stadium, accom-



Central Lenin Stadium, as seen from the Lenin Hills in Moscow.
Novosti Press Agency

modating 103,000, is flanked by a smaller arena, swimming pool, and indoor Sports Palace. Altogether there are nearly 70 stadiums in the city and 26 swimming pools, including a large, heated, open-air pool that is in use all year round. In addition there are some 290 soccer fields, 1,200 gymnasiums, and nearly 1,600 volleyball and basketball courts; most of these are attached to individual places of work or to sports clubs.

Parks

Outside the Garden Ring, Moscow is well provided with parks and open spaces. Gorky Central Park of Culture along the right bank of the Moskva is the closest to the centre and, with its fun fair, is very popular. By far the largest park, covering nearly 3,000 acres (1,200 hectares), is Izmaylovsky Park on the east side. To the northeast is the more formal Sokolniki Park, which leads on to an extensive tract of forest. North of the city are the Botanical Gardens of the Academy of Sciences and the grounds of the Moscow Timiryazev Academy of Agriculture. The Moscow Zoo, one of the world's leading zoos, is visited by more than 3,800,000 people every year. The Khimki Reservoir is used for boating and aquatic sports, but even more popular are the other reservoirs to the north, just outside Greater Moscow. The surrounding forest–park zone provides extensive space for recreation.

The health of the Muscovites is attended to at the neighbourhood level by almost 1,000 polyclinics, giving medical, dental, and maternity services. There are 193 hospitals, with a total of 93,500 beds, the largest being the Botkinskaya Hospital with 2,650 beds. Among specialist institutions are 21 maternity, 12 isolation, 16 mental, and 7 tuberculosis hospitals, supported by a number of specialist medical research institutions.

OUTLOOK

Development plan

The General Plan for the Development of Moscow published in 1971 covers the next 30 years. It assumes that by the year 2000 Moscow will have a stable population of about 8,500,000. Further housing construction will continue to be based on the micro-region neighbourhood unit but will provide more advanced services; there will be more variety in building styles, but emphasis will still be placed on high-rise buildings. The micro-region will be fitted into a more clearly defined functional structure. To this end the plan envisages eight city zones, a central zone and seven peripheral zones, each with local administrative, retailing, and entertainment functions. Dilapidated areas in the central zone, which serves the entire city area, will be redeveloped, but emphasis will be placed on preservation of its historic character and architectural monuments. The other zones will form wedges of housing and industry, separated by green wedges of open space. Existing plans to prevent new industrial development and to remove noxious factories from the city are retained as features of the plan; the intent will be to spread industry more evenly through the city in order to reduce the length of journeys to and from work. At the same time there will be major improvements to the public transport system, including doubling the length of subway lines, providing express services, and building airport links. Road widening and the building of express highways to cope with projected increases in car ownership also form part of the plan. Much of the plan is concerned with the links between Moscow and its surrounding metropolitan region, which (outside the strictly protected forest–park amenity zone) will take the brunt of future industrial and population growth; it is expected that the population of the surrounding area will double by the end of the century.

Moses

Moses was the gifted Hebrew leader who, in the 13th century BCE (before the Common Era, or BC), delivered his people from Egyptian slavery. In the Covenant ceremony at Mt. Sinai, where the Ten Commandments were promulgated, he founded the religious community known as Israel. As the interpreter of these Covenant stipulations, he was the organizer of the community's religious and civil traditions. In the Judaic tradition, he is revered as the greatest prophet and teacher, and Judaism has sometimes loosely been called Mosaism, or the Mosaic faith, in Western Christendom. His influence continues to be felt in the religious life, moral concerns, and social ethics of Western civilization, and therein lies his undying significance.

THE HISTORICAL PROBLEM

Historical views of Moses. Few historical figures have engendered such disparate interpretations as has Moses. Early Jewish and Christian traditions considered him the author of the Torah ("Law," or "Teaching"), also called the Pentateuch ("Five Books"), comprising the first five books of the Bible, and some conservative groups still believe in Mosaic authorship.

View of Martin Noth

Opposing this is the theory of the German scholar Martin Noth, who, while granting that Moses may have had something to do with the preparations for the conquest of Canaan, was very skeptical of the roles attributed to him by tradition. Although recognizing a historical core beneath the Exodus and Sinai traditions, Noth believed that two different groups experienced these events and transmitted the stories independently of each other. He contended that the biblical story tracing the Hebrews from Egypt to Canaan resulted from an editor's weaving separate themes and traditions around a main character Moses, actually an obscure person from Moab.

This article, following the lead of the biblical archaeologist and historian W.F. Albright, presents a point of view somewhere between these two extremes. While the essence of the biblical story (narrated between Exodus 1:8 and Deuteronomy 34:12) is accepted, it is recognized that during the centuries of oral and written transmission the account acquired layers of accretions. In general, the reconstruction of the documentary sources of the Pentateuch by literary critics is considered valid, but here the sources are viewed as varying versions of one series of events (see BIBLICAL LITERATURE: *Old Testament literature*). Other critical methods (studying the biblical text from the standpoint of literary form, oral tradition, style, redaction, and archaeology) are equally valid. The most accurate answer to a critical problem is thus likely to come from convergence of various lines of evidence. Despite the aid of critical scholarship, the sources are so sketchy that the man Moses can be pictured only in broad outline.

The date of Moses. According to the biblical account, Moses' parents were from the tribe of Levi, one of the groups in Egypt called Hebrews. Originally the term Hebrew had nothing to do with race or ethnic origin. It derived from Habiru, a variant spelling of Ḫapiru (Apiru), a designation of a class of people who made their living by hiring themselves out for various services. The biblical Hebrews had been in Egypt for generations, but apparently they became a threat, so one of the pharaohs enslaved them. Unfortunately, the personal name of the king is not given, and scholars have disagreed as to his identity and, hence, as to the date of the events of the narrative of Moses. One theory takes literally the statement in I Kings 6:1 that the Exodus from Egypt occurred 480 years before Solomon began building the Temple in Jerusalem. This occurred in the fourth year of his reign, about 960 BCE; therefore, the Exodus would date about 1440 BCE.

This conclusion, however, is at variance with most of the biblical and archaeological evidence. The storage cities Pithom and Rameses, built for the pharaoh by the Hebrews, were located in the northeastern part of the Egyptian delta, not far from Goshen, the district in which the Hebrews lived. It is implicit in the whole story that the pharaoh's palace and capital were in the area, but Thutmose III (the pharaoh in 1440) had his capital at Thebes, far to the south, and never conducted major building operations in the delta region. Moreover, Edom and Moab, petty kingdoms in Transjordan that forced Moses to circle east of them, were not yet settled and organized. Finally, as excavations have shown, the destruction of the cities the Hebrews claimed to have captured occurred about 1250, not 1400.

Inasmuch as tradition figured about 12 generations from Moses to Solomon, the reference to 480 years is most likely an editorial comment allowing 40 years for each generation. Since an actual generation was nearer 25 years, the most probable date for the Exodus is about

1290 BCE. If this is true, then the oppressive pharaoh noted in Exodus (1:2–2:23) was Seti I (reigned 1318–04), and the pharaoh during the Exodus was Ramses II (*c.* 1304–*c.* 1237). In short, Moses was probably born in the late 14th century BCE.

YEARS AND DEEDS

The formative years. One of the measures taken by the Egyptians to restrict the growth of the Hebrews was to order the death of all newborn Hebrew males. According to tradition, Moses' parents, Amram and Jochebed (whose other children were Aaron and Miriam), hid him for three months and then set him afloat on the Nile in a reed basket daubed with pitch. The child, found by the pharaoh's daughter while bathing, was reared in the Egyptian court. While many doubt the authenticity of this tradition, the name Moses (Hebrew Moshe) is derived from Egyptian *mose* ("is born") and is found in such names as Thutmose ([The God] Thoth Is Born). Originally,

it is inferred, Moses' name was longer, but the deity's name was dropped. This could have happened when Moses returned to his people or possibly even earlier, because the shortened form Mose was very popular at that time.

The young prince or courtier

Moses' years in the court are passed over in silence, but it is evident from his accomplishments later that he had instruction in religious, civil, and military matters. Since Egypt controlled Canaan (Palestine) and part of Syria and had contacts with other nations of the Fertile Crescent, Moses undoubtedly had general knowledge of life in the ancient Near East. During his education he learned somehow that he was a Hebrew, and his sense of concern and curiosity impelled him to visit his people. According to the biblical narrative, Moses lived 120 years and was 80 when he confronted Pharaoh, but there is no indication how old he was when he went to see the Hebrews. Later Jewish and Christian tradition assumed 40-year periods for his stay in the Egyptian court, his sojourn in Midian, and his wilderness wanderings.

Most likely Moses was about 25 when he took the inspection tour among his people. There he saw the oppressive measures under which they laboured. When he found an Egyptian taskmaster beating a Hebrew, probably to death, he could control his sense of justice no longer. After checking to make sure that no one was in sight, he killed the tough Egyptian overlord. As a prince in the court, Moses was probably in excellent physical condition, and apparently he knew the latest methods of combat.

The flush of victory pulled Moses back the next day. He had removed one threat to his people and was determined to assist them again. This time, however, he found two Hebrews fighting. After parting them, he questioned the offender in an attempt to mediate the disagreement. Two questions jolted him: "Who made you a prince and a judge over us? Do you intend to kill me as you killed the Egyptian?" The confidence of the self-appointed deliverer turned into fear. One of his own knew his "secret" and soon Pharaoh would, too. Realizing that he would have to flee, he went to Midian (mainly in northwest Arabia).

Moses in Midian. In noting the flight to Midian the narrative says nothing of the difficulties involved. Like Sinuhe, the Egyptian court official whose flight in about 1960 BCE was narrated in a famous story, Moses undoubtedly had to filter through the "Wall of the Ruler," a series of forts at the eastern border, approximately where the Suez Canal is now located. From there he made his way southeast through very desolate country. Unfortunately, the Bible does not specify the part of Midian in which Moses resided. Midian proper was east of the Gulf of Aqaba, in the northern section of Hejaz in Arabia, but there is evidence that some of the Midianite clans crossed over the Arabah (the great valley south of the Dead Sea) and settled in the eastern and southern sections of the Sinai Peninsula.

While Moses was resting at a well, according to the biblical account, seven daughters of the Midianite priest Jethro came to water their father's flocks. Other shepherds arrived and drove the girls away in order to water their own flocks. Again Moses showed his courage and prowess as a warrior because he took on the shepherds (perhaps with the girls' help) and routed them. Moses stayed on with Jethro and eventually married Zipporah, one of the daughters. In assuming the responsibility for Jethro's flocks, Moses roamed the wilderness looking for pasture.

The burning bush

One day at the base of a mountain, his attention was attracted by a flaming bush, but, oddly, it was not consumed. He had seen bushes brilliant with flamelike blossoms, but this phenomenon was different, and so he turned aside to investigate it. Before he could do so, he was warned to come no closer. Then he was ordered to remove his sandals because he was standing on holy ground.

Regardless of how one interprets the burning bush, the important fact is that Moses was conscious of an encounter with Deity. This God, who claimed to be the God of Abraham, Isaac, and Jacob, was calling him to deliver the Hebrews from Egypt. Although on his own he had previously been zealous to help his own people, now that he was being commissioned to deliver them he expressed doubt concerning his qualifications. The underlying reason was probably fear—he had fled from Sethos I, and he did not relish confrontation with Ramses II. God reassured Moses that in the future he and the Hebrews would worship at this mountain. Then Moses asked to know the name of the Deity commissioning him. The God of the fathers had been known mostly as El 'Elyon (God Most High) or El Shaddai (God of the Mountain or Almighty God), but he identified himself to Moses as Yahweh and gave instructions that he was to be called by his new name from then on. As the causative form of the verb "to be," Yahweh means He Who Creates (Brings Into Being). This revelation enabled Moses to understand the God of the Hebrews as the sovereign Lord over nature and the nations of the world.

Even after further assurances, Moses was still reluctant to accept Yahweh's call; therefore, he pleaded for release because he was a stammerer. Yahweh acknowledged the defect but promised to help him express himself. Awed by his assignment, Moses made a final desperate plea, "Oh, my Lord, send, I pray, some other person." Although angry at Moses, Yahweh would not yield. Moses would still be Yahweh's representative, but his golden-tongued brother Aaron would be the spokesman. Apparently Moses was ready to play the role of God to Pharaoh as long as Aaron would serve as his prophet. He returned to Jethro and requested permission to visit his people in Egypt, but he did not disclose that he had been commissioned by Yahweh.

Moses and Pharaoh. Ramses II became king as a teenager and reigned for 67 years. He aspired to defeat the Hittites and control all of Syria, but in the fifth year of his reign Ramses walked into a Hittite trap laid for him at Kadesh, on the Orontes River in Syria. By sheer determination he fought his way out, but in the light of his purpose the battle was an utter failure. Yet Ramses, like all the pharaohs, claimed to be divine; therefore, the defeat had to be interpreted as a marvellous victory in which he alone subdued the Hittites. His wounded ego expressed itself in massive building operations throughout Egypt, and before his reign ended the boast of his success literally filled acres of wall space.

Confrontation with Ramses

It was probably only a few years after the Kadesh incident that Moses and Aaron confronted Ramses with their demand, "Thus says the Lord, the God of Israel, 'Let my people go.'" As a god in human form Ramses was not accustomed to taking orders from lesser gods, let alone an unknown like Yahweh. "Who is the Lord," he inquired, "that I should heed his voice and let Israel go? I do not know the Lord, and moreover I will not let Israel go." Thus the stage was set for a long struggle between a distrustful ruler with an outsize ego and a prophet with a new understanding of Yahweh and his power.

Ramses increased the oppression of the Hebrews by the fiendish plan of requiring them to gather the straw binder for the bricks and still produce the same quota each day. Some of the Hebrews rebuffed Moses, and in frustration he asked Yahweh, "Why didst thou ever send me?" Moses' doubt was allayed by Yahweh's promise to take action against Pharaoh. Scholars differ widely concerning the narrative about the plagues. Some claim that three sources have been combined, but more recent scholarship finds only the two traditions. While granting that some of the plagues had a core of historicity, older critics tended to discount the present accounts as fantastic stories with pious decorations. A recent school of research suggests that, notwithstanding some later additions, all the plagues probably had a historical core.

