and monuments, or re-creating lost cities, by-gone landscapes, or ancient battles, and dressing thousands of extras in period costumes. Thunderstorms, tornadoes, snowstorms, earthquakes, volcanic eruptions, or tidal waves may be simulated, or monsters, spaceships, and cities of the future created. Film sets are constructed more solidly than stage scenery, but of the lightest, cheapest materials that will both look solid and photograph well.

Whether for black and white or for colour, their shades, proportions and shapes are chosen for the camera rather than the eye. The camera can deceive the viewer about scale, however, and the model makers and special effects men can reproduce virtually anything in miniature, from the aurora borealis shining on an igloo to a tempest destroying the Spanish Armada. A whole series of film monsters have attracted goggle-eyed audiences since the French pioneer Georges Méliès' formidable man-in-the-moon of 1902. Miracles can be achieved in

film, either in the colossal form of the crossing of the Red Sea by the children of Israel in Cecil B. DeMille's epic *The Ten Commandments* (1956) or in the comparatively simple treatment of angels and miracles in Pier Paolo Pasolini's *Gospel According to Saint Matthew* (1964). Film publicity makes much of the creations of the epics such as *Moby Dick* (1956) or *Cleopatra* (1963) but, even on a more modest scale, sets can contribute enormously to a picture, as in Ken Adam's sets for the James Bond series such as *Dr. No* (1962), *Goldfinger* (1964).

The Expressionist influence on set design

The strongest single artistic influence in motion picture set design was the German Expressionist cinema of the 1920s, which combined elements of Max Reinhardt's theatre, a Wagnerian philosophy of doom, and Expressionist painting and graphics. Expressionist films such as *The Cabinet of Dr. Caligari* (1919), *The Golem* (1920), *Nosferatu* (1922), and *Metropolis* (1926) created a world of fantasy and horror peopled with menacing, shadowy figures. In other German Expressionist motion pictures, such as *The Student of Prague* (1926) or *The Nibelungen* (1924), there was a Baroque beauty of architectural, woodland, and floral settings. The influence of Expressionism can be seen in later cinema in the work of the directors Orson Welles and Carl Dreyer, and in many gangster movies.

Fantastic settings and lighting effects were used by German Expressionist film makers in the 1920s. (Top) *Nosferatu* (1922) directed by F. W. Murnau. (Centre) *The Cabinet of Dr. Caligari* (1919) directed by Robert Wiene. (Bottom) *The Nibelungen* (1924) directed by Fritz Lang.

The subject and how it is treated will be reflected in all the elements of design in a motion picture. In the hectic atmosphere of a horror movie or a Hitchcock thriller, a studio set may pass unnoticed, even though it would seem disconcertingly artificial in another film. In a musical everything may look artificial: the chambermaid's bedroom may be a model of daintiness and taste. But Luis Buñuel in *Los Olvidados* (1950; *The Young and the Damned*), Satyajit Ray in *Pather Panchali* (1952), and Luchino Visconti in *La terra trema* (1948), render the peasant interiors, as well as the people who inhabit them, disturbingly real.

Lighting. In a medium consisting of the projection of impressions on a light-sensitive material, lighting is of very special importance. Daylight is the readiest, cheapest, and strongest source of lighting. Hollywood was said to owe its pre-eminence as a motion picture production centre to its sunny climate. Even in daylight shooting, however, artificial aids may be necessary to reduce the highlights or to lighten the shadows. In circumstances not involving daylight, shooting is entirely dependent on high-powered spotlights and floodlights.

Lighting, a part of camerawork, is under the control of the chief cameraman or lighting cameraman. In black and white films, lighting is of paramount importance in giving the overall light or dark tone of the scene and in providing for dramatic contrasts or emphasis within the scene. In color, the lighting works indirectly to bring out or modify the colour but is of equal importance. Lighting in the cinema is a method of composition, used to complement and reinforce the dramatic situation. Generally dark lighting is associated with tragedy and bright light with romance or comedy, but overlighting gives ghastly or unearthly effects, as in the memory sequence at the beginning of the Swedish director Ingmar Bergman's *Sawdust and Tinsel* (1953; also called *Naked Night*). Lighting an actor from above gives his face a spiritual effect; from below, an uncanny or evil appearance. Front lighting blurs faults but takes away character; side lighting gives relief and solidity but may show wrinkles and defects. Lighting from behind tends to idealize a subject and give it an ethereal quality.

Lighting as a method of composition

Fashions in film lighting have fluctuated through the years. Early films tended to be flat and uniform. Later, especially in German Expressionist films of the 1920s, strong contrasts of light and shade were favoured for their highly dramatic effect. Still later, this tendency was modified toward more balanced lighting. Even in dramatic scenes, the centre of interest now tends to be more discretely emphasized.

Related to lighting is the development of the print in the laboratory, where sections of film shot under different conditions can be modified to avoid a violent contrast where none is desired. Finally, the lighting of the projector that shows the picture and the brilliance of the screen are important. As light sources for the projector, both the traditional carbon arc and the modern Xenon lamp have advocates; what matters most is that the light should be powerful, brilliant, and unvarying throughout the projection of the picture.

Settings. A salient feature of the cinema is its ability to reproduce natural scenery. The appeal of some motion pictures lies chiefly in their natural settings. In the Swedish film *Elvira Madigan* (1967), the lushness of the greenery afforded a visual metaphor for a storybook romance between an aristocratic officer and a blonde showgirl that was doomed by the conventions of the time.

With the invention of lighter, more portable equipment, filming on location—that is, in an actual setting like the one in which the story takes place rather than in a studio set—became less difficult and expensive and more often used. As a result, many earlier motion pictures now look

artificial, since no studio set could equal the authenticity of a real location. Nonetheless, films must be shot in the studio when natural settings are unavailable, as in historical films, or too remote. In some cases, a film will be taken of a setting, such as a mountain range, and brought back to the studio, where, by means of "back projection," it will be used as a background against which the actors perform.

Costume. In Hollywood motion pictures, roughly from the 1920s through the 1940s, the costumes worn by the stars were a major force in setting fashions throughout the world. A motion picture was often an opportunity for an actress to wear one gorgeous costume after another. As the influence of motion picture costume on the world of fashion declined, the aesthetic and expressive functions of costume became more important in films, though costume was seldom completely realistic.

Costume and the actor's identity

Costume also once played a more important role in an actor's identity. Charlie Chaplin, Buster Keaton, W.C. Fields, Mae West, and other stars of the 1920s and 1930s all created characters in which costume was an integral part of the total identity. Later film comedians, such as Peter Sellers or Jerry Lewis, cannot be identified in the same way with any style of dress.

Makeup. Film makeup differs significantly from that of the stage, where heavy lines are required to convey a characteristic expression to the audience. By means of the camera, the motion picture audience can study the actor's face quite closely. The makeup must be flawless to stand up under such scrutiny, but since it need not be applied night after night, as in theatre, elaborate preparations are feasible. Many of the greatest film makers, such as Eisenstein, Carl Dreyer and Robert Bresson, have favoured simple naturalism in makeup—the unadorned lines of old age or a face caked with dust, running with perspiration. Whatever the style of makeup, its purpose is to idealize the face, to make it a more photogenic object, whether monster or ingenue. The efforts of wig makers, dentists, and plastic surgeons, as well as cosmeticians and others, are aimed at a heightened reality.

STYLE IN MOTION PICTURES

Since the motion picture is a group art, the importance of the contributions of those involved in making it may be difficult to assess. Cases have been put forward on behalf of the author of the story, the star, the studio, and the national industry as the primary artistic influence on the motion picture. Since the 1950s there has been an increasing tendency to credit the director with the merging of the myriad elements into an artistic style.

The auteur theory. Discussion of this point was stimulated by the "auteur theory" first propounded in 1954 by François Truffaut, who wrote for the French film journal *Cahiers du Cinema* and later became a major director. He attacked the French cinema for giving a dominant role to script writers, who wrote scenarios that allowed the director to do no more than frame them. Some directors, however, such as Bresson, Jean Renoir, Hitchcock, and others, were what Truffaut called *auteurs* (the French word for "authors") in that they wrote dialogue, invented their own stories, and made motion pictures that were an artistic whole, expressing their own style. The idea was taken up in France and elsewhere and led to a search for directors who were *auteurs*. It turned out that the chosen *auteur* was often a director not of high-budget popular films, which are more vulnerable to financial pressures, but of fast-moving, strong, commercial entertainment, such as Samuel Fuller, whose best works include such unpretentious Hollywood films as *I Shot Jesse James* (1949) and *House of Bamboo* (1955). This theory, like others, was useful insofar as it corresponded to the facts and offered an approach to an interpretation of a complex art. Also, by focussing attention on the professional director, the *auteur* critics helped correct a literary bias common in much film criticism. Carried to extremes, however, it resulted in a tendency to see no wrong in the work of an *auteur*. Most directors control some elements of a film and lack control over others and make films that reflect their best work only in part. In a group art with many elements interacting in shifting patterns of authority, generalization is difficult.

Directors and their styles. Of all the persons involved in making the motion picture, the director is usually the one in the best position to influence the total work with his own creative personality. Even under the studio system that prevailed in Hollywood during the 1930s and 1940s, when the directors were supposed to be the same as other corporate employees, their position was strong. Executive control was often uncertain, uninformed, or ineffectual, and authority tended to devolve upon the director. Later, when individual protection units supplanted the large studios, the director became still stronger.

The director's impact

The director lives with the motion picture. If he chooses, he usually can control every detail. Though the producer has financial control of the film and, with it, the authority to overrule, or even fire, the director, he seldom influences the artistic development of the picture as much as the director. The best directors tend to be men of strong personality who wield almost dictatorial power. Their genius lies in inspiring others, in either persuading or bullying a variety of creative persons to excel themselves.

A director's command of technical elements such as visual rhythm and the handling of the camera corresponds to a writers' command of words or a painter's control of the brush. Technical mastery is a prime virtue. Moreover, just as plain prose may represent a higher level of literature than more decorative writing, so can an unpretentious thriller directed by Alfred Hitchcock achieve a higher level of artistic expression than the blown-up epics of Cecil B. DeMille, or the grandiloquence of John Huston's *The Bible* (1966). The best director and the best stylist is not the one with the grandest manner but the one who can bring the varied elements of a picture together in a unified and near-perfect whole. Eisenstein's epic *Alexander Nevsky* (1938) is a great picture but so is a gossamer comedy like René Clair's *Sous Les Toits de Paris* (1930; *Under the Roofs of Paris*) or a miniature satire like *Simon of the Desert*(1965) by the Spanish director Luis Buñuel. The director's influence on the style of a film is far less direct than, for example, that of a writer on a novel. Charlie Chaplin, Erich von Stroheim, and Buster Keaton are recognized as master stylists, but they were more than directors. They dominated all their films, as writers, producers, actors—whatever was required. Their personality is evident in every film they made. In the work of lesser artists, some trick of style, some superficial characteristic, is sometimes taken for true style. The true style of a motion picture, however, is in its overall shape and handling. Hitchcock's style lies in his command of the medium to tell a gripping story at a spanking pace; to combine innocence and villainy in a macabre juxtaposition; to show the ordinary man caught in a web of danger; to depict continuously interesting situations and characters; to keep the audience in suspense; and at the end to provide a fast-moving climax. He does this, with verve and colour, by careful planning, by control of the actors, by a lifetime's knowledge of film making. The Indian director Satyajit Ray from the start developed a personal style—one that is gentle, unhurried, and deeply humane; he was able to do this because he made his own pictures, with modest means, outside the powerful Bombay film industry. In most cases, however, directors must cope with a system, an industry that, inevitably, will limit their freedom to express themselves. Only the exceptional or the veteran director will be free, and then only occasionally. For this reason, the style seen in a motion picture is more often not that of an individual but that of a country, a school, a group, or a movement.

The true style of a film

National styles and schools of motion pictures. In film making the international exchange of leading actors, actresses, directors, cameramen, and other film makers is common. Jean-Luc Godard's satirical motion picture, *Le Mépris* (1963; *Contempt*), shows an American producer and a German director making a picture of *The Odyssey* in France from an Italian script; there are more complex real examples. Many such pictures, by attempting to transcend national frontiers, lose their character altogether.

As a popular art, the motion picture has roots deep in

native soil; it is possible to discern national schools of film making. American silent comedy, for example, is reminiscent of an irreverent Yankee verve that was expressed in literature by Mark Twain, Artemus Ward, and Bret Harte. The western and the gangster picture were true native American products; that Hollywood was at its best dealing with an environment near at hand may be seen by comparing examples of those genres with the reverent but wooden *Story of Louis Pasteur* (1936). Two American masterpieces of the epic, *Gone With the Wind* (1939) and *The Birth of a Nation* (1915), deal with a central American theme, the U.S. Civil War and its aftermath.

Studio styles

In Hollywood at its peak, each motion picture company had its own "house" style, and whoever the director or stars, a picture from MGM, Warner Brothers, Paramount, or Columbia was recognizable. This was partly due to company policy in choosing subjects, to the influence of top executive producers, the work of the same scriptwriters, cameramen, lab workers, cutters, art directors, and others, and to the influence of a closely knit organization

Other countries also fostered distinctive native styles in film. Among the best British motion pictures were the cheerful comedies made by the Ealing studio after World War II, such as *Kind Hearts and Coronets* (1949) and *The Ladykillers* (1955). The settings, the actors, and the stories were all typically British. Across the English channel, the films of René Clair, Marcel Pagnol, and Sacha Guitry were distinctively French—light, elegant, poignant, and sophisticated. A later generation of film makers, the *nouvelle vague* or New Wave directors of the late 1950s, revealed a very different aspect of the French character—iconoclastic, idosyncratic, personal, hostile.

The Soviet directors of the silent era probably created the most consistently powerful films ever seen, singularly lacking in humour or in tender graces but expressing emotion on a grand scale; relationships can easily be drawn to Russian music and literature. The characteristics of each of the national schools are treated in detail in MOTION PICTURES, HISTORY OF. It will suffice here only to indicate the fact of their existence.

TYPES OF MOTION PICTURES

Popular and art films. The cinema audience of any nation can be divided roughly into a mass audience that seeks entertainment in films and a smaller group that is consciously concerned with artistic values in the motion picture. The films that appeal to these two groups, however, will vary from one nation to another and from one period to another. The Hollywood comedies of the 1920s by Charlie Chaplin, Buster Keaton, and others, for example, were originally popular entertainment but they were later taken up wholeheartedly by the art film audience. The comedies of Jerry Lewis received little serious critical attention in their native United States but a greal deal in France. The low-budget thrillers of directors who were adopted by *auteur* critics met a similar experience. And several films, such as *Easy Rider* (1969), which represented attempts to break away from the commercialism of the industry to do something of artistic merit, achieved a popular success far beyond that of patently commercial efforts. The distinction between popular entertainment and high art seems indisputable in most instances, but confusions of fashion and conflicts in artistic standards resulting from experiment and change make it difficult to generalize about them.

Origin of genres

Genres. Motion picture genres developed spontaneously for the most part. Since film making is so expensive, there has always been a strong tendency to imitate the most recent popular successes. If motion pictures involving the same type of subject matter continue to be successful over the years and are flexible enough to adapt to changing tastes, a genre is born.

The Western. The genre most often associated with films is the western. It began with *The Great Train Robbery* (1903), an immensely successful film that indicated the narrative power of the film more effectively than any of its predecessors. For the next half-century, the genre flourished in countless examples, featuring one cowboy star after another cut in the same heroic mold. By mid-20th century, it proved its ability to change with the times in *The Gunfighter* (1950) and *Shane* (1953), in both of which the protagonist attempted to live down his reputation as a fast-drawing gunman of the sort that had hitherto been idealized. In *Midnight Cowboy* (1969), which might be called an antiwestern, the cowboy image was reduced to a pathetic figure.

Gangster films. The next most popular genre is probably the gangster film. Examples appeared as early as *Musketeers of Pig Alley* (1912) by D.W. Griffith and *The Gangsters and the Girl* (1914) by Thomas Ince. The genre was greatly invigorated, however, in the late 1920s, when the prohibition of alcoholic beverages in the United States led to the burgeoning of racketeering. Outstanding films of this period were *Underworld* (1927), *Little Caesar* (1930), *The Public Enemy* (1931), and *Scarface* (1932). They became so popular that considerable public concern was expressed over the possible antisocial effects of glamourizing criminals, and some of the films were suppressed. Such films continued to be made, however, and set in contemporary situations, *e.g.*, *Rififi* (1954) set in France. The 1960s saw a revival of the Prohibition era gangster film in *The St. Valentine's Day Massacre* (1967) and the tremendously popular *Bonnie and Clyde* (1967). Gangster films are notable exceptions to the popular demand for happy endings; the gangster hero nearly always must die.

Musicals. The musical became popular with the introduction of sound in *The Jazz Singer* (1927), a silent film with several musical numbers featuring Al Jolson. Its immense success led to the immediate creation of the musical genre. In 1929 and 1930 a number of Broadway musicals, such as *Gold Diggers of Broadway*, were filmed. At the same time, the great French director René Clair proved his mastery of the element of sound in films such as *Sous Les Toits de Paris* (1930; *Under the Roofs of Paris*), which, unlike the American musicals, featured only a few songs in a primarily dramatic story. The musical remained predominantly a U.S. genre; no other nation produced dancers as popular as Fred Astaire and Ginger Rogers, or production numbers as spectacular and inventive as those of the choreographer–director Busby Berkeley. Among the masterpieces of this genre are *On the Town* (1949), *West Side Story* (1961), and *The Sound of Music* (1965), the last of which broke all previous motion picture records for earnings.

The rise and decline of genres. Not all genres enjoy such consistent popularity in motion pictures as those mentioned previously. "Mother" films, for example, were popular through the 1930s. This genre was epitomized by *Stella Dallas*, the story of a mother who sacrifices all for her daughter; it was an outstanding success in both a silent version in 1926 and a sound version in 1937. Similar works appeared regularly until the 1950s, when television became the major medium for these stories.

"Mother" films

Another example of the fluctuations of a particular genre may be seen in films about spies or secret agents, a recurring subject in films from the earliest days, but the James Bond films of the 1960s achieved unprecedented popularity. *Goldfinger* (1964) and *Thunderball* (1965) represented two of the most successful financial investments in motion picture history. That fact encouraged a spate of imitations, both in motion pictures and on television, that virtually exhausted the genre by the end of the decade, a relatively short life for a genre.

The serial. Also called the chapter-play or cliff-hanger, the serial flourished in the days of silent films, when cinema going was a weekly habit. Perhaps the most famous were Louis Feuillade's *Fantômas* (1913–14) and *Judex* (1916) in France and the U.S. series of the same period with Pearl White, such as *The Perils of Pauline*. In the 1960s, old serials were revived as period pieces of popular art, and their improbable plots, exaggerated acting, and old-fashioned decor were rediscovered by modern, sophisticated audiences. There are occasional art-house showings of complete series. The French director Georges Franju made a modern pastiche *Judex* (1963) based on the early serial style.

Interpretations. For want of a better term, "interpretation" may be used to describe the type of motion picture in which a play, a ballet, an opera, or some other work of another art form is kept virtually intact and recorded by the camera and microphone. Adaptations of novels or plays re-create the work in motion picture form, but interpretations merely give the performance a wider audience. The English director Tony Richardson's version of *Hamlet* (1970) is an example of such a filmed record of a theatrical performance. More camera movement was added in *Long Day's Journey Into Night* (1962) and *The Caretaker* (1963), but they remain essentially stage plays. The straightforward transcript of Laurence Olivier's stage play *Othello* (1966) affords a striking contrast to Orson Welles's *Othello* (1952), in which the play was very successfully transformed into a motion picture. Most motion pictures of operas and ballets may be classed as interpretations.