The basic cause, according to one interpretation, was an unusually high flooding of the Nile. The White Nile originates in the lake region of east central Africa, known today as Uganda. The flow is fairly even throughout the year because of consistent equatorial rains. The Blue Nile, on the other hand, originates in the headwaters of the Ethiopian highlands, and it varies from a small stream to a raging torrent. At the time Moses was bargaining with

Ramses, excessively heavy summer rains in Ethiopia washed powdery, carmine-red soil from the slopes of the hills. Around the Lake Tana region the blood-red torrent picked up bright red algae (known as flagellates) and their bacteria. Since there were no dams at that time, the Nile flowed blood-red clear to the Mediterranean. It probably reached the delta region in August. Thus, this rare natural event, it is held, set in motion a series of conditions that continued until the following March.

During these months Moses used the plagues of the frogs, gnats, mosquitoes, cattle murrain, boils, hail, locusts, and thick darkness to increase the pressure on Ramses. At first the King was adamant. The Hebrews were not the only disgruntled slaves, and, if he agreed to let them go, then other groups would want the same privilege. To protect his building program, he had to suppress the slave rebellion at its outset. Yet he could not discount the effect of the plagues, and grudgingly he began to acknowledge Yahweh's power. As an expedient attempt to restore order, he offered to let the Hebrews sacrifice in Goshen. When this failed, he suggested that they make offerings to Yahweh at the edge of the Egyptian border. Moses, however, insisted on a three-day journey into the wilderness. Pharaoh countered by allowing the Hebrew men to make the journey, but this, too, was rejected. As his final offer Pharaoh agreed to let the people go. He would keep the livestock, however, as the guarantee of their return. Moses spurned the condition, and in anger Pharaoh drove him out. After nine rounds with Pharaoh it appeared that the deliverance of the Hebrews was no nearer, but, in contrast to his earlier periods of doubt and frustration, Moses showed no despair. Apparently he had an inner assurance that Pharaoh would not have the last word.

From Goshen to Sinai. Chapters 11–14 of Exodus comprise an exceedingly complex section, and at times the traditions have contradictory statements. The drama is more blurred than usual, and scholars vary tremendously in their interpretation of the material. One tradition notes that Pharaoh was shaken when death took his son and that he ordered the Hebrews to leave. Another source indicates that Moses used the period of mourning for the first-born son as the occasion for fleeing secretly from the country. In either case, it is clear that Pharaoh finally had his forces pursue the Hebrews. Although tradition interpreted the Hebrew text to claim that about 2,000,000 people left Egypt, interpretation by critical methods reduces the number to 15,000 or so.

Yahweh's victory at the Reed Sea

The Egyptian army cornered them at the Sea of Reeds (papyrus), which barred their exit to the east. Later Jewish tradition understood the body of water to be the Red Sea, and this erroneous interpretation persists today, even in some of the most recent English translations of the Bible. Scholars disagree as to the precise location of the Reed Sea, but, since papyrus grows only in freshwater, it was most probably a shallow lake in the far northeastern corner of Egypt.

Hemmed in by the Egyptians, the people vented their complaints on Moses. According to one tradition, Moses shared their uneasiness, and he called to Yahweh for help. Another account claims that Moses confidently challenged them to be calm and watch for Yahweh's deliverance. A strong east wind blew all night, creating a dry corridor through the lake and permitting the Hebrews to cross. The pursuing Egyptians were destroyed when the waters returned. The timing of this natural event gave the final answer to Pharaoh's arrogant question, "Who is Yahweh?" Safely on the other side, Moses and his sister Miriam led the people in a victory song of praise to Yahweh (Ex. 15:1–21). The style of the poetry is similar to that of 14th-century Canaanite literature, and there is every reason to believe that the poem virtually preserves the original form of the song, with its refrain, "Sing to the Lord, for he has triumphed gloriously; the horse and his rider he has thrown into the sea."

The route of the Hebrews is contested by scholars, but the most likely possibility is the southern route to Jabal Mūsā, the traditional location of Mt. Sinai (Horeb), in the granite range at the southern tip of the Sinai Peninsula. The journey there traversed some very desolate country, and Moses had to contend with bitter complaints about the lack of water and food. Finally, however, he brought the people to "the mountain of God," where Yahweh had appeared to him in the burning bush.

The Covenant at Sinai. During the 14th century BCE the Hittites of Asia Minor made a number of treaties with neighbouring rulers who came under their control. The agreement was not between equals, but between the Hittite king (the suzerain) and a subordinate ruler (the vassal). In the prologue the Hittite ruler described himself as "the great king," the one granting the treaty. Then followed a historical survey of relationships between the Hittite suzerain and his vassal. Special attention to the kindnesses shown the underling by the overlord was intended to remind the vassal of his obligation to abide by the treaty stipulations. The basic requirement was an oath of loyalty. Since Egypt was involved with the Hittites in the international politics of the time, Moses probably learned about the Hittite treaty form during his years in the Egyptian court.

The revelation at Sinai: the Ten Commandments

The appearance of Yahweh in a terrific storm at Mt. Sinai, narrated in chapters 19 and 20 of Exodus, was a revelatory experience for Moses, just as the burning bush had been. Somehow he realized that the Hittite treaty was an accurate analogy of the relationship between Yahweh and the Hebrews. Yahweh had a claim upon them because he had delivered them. The only proper response to his love and care would be a pledge of obedience to his will. Scholars have tended to date the Decalogue (contained in the revelation at Sinai) after the conquest of Canaan, but there is absolutely nothing in these guidelines to indicate their origin in an agricultural context. More likely they were the stipulations in the covenant ceremony at Mt. Sinai.

Because Yahweh was proclaimed the only true God, one of the first commands was appropriately a ban against all other gods. Authorities have debated whether or not this understanding was interpreted as monotheism. Most certainly it was not the philosophical monotheism of later periods, but it was a practical monotheism in that any gods recognized by other nations were under Yahweh's control. Inasmuch as he had brought them into being and authorized their presence in his council, he was Lord over all gods and nations.

Another early command has been taken to mean a ban on making images of other gods, but originally the prohibition applied to representations of Yahweh himself. Worship in the ancient world was unthinkable without some idol or image; therefore, the uniqueness of Moses' restriction is all the more evident. Yahweh is the unimagable Deity who cannot be represented in material forms. Since Yahweh had revealed the meaning of his name to Moses, it was fitting that the Decalogue should also prohibit any magical or unethical use of his name. Undoubtedly the ideas underlying the other commands came from the religious culture of his day, but they were raised to a significantly higher level because of the holy, righteous character of Yahweh. Moses realized that, if the Covenant people were to have a stable, just society, they would have to emulate their God. Concern for his creatures would mean respect for them as persons. Murder, adultery, theft, lying, and covetousness would never be legitimate because they lead to chaos and breakdown of the community. Moreover, inasmuch as Yahweh had been concerned to protect the powerless Hebrews in Egypt, they in turn would have to guarantee justice for the orphans, widows, resident aliens, and any other disadvantaged persons under their jurisdiction.

Interpretations and elaborations

On confirmation of the Covenant, Moses and the people faced the task of living by the stipulations. This called for interpretations of the commands, and so Moses began issuing ordinances for specific situations. Many of these he drew from the case law of his day, but insight as to their selection and application probably came in the "tent of meeting" (a simple sanctuary tent pitched outside the camp), where Yahweh spoke to Moses "face to face, as a man speaks to his friend." Breaches of the Covenant necessitated means of atonement, which in

turn meant provision of a priesthood to function at sacrifices and in worship. In short, the rudiments of the whole Hebrew cult, according to tradition, originated at Sinai. At Jethro's suggestion Moses instituted a system of judges and hearings to regulate the civil aspects of the community. It was at Sinai, perhaps, where the people were organized into twelve tribes.

One of Moses' most remarkable characteristics was his concern for the Hebrews, in spite of their stubborn, rebellious ways. When they reverted to worshipping a young bull (probably made of limestone, instead of gold, as the biblical text says), Yahweh was ready to disown them and begin anew with Moses and his descendants. Moses rejected the offer, however, and later, when pleading for the forgiveness of the people, he even asked to have his own name blotted out of Yahweh's book of remembrance if the Lord would not forgive them.

From Sinai to Transjordan. After leaving Mt. Sinai, Moses faced increasing resistance and frustration, according to the narrative in the book of Numbers. Apparently his virility did not diminish during these years because he took a Cushite woman as his second wife. But Miriam, with the support of Aaron, opposed the marriage. At Kadesh-barnea the pessimistic majority report of the spies who had been sent out to reconnoitre thwarted Moses' desire to march north and conquer the land of Canaan. When he urged the people to reconsider their action they almost stoned him. But here again, according to tradition, Moses interceded for the people with Yahweh, who threatened to destroy them and raise up another and greater nation. In one instance, however, tradition recalled that Moses' anger overrode his compassion. At Meribah, probably in the area of Kadesh-barnea, Moses addressed the complaining people as rebels and struck a rock twice in anger, whereupon water flowed forth for the thirsty people. He had been angry before in defense of Yahweh's name, honour, and cause, but this time his anger stemmed from utter frustration with his contentious people. Although tradition interpreted this lapse as the reason why Yahweh would not permit Moses to enter Canaan, the remarkable fact is that Moses was able to bear up under such continuous pressure.

In Transjordan the new states of Edom and Moab, vassals of the Midianites, rejected Moses' request for passage. He wisely circled east of them and moved north to conquer Sihon, king of the Amorites, and Og, king of Bashan. After Moses permitted some of the tribes to settle in Transjordan, it evoked opposition from the Moabites and their Midianite overlords. They hired the Syrian diviner Balaam to put a curse on the Hebrews, but instead he pronounced a blessing. Some scholars interpret this as proof that Balaam was a convert to Yahwism. If this be true, he must have reverted later on, because the biblical tradition implies that Balaam incited his former employers to weaken the Hebrews by religious seduction. Moses responded to the enmity of the Midianites with a successful holy war against them shortly before his death.

Final conflict against the Midianites

As his last official act Moses renewed the Sinai Covenant with those who had survived the wilderness wanderings. From his camp in the Jordan Valley, Moses climbed to a vantage point on Mt. Pisgah. There he viewed the land of promise. The Hebrews never saw him again, and the circumstances of his death and burial remain shrouded in mystery. Tradition claimed that Yahweh buried him in the valley opposite Beth-peor, the shrine of the people's apostasy.

MOSES THE MAN

Although time undoubtedly enhanced the portrait of Moses, a basic picture emerges from the sources. Five times the narratives claim that Moses kept written records (Ex. 17:14; 24:4; 34:27–28; Num. 33:2; and Deut. 31:9, 24–26). Even with a generous interpretation of the extent of these writings, they do not amount to more than a fifth of the total Pentateuch; therefore, the traditional claim of Mosaic authorship of the whole Pentateuch is untenable. Moses formulated the Decalogue, mediated the Covenant, and began the process of rendering and codifying supplemental interpretations of the Covenant stipulations. Undoubtedly he kept some records, and they served as the core of the growing corpus of law and tradition. In a general sense, therefore, the first five books of the Hebrew Bible can be described as Mosaic. Without him there would have been no Israel and no collection known as Torah.

Moses was a gifted, well-trained person, but his true greatness was probably due to his personal experience of and relationship with Yahweh. This former stammering murderer understood his preservation and destiny as coming from the grace of a merciful Lord who had given him another chance. Moses had an understanding spirit and a forgiving heart because he knew how much Yahweh had forgiven him. He was truly humble because he recognized that his gifts and strength came from Yahweh.

The multiple roles of Moses

Because of the uniqueness of his situation, Moses had to function in a number of roles. As Yahweh's agent in the deliverance of the Hebrews, he was their prophet and leader. As mediator of the Covenant, he was the founder of the community. As interpreter of the Covenant, he was an organizer and legislator. As intercessor for the people, he was their priest. Moses had a special combination of gifts and graces that made it impossible to replace him. Although his successor, Joshua, and the priest Eleazar, the son of Aaron, tried to do so, together they did not measure up to him. Later prophets were great men who spoke out of the spirit that Moses had, but they were not called to function in so many roles. As tradition claimed, he was indeed the greatest of the prophets, and, as history shows, few of mankind's great personalities outrank him in influence.

Mössbauer Effect

The Mössbauer effect is a nuclear process permitting the resonance absorption of gamma rays. It is made possible by fixing atomic nuclei in the lattice of solids so that energy is not lost in recoil during the emission and absorption of radiation.

The Mössbauer effect is one of the important discoveries of the 20th century and has become as useful a scientific tool as nuclear magnetic resonance apparatus or the laser. Since the announcement of its discovery by Rudolf L. Mössbauer in 1958, more than a thousand research papers making use of the principle have been published in fields as diverse as physics, chemistry, metallurgy, and biology. In order to understand the basis of the Mössbauer effect and appreciate its significance it is necessary to understand several fundamental principles.

Doppler shift

General principles. The first is the Doppler shift. When a locomotive whistles, the frequency, or pitch, of the sound waves is increased while the whistle is approaching a listener and decreased as the whistle recedes. The Doppler formula expresses this change, or shift in frequency, of the waves as a linear function of the velocity of the locomotive. Similarly, when the nucleus of an atom radiates electromagnetic energy in the form of a wave packet known as a gamma ray photon it is also subject to the Doppler shift. The frequency change, which is perceived as an energy change, depends on how fast the nucleus is moving with respect to the observer.

The second concept, that of nuclear recoil, may be illustrated by the behaviour of a rifle. If it is held loosely during firing, its recoil, or "kick," will be violent. If it is firmly held against the marksman's shoulder, the recoil will be greatly reduced. The difference in the two situations results from the fact that momentum (the product of mass and velocity) is conserved: the momentum of the system that fires a projectile must be opposite and equal to that of the projectile. By supporting the rifle firmly, the marksman includes his body, with its much greater mass, as part of the firing system and the backward velocity of the system is correspondingly reduced. An atomic nucleus is subject to the same law. When radiation is emitted in the form of a gamma ray, the atom with its nucleus experiences a recoil due to the momentum of the gamma ray. A similar recoil occurs during absorption of radiation by a nucleus.