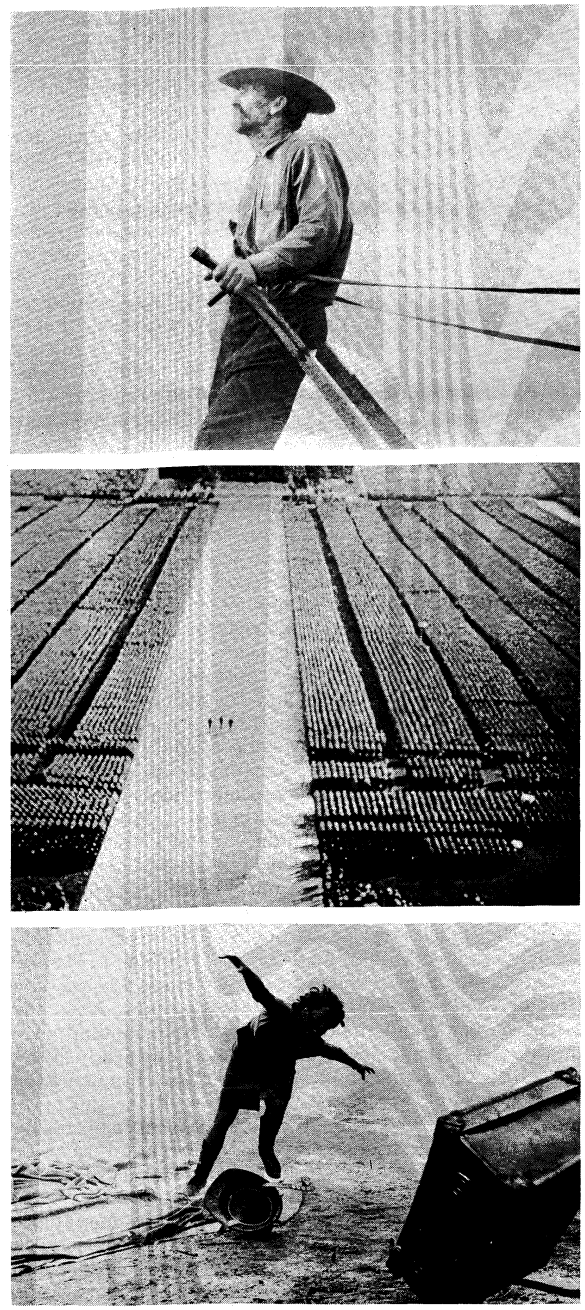
Children's pictures. Motion pictures made specifically for children are rare compared with, for example, the number of books made for children. In the 1930s, the effect of motion pictures on young people was hotly debated. The Children's Film Foundation was established in England, and in America a National Children's Film Library Committee was formed, not, like the English body, to make pictures but to select from normal commercial production those suitable for children. Few outstanding children's pictures have ever been produced and, with the advent of television, the number diminished. There has been more production of children's pictures in east European countries than in the West. While pictures produced especially for children seem deserving of support, the best children's pictures, like the best children's books, often are simply the best pictures, which appeal to audiences of all ages—such as Robert Flaherty's classic *Nanook of the North* (1922), Harold Lloyd's *Safety Last* (1923), *The Wizard of Oz* (1939), or *Le Ballon Rouge* (1956).

News and documentary films. For all of its ability to show the actual world, the motion picture failed to provide genuine news until it did so by means of television. Too stale and infrequent for day-to-day coverage, newsreels showed not news but parades, ceremonies, sporting events, bridge building, launching of ships, and similar events. *The March of Time*, inspired by Time magazine and produced by Louis de Rochemont from 1935 to 1951, was a series in which a topic of political or social importance was discussed in depth in a 30-minute film. The series was an immediate and continued success. It is television, however, that has developed the screen presentation of news, comment, and discussion beyond anything known before.

It is not in the straight presentation of reality but in its creative interpretation in the form of the documentary that the motion picture has produced works of lasting value. Among the pioneers of the documentary were the American Robert Flaherty, creator of *Nanook of the North* (1922), and the Russian theorist Dziga Vertov, whose films include *The Man with the Movie Camera* (1929). It was the British director John Grierson, however, who had the greatest influence. Although he is not to be compared to Flaherty as a film maker, he had the gift of organizing others and negotiating with officials, and he was a persuasive writer. Beginning with his own *Drifters* (1929) a school of fine directors followed his lead in producing a succession of memorable documentaries through the 1930s. With the outbreak of World War II, Humphrey Jennings' *Fires Were Started* (1943), and Harry Watt's *Target for Tonight* (1941), two among many outstanding British wartime documentaries, dramatized Britain's war effort better than fictional films could.

The British documentarists

In America, Pare Lorentz made dramatic documentaries about soil erosion and the dust bowl, such as *The Plough that Broke the Plains* (1936) and *The River* (1937), during the era of the Great Depression, and, during World War II, Frank Capra, who had been an outstanding director of Hollywood comedies, made a series of documentaries under the title *Why We Fight*. The later French movement, *cinéma vérité* which has already been mentioned, made films that are much closer to journalism than to the careful compositions of the English documentary school. Though often untidy, they are fresh and realistic. Television deeply affected the development of the documentary film in two major ways: by providing a training ground for documentary directors, and by building a supply of news film that could be adapted to documentary form. *Point of Order* (1964), a U.S. documentary film that ran successfully in motion picture theatres, was made from television films of the U.S. Senate hearings on the charges and countercharges made by Sen. Joseph MacCarthy and the U.S. Army. *The War Game* (1966), a British television documentary, enjoyed a similar cinematic success.



Documentary film techniques have often been adopted for political or ideological ends. (Top) *The Plough that Broke the Plains* (1936), a U.S. government-sponsored film directed by Pare Lorentz, publicized New Deal measures to combat soil erosion. (Centre) *Triumph of the Will* (1936), directed by Leni Riefenstahl, was sponsored by the German government to convey the power of Naziism. (Bottom) *The War Game* (1966), a BBC television production directed by Peter Watkins, used a documentary technique to show what might have happened if Britain suffered nuclear devastation.

Propaganda. In presenting a background, an environment, and characters who behave in a certain way, every motion picture may be said to be propaganda of a kind. The term may be restricted, however, to pictures made deliberately to influence opinion or to argue a point. The most powerful and most consistent use of the cinema for propaganda has been by the U.S.S.R. After the 1917 Russian Revolution, Soviet films exploded on the screen with fervent conviction. Gradually, however, the pictures became lifeless, and in the 1930s and 1940s, during the Stalin regime, the great directors such as Eisenstein and Aleksandr Dovzhenko worked under severe restraints. A curious feature of Russian pictures is the selection of actors who exactly resemble revolutionary heros—Lenin and Stalin especially. The Stalin pictures were frequently seen by him and were even said to have influenced his conduct. Nazi Germany produced its own brand of propaganda pictures in the 1930s, the most striking being Leni Riefenstahl's *Triumph of the Will* (1936), a terrifying spectacle of a tremendous Nazi rally.

THE STUDY AND APPRECIATION OF MOTION PICTURES

Writings about film. Criticism of motion pictures generally follows the pattern of the other arts, though it has some peculiar features. In the criticism of painting, music, theatre, and literature, some technical knowledge of the medium has generally been required. Motion picture reviewers, however, rarely have any experience of film making. A lack of experience in film making is not necessarily a handicap. Film is such a complex medium that a technician is unlikely to be expert in every aspect of it and may well be overly conscious of his specialty. Also, if the technique is complex, the results are plain to view, and an intelligent critic may well appreciate such technicalities as fine camerawork, tight editing, authentic location shooting, or competent direction without knowing in detail how the result was achieved.

Film criticism

Besides reviews in the daily and weekly press, there are for motion picture enthusiasts specialized monthlies or quarterlies, each with its particular style and reputation —such as the U.S. journals *Film Quarterly* and *Films in Review*, the British quarterly *Sight and Sound*, the French *Cahiers du Cinéma*, the Italian *Bianco e Nero*, the German *Kino*, and many others. At the popular level there are fan magazines, many of which are short-lived, though *Picture Show* and *Photoplay* have continued from 1919 and 1921, respectively. Trade journals appear in most countries, and, though primarily of specialized interest, the files are useful sources of historical information.

Writing about the cinema ranges from serious studies of its economic, sociological, and technical aspects to light memoirs, ephemeral gossip, and catchpenny biographies of actresses, actors, producers, or directors who happen to be in the news. There has been less writing about film history and aesthetics because of the youth of the art, the fact that it has not been taken seriously, and the difficulty of access to research materials. Although documentation is improving, leading to more and better historical writing, the application of scholarly attitudes to motion pictures is still restricted.

The largest book library specializing in motion pictures is at the Czech Film Archive in Prague, 70,000 volumes. The British Film Institute has 18,000 books and pamphlets besides newspaper cuttings and 100,000 index references, now on microfilm. Other libraries are at the Museum of Modern Art in New York, the University of California at Los Angeles, Institut des Hautes Études Cinématographiques in Paris, and the Centro Sperimentale in Rome.

Preservation of film. The permanence of the motion picture medium—the fact that films can be stored and reproduced indefinitely—not only makes it an enduring theatrical art but also a vivid record of past life. Though motion pictures may last forever, however, relatively few have been preserved and many of these are in poor condition. One reason is that inflammable nitrate film stock, which was generally used until the 1940s, when it was replaced by an acetate film stock, is chemically unstable. Also, as a projector runs and jerks the film, it is eventually worn, scratched, or damaged. Still another factor is that commercial conditions of film making discouraged preservation. In the trade the stress was on the present and the future. It is easier to find copies of early pictures made independently, because only the big companies had systems in force for junking (*i.e.*, destroying) old films. In the past movies have been best preserved when a film maker such as Chaplin or Disney has had control over his own work and a personal interest in preserving and representing it. Recently, renters have begun to appreciate the possibility of revivals and reissues, and attitudes are changing.

Film preservation that allows access to old pictures is costly, requiring careful scientific control of storage conditions. Few private organizations or governments have been willing to spend the necessary funds. The earliest film archive was the Swedish Film History Collection begun in 1933. Archives in Paris, London, and New York followed shortly afterward. An international federation (FIAF; Fédération Internationale des Archives du Film) was founded with headquarters in Paris in 1938. The archivists' problems are many: first, selecting the motion pictures to be preserved; second, acquiring copies (a negative or a fine-grain positive if possible) in good condition; third, storing them under the best possible conditions of temperature and humidity; fourth, cataloguing them and keeping some record of their contents; and fifth, letting them be viewed or letting stills or extracts be taken, without damaging the copies. The ideal solution to the problem of choice would be to preserve everything, but the cost would be prohibitive. Even with a limited selection, acquisition is expensive and difficult. The storage of nitrate film necessitates regular testing to see whether it has deteriorated enough to require copying and destruction. Safety film, which was introduced in the 1940s, has an acetate base and an indefinite life and is considered the best means of preserving motion pictures, better than the later magnetic or videotape. Access remains a problem because a projector damages a film. Either an expendable viewing copy is needed or a table viewer has to be used. Motion picture companies and television companies have their own film collections but only for currently popular films.

Problems of the archivists

Film societies. These groups represent an intellectual fringe interested in studying the art of the cinema, discussing motion pictures among themselves or with visiting film makers or lecturers, and making films individually or together. In England and America *ciné-club* is the term used for a group more interested in film making, but on the Continent it corresponds to a film society, formed primarily to see out-of-the-way motion pictures.

The first film society was The Film Society of London, founded in 1925 by H.G. Wells, George Bernard Shaw, Augustus John, John Maynard Keynes, and other dignitaries who wanted to see French, German, and Russian pictures that commercial exhibitors did not handle. The movement spread rapidly. To a great extent the original interest in foreign films was met later by the spread of art cinemas. Nonetheless, film societies proliferated, mostly through the use of 16-mm film and portable, easily run projectors, and lending libraries. Many groups were centred in schools and universities, clubs, hospitals, businesses, and neighbourhoods. By 1961 film societies existed in 46 countries with a total membership estimated at more than 4,000,000. By the 1970s there were several thousand such groups in the United States. In contrast to the casual, impersonal nature of commercial exhibition, they provided the enthusiast with historical perspective to film viewing and analyses and discussions of aesthetic qualities. They also fostered experiments in film making.

RUDOLPH ARNHEIM, *Film as Art* (1958), an original approach, though not fully developed, comparing the motion picture to the real world; BELA BALAZS, *Filmkultúra* (1948; Eng. trans., *Theory of the Film*, 1952), a somewhat dated but interesting account, especially on the close-up and the human face; ANDRE BAZIN, *Qu'est que le cinéma?*, 4 vol. (1958–62; Eng. trans. of selections, *What Is Cinema?*, 1967), essays by a French critic with wide knowledge and penetrating insight; GEORGE BLUESTONE, *Novels into Film* (1961), a specialized aspect of motion pictures, but the

analysis of particular cases leads to valuable comment on the aesthetics of the cinema; KENNETH BROWNLOW, *The Parade's Gone By* (1968), a nostalgic book, mostly about the early days of Hollywood, with information and perceptive comment about every aspect of motion pictures; SERGEY EISENSTEIN, *The Film Sense* (Eng. trans. 1948), a classic of motion picture theory, but difficult reading; ARTHUR KNIGHT, *The Liveliest Art* (1957), the best and most readable short general history, with valuable comment on many aspects of cinema; SIEGFRIED KRACAUER, *The Nature of Film* (1961), an exhaustive examination of motion picture aesthetics, though sometimes slow reading; ERNEST LINDGREN, *The Art of the Film*, 2nd ed. (1963), a readable and excellent introduction; EDGAR MORIN, *Les Stars* (1957; Eng. trans., 1960), a fascinating account of the star system; V.I. PUDOVKIN, *Film Technique and Film Acting* (Eng. trans. 1958), a classic of film aesthetics by a great Russian silent director, who is easier to read than his colleague Eisenstein; KAREL REISZ, *The Technique of Film Editing* (1953), a readable account of a central technique of motion pictures; R. STEPHENSON and J.R. DEBRIX, *The Cinema as Art* (1966), an aesthetic analysis of the whole range of motion picture techniques in terms of the picture on the screen.

(R.St.)

Motion Pictures, History of

The motion picture's prehistory is almost as long as its history. The evolution of the first cinema machines was a slow and gradual process; in the first years after their invention, discovering the applications of those machines also came very slowly and tentatively. Their possibilities began to be understood in the second decade of the 20th century and an astonishing explosion of creativity followed. The essential problem facing the earliest film makers was to free the motion picture from the tyranny of time and space. Once the film artist had discovered that his film could leap forward or backward in time, could mirror subjective time as well as its literal passing, could dart anywhere in the world at will (including into the thoughts of its characters), could simulate the feeling of an experience as well as its appearance, could use the rhythms of an event to depict it as well as a literal dramatization, the essential problem of visual-film aesthetics had been solved.

The introduction of synchronized sound threatened the motion picture with a second tyranny of time and space —for the spoken word can restrict the location and duration of a scene as concretely as the earlier assumption that the motion-picture camera was analogous to a single spectator in the theatre. As they did 15 years before, the film artists of the early '30s learned to master the new machine and then learned to make it work for them rather than against them. The artist integrated dialogue and picture, just as his predecessor of the silent era integrated composition and cutting, space and time, texture and rhythm. In the years preceding World War II, most film artists sought effective and evocative visual accompaniment for dialogue. The dependence on sound made the film world less flexible than in the silent era, more allied to space and time in the natural world. Like speech itself, the film world became more logical, more literal, and more linear than it had been in the late silent period.

Since World War II the film artist has worked on destroying that logic. The introduction of the wide screen and the almost total domination of colour, the reappearance of obtrusive editing and subjective camerawork, the reliance on music, sound, and silence in addition to dialogue have all created as flexible a motion picture as in the most fertile years of the silents. The visual techniques of films made after 1960 are closer in many ways to silent methods than to those of the intervening 30 years. This fact may partially explain the recent renaissance of silent films and their revivals in theatres and on television.

Commercial factors

Audience demands and the perceptions of businessmen about those demands determined the history of the motion picture as forcefully as the discovery of the aesthetic principles of the art. For example, although both film producers and film critics believed (or hoped) that silent and sound films would coexist, the public, pursuing novelty, refused to buy tickets to silent motion pictures. Commerce inevitably determines the direction of the film art; the film artist uncovers and develops all the aesthetic possibilities once that general direction has been charted. In the history of motion pictures, therefore, commercial realities, aesthetic principles, mechanical innovation, and audience taste are inextricably linked.

This article traces the historical development of the motion picture. Other aspects of the medium are treated in MOTION PICTURES, ART OF; MOTION PICTURES, TECHNOLOGY OF; MOTION-PICTURE INDUSTRY; and ANIMATION.

This article is divided into the following sections:

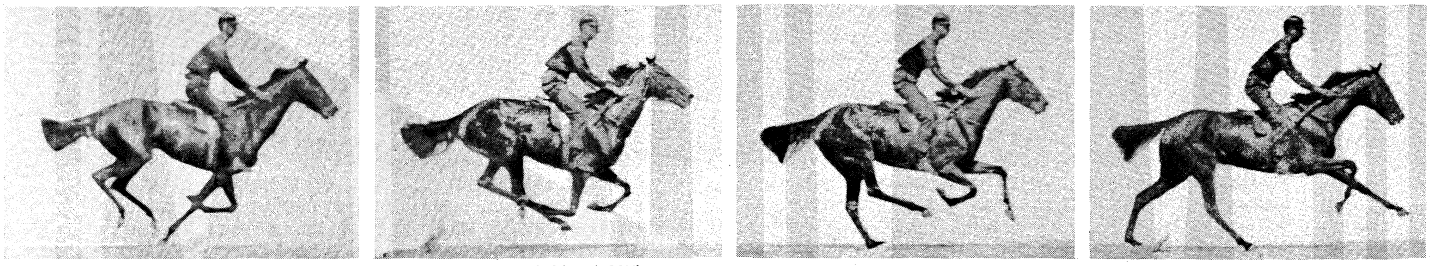
    India
V. Recent trends

I. Origins: 1815–95

The motion picture was born in the final decade of the 19th century from the fusion of three separate mechanical interests of that mechanically minded century: the persistence-of-vision toys, still photography, and mechanized audience entertainments. The persistence-of-vision toys capitalized on the physiological fact that the brain retains the images of the eye for an instant longer than the eye actually records them. This retention allows a series of separate pictures to blend into one another and appear as a fluid and continuous action. This optical illusion, essential to motion pictures (a motion picture is merely a synthesis of individual still photographs or frames), was the basis of many 19th-century toys. Called by curious, ornate names, such as Phenakistiscope, Zoetrope, Choreutoscope, Praxinoscope, and Stroboscope, these toys were merely some kind of circular, revolving machine with drawn figures upon it, each in a slightly different phase of movement. The circle could be a flat board, a revolving drum, or even a complex rotating machine with different planes and mirrors. But the principle of the machines was identical—to bring the inanimate to life and the apparently still into motion by spinning the disc or drum.

Early still cameras

But without photographs of the natural world, there could be no motion pictures of the natural world. The camera can be traced back to Leonardo da Vinci's diagram of the *camera obscura*, the little box that captured an inverted image of the world opposite the lens (originally, simply a hole) on the rear wall of the box. Early in the 19th century, scientists began looking for the means to replace that wall with a photographic plate that could retain the image opposite the lens clearly and permanent-



An early series of photographs by Eadweard Muybridge (1887).

ly. Those experiments culminated in France in 1839 with the collaborative efforts of Louis-Jacques-Mandé Daguerre and Joseph-Nicéphore Niepce. Daguerre's first photographs required an exposure time of 15 minutes; the motion picture would require at least 16 exposures per second. There could be no motion picture until the photographic equipment and material became faster and more sensitive. By 1870 the still camera had acquired a shutter, and shutter speeds of 1/1000 of a second were being used.

The work of Eadweard Muybridge

The first man to apply still photographs to motion photography was Eadweard Muybridge, an English adventurer who emigrated to California in the years following the 1849 Gold Rush. In 1872 the governor of California, Leland Stanford, employed Muybridge to help him win a bet. Stanford, an avid horse breeder and racer, bet one of his rivals that, at some point in the galloping horse's stride, all four hooves leave the earth. In 1877 Muybridge's discovery won Stanford the $25,000 bet. Muybridge placed 12 still cameras alongside the race track; he stretched strings across the track, each attached to the shutter of one camera. As the horse galloped down the track, his hooves broke a string and tripped a shutter, exposing one phase of his movement. Muybridge realized that the original movement could be resynthesized by mounting these still photographs on a revolving wheel and projecting them with a magic lantern. For the next 20 years, Muybridge continued shooting and projecting these "pictures in motion." But they were not really motion pictures, for the photographs had been taken with 12 or 20 or, eventually, 40 cameras, not with one.

A Frenchman, Étienne-Jules Marey, took the first motion pictures with a single camera in 1882. Inspired by Muybridge's work, Marey constructed a photographic rifle that exposed 12 images in one second of "pulling the trigger." The images were recorded on a single glass plate in the chamber of the "rifle," which rotated 12 times during the second of shooting. But this early camera and Marey's subsequent improvements on it still did not permit more than a few seconds of action. Further development of the motion picture required photographic material other than the single photographic plate.