Resonance absorption

Finally, it is necessary to understand the principles governing the absorption of gamma rays by nuclei. Nuclei can exist only in certain definite energy states. For a gamma ray to be absorbed its energy must be exactly equal to the difference between two of these states. Such an absorption is called resonance absorption. A gamma ray that is ejected from a nucleus in a free atom cannot be resonantly absorbed by a similar nucleus in another atom because its energy is less than the resonance energy by an amount equal to the kinetic energy given to the recoiling source nucleus.

The Mössbauer effect may be defined as recoil-free gamma ray resonance absorption. As a graduate student at the Max-Planck-Institut in Heidelberg, while investigating the scattering of gamma rays from iridium-191 at liquid air temperature, Mössbauer discovered that he had achieved resonant absorption. By using atomic nuclei fixed in the lattice of a crystalline solid so that the whole mass of the solid was involved in the momentum transfer, the recoil energy loss of the nuclei had become negligible. It was Mössbauer's perception of the mechanism that leads to the absence of recoil and Doppler shift that constitutes the essence of his scientific contribution.

Principles of application. By imbedding the same kind of nuclei in two solids, those in one solid being in a radiating or excited state and those in the other being in an absorbing or ground state, it is possible to use gamma radiation from the first solid for resonant absorption in the second. The method is so sensitive that if one solid moves relative to the other with a velocity as small as a tenth of a centimetre per second the resonance is destroyed by the Doppler shift in the gamma ray energy. In this fact lies the usefulness of the Mössbauer effect as a tool of experimental physics. If an energy state of the radiating or absorbing nucleus is disturbed by any external effect, resonance absorption will also be nullified. Then, by varying the relative velocity of the radiating and absorbing solids until resonant absorption is re-established, the precise magnitude of the disturbing effect can be determined.

Apparatus. The Mössbauer effect is usually observed by measuring the transmission of gamma rays from a radioactive source through an absorber containing the same isotope in the ground state. The device used for this experiment is termed a Mössbauer effect Doppler-velocity spectrometer because it utilizes the Doppler shift to scan a region of energy in the vicinity of the energy of the gamma ray itself. A spectrometer utilizing this concept is shown schematically in Figure 1. A radioactive source is

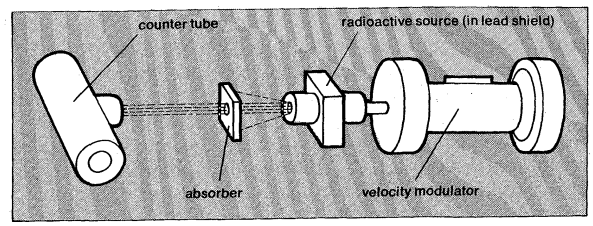

Figure 1: Spectrometer utilizing Mössbauer effect concept. Effect is usually observed by measuring transmission of gamma rays from radioactive source through absorber containing resonant isotope.

mounted on an electromechanical transducer that moves with a well-defined velocity. Generally, velocities of a few centimetres per second are required. The energy of the emitted gamma rays is shifted, due to the Doppler effect, by an amount proportional to the velocity. In this example, nuclei of the radioactive source and the resonant absorber are identical, not having been perturbed by an outside field. The gamma rays pass through an absorber containing the resonant isotope and are detected by a proportional counter. The gamma rays detected per second are plotted as a function of the Doppler velocity, resulting in a Mössbauer effect absorption spectrum like that shown in Figure 2. The drop in counting rate in the

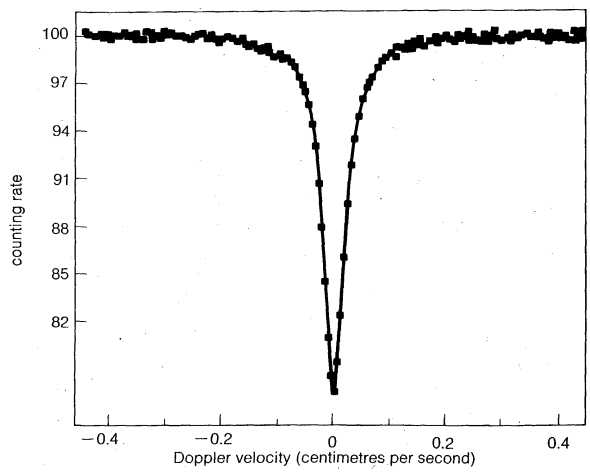

Figure 2: Plot of intensity of gamma ray flux passing through absorber as function of Doppler velocity applied to source. Dip in centre is caused by nuclear resonant absorption (see text).

centre is due to resonant absorption; *i.e.*, the Mössbauer effect. At high positive or negative velocity, the resonant absorption has been destroyed by the Doppler shift.

Isotope suitability. The Mössbauer effect has been observed in more than 35 isotopes. Suitable isotopes must have a stable or long-lived ground state and a low-lying excited state that decays to an appreciable extent by gamma ray emission. The condition on the energy of the excited state arises from need to achieve recoil-free gamma ray emissions. Only if the free-atom recoil energy is small compared to the characteristic lattice vibration energy will there be a finite probability that momentum conservation is satisfied by the recoil of the crystal as a whole with negligible loss of energy. The resulting gamma

ray has the full energy of the nuclear transition and is not broadened by thermal vibrations. It consequently has the exact energy for recoil-free resonant reabsorption by a nucleus in its ground state. The condition on the magnitude of the free-atom recoil energy generally restricts the Mössbauer effect to gamma rays with energy less than 150 KeV. The natural width of a resonance or nuclear level, Γ, is related to its lifetime, τ, by $\Gamma\tau = h/2\pi$, in which h is Planck's constant. The lifetime of the excited state must be greater than 10^{-11} second; otherwise the resonance level would be so broad that the distinction between ordinary and recoil-free emission is lost. The longest useful lifetime is about 10^{-5} sec because the corresponding width is comparable to that due to other mechanisms.

Applications. Mössbauer's discovery has had far-reaching consequences because it has made available electromagnetic radiation (gamma rays) whose frequency is more precisely defined than any other known to date and has provided a new technique for measuring the interaction of nuclei with their environment. Energy resolution better than one part in 10^{12} has been achieved with recoil-free gamma rays. This has made possible experiments in areas as diverse as chemistry, nuclear and solid-state physics, and relativity. Mössbauer received the Nobel Prize in 1961 for his work.

Resolution

The Mössbauer effect has found application in many areas of science. In relativity studies the high precision with which the energy of the gamma ray can be measured has made possible a direct demonstration of the gravitational red-shift; *i.e.*, the change in the energy of a quantum of electromagnetic radiation as it moves through a gravitational field. This was accomplished by measuring the Doppler shift required to compensate for the change in the energy of the gamma ray resulting from a change in vertical position of 2,260 centimetres through the earth's gravitational field. The measured change amounted to 2.5 parts in 10^{15} (a Doppler velocity of 2.7 millimetres per hour) and was in close agreement with theoretical predictions. That is, it was found that a photon of energy E behaves as though it had a mass of E/c^2, in which c is the velocity of light. In a related experiment it was found that the energy of the recoil-free gamma ray decreases with increasing source temperature. This thermal red-shift can be interpreted in a number of ways. It may be viewed as a second-order relativistic Doppler effect resulting from the mean square velocity of the atoms in the solid; *i.e.*, the thermal motion. On the other hand, it can be viewed as a direct demonstration of the relativistic time dilation; *i.e.*, the slowing down of the clock in a moving coordinate system, here the atom, when viewed by a stationary observer. It has been argued that the Mössbauer effect thermal red-shift provides direct experimental resolution of the famous twin paradox of relativity by showing that a space traveller will be younger upon return to Earth than his stay-at-home twin.

Nuclear physics. Applications in nuclear physics are manifold. The Mössbauer effect makes possible the direct measurement of a gamma ray line width, which corresponds to the width of the decaying nuclear level. Results are in close agreement with the measured decay time, indicating that the width of recoil-free gamma rays in fact is determined entirely by the lifetime of the decaying state. The isomer shift, the change in the energy of a nuclear gamma ray due to the electrostatic interaction between nuclear and electronic charge, provides a measurement of the change in the nuclear-charge radius when the nucleus is raised to an excited state. The splitting of nuclear levels into hyperfine components by electric field gradients in crystals of low symmetry or by magnetic fields in ferromagnets makes possible the measurement of nuclear electric quadrupole and magnetic dipole moments. Both isomer shifts and hyperfine structure splittings are readily resolved in Mössbauer spectra. The energy width of a Mössbauer resonance provides a direct measurement of the width of the excited state involved in the gamma ray emission and absorption process. From the width, the lifetime of the excited state can be directly obtained.

Solid-state physics. Applications in solid-state physics fall broadly into the categories of lattice dynamics and hyperfine interactions, although contributions have been made in other areas. The probability that a gamma ray emission process will be recoil free depends on the amplitude of the thermal vibrations compared to the wavelength of the gamma ray. A measurement of the fraction of emission events that are recoil free as determined by their ability to be resonantly absorbed provides the mean square amplitude of the thermal motion in the solid. Using single crystals, the amplitude of the motion can be measured in specific crystallographic directions, providing a stringent test of lattice dynamical models. The thermal red-shift mentioned above gives in addition the mean square thermal velocity.

Magnetic hyperfine interactions have been particularly useful in the study of magnetically ordered materials; *i.e.*, ferromagnets, ferrimagnets, and antiferromagnets. The hyperfine interaction gives an indirect measure of the magnetization of the lattice of magnetic ions and has been used to elucidate the details of magnetic interactions as well as their temperature dependence.

Chemistry. Applications in chemistry are based largely on the isomer shift and quadrupole splitting. The former measures the s-electron charge density at the nucleus and gives information on the character of chemical bonds; *e.g.*, valence and covalence. The latter is sensitive both to the symmetry of the structural environment and to the wave function of the outer electrons of the atom containing the Mössbauer nucleus. The technique has been applied to the study of metal-organic compounds of tin and iron, including hemoproteins; to inorganic compounds of iron, tin, iodine, and the rare earths; as well as to clathrates, catalysts, and glasses containing dilute Mössbauer isotopes.

Theory. The emission of a gamma ray by a nucleus is governed by the physical laws of conservation of momentum and energy. The former requires that the recoil momentum of the nucleus, p, be equal to that of the gamma ray, E/c, in which c is the velocity of light. This gives the free-atom recoil energy, $E_R = p^2/2m$, as being $E^2/2mc^2$. Conservation of energy then requires that the energy of the gamma ray be equal to the energy available in the nuclear transition minus the recoil energy.

Energy calculation

The fraction of total energy lost in recoil is somewhat small, ranging from two parts in 10^8 to one part in 10^6 for isotopes that can be used in Mössbauer experiments. This recoil-energy loss is, however, much greater than the natural width of resonant absorption, so that gamma rays emitted from the nuclei of free atoms with recoil are not resonantly absorbed. Characteristic values of the fractional width Γ/E for natural widths range from one part in 10^{14} to one part in 10^9. The recoil-free process that is fundamental to the occurrence of the Mössbauer effect takes place only for atoms bound in solids and viscous liquids. In the classical sense, one may think of momentum conservation as being satisfied by the recoil of a macroscopic piece of solid. The recoil-energy loss, being inversely proportional to the mass of the recoiling entity, then is vanishingly small.

A more accurate picture of the origin of the recoil-free process is obtained within the domain of quantum mechanics. An atomic solid is pictured as a complex vibrational system consisting of elastically coupled masses in a regular three-dimensional array. Such a system is known to have a well-defined vibrational spectrum. An impulse applied to an individual atom, such as the recoil due to gamma ray emission, can in general change the state of excitation of the solid only by discrete amounts or phonons. Phonons are the quanta corresponding to the intervals between allowed states of the vibrational spectrum. A detailed evaluation shows that as the magnitude of the impulse is reduced, the probability increases that the quantum state of the solid will remain unchanged. These so-called zero-phonon events correspond to the recoil-free events that give rise to the Mössbauer effect.

The probability, f, for recoil-free emission depends on the amplitude of the thermal motion of the emitting atom compared to the wavelength of the gamma radiation, λ:

Recoil-free emission

$$f = \exp\left[-4\pi^2\overline{x^2}/\lambda^2\right]$$

in which $\overline{x^2}$ is the mean square vibrational displacement in the direction of gamma ray emission. This expression can be evaluated for specific models of lattice vibrations. Using the model introduced by Peter J.W. Debye in his theory of heat capacity of monatomic solids, the recoil-free fraction has the form

$$f = \exp\left[-\frac{E_R}{k\Theta_D}\left(\frac{3}{2}+\frac{\pi^2T^2}{\Theta_D{}^2}\right)\right];\ T << \Theta_D,$$

in which Θ_D is the Debye temperature, T is the temperature of the solid, E_R the free-atom recoil energy, and $k\Theta_D$ the energy of the most energetic phonon that can exist in the lattice. Examples are known in which f is very close to unity, making the Mössbauer effect a prominent part of the gamma ray absorption process.

The most important property of the recoil-free gamma rays is that their width is entirely determined by the width of the decaying nuclear state. Doppler broadening by the thermal vibrations of the emitting atom is completely absent in the recoil-free part. It has the expected value, however, when the entire emission spectrum is considered. It is interesting to note that in the years before Mössbauer's discovery, resonant scattering of nuclear gamma rays that *had* suffered a recoil energy loss had been repeatedly studied by using various techniques to compensate for energy shift. These experiments were subject to thermal Doppler broadening and did not provide the high resolution that is the main reason for the importance of the Mössbauer effect.