EDISON AND HIS LABORATORY

Claims to the invention of the motion picture

Because this material—celluloid roll film—was invented by George Eastman in the United States, another American, Thomas A. Edison, often receives credit for inventing the motion picture, for the Edison laboratory applied Eastman's celluloid film to motion picture photography. Edison's claim, however, is quite fuzzy. First, Edison did not invent any motion-picture machines, although he took credit for others' inventions. Invented as early as 1888, the Edison motion-picture camera, called a Kinetograph, was the work of William Kennedy Laurie Dickson, an Englishman who migrated to the U.S. and worked in Edison's laboratory. The Edison projector, the 1896 Vitascope, was the invention of Thomas Armat, an independent American inventor who, like hundreds of similiar Americans in the 1890s, had been tinkering with various motion-photography machines. Second, although the Edison laboratory indisputably produced the first motion-picture camera, Edison opposed projecting motion pictures on a screen. As a result, England (William Friese-Greene), France (Louis-Aimé-Auguste Le Prince), and Germany (Max and Emil Skladanowsky) all claim invention of the motion picture because inventors of these countries either patented machines for projecting motion pictures or actually projected pictures in public before Edison did.

Edison cared very little about motion photography. After inventing his phonograph, Edison merely wanted a machine that might supplement the music with pictures. But Dickson, certainly the most important pioneer in the earliest years of U.S. cinema, realized the power of the motion picture. It was Dickson who decided to use George Eastman's new celluloid film rather than etch the tiny pictures on wax cylinders, a way analogous to that used to make phonograph recordings. In 1889 Dickson shot the first film in the U.S. on celluloid, *Fred Ott's Sneeze*, a medium close-up of one of the workers in the Edison factory sneezing for and at the camera. Dickson also invented the Kinetoscope, a little peep-show viewer that displayed *Fred Ott's Sneeze* and other filmed items to the eye of a single spectator. Edison felt a motion picture could only make money if each curious customer looked into the viewer alone—and paid his coin each time. Finally, it was Dickson who helped perfect one of the first U.S.-made motion-picture projectors.

Edison patented Dickson's Kinetograph and Kinetoscope in 1891, but slowness of manufacture kept them from making a real impact until 1894. The Kinetograph ran at a speed of 48 frames per second (a speed that Edison believed produced the most realistic impression of movement). The body of the camera could hold only 50 feet of film on a series of loops and spindles; therefore, it contained only a few seconds of unedited action. To extend the spectacle, the film ran continuously, its ending leading directly into its beginning, as in the persistence-of-vision toys. Among the most significant and lasting details of this film machine were the little perforations, four pairs per frame, that Dickson added to the sides of the celluloid strip to keep the film moving both in the Kinetograph and in the Kinetoscope.

Among the early Edison filmstrips (1893–96) were dancing girls (*e.g., Annabella* and *Carmencita*), gymnastic knock-abouts (*e.g., Fun in a Chinese Laundry,* in which a policeman chases a limber Chinese man around a painted set), historical pageantry (*e.g., The Execution of Mary Queen of Scots,* in which Mary's head bounces off like a basketball), and re-creations of Broadway plays (*e.g., The John Rice–May Irwin Kiss,* the first close-up screen embrace, which predictably produced the first wave of moral reaction against the motion pictures). The Edison films were shot on an indoor set, with an inert camera that masqueraded as a spectator in the theatre. The Edison movie studio was patterned after a theatre—the camera was a stationary audience and the performer acted on a specially erected stage.

Edison's decision against projection

Edison's decision against projection was a serious mistake. It eventually cost him prestige, millions of dollars, and over a decade in fruitless lawsuits. In assessing the commercial possibilities of the motion picture, Edison should have realized that 19th-century audiences delighted in mechanical shows combining movement, figures, and light. Magic-lantern shows and their variants (the Phantasmagoria, the Projecting Phenakistascope, the Panorama, and the Diorama) were popular before there was ever a motion picture. The photoplay of Alexander Black, an American novelist, lecturer, and photography "fiend," produced (1894) an evening in the theatre that combined a melodramatic plot, live actors, and pro-

jected slides. This type of entertainment was the immediate ancestor of the fictional motion-picture story. The projecting of motion pictures for paying audiences was an inevitable culmination of the urge of the entire 19th century.

THE LUMIERE BROTHERS

Because Edison refused to extend his U.S. patent on the Kinetograph and Kinetoscope to Europe, the most significant motion-picture inventions between 1895 and 1900 came from Europe. The Europeans took Edison's early machines, copied them, and improved on them. The most important of these early European inventors were the French brothers Auguste and Louis Lumière, who extended the family business of manufacturing still cameras and photographic plate into motion-picture equipment. The Lumières improved on the Edison machines in three ways. First, they invented a light, portable, hand-cranked camera that could shoot anywhere. (Edison insisted on running his bulky Kinetograph with electricity.) Second, the Lumières slowed the camera speed to 16 frames per second, which not only required less film but also allowed a projector to run more smoothly and quietly. And, third, the Lumières used the same machine to shoot, project, and print the pictures. Because the machine necessarily used the same principle of intermittent motion (each frame stopping momentarily before the lens and then moving on) in both shooting and projecting, the primary technical obstacle to clear, smooth projection had been hurdled. Edison's early experiments with projection, as well as the other early U.S. attempts, erroneously used continuous motion of the film past the light source, not intermittent motion.

The Lumières shot their first film early in 1895. Unlike *Fred Ott's Sneeze*, the Lumière film, *La Sortie des ouvriers de l'usine Lumière* ("Workers Leaving the Lumière Factory"), showing workers going about their daily business, was spontaneous and unstaged. This difference between the Lumière "aesthetic" and the Edison "aesthetic" was consistent through most of their films—Edison was the father of the fictional, "theatrical" film, Lumière of the natural, "documentary" film. The Lumière films were usually shot outdoors. They tended to capture some life process actually occurring in front of the lens rather than something especially prepared for the camera. Among the most famous early Lumière films are *L'Arrivée d' un train en gare* ("The Arrival of a Train in the Station), parodied 70 years later in Jean-Luc Godard's *Les Carabiniers*; *Le Repas de bébé* (a sequence showing parents feeding their infant) and *L'Arroseur arrosée* (a comic film about a gardener who gets his face doused by a mischievous boy). The last film, one of the first bits of slapstick comedy on film, is the ancestor of the later great silent comedies. It contains many of the essential comic elements in miniature: the butt (the gardener), the comic antagonist (the mischievous boy), the comic physical object (a hose), the comic discovery, and justice (the gardener's catching the boy and then administering a spanking).

Early slapstick film

Lumière films were fresher, freer, and more active and alive than Edison's, although the Lumières still considered themselves manufacturers and scientists, not artists. Their firm made thousands of films that were listed in a catalog—the filmstrips being sold outright. In over five years of making these filmstrips, the Lumières did not vary their aims or methods. They took "views" (a view of a place, a process, an event) and did not edit them. The novelty of seeing the natural world mechanically recorded was exploited, and, therefore, they did not use the camera to any effect other than capturing the view. When the novelty died, the Lumière business also died, eclipsed by shrewder businessmen and more imaginative artists. The Lumières first displayed their films to a paying public in the basement salon of Paris' Grande Cafe on December 28, 1895—the date that marks the end in the first era of cinema history, for the mechanical toy passed out of the hands of the inventors and into the hands of artists, financiers, and the public.

II. Filmstrips and "one reelers": 1896–1907

EUROPE

Artistic and commercial development progressed more quickly in Europe than in the U.S. In the first decade of motion-picture history, the best films came from France and England.

France. In 1896 the Pathé brothers and Leon Gaumont in France began their commercial conquest of the European industry. In the same year, the magician Georges Méliès began shooting films of magical tricks. Méliès saw that by stopping and then starting the camera again not only could rabbits be pulled out of hats, but hats could be made to appear where there previously were none or made to disappear from where they previously had been or made to turn into rabbits themselves. Méliès' use of stop-action, as this technique came to be called, was his single contribution to developing the unique powers of the cinema. In other respects, he was like the other film directors of his era in that he saw the motion picture as the stepchild of the stage. Like Edison, Méliès used the stationary camera, the especially erected stage for the action, and the two-dimensional scenographic conventions of the theatre.

Méliès' showmanship

Despite this subservience to the theatre, Méliès' films are clever, surprising, and funny. He reveals his showmanship by filling the screen with elaborately moving scenery, with chorus lines of scantily attired ladies, and with the quirky, jerky gymnastics of acrobats, who cavort in his films as gremlins, demons, devils, elves, or moon creatures. Typical Méliès plots include the Gypsy's curse (a hex on some object causes it to erupt into fantastic activity), the drunken dream (too much wine leads to fantastic nightmare incidents and creatures), and the journey to a bizarre region (for example, his most famous, *Le Voyage dans la lune* [*A Trip to the Moon*], of 1902, or *La Conquête du pôle* [*Conquest of the Pole*], of 1912). In addition to miraculous tricks, Méliès exhibited a whimsical, anti-intellectual humor that perpetually debunked the pretensions of scientists, doctors, and professors. Méliès' company, Star Films, achieved worldwide distribution for its films and influenced film ideas in every country where the films were shown. In the U.S. many of Méliès' films were pirated and duplicated. With the collapse of the company on the eve of World War I, Méliès disappeared; however, he was redeemed from obscurity more than a decade later by enthusiastic French filmgoers.

Another remarkable director of early French films was Ferdinand Zecca, head of production at Pathé. Zecca's most notable contribution to the motion picture was the chase sequence, demonstrating the vitality of motion. By taking his camera outdoors, Zecca freed the films from many of the spatial limitations they experienced in the studios of Edison, Méliès, and other contemporaries. The speed and energy of Zecca's running bodies compensated for his passive use of the camera and lack of editing. One of the striking facts of early cinema history is that, for the

La Sortie des ouvriers de l'usine Lumière (1895); "Workers Leaving the Lumière Factory."

first 15 years of motion pictures, the films that have life were those shot outdoors, where life was already available to the lens.

The final significant trend of the prewar French film demonstrated this principle very clearly, if unintentionally. In 1907 a film company calling itself the Film d'Art decided to bring "seriousness" into the motion picture. This self-conscious enterprise (the French were the first to become conscious of the film as an art rather than a novelty) intended to introduce the great writers, musicians, and actors of the French stage to the humble audiences of the motion picture. The company made several films based on the melodramas of Alexandre Dumas (*père*), Eugène Scribe, and Victorien Sardou, featuring the Comédie-Française (the national theatre of France) and the internationally renowned actress Sarah Bernhardt. The most famous of their efforts, *Queen Elizabeth* (1912), was a plodding, overacted, pretentious work that ironically showed less intelligence than Méliès and less vitality than Zecca.

A Trip to the Moon (1902), directed by Georges Méliès.