BIBLIOGRAPHY. The discovery of the effect was reported by R.L. MOSSBAUER in papers that presented evidence for the existence of the effect, its theoretical interpretation, as well as a discussion of its possible applications. His papers (all in German) may be found in these journals: *Z. Phys.*, 151:124–143 (1958); *Naturwissenschaften*, 45:538 (1958), and *Z. Naturf.*, 14a:211–216 (1959). His Nobel Lecture, "Recoilless Nuclear Resonance Absorption of Gamma Radiation," was reprinted in *Science*, 137:731–738 (1962). Introductory treatments are given in H. FRAUENFELDER, *The Mössbauer Effect* (1962); G.K. WERTHEIM, *Mössbauer Effect: Principles and Applications* (1964); and in V.I. GOLDANSKII, *The Mössbauer Effect and Its Applications in Chemistry* (1964). More detailed treatment of selected topics are available in V.I. GOLDANSKII and R.H. HERBER (eds.), *Chemical Applications of Mössbauer Spectroscopy* (1968); and in I.J. GRUVERMAN (ed.), *Mössbauer Effect Methodology*, 4 vol. (1965–68).

(G.K.W.)

Motion-Picture Industry

The term motion-picture industry as it is generally used refers to the *theatrical* motion-picture industry, which produces works of dramatic art or of mass entertainment for national and international markets.

Scope of the industry

Although the industry was once associated primarily with Hollywood, theatrical film production there had come to a virtual standstill in the late 1960s. Asian nations produced more films, especially Japan, which made some 700 films a year, and India, which made about half that many. American-financed and produced films, however, continued to dominate the screens of most of the world. In each of the nations of Western Europe, for example, U.S.-backed films earned far greater revenues than the films of any other nation; and in many places, such as the Scandinavian countries, they earned more than domestically made films. From the 1920s onward, American films so monopolized the international film market that severe import restrictions were imposed on them virtually everywhere to protect domestic film industries. The American patterns of production, distribution, and exhibition, however, were generally adopted by the film industries of other nations, and this article focusses on these patterns.

In addition to the theatrical motion-picture industry, there is an industrial motion-picture industry, which produces films under contract to a single buyer-user, typically a large corporation or institution, which may utilize the film either for internal purposes or for external purposes, such as consumer-product advertising or public relations. There is also an educational film industry, which also produces, under contract, material to be used in government or private classrooms, in technical training facilities, or for teaching and vocational aids for the underprivileged. Another part of the motion-picture industry as a whole consists of the basic raw material and equipment companies, which develop and refine products marketed to all industrial and private customers. Finally, there is an amateur and semiprofessional market that produces personal films, some of which receive public exhibition, such as the so-called underground films often containing artistic, social, or political protest. Individual experimentalists, however, often gravitate to the theatrical film industry.

THE INDUSTRY AND SOCIETY

From the time films began telling a story in the first years of the 20th century, their enormous potential influence on mass audiences has been recognized. In times of crisis the national film industries everywhere have been mobilized to mold public opinion. When Germany was cut off from the major sources of films in World War I, for example, the German government considered films important enough for purposes of morale and propaganda to establish its own industry, despite severe wartime scarcities. Later, under the regime of Adolf Hitler, outright political propaganda again became its major aim in films such as *Triumph of the Will* (1936) by Leni Riefenstahl. At various times the influence of the film has been thought so powerful as to require control by society, usually through censorship. Nonetheless, there are many who feel that films do not influence the behaviour of their audiences as much as they reflect it. This question lies at the root of the unending debate between those who would censor films and those who would have no restraints whatever. Historically, nations with strong central governments have acted as if films caused important changes in those who watch them and therefore must be regulated.

In democratic societies, points of view on the issue of controls vary. Film artists, even though they may control their own films, contend that films mirror life, and not vice versa. Producers, by financing genres as long as the public responds to them and by dropping them when they lose popularity, seem to support the view that audiences determine film content. Many critics, however, attribute a far more causal influence to films in relation to audiences. Film stars are modern folk heroes, who sanction such matters as clothing styles and such habits as smoking or drinking. Like no other medium, magnified pictures and amplified sound give powerful authority to even the most insignificant actions and phrases.

This uncertainty over their power is reflected in the films of all nations. Most films are curious mixtures of appeals to the broadest possible audience and cautious accommodations to official or unofficial pressures. In all nations where films are important, producers have attempted to attract audiences by offering, more than ever before, sensational material, and such material in turn has brought demands for censorship. The fluctuations of the U.S. film industry are illuminating in this regard.

Censorship

Federal censorship was never imposed, but state and municipal censorship was widespread. The industry's first major trade organization, the Motion Picture Producers and Distributors of America, later known as the Motion Picture Association of America, was formed in 1922 in response to public concern over the possible demoralizing effect of films. It fended off criticism successfully until the introduction of sound, after 1926, led to more sophisticated, and therefore more controversial, stories. The Motion Picture Production Code adopted by the industry in 1930 was at first loosely enforced. In 1932–33, as audiences diminished at the outset of the Great Depression, producers tried to lure them back with franker films. Then, under strong public pressure, strict enforcement of the Code prevailed until the 1950s.

When a serious decline in film attendance accompanied the advent of television, producers again turned to bolder screen material. In 1952 the U.S. Supreme Court overruled its 1915 decision that motion pictures were not protected by the free-speech guaranty of the First Amend-

ment to the Constitution. The Production Code was modernized in 1956 and overhauled in 1966, but its power had waned. A film-classification system was introduced in 1968, similar to one in effect in Britain, but failed to check either the production or the attendance of films exploiting sex and violence. The *X* rating, which was intended to warn that persons under 17 should not attend, seemed to become a special attraction to a large part of the public. When the Swedish film *I Am Curious (Yellow)* was finally shown in the United States in 1969 after several widely publicized trials and appeals, it quickly earned millions of dollars despite its *X* rating, its mediocre reviews, and its Swedish political orientation. Public interest in major-studio sex-oriented films, however, proved to be as unpredictable as for other types of film.

The pattern of censorship was repeated in other nations throughout the world. To protect their own film industries against the appeal of the frankness of imported films, the United Kingdom, Italy, West Germany, India, Japan, and other nations carefully re-examined their previous attitudes toward censorship in the late 1960s. Accompanying the trend toward more explicit portrayals of sex and violence was the increase in films of social and political protest. Again, there were those who found such films a significant advance in the maturity of the film art, as well as many who saw in them the potential threat of manipulating mass audiences toward questionable political ends.

With the relaxation of the Code, however, it became evident that the limitations imposed by the Code alone had not been responsible for the dullness and mediocrity of so many films. Mass production of films had induced a tendency toward the path of least resistance. It was artistically easier and economically safer to repeat previously successful situations than to create better films.

ECONOMICS OF THE MOTION-PICTURE INDUSTRY

The theatrical motion-picture industry tends to be highly speculative, with control resting in the hands of entrepreneurs. Even in nations with a high degree of state control, film making involves high risks and huge expenses; and investments usually are made only in those who have proved their ability to create popular successes or to achieve other goals of the government.

The U.S. film industry was for more than 50 years the primary supplier of the world's most popular screen entertainment, usually relegating to a distant secondary position other national film industries. By the mid-1920s, for instance, U.S. films had captured 90 percent of the British market and over two-thirds of the French and Italian markets. Thus U.S. industry practices set patterns in the primary areas of production (manufacturing), distribution (wholesaling-marketing), and exhibition (retailing).

Production. By 1915, film manufacturing became based in Hollywood, a suburb of Los Angeles. As they evolved in the 1920s and 1930s, the large Hollywood film companies such as Metro-Goldwyn-Mayer, 20th Century-Fox, Paramount, Warner Brothers, and RKO typically owned studios presided over by a corporate officer in charge of production, such men as Irving Thalberg, Louis B. Mayer, or Darryl F. Zanuck. Planning was based on selected stories, or "properties," to be filmed in the course of a year. The season's "product" was balanced to provide what seemed to be a proper mixture of subject matter, costs, and broadest possible audience appeal.

The Hollywood studio pattern

The most ambitious films, in terms of cost and creative effort, were called "A" films; "B" and "C" films represented lesser financial efforts. In addition, shorter films, of 10–20 minutes' duration, devoted to news events, sports, travel, music, animated cartoons, and serials, rounded out production schedules.

Production was carried out by the studio's pool of employees, artists, and technicians, some of whom were under exclusive personal-service contracts. Against strong studio resistance, they organized labour unions and guilds in the 1930s to establish minimum working conditions and standards.

A studio would assign its creative talent to one film after another on a basis of overall production plans and without significant allowance for an artist's personal preferences. Only after a performer or director had achieved fame might his assignments be renegotiated, and not always then. Even after she became a star, Bette Davis, for example, had long and bitter feuds with her studio over her roles. Studios also traded their contract talent with each other for corporate profit under "loan-out" agreements.

The positive effect of this system was the development of a studio's "stock company," recruited from the legitimate theatre or from the ranks of novices and perfected by repeated work. Newer talents emerged from the proving ground of B and C films to prominence in an A product. The more ambitious A films were likely to be adaptations of well-known books and stage plays. The B and C productions were the realm of original screenplays by the studio's writers and, hence, later came to be appreciated more than the A films by cinema purists. In adapting from another medium, studios often modified story lines to suit the artists assigned. Film adaptations of plays permitted greater versatility in settings and action than was physically possible on the stage. Film versions of novels, however, tended to compress characters and simplify characterizations. More educated audiences often deplored film adaptations in comparison with the original material, but mass audiences registered little disapproval.

In the silent film era, story developments not immediately apparent from gesture were made explicit through "title cards" inserted in the film; for export purposes, simple substitutions were made. After sound films were introduced, three methods were used for surmounting language barriers: multiple casts, subtitling, and voice substitution or "dubbing." The first method was least used because it was too expensive to tie up studio sets while separate lingual casts were filmed.

Language barriers

Subtitling involves the printing of dialogue translations at the bottom of the screen while performers are heard in their native language. Dubbing, on the other hand, employs trained voice specialists who synchronize translated dialogue to lip movements. A few performers are multilingual, but most stars have rarely been heard in their natural voices outside their native lands; the same voice substitutes consistently dub the same foreign stars.

Distribution and exhibition. Despite the publicity emphasis on stars, films, and studios, the seat of industry power was distribution; studios were simply manufacturing subsidiaries of worldwide distribution companies. Distribution executives viewed the annual output of a studio as a mixed product line for a single mass audience. Marketing considerations were based on the whole schedule. During periods of great attendance, such as holidays, the most expensive films would be released, and lesser products would fill out the schedule. Occasionally, one of the minor films would become a surprise hit, or, in the industry term, a "sleeper."

In determining patterns of distribution, the large companies gave their films first to their theatre-chain subsidiaries. But each large distribution company was dominant in exhibition only in certain geographical areas. Accordingly, reciprocal arrangements were made with the theatre chains of other distribution companies. Afterward, the films of smaller studios might be acquired. A system of time "clearances" fixed the number of days before the films that had been shown by the company-affiliated theatres might be exhibited by independent theatres in the same area. Distribution executives also initiated promotional campaigns for films, including personal appearances by stars at major premieres.

Films were distributed through a network of "branches" or "exchanges" located in major cities. These exchanges supervised sales to theatres, inspection and routing of prints to theatres, and collections of income from exhibitors.

In the decades of growth of the U.S. film industry, other nations instituted legal measures to protect their domestic film industries from annihilation in their competition with American films. Tariffs were placed on U.S. films by some governments, and admission prices were fixed at a higher level for U.S. films than for domestic films. France, Spain, and Italy, after World War II, attempted

Protection against U.S. films

unsuccessfully to compel reciprocity, which would have required their films to be shown in the United States in some proportion to their showings of U.S. films. The two principal methods, however, were a mandatory quota system, whereby a percentage of a theatre's operating time was reserved for domestically made films, and various types of subsidy to domestic film makers.

The exhibition arm of the industry evolved from carnival peep shows in the 1890s, through makeshift locations such as funeral parlours, to theatres originally built for stage plays. With growth, centralized booking and business methods were imposed. Luxuriously appointed new theatres were built, such as the 6,000-seat Roxy in New York City, built in 1927 at a cost of $8,000,000.

Apart from rewiring for sound films after 1926, no major innovation occurred in exhibition until the introduction in 1939 of the outdoor, drive-in theatre. Once located in remote suburban areas, these theatres flourished with population expansion and, after World War II, began to book new films. Attendance at drive-in theatres rose to about one-quarter of the U.S. total movie attendance. Portable exhibition apparatus also serves remote population areas in many countries.

Dispersal of theatre chains

Because of the tight control exerted by major film companies over exhibition, the U.S. government in 1938 brought suit against the large companies for restraint of trade. Not until the 1949–53 period, however, were they forced to dispose of their theatre subsidiaries. They were also forced to abandon the long-standing practice of "block-booking"; that is, selling an entire season's output of films on one contract. Outside the U.S., theatre ownership and block-booking remained standard practices of some U.S. companies.

Following the enforced sale of theatre chains and facing steadily declining audiences because of television, the large studios could no longer keep great numbers of artists and technicians under contract. Major talent agencies such as Music Corporation of America and some individual agents, whose clients no longer had employment guaranteed by long studio contracts, began "packaging" important film projects, which typically involved many of their clients. These packages were then sold to large film companies, which remained the source of production financing and the means of worldwide distribution. United Artists, Columbia, and Universal in this period became stronger competitors to the surviving larger companies.

Losses and gains from television

Television, still the principal competitor of theatrical films, also became an economic ally because of the demand for programming. Film companies eagerly competed to produce program series for television. Some of these corporations maintained financial liquidity by selling films that were too old to be shown in theatres to local television stations for showing in off hours. After 1965 they earned significantly greater revenue from television by renting more recent films for television network exhibition during peak audience hours. Immediately after *The Bridge on the River Kwai* (1958) attracted 60,000,000 television viewers in 1966, CBS-TV paid Metro-Goldwyn-Mayer $52,800,000 for 63 films, and other networks and studios made similar agreements.

Wide-screen processes, often with stereophonic sound, such as Cinerama, VistaVision, Todd-AO, and, especially, CinemaScope, came to be the hope of the surviving studios in the 1950s, since these processes created a product that could not be duplicated adequately by home television equipment.