England. In England, inventors such as Robert William Paul and Birt Acres also copied the Edison machines to improve on them. A group of innovative artists used those machines to make some of the most imaginative films of the first decade of the 20th century. Often called the school of Brighton, these British film makers included G. Albert Smith, James Williamson, Esme Collings, Cecil Hepworth, and Charles Urban. Their films were notable for experiments with the moving camera, the close-up, and the rhythms of editing. Cecil Hepworth's *Rescued by Rover* (1905), a melodramatic story of an infant who is stolen away by a Gypsy and then rescued by a faithful collie, is probably the most fluidly and coherently edited film in the first 15 years of cinema history. The British

School of Brighton

also began developing the motion picture as a social document (for example, *Tatters, A Child of the Slums*, made by Collings in 1905). Members of the school of Brighton also elaborated on many of the filming tricks and surprises they had seen in the Méliès films.

UNITED STATES

Both artistic and commercial progress was slowed in the U.S. by what could be called either fertile opportunism or lawless chaos. The first official public screening of a motion picture in the U.S. was on April 23, 1896, in a New York City music hall, Koster and Bial's (at 34th Street and Broadway). For almost ten years, the motion picture did not have a U.S. home of its own but merely appeared as one act on a vaudeville bill. Eventually, the novelty of seeing the mechanical marvel wore off. U.S. films did not innovate but copied the same items—one-joke pranks modelled after the Lumières' *L'Arroseur arrosée*, inevitable "views" of people and places, speeding trains (the favourite film subject of all), historical pageants, and dancing girls. The U.S. film pioneers seemed to occupy themselves more with piracy—stealing each other's machines, machine parts, ideas, and even the film-strips themselves—than with invention.

By 1897 Edison's two major film producing rivals, the American Mutoscope and Biograph Company and the Vitagraph Company, had pirated themselves into existence. Biograph, as the former company came to be called, manufactured a peep-show viewer (the Mutoscope) that outperformed Edison's Kinetoscope and is still found at carnivals, amusement parks, and penny arcades. The Mutoscope used large cardboard photographs flipped by a hand crank rather than the Kinetoscope's whirring strip of film driven by electricity. The inventive intelligence behind Biograph was William Kennedy Laurie Dickson, who took his Edison secrets with him and put them to his own use.

Vitagraph Company

Vitagraph's founder and director of production was J. Stuart Blackton, a former newspaper cartoonist and a former friend of Edison's. The friendship cooled when Blackton received a Vitascope franchise, copied Edison's machine, and formed his own company with his partners, William "Pop" Rock and Albert E. Smith, choosing a name as close to Edison's as the law would allow. Among the other U.S. pioneers busily engaged in invention, imitation, and piracy were George Kleine, George K. Spoor, Sigmund Lubin, and William Selig.

There could be no progress of U.S. film art without some stabilization of the U.S. film industry. This stabilization process worked itself out slowly in the years preceding World War I. First, motion-picture equipment and, more important, the finished films required legal protection. Edison began suing all his competitors in 1897 for piracy and theft. Thomas Armat's projector

(which Edison bought, claimed, and named the Vitascope) required the film to be threaded with a small loop to relax the tension on the film (all projectors today use such a loop). This Armat loop ironically became known as the Latham loop because an earlier U.S. inventor, Woodville Latham, used such a loop in his camera. Because Edison owned both the Armat and Latham patents, he sued everyone who used the Latham loop. Later, Armat sued Edison; Biograph bought Latham's patent so that they too could sue Edison; and suit and countersuit continued in the courts for ten years.

This "war of the patents" eventually produced an uneasy stability and unanimity. In 1908 the major U.S. producing companies decided to call a truce. They would share all the patent rights among themselves, and they would keep all competitors out of the film business permanently. Those companies—Edison, Biograph, Vitagraph, Essanay (S and A—Spoor and Anderson), Lubin, Selig, Kalem (KLM), Méliès, and Pathé (both of the latter had begun producing in the United States)—combined as the Motion Picture Patents Company. This "company" had sufficient power to monopolize the industry because the members made the best pictures and because those members would cancel their valuable contract for raw film stock with George Eastman if he sold to anyone else. Furthermore, no theatres could rent Patents Company films if they rented from any other company.

Theatres that showed films exclusively were the real source of stability in the U.S. film industry and became a sign of the industry's growth. The first nickelodeon opened in Pittsburgh in 1905. By 1908, the year of the patent settlement, there were thousands of these theatres in the U.S. No longer did the film producer sell the filmstrip to a projectionist who toured from city to city, going from vaudeville house to vaudeville house. The permanent movie theatre developed a regular clientele. The owner of such a theatre needed many films, however, to keep his regular customers. Because a film program lasted one hour and each film only ten minutes (one reel of 1,000 feet or less), it took at least six one-reel films to make a full program. And some theatre owners changed programs as often as twice a day. For this system of exhibition, the theatre owner needed to rent films, not buy them. Between the film-producing companies and the theatre owner, or "exhibitor," stepped a middleman, the "distributor," or "distribution exchange," who bought or leased films from the producer and then rented prints to theatres. When the Motion Picture Patents Company was organized in 1908, it also created a monopolistic exchange system for distributing its films, the General Film Company, thereby increasing its power and control over the industry.

Monopoly challenged

Ironically, the solution of 1908 was a temporary one. No sooner had the Patents Company been formed than certain theatre owners rebelled against the monopolistic, anti-competitive control of what they considered an illegal trust. They sued the Motion Picture Patents Company and its General Film Company; the film industry went back into the courts. Even more devastating, the rebels formed independent film-producing companies, independent distribution exchanges, and independent circuits of theatres to show the films. Among the early independents were Carl Laemmle (the founder of Universal Pictures Company) and William Fox (the founder of the Fox Film Corporation), who were to become far more rich and famous than the founders of the Motion Picture Patents Company. In its creation of stability, the Patents Company unknowingly eliminated itself by supporting the one-reel film as opposed to the lengthy feature film and by supporting the use of anonymous screen players as opposed to the star system. Within ten years, the U.S. film industry would be based on stars in feature films. The Motion Picture Patents Company summed up the past; the independent film makers carried the art and industry into the future.

The only significant U.S. film artist of the motion picture's first decade was Edwin S. Porter. Director of production at Edison, Porter made *The Great Train Robbery*, his most famous and important film, in 1903. Often

The Great Train Robbery (1903), directed by Edwin S. Porter.

mistakenly called the first motion picture to tell a story, this film was important not because it told a story (motion pictures had told stories for at least seven years) but because of the way it told it. In its story of four bandits who rob a train, shoot one of its passengers, and eventually die in a shoot-out with the posse, Porter cut backward in time (switching focus from the bandits to the telegraph operator who summons the posse), and he cut back and forth in space between the formation of the posse and the flight of the bandits. Porter's most distinctive technique in the film was that he cut; these cuts produced an ellipsis that allowed the audience to infer a perfectly clear continuity despite the gaps in time and space.

The Great Train Robbery was the biggest commercial success of its time and held the screen for at least ten years. Most of Porter's other films, however, lack its fluidity and freeness. The vitality of Porter's films is most evident in the scenes shot outdoors. *The Life of an American Cowboy* (1903), for instance, contains outdoor scenes that are fresh and vital, while the indoor scenes seem posed and staged. Porter's use of editing as the basis of motion-picture construction was certainly inconsistent and probably unconscious. Whereas Porter's *Life of an American Fireman* (1903) contains rhythmic editing and even narrative crosscutting, his *Uncle Tom's Cabin* (1903) is a pure stage piece, and *The Dream of a Rarebit Fiend* (1906), though occasionally quite amusing, is a mere copy of Méliès.

Porter's use of natural scenery

III. The silent feature: 1908–28

UNITED STATES

The age of D.W. Griffith. The conscious discovery of the aesthetics of the motion picture begins with D.W. Griffith. To some extent, it also ends there. There was not one device of the visual, black-and-white cinema that Griffith did not master or point the way for others to control. Griffith's two general discoveries were the effects of composition and cutting—the manipulation of space and time. Griffith developed the texture, the look, the feel, and the tone of the individual shot, as well as the rhythms, the meaning, the kinetic sensations, and the intellectual commentary of joining the shots. His central realization was that the basis of film construction was the shot, not the scene (as Méliès, Zecca, and usually Porter had defined it), and that the motion picture was a new kind of language with a "grammar and rhetoric" of its own. The combining of shots into scenes, scenes into sequences, and sequences into whole plots was parallel to the combining of words into sentences, sentences into paragraphs, and paragraphs into whole arguments. Griffith made these discoveries not in theory but empirically by making hundreds of films.

Early films. Born in Kentucky in 1880, Griffith considered himself a playwright, not a film actor, but he debased himself (such was the early prejudice against the "flickers") to earn a steady $5 a day. He began acting in motion pictures in 1907, playing a lumberjack in Edwin

S. Porter's *Rescued from an Eagle's Nest*, a melodramatic one reeler about an infant stolen away from its family by a large black bird. Only a year later, Griffith directed his first film, for the Biograph Company, *The Adventures of Dollie*, another melodramatic one reeler about a stolen infant—this time by Gypsies. In the five years between 1908 and 1913, Griffith directed over 150 films. This experience gave him the opportunity to experiment weekly, to note the results, and then to polish and develop the most effective elements in his next week's film.

Griffith rejected the notion of the "standard shot" then supported by the Motion Picture Patents Company. According to the Patents Company's reasoning, why should the public pay to see half an actor when it could see the whole figure for the same price? Griffith developed a whole series of shots from extreme close-up (of a single object, face, or feature) to extreme far shot (a vast panorama). Griffith discovered that the emotional content of the shot, its structural role in the plot, and the human and thematic information that it conveyed must determine the composition of the frame, not any maxims based on an erroneous analogy with the stage. Griffith also developed the rhythms of editing to link the shots: when to cut languidly to give the impression of quietness and ease, when to use quick cuts to give the impression of tension and speed, when to cut subjectively to reveal a character's thoughts or intentions.

Griffith developed the technique of masking, in which a part of the screen rectangle is blacked out to focus attention on some circle, oval, horizontal plane, or other shape of light and image within the frame. He developed the irising effect, in which a scene began with a small circle of light within the frame and then expanded to fill the screen; and he ended a scene in the reverse manner, shrinking the full image into a tiny point of light. Griffith began integrating the pan shot (a horizontal or vertical movement of the camera on its fixed tripod) and the travelling shot or tracking shot (the whole camera moving to accompany the action) into his emotional and narrative screen language. The significance of Griffith's contributions was not that he invented these shots (many had been used before) but that he synthesized them all into a coherent and powerful way of telling a story.