European films in foreign markets

The trend away from large-studio mass-production film making was not confined to the United States but was worldwide. In Europe, major studio features declined in favour of films that were the personal expression of talented directors. In Italy, Roberto Rossellini and Vittorio de Sica created low-budget but highly artistic films such as *Open City* (1946) and *The Bicycle Thief* (1949), which became better known throughout the world than any previous Italian films had been; and later Federico Fellini and Michelangelo Antonioni achieved even greater international renown. In France, the "New Wave" directors such as Jean-Luc Godard, François Truffaut, and Alain Resnais all began as critics of the products of the French film industry and then in the later 1950s began developing their own distinctive directorial styles using determinedly anti-studio techniques.

A major development in the postwar period was the emergence of an international audience for these "art" films, often in a foreign language. Once the province of smaller independent exhibitors who could not obtain regular products, foreign films attracted growing audiences to the extent that large film companies re-evaluated both the aesthetics and the economics of their product. In the United States in the decade after World War II, imported films increased 233 percent while U.S.-made films declined by 28 percent.

The U.S.-Canadian market was always tempting to the European film industry not only because of the size of the film audience but also because of the large box-office revenues that resulted from the higher ticket prices. In the 1950s European films began to achieve unprecedented successes in this market. In 1958 the French film *And God Created Woman* earned $4,000,000 there, more than twice as much as all French films had earned there the preceding year, and the Greek film *Never on Sunday* in 1961 earned a comparable amount, representing 20 times its reported cost of production. Such films, however, were handled by major U.S. distributors, who were accused of closing the market to all foreign films except the ones they chose to exploit. The British firm of J. Arthur Rank in 1957 made a concerted effort to set up its own distributing organization in the United States, but it failed in two years.

Decline of Hollywood

An overriding economic fact of the 1950s was that because of rising expenses and diminishing audiences, a major Hollywood feature could no longer earn back its cost exclusively from U.S. audiences. Previously, films were directed to U.S. audiences; returns from foreign distribution were "extra." From the 1950s onward, non-U.S. markets had to be taken into account in the production. Similarly, the film industries of other nations also relied on foreign audiences. Disastrous aesthetic consequences sometimes resulted from the producer's fear of offending *any* potential audience and from the increase in huge, international, multilingual productions, with each leading performer from a different nation and sometimes speaking a different language, so that no version was released without some major roles dubbed.

Before World War II, U.S. film companies regularly imported recognized foreign film artists to Hollywood. After the war, however, a combination of factors—foreign currency restrictions, foreign-protectionist measures such as quotas and subsidies, increased costs of filming in Hollywood, and U.S. audience interest in foreign films—caused a major shift in policy. Through long-established foreign subsidiary companies, the U.S. film companies began producing films all over the world. By adroit use of local artists and technicians, these films qualified not only under national quotas but also received national subsidies. As a result, such a film came to that nation's theatre screens with the appeal of an imported U.S. film while enjoying the financial advantages of a domestic film. Such overseas, or "runaway," productions, in addition to the trend toward the realism of films shot on location and away from artificial studio settings, left Hollywood studios practically devoid of feature production.

By 1969–70, the large surviving U.S. companies, retrenching in production, aimed toward a level of 15–20 features per year, about 25 percent of pre-1950 levels. The cutbacks included disposal of burdensome studio ownership and other real-estate operations. Distribution was reorganized to permit fewer sales offices but greater sales impact in key areas. Financing for more independently made films became available from industrial companies and investing groups. Artists deferred high salaries of former times in return for larger film ownership, thus reducing production costs. Exhibitors sought quality films from any source rather than relying only on established companies. In place of the former single-audience production concept, films were made for various segments of the total audience, such as treatments of social and political problems for younger audiences.

The so-called independent producer (who with hardly an

The independent production

exception was financially dependent on major film companies) faced greater opportunities and challenges than before. With a decline in studio production, the independent producer had to arrange details that studio staffs previously handled. These included arranging for production financing, loan collateral, completion bonds (necessary to guarantee a finished film in a releasable form), and laboratory processing; negotiating with creative talent, technicians' unions, and potential distributors; production budgeting; selection of studio rental facilities and exterior locations; and actual supervision of filming. After production is complete, the independent producer must also be conversant with advertising and promotion, distribution practices, and censorship problems peculiar to various countries. To monitor his financial obligations he needs expert legal and auditing advice.

After World War II, the major film-producing nations of Western Europe formed agreements to facilitate international coproductions; that is, films made jointly by teams from two or more nations, which are designed to appeal to audiences of each as much as would a domestically produced work. With the expectation of vastly greater revenues than could be expected from a purely domestic production, larger budgets could be allocated. By the late 1950s, France invested far more in coproductions than in its national films. French-Italian coproductions numbered nearly 800 between 1950 and 1965. Featuring mixed Italian and French casts, some of these films, such as *L'avventura* (1959), *La dolce vita* (1960), and *Last Year at Marienbad* (1962), were masterpieces, but most were ill-coordinated productions, usually filmed in wide screen and colour, that strove only for a fast return on the investment.

Flow of film income. Box-office receipts typically are divided between the exhibitor and the distributor according to a negotiated contract, usually on a variable percentage of the box-office gross. For a popular film, the distributor may receive as much as 90 percent of the gross; thus, when the British-made James Bond series was at its peak of popularity, *Thunderball* (1965) was able to recover its $15,000,000 cost only seven weeks after its release. Advertising expenses are usually split between distributor and exhibitor on a similar basis. Exhibitors retain all income from concessions, which in drive-ins may bring as much as 40 percent of total receipts. That portion of the box-office total remitted to the distributor is known as "film rental" in the U.S. and "film hire" in other English-speaking areas. It is subject to a fixed percentage-distribution fee meant to support the existence of the distribution company. The remainder of the rental is first applied to direct charges for money advanced to the producer by the distributor for prints, advertising, etc., then is remitted to the producer or production company to pay for production costs. These typically include a percentage-overhead charge meant to compensate for intangible costs of corporate administrative and operational support not otherwise directly chargeable to production.

PERIPHERAL ACTIVITIES

Although known primarily for its theatrical films, the motion-picture industry long has been involved in interactions with other industries. Large film companies own music-publishing companies, operate phonograph-record and tape production and distribution companies, and license properties to outside firms specializing in the merchandising of novelty goods. Some of these companies also own television and radio stations.

As music publishers, film companies share with composers in royalties received from song performances. Also, their songs provide inexpensive music for their films, while increasing exposure of the songs. Outside the United States a percentage of theatrical box-office income is allocated to music publishers and composers through performing rights societies that act as collection agents for royalties. The development of phonograph and tape labels as film company subsidiaries permits cross-promotion of film music through sound-track albums and records, as well as the development and exploitation of artists and songs not directly related to any films.

Additional revenue derives from the licensing of company-owned tradenames and likenesses—such as Walt Disney's Mickey Mouse, Donald Duck, and other animated cartoon characters—to merchandising companies specializing in comic books, jewelry, and other consumer novelty items. As customers, film companies regularly acquire motion-picture rights to stage plays, novels, and other published material and properties originally produced on radio or television broadcasts. The prices paid for such rights can be very high: the screen rights for *My Fair Lady* were sold for $5,500,000 in 1962. The justification for such large expenditures is that the properties already are known to the public, hence the possibility of greater film income, which might offset the cost of rights.

Films often increase the artistic reputations and financial status of writers, authors, composers, and other original producers of properties, creating a market for the revival of plays and the republication of books. In fact, novels are sometimes written after a screenplay and published as paperbacks when the film is released. In the 1960s a market for the screenplays themselves developed.

FESTIVALS AND AWARDS

The effects of awards on the motion-picture industry have varied greatly, and the proliferation of awards further diffused their impact. Historically, the U.S. industry, with its overwhelming control of the world's screens, long had virtually no interest in film awards except for its own "Oscars," voted each year since 1929 by the Academy of Motion Picture Arts and Sciences. The Academy, which grew to about 3,000 members representing various artistic and technical disciplines, originally intended its annual awards as modest, peer-group citations within the tightly knit Hollywood industry. After media coverage created widespread interest, however, an increase in box-office revenues for winning films was noticed, and the Oscar became valuable in merchandising. The prestige of its artistic judgments, however, failed to keep pace with its economic power. Serious students of the film tended to place more credence in the awards of the New York Film Critics (founded in 1935), and the later National Society of Film Critics (1966), as well as in the oldest U.S. reviewing organization, the National Board of Review of Motion Pictures (1909). Meanwhile, foreign festivals provided a forum for promotion and recognition of artistic achievements of all other national film industries. The first of these was founded at Venice, Italy, in 1932, with the help of the Fascist regime. It was unique until after World War II when the Cannes Festival was founded. Festivals then assumed increasing importance. Struggling nations, rebuilding their shattered film industries, saw in festivals a chance for world recognition. International political alliances were being reformed, and festivals provided an environment for interaction. And the growing interest everywhere in film imports made the festivals an international marketplace for distributors. Festivals were initiated at Berlin; Moscow; Karlovy Vary, Czechoslovakia; London; San Francisco; Chicago; and New York City. Festivals for short films were held at Edinburgh; at Mannheim and Oberhausen, Germany; and at Tours, France. A Southeast Asia film festival was held annually in different places, and at Vienna, a festival for nontheatrical films was a great success. Through the early 1960s, however, the U.S. film industry remained wary of festivals; films that won festival awards did not necessarily do well at the box office, though a poor reaction at a festival might reduce the audience for a serious film. After 1965, however, distributor attitudes changed as investments mounted in films for specialized audiences, particularly in "foreign" films backed by U.S. companies. Favourable critical acclaim became a vital promotional aid. At the same time, however, the aggressive foreign activities of U.S. companies diminished the value of festivals as a marketplace. Long before festival screening, most quality foreign films had been acquired by U.S. distributors. The past role of festivals also was challenged when the Cannes festival of 1968 became the centre of revolutionary demonstrations. Thereafter, the "glamour" of these events was played down and the awards de-emphasized. The Venice festival

Academy Awards

suspended its awards entirely. Nonetheless, interest in the festivals persisted. In 1970, more than 10,000 persons attended the Cannes festival, and some 300 films were shown; and in a striking reversal of tradition, the top prize went to a U.S. film, *M*A*S*H*, and two other key awards went to films produced by U.S. companies.

BIBLIOGRAPHY. A scholarly approach to the subject may be found in T.H. GUBACK, *The International Film Industry: Western Europe and America Since 1945* (1969). This book analyzes the development of the film industries of western Europe and the U.S. since World War II and presents data on their influence on each other. The author also explores the means the U.S. industry and others have used to circumvent measures to protect domestic industries. Other comprehensive works are TERRY RAMSAYE, *A Million and One Nights* (1926), a two-volume history of the early decades of the industry; and ARTHUR KNIGHT, *The Liveliest Art* (1957), perhaps the best of the contemporary histories, providing both artistic and industrial overviews.

Accurate and readable biographies of industry pioneers by a responsible film journalist include BOSLEY CROWTHER, *The Lion's Share* (1957), a corporate history of Loew's, Inc., parent company of MGM, and *Hollywood Rajah* (1960), a biography of Louis B. Mayer, longtime MGM studio head. Valuable insight into classic studio methods is provided in the trilogy of R.J. THOMAS: *King Cohn* (1967), a biography of Harry Cohn, cofounder of Columbia Pictures Corp.; *Thalberg: Life and Legend* (1969), the story of Irving G. Thalberg, creative assistant to Mayer at MGM; and *Selznick* (1970), embracing the family and career of producer David O. Selznick. An early biography, replete with corporate infighting and financial manoeuvrings far removed from the glamour of film, is SINCLAIR'S *Upton Sinclair Presents William Fox* (1933), a subjective study, but far more credible than the reader might imagine.

The industry is covered by many trade journals, of which *Variety* and *Daily Variety* are considered the most reliable.

(A.D.M.)

Motion Pictures, Art of

A remarkably effective medium in conveying drama and especially in the evocation of emotion, motion pictures consist of the projection of luminous moving images onto a screen. The art of motion pictures is exceedingly complex, requiring contributions from nearly all of the other arts as well as countless technical skills. Nonetheless, probably no other art has proliferated as much in the 20th century nor can any other equal it in popularity or influence.

The newest fine art

The motion picture is the newest of the generally recognized "fine arts." It is the product of photographic and technological developments that culminated by 1900 in practical devices for the recording of a moving image and its projection onto a flat surface. During its early development, the motion picture was discounted by many critics for its subservience to commercial interests, for the immediacy of its appeal to the uninstructed, for its mechanical technique, and for its apparent lack of an identifiable artist as its primary creator. After the middle of the 20th century, however, increasing attention was devoted to it as a form of artistic endeavour that is as legitimate as the theatre, literature, music, or the visual arts.

Throughout its history, the motion picture steadily became more complex. Even the silent film was capable of a wide range of expression, the possibilities of which were far from exhausted when it was superseded by sound films in the late 1920s. Subsequently, the medium was enriched with complex sound tracks, combining a half-dozen separate recordings. Colours and wide screens added new breadth, and improvements in lenses, film stock, and processing techniques permitted trick effects of all kinds.

In an art in which spectacular effects were commonplace, the qualities of simplicity and spareness became virtues. Gradually, it was learned that the music of a motion picture should not demand the attention that symphonic music does, that there should be less dialogue in a film than there is in a play, that the visual composition should be less intricate than that of a painting, that the acting must be more restrained than theatrical acting. To a considerable extent, the motion picture discovered its own identity through its difficulties in adapting elements of the other arts.

This article will analyze the many elements involved in the creation and appreciation of works of art in motion pictures. The article has the following sections:

Essential characteristics of motion pictures
Expressive elements of motion pictures
Style in motion picture
Types of motion pictures
The study and appreciation of motion pictures

A detailed account of the growth and development of motion pictures as an art will be found in the article MOTION PICTURES, HISTORY OF, and its technical and scientific development is treated in MOTION PICTURES, TECHNOLOGY OF. Commercial aspects of motion picture production and distribution are discussed in MOTION PICTURE INDUSTRY.

ESSENTIAL CHARACTERISTICS OF MOTION PICTURES

In its short history, the art of motion pictures has frequently undergone changes that seemed fundamental, such as that resulting from the introduction of sound. It exists today in styles that differ significantly from country to country and in forms as diverse as the documentary created by one man with a hand-held camera and the multimillion-dollar "epic," involving hundreds of performers and technicians. Despite its diversity, however, an essential unchanging nature can be discerned in most of its manifestations.