Griffith's influence on acting

In addition, Griffith improved screen acting. No longer would actors demonstrate their emotions with grandiose gestures borrowed from the stage. Actors became people, subtly responding rather than gesticulating. Many of the most important and accomplished silent actors worked first for Griffith—Mary Pickford, Lionel Barrymore, Lillian and Dorothy Gish, Robert Harron, Henry B. Walthall, Erich von Stroheim, Richard Barthelmess, Mae Marsh, Blanche Sweet, Donald Crisp. Griffith also began solving the problem of making the indoor world look as real, as three-dimensional, and as fully textured as the outdoors. His sets gradually became more detailed and developed. His lighting gradually overcame the flatness of earlier indoor scenes that were really filmed outdoors (in most early films sunlight was diffused with muslin to light an indoor scene). The tone and texture of Griffith's lighting began to capture the feeling of indoor life.

Griffith's one reelers were of various types. He excelled in melodramas—the attack of vicious, irrational forces on the good and innocent. In *The Lonely Villa* (1909) and *The Lonedale Operator* (1911), Griffith developed the climactic chase, in which the husband or suitor arrives just in time to save his wife, children, or sweetheart. The switching from attacker to victim to rescuer—and the tense, nervous rhythms of Griffith's editing—played important parts in these exciting climaxes. Griffith also made domestic comedies such as *Mr. Jones Has a Card Party* (1908) and *Effecting a Cure* (1910), which laughed at the marital conflict between husbands who liked to drink, play cards, and woo the ladies and their moralistic wives who were following the principles of temperance advocate Carrie Nation. He made rural, folksy comedies such as *Examination Day at School* (1910) and *A Country Cupid* (1911), which examined the gentle tenderness of the country life that Griffith knew and loved so well. And he made social dramas such as *A Corner in Wheat* (1909) and *The Musketeers of Pig Alley* (1912), which examined such social and moral problems as the selfish gluttony of the rich, the pathetic poverty of the farmer, and the vicious corruption in city slums.

Despite the temptation to treat Griffith as simply a master technician, the motion picture's first, he was also its first intellectual and poet. Griffith was the first to realize the motion picture's potential for presenting a personal interpretation of human values and social assumptions. If Griffith's moral system was uncomfortably sentimental and romantically naïve, it was undeniably consistent throughout his career, and he was passionately, sincerely committed to it. Griffith believed in the family, the home, virginity, fidelity, social peace, the preservation of tradition, and the equitable distribution of material wealth and human necessities. His models of virtue were consistently women, or rather girls—blonde, thin, angelic, frail, usually in their teens. The Griffith ideal was gentleness, and the Griffith moral centre was the heart. If people treated each other gently, lovingly, there would be no wars, no poverty, and no vice.

Griffith's moral system

But the Griffith gentle ideal inevitably collided in his films with the brutal realities of human existence. This reality could take the form of either a specific human menace or a general social evil. Griffith treated moral villainy as psychological depravity. The man who wishes to molest an innocent girl, disrupt a happy home, or grab as much money for himself as possible is a psychopathic beast. He is violating the essential human laws that make life livable. And general social problems, such as wars, poverty, slums, drunkenness, and strikes, were merely the consequences of this selfish, demonic lust for more power or money than any man has the right to have.

In his late one reelers, Griffith was able to give his sentimental moral system vitality and texture. First, there is a lot of sarcastic comedy in the early Griffith films, a sly delight in debunking moralistic, prudish ladies who are so ugly that they can have nothing to do with men except make them miserable. Second, there is a genuine tenderness for simple, rural people, a feeling for gentle, smiling faces that shows itself in *The New York Hat* (1912) and a feeling for the warmth and richness of the soil that shows itself in the loving, languid shots of the fields and planting in *A Corner in Wheat*. Third, Griffith's use of objects, such as hats, wrenches, telephones, pistols, and locomotives, communicated more and more information in a believable, economical, effective way. This use of objects in the one reelers would later develop into Griffith's concrete symbolism—the use of animals to convey emotional states and human attitudes, of flowers to convey the sense of beauty, fragility, and mortality.

Birth of a Nation and Intolerance. Griffith reached the peak of his career with two mammoth feature films, *The Birth of a Nation* (1915) and *Intolerance* (1916). Griffith left Biograph in 1914 when the company refused to make feature films. Following the lead of *Queen Elizabeth* and the Italian spectacles of 1912–14 (*Quo Vadis?, Cabiria, Anthony and Cleopatra*), Griffith wanted to make long films. He took his talented cameraman (G.W. "Billy" Bitzer) and actors with him, leaving Biograph so desolate that this greatest of all the Patents Company studios soon collapsed. Biograph's second most important director, Mack Sennett, had "gone independent" the year before.

The Birth of a Nation was a story of the gentle pre-Civil War South (Griffith's ideal of a serene, sensitive social system) and its violent demise in the brutal war and horrifying postwar Reconstruction (Griffith's symbols of social chaos and disruption). Out of the ashes of this struggle, a new nation is born, symbolized by the marriage of the Southern soldier Ben Cameron (Henry B. Walthall) and the Northern girl Elsie Stoneman (Lillian Gish). Within this overall symbolic framework, Griffith fills the screen for over three hours with scenes of spectacle, tender human details, careful reconstruction of the era's architecture and costume, exciting melodramatic suspense, and a grandiose allegorical image of the future of humanity.

Impressiveness of *The Birth of a Nation*

It is difficult to say whether *The Birth of a Nation* is most impressive for its huge spectacle or its tiny details, its exciting suspense or its intellectual commitment. Despite the oversimplifications in the film's theme, it was the most massive piece of cinematic thought that had yet been attempted. Among the huge scenes are the sweeping shots of Civil War battles and the detailed historical facsimiles in which Griffith carefully re-creates Ford's Theatre, the Appomatox Court House, and the South Carolina legislature. The film's gentle, touching moments include the early scenes in the prewar South (Griffith uses playful puppies and kittens as symbols), the wooing scenes between Ben and Elsie (symbols include a cooing dove and a remarkably Freudian bedpost), and the painful, sorrowful return of Ben from the war, when he discovers that his once thriving town is desolate and ruined.

Griffith was especially careful in his handling of the scenes of suspense. There are four of them in the film, each one more developed and fuller than the one preceding it. In the first of them, the Cameron home (and women) is attacked by a renegade band of Northern soldiers—all black except for their white leader. In the second the youngest Cameron girl is pursued through the woods by Gus, a vicious black man whose threats of marriage drive the girl to her death. And the final two occur simultaneously at the film's climax, revealing Griffith's complete awareness of rhythmic construction. While the evil mulatto politician Lynch tries to force Elsie into marriage, the other members of the Cameron family are trapped inside a little cabin, mercilessly attacked by Northern soldiers. Both last-minute rescues take place within the same last minute, giving the film one of the most exciting, breathless climaxes in film history. Griffith underscored the film's excitement with two additional contributions to film "rhetoric"—music (Griffith released a musical score cued to the film's effects for the theatre's piano or orchestra) and colour tinting (Griffith tinted sequences in blue, orange, yellow, green, or red to intensify their emotional tone).

Throughout *The Birth of a Nation* the theme of miscegenation and racial conflict runs strong. The film's villains are mulattoes, who want to seize power (and white womanhood), and a vain, white Northern liberal, Congressman Stoneman, who, out of misguided ideas of social justice (and because of pressure from his mulatto mistress), wants to give power to the black man. In typical Griffith fashion, erring political ideas can be traced to sexual corruption. The valiant heroes in the film's last-minute rescue, the forces of good in the film, are members of the Ku Klux Klan, led by Ben Cameron, the film's protagonist. Although Griffith's attitude was unquestionably racist, his primary target was not the black man himself but the mixture of the races and the destruction of established political power. According to Griffith's interpretation of the Civil War, a group of selfish, lustful, power-hungry men would simply not let a very beautiful, peaceful social order alone. Griffith realized that the very importation of black slaves planted the poisonous seed that would eventually destroy the South, but he could not help looking at the social system that was built on slavery with warm affection. This interpretation of history predictably caused a stormy social reaction, protests and riots in some cities, censorship and banning of the film in others. The reaction to the film was not only noisy but profitable, its receipts soaring into unheard-of millions of entertainment dollars.

Negative reaction

Griffith was more stung by the social controversy than pleased with the profits. He thought he had painted a balanced picture of the black man (*i.e.*, he had sketched a few "faithful souls" who were really "Uncle Toms," or blacks sympathetic to the whites) and had softened the racial bias of his source, Thomas Dixon's novel *The Clansman*. This anger led him to write a pamphlet on "the freedom of the screen." It also fired him for his next major project, *Intolerance*, of which he felt himself the victim. This film wove together four stories, unified by the theme of intolerance through the ages and a recurring metaphoric image, a mother rocking a cradle, who symbolizes eternal humanity fulfilling its evolutionary destiny through the ages. In each of the four ages, there is intolerance (or injustice). An intolerant religious leader of Babylon envies Belshazzar, the country's ruler, and betrays his own country to the Persian invaders. The intolerant Pharisees drive Christ to the cross. The intolerant Catholics slaughter the Huguenots. And intolerant modern bigots drive sympathetic people to the brutal city, drive women into prostitution, drive mother and child apart, and almost drive an innocent man to the gallows. In all four stories, differences of religious belief and moral opinion produce the catastrophe.

The Babylon and modern sequences are the most developed. Most significant about Griffith's Babylon episode were the immensity of its sets, the detail and size of its battle sequences, the exuberant, jaunty comedy of the tomboyish "Mountain Girl" (Constance Talmadge), who loyally tries to protect Belshazzar, and the tender, ideal love of Belshazzar and his queen, symbolized by a tiny cart of roses pulled by delicate white doves. For Griffith, Babylon paralleled the prewar South—an idyllic land of peace and comfort—destroyed by the forces of rapine and death that sprung from the envy and ambition of a few men. The film's modern sequence was far more

complex. Griffith condemns social-reforming ladies who turn to reform when they can no longer turn a man's fancy. But Griffith equally condemns the rich owner of a factory who is so insensitive to human needs that he starves his workers into a strike and then mows them down with his own private army of detectives. Griffith also shows the poverty in cities, the illicit means of making money when there are no legitimate jobs, and the resulting disruption of the essential human unit—mother, father, and child.

Interwoven climaxes of *Intolerance*

Griffith culminates all four stories with four interwoven climaxes. The Mountain Girl races home to warn Belshazzar; Christ drags the cross toward Calvary; a Huguenot races home to save his family from slaughter; the governor and the mother race to save her innocent husband from execution. The breathtaking effect of leaping from century to century, chase to chase is overwhelming. But, after the breathtaking excitement, Griffith ends the film, as he did *The Birth of a Nation*, with an allegorical pageant. Angels appear in the heavens; prisons dissolve into fields of flowers; roses bloom in the rocking cradle. As in the earlier epic, this pageant is irrelevant to the film's story, a sure sign of the simplicity of Griffith's ideological system. Whereas Griffith was very able with human details and melodramatic excitement, he was very weak at abstract speculation about the nature of man and the direction of history. Beneath the immense structural framework of *Intolerance* was the trite homily that nasty people are not nice and may do nasty things.

Later films. The narrowness of Griffith's vision was at least partly responsible for his decline in the years following *Intolerance*. The attitudes and films of other directors became far more complex and popular once Griffith had shown them the way to incorporate ideas into exciting motion-picture entertainment. Movie audiences of the 1920s became too sophisticated and too materialistic for Griffith's sentimental simplicities. The later Griffith films were not, however, without their virtues: *Hearts of the World* (1918) was a tender study of war-torn Europe and an attempt to redress Griffith's injury to the black man; *Broken Blossoms* (1919) was a poetic story of the London slums in which a gentle Chinese man, a delicate girl, and a brutal boxer all tangle and die; *Way Down East* (1920) was an affectionate look at the rural United States, culminating in a spectacular rescue sequence when Richard Barthelmess saves Lillian Gish as she floats on an ice cake toward the murderous falls; *Orphans of the Storm* (1921) contained careful Dickensian evocations of the French Revolution (Dickens was Griffith's favourite author); *America* (1924) used luminous, soft-focus photography. But the later Griffith films lacked the spark and the opportune historical timing of his two epics. The motion-picture industry caught up with Griffith's pioneering leadership very quickly. After two disastrous attempts with synchronized sound, Griffith was forced into involuntary retirement in 1930.

The early age of comedy. The dawn of the age of Griffith was also the dawn of the age of comedy.

Mack Sennett. In 1907 Mack Sennett began working in films. He worked for Griffith at Biograph between 1908 and 1912. And out of Sennett's films came, in turn, such pupils as Charlie Chaplin, Fatty Arbuckle, Marie Dressler, Mabel Normand, Ben Turpin, Billy Bevan, Harold Lloyd, Harry Langdon, and Charlie Chase. Sennett left Biograph in 1913 to direct comic films for an independent company, Keystone. Sennett's Keystone comedies were improvisational, spontaneous, and very, very fast. Sennett packed his cameras, performers, and crew off to some nearby location, shot some footage, then returned to his little studio to finish the interlinking continuity. The dominant technique of the films was speed; the dominant activity was hitting, kicking, bashing, and crashing; and the dominant intellectual attitude was that nothing should be taken seriously, especially something that took itself seriously.

Sennett's comedies reduced men to machines. His distant shots reduced people into things, making them close cousins to the other machines that zip through Sennett films—automobiles, airplanes, bicycles, boats. Sennett increased the impression of mechanization with his mechanical camera tricks—undercranking, reversal, combining animated drawings with live action. The Sennett world at Keystone was one of pure mechanical fun, total irrationality, the surprises of incongruity, impossibility, and the *non sequitur*. Motion for the sake of motion and speed for the sake of speed were the essential cinematic delights. The Keystones reduced serious social questions to absurd comic stereotypes—the impolite, but often funny, jokes about Jews, Germans, blacks, and the like implied an honesty and easiness about racial and class differences in U.S. society that later disappeared. Among Sennett's other comic targets were rich snobs, moralistic ladies, preachers, professors, and, ultimately, the police—who were the dizziest, daffiest, most incompetent toy soldiers on the Sennett lot. Sennett claimed that his primary target was pretention. His special delight was applying a kick in the pants, a brick in the head, or a pie in the face as an antidote to pretentiousness. But Sennett delighted in the kick, brick, or pie for its own sake as well.

Mack Sennett's Keystone Cops in a typical scene from *On Edge* (*c.* 1915).

Sennett's parodies of other films

Sennett also enjoyed parodying other films, which he often found absurdly pretentious. Those Keystone films that had a plot at all (many were simply fighting, chasing, and running around) usually made fun of other plots. He parodied the story of the pure country girl engulfed in the wiles of the big city in *Tillie's Punctured Romance* (1914); he parodied westerns in *A Versatile Villain* (1915); he parodied Griffith's last-minute rescues in *Barney Oldfield's Race for Life* (1914) and *Teddy at the Throttle* (1917); he parodied romance and young love in the "Fatty and Mabel" series, and romance and domestic bliss in the "Charlie and Mabel" series. In his later films, Sennett produced hilarious parodies in which the cross-eyed comedian Ben Turpin reduced the great stars of the era (*e.g.*, Rudolph Valentino, Erich von Stroheim, and William S. Hart) to the absurd.

Sennett's style of comedy was a kind of summary of what had preceded it—a synthesis of Georges Méliès' mechanical tricks with the camera, of the jests and pranks stemming from *L'Arroseur arrosée*, and of the frantic chases conceived by Zecca and copied by numerous imitators. Sennett, in turn, passed on this delight in irrational surprise and physical movement to his many descendants.

Early Chaplin. The man who was to take comedy in a new direction, Charlie Chaplin, began working as one of Sennett's mechanical toys. It was Sennett's definition of comedy as speed and machine that helped define Chaplin's sense of comedy as human and supple. Although Chaplin consistently felt that Sennett did everything too quickly, that his own style of comedy had no place in Sennett's world of clockwork puppets, Chaplin's year at Keystone was extremely valuable. Knowing nothing about film acting, editing, and construction, Chaplin became so proficient within a year that he directed some of

the best Keystone films that Sennett produced—*Dough and Dynamite, The Rounders, The New Janitor* (1914). In his second Keystone film, *Kid Auto Races at Venice* (1914), a delightful little improvisation about a troublesome tramp who interferes with a camera crew that is trying to take pictures of the races, Chaplin first wore his tramp costume of baggy trousers, enormous shoes, tight vest, derby hat, and a cane. Throughout his Keystone year, Chaplin refined both the costume and the character of the tramp.

Genesis of Chaplin's tramp

Another valuable Keystone lesson was Chaplin's discovery of objects. If Sennett turned people into inanimate objects, Chaplin turned objects into living beings. In *His Favorite Pastime* Charlie fights with a swinging saloon door; in *Mabel's Married Life* he fights with a boxing dummy; in *Dough and Dynamite* he turns baking dough into bracelets, boxing gloves, and bricks. The Chaplin comic technique was built around this transposition of objects—turning one kind of thing into something else. This transposition would dominate such later films as *The Pawnshop* (he turns an alarm clock into a can of tuna, a sick patient, an infected tooth, a precious jewel), *One A.M.* (he turns a collapsing bed into a dancing and sparring partner), *The Gold Rush* (he turns a boiled shoe into a gourmet feast), and *The Great Dictator* (he turns the globe of the Earth into an ethereal balloon and a performing seal's toy ball).

At Keystone, Chaplin also began to perceive that the world was not as simple and as silly as Sennett made it. The police were not merely incompetent clowns; they enforced the law. Further, they enforced laws that had been written by people who owned property to protect property. Chaplin began to realize that the essential human need was not how to get one's hands on a pie to hurl in someone's face but how to get one's hands on a loaf of bread if one is hungry. Even in the Keystones, Chaplin began building his films around more serious social themes, such as the need for material comfort and for human companionship or the contrast between the man of nature and the regulations of society. Chaplin could not develop many of these ideas with Sennett. At Keystone he remained a tough, gritty, jaunty tramp who kicked anybody in the pants who kicked him—and often even if they had not. To develop his own ideas, Chaplin had to go his own way.

Use of serious social themes

In 1915 Chaplin received a one-year contract to make primarily two-reel comedies for Essanay (most of his Keystone films were one reelers) at a total salary of $75,000. In 1916 he received a contract to make 12 two reelers for the Mutual Film Corporation at a total salary of $670,000. And in 1918 he signed a contract with the First National Company to make nine pictures (of two reels or more) for $1,000,000, plus a percentage of the profits. These astounding figures indicate three things: Chaplin's enormous popularity, the conversion of the motion picture from cheap novelty to big business, and Chaplin's success at going his own way. Many of Chaplin's early Essanay films were in the Sennett mold, such as *His New Job* (a parody of pretentious films and film stars) and *A Night Out* (a physical film of drunken stunts with Ben Turpin). But in *The Tramp* (1915) Charlie played a man of nature who sided with the pretty girl against his fellow tramps and who lost her when his rival, the handsome city slicker, returned to her farm. In *The Bank* (1915) he played a poor janitor in the institution dedicated to money who performs a heroic action only to wake to discover that his heroism was a dream. He demonstrated in *Police* (1915) that moralistic preachers are hypocrites pursuing their own gain and that policemen are more interested in their vanity and self-respect than in helping anyone in trouble. Despite the growing social commentary in his films, Chaplin never failed to be funny, combining serious implications with hilarious uses of props, mime, and human conflict. His mastery of the cinematic medium also became more controlled. He realized that his comic style was best suited to the medium shot with a very spare use of cutting, since cutting would detract from his delicate mime.

At Mutual the Chaplin films took a further leap in cinematic control, structural unity, and the integration of comic action with serious content. He reached perfection in the short film. Chaplin in *The Rink* (1916), for example, glides magnificently on roller skates, an act repeated in *Modern Times*, using his physical grace to avoid his rich enemy and the police. In *The Floorwalker* (1916) he miraculously captures the store's thief, who also turns out to be its owner. A frequent motif of the Chaplin films is that the boss steals from his own business, but Charlie is constantly accused of such crimes since he appears so shabby and unrespectable. If the rich man does not steal, he is often guilty of callousness and brutality. Whereas the actress Edna Purviance—blonde, sweet, mild—plays the consistent ideal of gentleness and beauty in the Mutual films, Eric Campbell—huge, brutish, mean—plays Charlie's consistent foe. Eric, the physical heavy, also becomes the societal heavy—a rich man, foreman, or boss. He was the embodiment of social success, as Charlie was of social failure. Chaplin's comic reversal is that the tramp's worthlessness is more valuable in human terms than the success of the characters acted by