A number of factors immediately come to mind in connection with the motion picture experience. For one thing, there is something mildly hypnotic about the illusion of movement that holds the attention and may even lower critical resistance. Also, the accuracy of the motion picture image is compelling because it is made by a non-human, scientific process. And, the motion picture gives what has been called a strong sense of being *present*; the film image always appears to be in the present tense. There is also the concrete nature of film; it appears to show actual people and things.

No less important than any of the above are the conditions under which the motion picture ideally is seen, where everything helps to dominate the spectator. He is taken from his everyday environment, partially isolated from others, and comfortably seated in an air-conditioned auditorium. There, the darkness concentrates his attention and prevents comparison of the image on the screen with the objects or people around him. For a while, he lives in the world the motion picture unfolds before him.

Still, the escape into the world of the film is not complete. Only rarely does the audience react as if the events on the screen were real; for instance, by ducking before an onrushing locomotive in a special three-dimensional effect. Moreover, such effects are considered to be a relatively low form of the art of motion pictures. Much more often, the viewer will expect a film to be true to certain unwritten conventions than to the real world. Sometimes, he will expect exact realism in details of dress or locale, but just as often he will expect the film to escape from the real world and make him exercise his imagination, a demand made by great works of art in all forms. If an indirect statement stimulates the spectator's imagination, he will complete the picture much more vividly for himself than the artist could. Fidelity in the reproduction of details is much less important than the appeal made by the story to an emotional response. If the audience senses the film maker is overstating his case merely to evoke an emotional response, the spell is broken. Between the artist and the audience, there is a constant, changing, unformulated relationship of taste. The bounds of this sort of taste depend on the particular motion picture, the audience, and the occasion, but the relationship is always present and the artist must work within it.

The unwritten conventions

The essential characteristics of the motion picture can be divided into those characteristics that pertain primarily to the motion picture image, those that pertain to motion pictures as a unique medium for works of art, and

those that derive from the experience of viewing motion pictures.

Qualities of the film image. The primary unit of expression in film is the image, or the single shot. The attribution of magical properties to images has a long history; this association is well documented among many primitive peoples, and it is even reflected in the term magic lantern as a synonym for the film projector. Any image taken out of the everyday world and projected onto a screen to some extent appears to become magically transmuted. This magical quality helps to explain the enthusiastic reception accorded such early films as *La Sortie des ouvriers de l'usine Lumière* ("Workers Leaving the Lumière Factory), which were merely photographic records of commonplace scenes in Paris in the 1890s by the French film pioneers, the Lumière brothers.

Intensity, intimacy, ubiquity. One critic singled out the qualities of intensity, intimacy, and ubiquity as the salient characteristics of the motion picture image. Its intensity derives from its power to hold the complete attention of the spectator on whatever bit of reality is being shown. Outside the theatre, a person's attention is usually dispersed in the endless reality around him except for sporadic moments of concentration on what he selects for closer scrutiny. In the cinema he is compelled to look at something that not he but the film maker has selected, for reasons that are not always immediately apparent. This quality of intensity becomes most noticeable when the camera remains fixed on something for a longer time than seems warranted, and the spectator gradually becomes acutely conscious of his loss of volition over his own attention. This technique is not often used but is most effective when used well.

The intimacy of the film image is related to the camera's ability to see things in greater detail than the eye can. This ability is demonstrated in long-distance shots through a telephoto lens as well as in closeups. At the beginning of the Japanese film *Woman of the Dunes* (1964), a pervading theme of the film was indicated by shots of grains of sand many times enlarged.

The impression of ubiquity—being everywhere at once—is achieved in part by the camera's apparent freedom to move from place to place or to approach or withdraw instantaneously. No less important to this illusion of ubiquity is the effect achieved by editing, which allows countless images representing a long, elaborate action, to be presented in a comparatively short film.

Particularity. Other equally important characteristics of the film image may be singled out. One of these is its particularity. The language of words lends itself to generalization and abstraction. In themselves, words such as man or house do not suggest a particular man or a particular house but men and houses in general; and more abstract terms such as love or dishonesty have even less precise associations with specific things. Motion pictures, on the other hand, only show particular things—a particular man or a particular house. In this way a film image may be less ambiguous than the language of words but also less evocative, less likely to be enriched by imagination, association, or recollection. Despite its particularity, however, the motion picture image may also be ambiguous in that it *shows* but does not *explain*. It does not in itself tell what it means, and people instinctively search for meanings in images. This is why commentary is so important in a documentary film. It is also why the juxtapositions of montage are so effective—the spectator compulsively searches for the reason behind that particular sequence of images.

The mind and the eye

Neutrality. Another characteristic of the film image is its neutrality. The world a person sees around him is strongly influenced by his emotions and his interests. A plumber fixing pipes in a museum may not see the masterpieces around him, while an angry man may hear an insult where none was intended. The camera, however, reproduces everything in front of it, without feeling. An important part of any artist's training is to cultivate a neutrality of vision, the ability to see everything fresh; the camera possesses this faculty naturally. When a film appears to be charged with emotion, it is usually because the director has carefully manipulated the images to give this illusion. In everyday life, the eyes follow the mind; in the cinema, the mind follows the eyes.

Characteristics of the medium. Four characteristics may be stressed as factors that differentiate the motion picture medium, either in degree or in kind, from other mediums for works of art: luminosity, realism, movement, and montage.

Luminosity. The intense brightness of the picture projected by powerful light onto a coated screen in itself transforms the most mundane element of reality. The appeal of a luminous picture is attested by efforts of advertisers to achieve luminous effects in posters and displays and in the popularity of viewing still photographs as transparencies rather than as ordinary prints. The luminosity of the motion picture image also results in a considerable range of tone, between the brightest highlight and the deepest black. Both in black and white and in colour films, the most delicate gradations in the image are therefore possible.

Realism. Another essential element of the motion picture image is that it gives an impression of reality. Whether in a drama enacted expressly for the camera or in a documentary film of an event at which the camera just happened to be present, this feeling of realism deriving from motion picture photography accounts for much of the force of motion pictures. Animated films, which lack this element of photographic realism, tend to be taken much less seriously by adults.

The attempt of the motion picture to reproduce three-dimensional reality on a flat screen presents the same problems and opportunities that are encountered in still photography and in painting. Like still photography, cinematography tends to exaggerate perspective, so that effects of great depth, with dramatic contrasts between foreground and background are possible. On the other hand, in Japanese films as in Japanese paintings, there often seems to be no perspective at all.

Movement. As a feature of the motion picture, movement is so obvious that its central importance is sometimes forgotten. As has been noted above, the motion picture has much in common with the graphic arts. The added dimension of movement transforms it, allowing it to unfold a narrative or a drama in time, in a way no other graphic art can. Both in film making and in film appreciation, movement must constantly be borne in mind: composition in the motion picture is kinetic rather than static. It is not a single colour but the cumulative effect that matters, not a single situation but a developing plot. The composition within any frame, or exposure, of a motion picture is less important than the relationship of that frame to those that precede and follow it.

Montage. Perhaps the most essential characteristic of the motion picture is montage, from the French *monter*, "to assemble." Montage refers to the editing of the film, the cutting and piecing together of exposed film in a manner that best conveys the intent of the work. Montage is what distinguished motion pictures from the performing arts, which exist only within a performance. The motion picture, by contrast, uses the performances as the raw material, which is built up as a novel or an essay or a painting, studiously put together piece by piece, with an allowance for trial and error, second thoughts, and, if necessary, reshooting. The order in which the segments of film are presented can have drastically different dramatic effects.

Several major contributions to the theory of the montage were made by Soviet directors. After the Russian Revolution of 1917, Soviet films were encouraged for their propaganda value, but film stocks were scarce. Soviet directors carefully studied the films of D.W. Griffith and other masters to make the most effective use of their own meagre resources. One of these early Russian directors, Lev Kuleshov (1899–), conducted an experiment involving identical shots of an actor's expressionless face. He inserted it in a film before a shot of a bowl of soup, again before a shot of a child playing, and still again before one of a dead old woman. An unsuspecting audience, which was asked to evaluate the actor's per-

Kuleshov's experiment

Through skillful use of montage in this sequence from *Potemkin* (1925) Sergey Eisenstein created a feeling of horror and outrage. The film deals with a mutiny aboard the Russian cruiser "Potemkin" during an abortive antitsarist uprising in 1905. (A) The people of Odessa assembled on the harbour steps to cheer the victorious crew of the "Potemkin." (B) The tsar's Cossacks firing into the crowd. (C) The carnage after the first volleys. (D) The shock and fury of a student onlooker (played by Eisenstein). (E) The relentless advance of the Cossacks. (F) The defiance of a mother holding her slaughtered child.

formance, praised his ability to express respectively hunger, tenderness, and grief.

Sergey Eisenstein (1898–1948), who excelled both as a director and as a teacher, based much of his theory of film on montage, which he compared to the compounding of characters in Japanese writing. The character for "dog" added to the character for "mouth," he noted, results not merely in "dog's mouth" but in the new concept of "bark"; similarly, film montage results in more than the sum of its parts. Still another great Russian director, Vsevolod I. Pudovkin (1893–1953), also stressed the importance of the carry-over in the spectator's mind. Only if an object is presented as part of a synthesis, he said, is it endowed with filmic life.

Two types of montage have been distinguished—narrative montage, which is intended primarily to tell the story, and expressive montage, which is intended to produce an immediate effect, much like that of a metaphor in literature. It was in expressive montage that Eisenstein was chiefly interested both in his writing and in his films. In his *Strike* (1924) there is a famous example in which a shot of workers being cut down by cavalry is followed by one of cattle being slaughtered.

The motion picture experience. Other distinguishing characteristics of the motion picture are more closely related to the conditions under which they are normally seen. These are: collectivity, impersonality, and accessibility.

(Left) The academy screen tightly frames individual figures and expresses their powerful emotions in this scene from Carl Dreyer's *Passion of Joan of Arc* (1929). (Right) Broad, spectacular crowd scenes are presented well on the CinemaScope screen, as in this frame from *The Robe* (1953), the first film made in the CinemaScope process.

Collectivity. The kinetoscope, a peep-show motion picture that could be seen by only one person at a time, became obsolescent soon after it was introduced by Thomas A. Edison in 1894 because it could not compete with projected films, which could accommodate audiences. Since that time, an atmosphere of group entertainment has been associated with films. Even for films being seen on television, this aspect of community viewing remains significant; though the audience before any particular set may be small compared with a theatre audience, each spectator brings to it his past associations of films seen in the theatre and the realization that as he watches, millions of others do so too.

Impersonality. Although the motion picture experience is a group experience, it is exceptional for its impersonal nature. The cinema is quite different from the theatre, in which the audience feels the presence of the actors. The cinema is less inhibiting: people come and go as they please, unnoticed, in an easy, relaxing atmosphere. There is comparatively little feeling of association with the other members of the cinema audience. By contrast, at a sporting event, rivalry and intense partisanship are shared openly by the spectators; at a popular music festival, audience participation may reach a level of hysteria; at a concert of classical music, the demand for quiet and serious listening is deeply felt. The informality of the cinema has probably contributed to the tendency to regard it less seriously than other performing arts.

Accessibility. Another basic feature of motion pictures is their accessibility to an audience of vast size. A drama presented in a theatre could be attended by no more than a few thousand persons at a time. In a film, however, the same drama and the same performers may be seen throughout the world by millions of people almost simultaneously. Accessibility has been a determining characteristic of films. From the start, they were a sidewalk attraction, and with the advent of television in addition to cinemas, motion pictures are available almost anywhere at almost any time. This mass audience allowed the motion picture industry to develop vast production and distribution organizations, but it also limited the artistic development of films, since it was commercially safer to present the simplest and least demanding entertainment that would appeal to the widest audience. After television took over much of this mass audience in the 1950s, the motion picture was taken much more seriously as an art.

Effect of the mass audience

EXPRESSIVE ELEMENTS OF MOTION PICTURES

Many observers have seen in films a means of expression comparable to a language. The French poet and film maker Jean Cocteau (1889–1963), for example, called the cinema "picture writing." The language of motion pictures, however, is not the language of words, even though spoken dialogue has been an integral part of motion pictures since the late 1920s and written captions were usually required to explain the action before that. It is primarily in its images that the language of the cinema must be sought.

Cinematographic expression. The film maker has a number of ways of modifying the camera's neutrality and thereby the "reality" that is conveyed to the audience. It is largely by means of these devices that the motion picture becomes such an expressive medium. Several of these expressive techniques should be emphasized. First, there is framing; that is, carefully selecting what will be included within each frame of the film and what will be excluded. Second, there is scale, the size and placement of a particular object or a part of a scene in relation to the rest; a relationship that is determined by the placement of the camera. Third is camera movement, or the lack of it, during shooting. Fourth, there are the peculiar advantages of either colour or black and white photography that can be exploited. Finally, through the skill of the cinematographer and his knowledge of laboratory processes, other highly expressive techniques can be achieved. Each of these means of expression will be discussed below.

Framing. The process of framing is intended to eliminate what is unessential in the motion picture, to direct the spectator's attention to what is important, and to give it special meaning and force. Each frame of film, which corresponds in shape to the image projected on the screen, forms the basis for a graphic composition in the same way as the frame of a painting encloses the area in which the painting must be organized. Several different ratios of frame height to frame width (called "aspect ratios") have been used in motion pictures. The most common is 1 to 1.33, or 3 to 4, a ratio corresponding to the dimensions of the frame of 35-mm film. By using 70-mm film or a special CinemaScope lens, an image with wider horizontal and shorter vertical dimensions is achieved—a proportion of about 2 to 5, or between 1 to 2.25 and 1 to 2.65. A similar effect, called wide screen, was sometimes achieved without the expensive equipment required for CinemaScope by using 35-mm film and masking the top or bottom, or both, giving a ratio of 1 to 1.75, or 4 to 7. Though most cinemas installed wide screens in the 1950s, the normal or academy screen again became more popular in the next decade.

The aspect ratio

The academy screen offers several advantages in composition over those of greater width. An expansive effect is more easily achieved on the academy screen by photographing small-scale figures in the foreground or background with the sky or hills towering above them. Feats of mountain climbing, the monumentality of trees in a forest, or the oppressiveness of a city's skyscrapers are effectively rendered on the academy screen. Wider screens may be more vivid in expressing the loneliness of a prairie, such as that of the Texas panhandle in which *Hud* (1963) was set, or the vastness of the desert, as in *Lawrence of Arabia* (1962). On the other hand, they cause distinct disadvantages for tête-à-tête, or love, scenes.

Regardless of its ratio, the frame may be divided to

show two or more scenes at the same time. In *The Thomas Crown Affair* (1968), for example, the mastermind of a bank robbery and his accomplices are seen talking to each other by telephone, all at the same time, by means of multiple images.

A most effective use of framing consists of temporarily excluding a vital part of the action to stimulate the spectator's interest. For example, the camera may remain fixed on the hero while the villain is perceived only by a voice saying, "Hands up!" or in a science fiction film, the camera may linger on the horror expressed by the victim before revealing the monster that causes it.

Finally, very strong dramatic effects may be obtained by oblique framing; that is, by turning the camera sideways so that the image on the screen appears askew. This was done in an early Russian film *The Ghost That Never Returns* (1929), in which a prison riot shown by oblique framing gives the impression that the building is being pushed over. A more lyrical effect is seen in *Women in Love* (1969), in which the image of two young lovers walking naked among flowers and trees, is turned sideways, as if they were floating.

Scale. Since scale in the cinema constantly changes from shot to shot, the spectator can easily be deceived about the size of objects. When appearing next to enormous tables and chairs, for instance, the actors can be made to look like midgets or children, as in the Stan Laurel and Oliver Hardy comedy *Brats* (1930). By contrast, in *King Kong* (1933) a small-scale model of New York City gave the illusion of the actual city under attack by a giant gorilla. Scale may have a marked effect on the emotional tone of a scene. In the distance an actor may seem lonely, remote, helpless, pathetic; close up, he may appear powerful, threatening, bestial. The range of shots for artistic purposes is from an extreme long shot (the widest view on the smallest scale), with houses or ships appearing as tiny dots on the horizon, through medium shots, two shots (*i.e.*, a shot of convenient size to include two actors) and others, to the close-up, with part of a face, an eye, or a fist, filling the screen (the most restricted view on the largest scale). Telescopic or microscopic shots beyond these extremes are usually of scientific rather than of artistic interest.

Range of shots

Different scales may be evident in the same shot, as in a scene in *The Train* (1964) in which a dead Nazi looks like a huge but now-harmless monster lying in the foreground while the much smaller figures of the French Resistance fighters escape into the background. In *Zabriskie Point* (1968) there is a shot in which a policeman bulks large in the foreground, a girl stands in the middleground, and the fugitive she is protecting is hidden by a tiny comfort station in the background. As has been noted, the camera exaggerates perspective, and this exaggeration adds to the dramatic effect. It is most striking in an ordinary still photograph of an enormous hand or a sunbather's giant feet that were close to the camera lens. In cinematography, the director ordinarily will minimize the effect of this distortion, but occasionally he will use it in an extreme form. In *Easy Rider* (1969), for instance, it was used to give an atmosphere of hallucination and nightmare to a drug-taking session.

A still from Michelangelo Antonioni's *Zabriskie Point* (1968), in which perspective makes the policeman appear overwhelming in relation to the girl while, at the same time, he looms as an easy target for the fugitive hiding behind one of the structures in the background.

Finally, scale will be affected by what precedes and follows. The close-up will have its most dramatic impact coming after long or medium shots, and after many close ups, it is a relief to escape to the middle or far distance.

Shooting angle. Another element in motion picture language is shooting angle. In common language, the phrases "to look up to" and "to look down on" have connotations of admiration and condescension in addition to their obvious reference to physical viewpoint. In one sense or another, children, dogs, and beggars are often looked down upon; while the preacher in his pulpit, the judge on the bench, and the policeman on his horse are looked up to. Even a slight upward or downward angle of a camera is enough to express a mood of inferiority or superiority. A downward angle gives a more expansive, a freer view; an upward angle gives a shut-in, imprisoned feeling. In both cases, the emotional effect of the shot is increased.

Upward or downward shooting angles lead to questions of objectivity and subjectivity. In most motion pictures, both for variety and for breadth of treatment, the camera's viewpoint will switch from one character to another, and sometimes will be associated with none of the characters but will merely look on. The camera might take the viewpoint of the heroine, looking with dismay at the villain as he breaks into her room; in this case, an upward camera angle will give a subjective impression of her fear. Similar subjectivity may be seen in a shot of buildings reeling in the way they might appear to a drunken man, as in the German classic *The Last Laugh* (1924), or in a rapid camera movement from a window to the pavement below to express a thought of suicide, as in the Italian neorealist film *Umberto D.* (1952). Occasionally, an entire motion picture may be shot from one person's point of view, usually with a "stream of consciousness" commentary, speaking the person's thoughts. A well-known picture in this style is the first American film of the British director Alfred Hitchcock, *Rebecca* (1940), in which the heroine, an innocent young girl who marries a wealthy widower, dramatically uncovers his turbulent past.

The camera's "point of view"

Extreme upward or downward angles are too far removed from ordinary experience to have many applications in motion pictures, but they may express exceptional situations—a sick man on his back, a baby's or a dog's point of view, a man in a pit or in a coffin, a spy covertly looking down on an enemy meeting. As with scale, the shots that precede and follow will alter the effect of the shooting angle. Upward angles will be stronger following a level or downward-looking camera, and vice versa.

Camera movement. Another factor in motion picture language is camera movement. Film makers experimented with camera movement very early in film history (from the 1910s onward), but it was considered artificial, and equipment had not been developed for moving the camera evenly and holding it steady. After the 1930s, however, camera movement was much more frequently used.

The most common movement is to turn (or pan, from the word panorama) the camera horizontally so that it sweeps around the scene. It can also be tilted up or down in a vertical panning shot, or in a diagonal pan, as when it follows an actor up a stairway. Almost as common today is the tracking (or trucking) shot, in which the camera is moved bodily forward toward an object, backward away from it, or sideways along a street, a wall, a beach, a table. The camera may pan while it is tracking, a complex combined movement. A camera movement that is frequently used imitates the gaze of a traveller in a car or train turning to focus on a point of interest as he moves past it. Tracking shots may be made from a camera mounted on a dolly (or trolley), sometimes riding on rails, or from a crane, or boom. The aerial movements

Panning and tracking

Innovative use of multiple images was made by Abel Gance in *Napoléon* (1926). Here the main vista is projected across three screens with three projectors, while on the centre screen additional images of a map and a woman's face are superimposed.
From the National Film Archive, London

of a crane are freer, but the trolley can travel more easily. Cameras may be mounted on automobiles, trains, planes, or balloons. Although a machine-mounted camera gives a steadier effect on the screen, the director may sometimes want the unsteadiness or jerkiness of a hand-held camera. Hand-held cameras are used when standard equipment is too bulky or too expensive. Occasionally, extreme movements are used: the innovative French director Abel Gance in *Napoléon* (1926) had his cameras thrown as snowballs, fired as cannonballs, dropped from a cliff into the sea, fixed to the saddle of a cantering horse, and mounted on a swinging platform.

The effect of camera movement will depend on the context and on the pace of movement. At a deliberate pace the camera can explore a scene and reveal significant details. If it is raised well above the ground the movement has a dreamlike power and, when combined with slow motion, may give a somnolent impression or express recollection or hallucination. The camera movement may end dramatically on a dagger, on a gun half-hidden in an assailant's hand, or on a suspicious bulge in a pocket. It may link the hero walking in the garden and the heroine watching him with loving eyes from a window. It may bring a dramatic surprise as in the American western *Stagecoach* (1939), when director John Ford had the camera, mounted high above a rocky defile, move slowly from the stagecoach below to reveal a band of Indians waiting in ambush. On the other hand, the camera may simply turn away from a scene to leave the remainder to the spectator's imagination, as when it withdraws from a torture scene or from a love scene. In filming a conversation the camera may turn from one speaker to the other, animating the scene with its own movement and showing the expression of the speaker, or listener, more closely than would be possible with a two shot, which would encompass both at once. Camera movement may be used to change the scene to a distant place, to a different period of time, or to an imaginary world. Very rapid camera movements (which are often affected by a zoom lens—one that rapidly brings the image forward to a close-up or makes it recede into the background) may express a sudden surge of emotion or a contemplated action, such as in the suicide example from *Umberto D.* already mentioned. In *The Rains Came* (1939), as the heroine realizes with horror that she has drunk from a glass that may be contaminated with typhus, the camera rushes forward to a close-up on the fatal glass, shining in the darkness.

Zooming

The introduction of camera movement significantly affected the style of motion pictures, enabling the action to be followed more smoothly and continuously than was possible when it was broken up into brief shots.

In extreme cutting styles, the audience may lose the dramatic relationship between shots of brief duration. Shots that last too long, on the other hand, may cause the spectator's attention to wander.

Colour and black and white. Early attempts to obtain colour effects in the cinema were made by using film stock tinted all one shade. Though sepia, for instance, was effective for occasional use, it was in the long run too artificial. In some motion pictures every frame was hand coloured, but that method was too laborious for continued use. More important, black and white proved to be an entirely acceptable medium, with an artistic quality of its own.

A few films were made in the 1920s and earlier, by various colour processes, but a practical commercial system was not perfected until Technicolor was introduced in Walt Disney's animated short *Flowers and Trees* (1932) and in the feature film *Becky Sharp* (1935). The introduction of colour was less revolutionary than the introduction of sound; though the silent film soon disappeared, the black and white film has continued to coexist with colour.

A black and white motion picture is not merely a picture that lacks colour but an artistic creation with positive qualities of its own. An ample range of effects can be obtained—from precise images in which every hair, every grain can be clearly seen, to a smudged charcoal effect. Oddly, black and white often gives a stronger impression of realism than colour does, perhaps because of associations with newsreels and newspaper photographs. Black and white may suggest the hard news of the daily paper, while colour may connote the fantasies of glossy fashion magazines, advertisements, and comic strips. In the cinema, black and white composition is often stronger and more dramatic than colour, cutting can be more forceful, and the coloured image tends to lose depth.

Use of black and white for realism

Nevertheless, colour introduced a new world into the cinema and steadily grew more effective. Colour can have a powerful dramatic effect. In *The Damned* (1969), the Italian director Luchino Visconti used the flaming red of a blast furnace to represent the hellish power of the Nazis, and garish whites and reds in a drunken homosexual orgy ending in a massacre. Colour can be used symbolically—in Eisenstein's *Ivan the Terrible,* Part II (1946), red turning to a bluish shade represents the fear of a pretender about to be assassinated.

Role of the cinematographer. Cameramen remain virtually unknown outside the industry even though the cameraman's contribution to a movie sometimes matches that of the director in importance. Although the director has ultimate control over the visual image, the cameraman actually records it on film, translating the director's ideas and creating the atmosphere and the look of the film. The association between cameraman and the processing laboratory is also of highest importance because he often spends hours there after shooting, checking the negative. On feature films there is a camera team and responsibility is shared.

The cameramen are responsible for exact framing, sometimes for screens of more than one type. They also must decide upon the use of masking, the choice of lens, the camera angle, and the control of camera movement. They must either keep the focus sharp or put all or part of the picture out of focus if this effect is required. The cameraman will also control slow motion or accelerated motion; with early hand-cranked cameras, he simply slowed down or cranked faster, but later special controls and cameras were developed. Trick photography was once effected by simple manipulation of the camera: magical transformations were made simply by stopping it and changing the scene; and the impression of backward

motion was achieved by turning the camera upside down and reversing the film. More elaborate processes are now at the photographer's command involving laboratory technicians as much as the camera crew. Many effects require the actors to perform against a background of previously prepared film. The cameraman must be in command of all these processes. The best of them will give the picture a visual style that is peculiarly their own.

Editing. The process of trimming and piecing together lengths of film in order to make an artistically concise and complete motion picture is probably the most important technique of film language. The terms editing, cutting, and montage are often applied interchangeably to the process. In montage the emphasis is on the juxtaposition of ideas resulting from this process, cutting stresses the physical work with the actual strips of film, and editing encompasses both.

Editing, cutting, and montage

In a single shot (*i.e.*, the film exposed at one time, without interruption, by one camera), a motion picture contains a copy of some part of the real world; by effective editing, this world may be taken apart and put together again in the form of a work of art. Editing permits sudden changes in viewpoint from outside to inside, from one character to another or one place to another, from far away to close at hand. Most editing within a scene is made unobtrusive by correlating it with the action or the dialogue. From scene to scene, editing must establish the change in time or place as the story requires; it resembles the changing of sets in the theatre, though in the cinema changes are far more frequent, and are more like the chapters or paragraphs of a novel. The cut may be made startling rather than unobtrusive—for instance, by a sudden close-up of a strange face. Or the picture may fade out and fade in, the screen being left dark for a moment. Or it may dissolve, or mix, to a new scene, one image showing on top of the other for a moment. The film makers may use other devices, such as a wipe (*i.e.*, a line moving across the screen that wipes out the preceding image while introducing the next); or irising, gradually reducing the old image from the edges to a pinpoint size and then expanding the new one in the reverse way; or a turnover (the entire screen seems to turn over, with the new image seeming to appear on what was the reverse side). The director may introduce his own creative touches in cutting. The German-born director Max Ophüls, for example, connected the separate episodes of *La Ronde* (1950) by means of the musical leitmotiv of a hurdy-gurdy tune. In *Vivre sa vie* (1962; *My Life to Live*), Jean-Luc Godard, one of the outstanding French New Wave directors of the late 1950s, introduced chapter headings marking the heroine's step-by-step involvement in prostitution and ultimately, her murder, as if it were a didactic 19th-century novel. And Alfred Hitchcock, probably the greatest director of suspense films, in his British film *The Thirty-Nine Steps* (1935) cut from a woman's scream to the similar sound of a train whistle, an effect so dramatic that it was frequently imitated thereafter. By skillful editing highly dramatic effects may be achieved more easily than if they were staged. In the American western film *Butch Cassidy and the Sundance Kid* (1969), for example, the title characters are seen cornered by lawmen on a high cliff overlooking a river, into which they make an almost suicidal leap to their escape. Actually, the scenes involving the two leading actors on the cliff, and those of the dives were shot weeks apart, and they involved different crews and even different rivers, yet the audience readily accepts the illusion created by the editing.

The editor's function. Like camerawork, editing is a function that is ordinarily hidden from the audience, but it is vital to the finished picture. It is the editor's job to judge the length of each shot, choosing the exact moment to cut. The length of a shot may depend upon the amount of detail it contains, its scale, its dramatic impact, or its context in relation to the shots that precede and follow it. Though the audience is unconscious of these judgments, the impact of the finished film will depend on how well they are made.

The director will generally view the day's rushes (*i.e.*, advance prints of the film shot that day) and, in consultation, select what is to be used. Thereafter, he may spend a good deal of time in the cutting room or none at all. In some cases, the editor may be influential in rearranging shots, discarding them, or even ordering reshooting or additional shooting. An important factor in the work of the editor is the cutting ratio—the proportion of film shot to that used in the final film. Some directors shoot as little as two or three times as much as is required, while others may shoot six times as much or even more. In its widest sense, editing includes mixing the sounds and correlating them with the visual film, a process that is even more complex than cutting the visual film.

Cutting ratio

Cinema time. The motion picture has been defined as a series of images of space that are arranged in time. The time of film language is quite different from that of reality and that conveyed by the other arts, such as drama and literature. Movement on the screen is produced by showing the spectator every second 24 frames, or still photographs, with dark intervals between them. The movement seems to be at the same rate as that of ordinary life only if the pictures are taken and shown at the same speed. Slow motion may be achieved either by speeding up the camera or slowing down the projector, and accelerated motion is obtained in the opposite way. In common practice, the speed of the projector is constant, and the speed of the camera is varied to achieve these effects. Like extremes of scale, extremes of speed, such as accelerated motion films of plant growth, or slow-motion films of bullets, explosions, or materials being broken, are of less interest to the art of motion pictures than to science. But moderate slow motion can express dreams, or ecstasy, while accelerated motion is often very effective in comedy. The cinema can give the illusion of reversing time by showing events happening backward, or of holding time still by showing the same image again and again.

Time conventions. Despite the possibilities for manipulating it, the time presented in a single shot of film is ordinarily the time of the real world. From shot to shot, however, the time is presented according to certain conventions. In most motion pictures, the story may be assumed to be presented in chronological order and in real time except when certain conventions are invoked, such as: (1) ellipsis, (2) repetition for emphasis, (3) flashbacks, or (4) thought, or dream, sequences.

The narrative may be advanced with immense speed and economy simply by the omission, or ellipsis, of what is not essential. Generally, if a great span of time is elided between shots, some emphasis will be required on the cutting itself. A straight cut may be used between a shot of a girl dressing for a ball and a shot of her at the ball itself. To show a lapse of years, however, it might be necessary to fade one shot slowly from the screen and fade the next in, or to use a dissolve, or mix, which shows both shots superimposed as one supersedes the other.

To emphasize important scenes of short duration, repetition is an effective device. Such a scene may be shown from different angles, from a distance and then close up, and it may occupy much more time on the screen than the actual event would. By emphasizing what is important and eliminating the rest a motion picture can give the illusion of covering a lifetime in only 90 minutes.

A flashback is an interruption of the actual chronology of a story to relate a significant event of an earlier time. The flash forward, a much less used device, interjects future events in the same way. These devices require special optical effects, such as fades, dissolves, or irising, to stress the break in continuity. The break can also be stressed by the use of a melody associated with the past, or by an unusual camera movement, as well as by the more obvious devices of using noticeably different period styles in the settings or having the actors made up to look much older or younger.

Flashback and flash forward

A thought or dream sequence requires similar emphasis on the departure from chronology of real time. Nearly all of *La Rivière de l'Hibou* (1962), a prize-winning French short film adapted from Ambrose Bierce's 1891 short story, *An Occurrence at Owl Creek Bridge*, consists of the fleeting last thoughts of a man about to be hanged; by

not indicating a break between the actual events of the hanging and the fantasy of the condemned man, the film deceives the audience, until the very end, into thinking he is making an escape.

Tempo. The tempo or pace that an audience senses in a film may be influenced in three ways: by the actual speed and rhythm of movement and cuts within the film, by the accompanying music, and by the content of the story. For most people, time seems to pass quickly during moments of happiness, excitement, or exhilaration, and slowly during sadness or boredom. In films, it is possible to reverse this apparent cause-and-effect relationship and to induce a feeling of happiness, excitement, or exhilaration by making the picture seem to move quickly. Means of accomplishing this include lively music, quick cutting, or fast action. Conversely, a sense of sadness or boredom can be induced by solemn music or immobility of the images.

A feeling of suspense is unusual in combining excitement with a sense that time is passing slowly. Much of the suspense depends upon the audience's awareness of a danger unknown to the characters in the film. The height of the excitement that may be achieved in this way is sometimes seen in children and unsophisticated spectators who shout out to warn the actors.

Tempo is not necessarily related to the actual length of a motion picture. A poorly made short film may drag, while *Intolerance* (1916), D.W. Griffith's 3½-hour masterpiece, or *Greed* (1924), which its German–American director Erich von Stroheim cut from ten hours to four hours and then to two, still commands the full attention of connoisseurs. Regrettably, the length of a film has more often been determined by commercial than by artistic considerations.

Sound. Mechanical reproduction of sound was developed as early as the first motion pictures, but the problems of amplifying sound sufficiently for an audience and synchronizing it with the film image were not solved until the late 1920s. Although sound attracted crowds to the cinema to hear the new miracle, the artistic levels of the best silent pictures were not reached immediately. The new "talkies" were mostly poor imitations of theatrical plays, with dialogue and sound used indiscriminately. Sound equipment was cumbersome and imperfect. The mobile camera of the silent film lost its freedom, and the editing of film tied to a sound track became stodgy and slow.

Only gradually did film makers realize that dialogue is a much more important element in a play than in a film, and that much that the play must express in words can be shown in pictures in films.

When film makers learned to use it, of course, sound resulted in great advantages. The cumbersome captions of the silent film could be dropped; certain strained methods of showing sound in pictures, such as shots of factory whistles, guns firing, or rows of clapping hands, became unnecessary. Good music could be composed for a film and enjoyed in the humblest as well as the grandest cinema. Just as the visual image in the frame of a motion picture was elevated from the profusion of nature and could be seen fresh, so could sound be isolated for artistic purposes—the screech of automobile tires, the ticking of a watch, the baying of hounds, the whinny of a horse.

Dramatic effect of sound

The dramatic effect of sound could be tremendous. The rushing, crackling sound of a great fire in the last scene of Robert Bresson's *Trial of Joan of Arc* (1962) is as terrifying as any visual effect could be. In Hitchcock's *Torn Curtain* (1966) there is a desperate struggle in the kitchen of a lonely farmhouse; as the doomed man's head is held in an oven, and his hands (the only thing in the picture) convulsively twitch, the sound of hissing gas dominates the scene. It should be stressed that the introduction of sound made it possible to use *silence* with a dramatic effect that is more telling than either words or music.

Like images, sounds represent subjective thoughts, indicating not what the character is saying but what is in his mind. A famous example is in Alfred Hitchcock's *Blackmail* (1929), the first English sound film, in which the words "knife, knife, knife" are repeated in the thoughts of a frightened girl who thinks she has committed a murder.

In terms of montage, the sound, dialogue, and music are used in combination not only with each other but also with the visual image. They can overlap and vary in intensity in a flexible and complex pattern.

Music. The live music that accompanied silent films varied from a full orchestra to a honky-tonk piano, according to the size of the cinema. Music was also effectively used on the film set to improve an actor's performance. With sound, music became an integral part of the picture on the screen. Early mood music was so expressive that it now seems overblown. Later, film makers learned the virtue of restraint, using better music but less frequently and with more effect. Music has an important function in emotional climaxes to relieve or sublimate intolerable intensity—of grief, pain, or ecstasy. *The Gospel According to Saint Matthew* (1964) by the Italian director Pier Paolo Pasolini reveals how effective periods of silence can be, and how great music can ennoble the scenes of Christ's persecution and agony on the cross.

The sound track is generally more complex than the visual film. It may involve mixing together tracks of dialogue, background noises, and music recorded at different times; they all must be matched to each other and to the visual film. Though the audience may hear it simply as an accompaniment to what they see, the sound may be the most expensive and difficult part of a motion picture. There is an increasing use of electronic music for astringent effects, as in *2001* (1968). Music may be used symbolically: in *Léon Morin, Prêtre* (1961; *Leon Morin, Priest*) a sequence of harsh chords represents the German occupation forces, and a dancing bugle motif represents the Italian troops. Organ music is used in scenes showing the heroine with the priest in church, and piano music when they are in his flat. Hurdy-gurdy music represents two gossiping spinsters, and in a climactic scene louder and louder electronic music represents the heroine's obsessive sexual feeling for the priest, until she reaches out to take his hand.

Sound engineering. It is the function of the sound engineer to select and modify sound as the cameraman selects his images. Since the noise of crockery, cutlery, or paper or the chirping of crickets would be intolerable transferred in full volume to the screen, the sound engineer must tone them down. Treble and bass must be balanced. In other cases, in order to get the effect needed, sound has to be built up and orchestrated as if it were music. Again, sound need not correspond exactly with the visual images. Artistic use can be made of asynchronism; that is, contrasting the sound to the visual image rather than reflecting it. Motion picture sound is capable of remarkable delicacy, richness, and variety. Sound libraries put most conceivable sounds readily at the disposal of film makers. Instruments and voices can be modified, overlapped, echoed, or given a resonance and volume that transform them. Dialogue can be crystal clear, bringing the audience far closer to an actor than in the theatre, or it may deliberately reproduce the careless enunciation of everyday speech.

Dubbing

Dubbing (*i.e.*, recording the voices after the film has been shot, carefully matching the spoken or sung words to the lip movements in the film) allows the film to be shown in many languages, though many of the most serious students of the art prefer to see a film in its original language with subtitles. In musicals the sound of a song is ordinarily recorded after the film has been shot, sometimes by a singer other than the actor.

The script. Although conventions vary from one country to another, the script usually develops over a number of distinct stages from a synopsis of the original idea, through a "treatment" that contains an outline and considerably more detail, to a shooting script. Although the terms are used ambiguously, script, or screenplay, usually refers to the dialogue and the annotations necessary to understand the action; and a script reads much like other printed forms of dramatic literature, while "shooting script" or "scenario" more often implies not only all of the dialogue but also extensive technical details regarding

the setting, the camera work, and other factors. Moreover, a shooting script may have the scenes arranged in the order in which they will be shot, a radically different arrangement from that of the film itself since all the scenes involving the same actors and sets are ordinarily shot at the same time, for economy. Some scripts are subsequently modified into novels and distributed in book form, such as the U.S. bestseller *Love Story* (1970) by Erich Segal, and, in the instance of Dylan Thomas's *The Doctor and the Devils* (1953), a script became a literary work without ever having been made into a motion picture. Generally, more elaborate productions require more elaborate shooting scripts, while more personal films may be made without any form of written script.

Different directors follow different methods in working with scripts: D.W. Griffith and other early directors worked virtually without a script; Hitchcock plans the script thoroughly before shooting any film. Exponents of *cinéma vérité* ("cinema truth"), a French movement of the 1960s, produced movies by first tape-recording interviews, conversation, and opinions; they then shot visual images to correspond with the words and finally created the film in the cutting room.

Adaptation from other art forms must take into account differences of complexity and scale in film. A film often must omit characters and incidents that were in the novel from which it is adapted, for example, and the pace usually must be accelerated. Ordinarily, only a fraction of a novel's dialogue can be included. In an adaptation of a play, the curtailment is less severe, but much dialogue still must be cut or expressed visually. On the other hand, movement and cutting can be used to vary the scene and express more in a given time. For a successful adaptation, film makers must recreate a work as a motion picture.

Although many eminent literary authors, including F. Scott Fitzgerald and Aldous Huxley, have worked on film scripts, the ability to write a good one requires a stronger consciousness of visual possibilities than many novelists develop. The American novelist William Faulkner, who worked on a number of Hollywood motion pictures directed by Howard Hawks, attested to the superior ability of the relatively unknown scriptwriters to express in a concise visual shot what Faulkner himself would have conveyed less effectively by means of dialogue.

Motion picture acting. Of all the artists involved in films, the actors and actresses are closest to the audience. The public more often goes to see a motion picture for its stars than for any other single reason. The divergent techniques of stage and film acting are well understood, and there are many leading players who excel in both. But the greatest film stars have a talent peculiar to the screen alone. This talent in many instances seems to be related not to how well they act, but to the sort of person they appear to be.

Being oneself

Film acting requires less training and skill than stage acting, but much more restraint. "Don't act, think," was the advice of the eminent German director of the 1920s, Friedrich W. Murnau. While the stage actor may be praised for a performance that is highly wrought, the film star usually must appear to be himself. Few, however, seem able to achieve the greatest success. Not only is it difficult to appear to be oneself but also the self that is revealed must be photogenic and able to sustain its appeal under the camera's relentless scrutiny. Cinema audiences generally feel closer to the personality on the screen; the stage performance remains a performance. Many stars remain the same from picture to picture, but some film actors such as the U.S. actor of the 1920s Lon Chaney, the "man of a thousand faces," drastically change their appearance from one film to another. A motion picture performance can be synthesized bit by bit, by the joint efforts of the actor, the director, the cameraman, and others. The conditions of film production are such that some actors find them trying; they may have to put up with long hours on the set and endless repetition. If they require less talent than theatrical performers, they need other qualities, which are perhaps equally rare.

Motion picture design. Under the heading of design, all of the elements of a picture's setting may be included —art direction, scenic composition, set design, costume, and makeup. At its simplest and most naturalistic, the camera can choose and frame ordinary people in a real location. At its most elaborate, motion picture production may involve the expenditure of vast sums to put up gigantic sets that require building houses, ships, churches,
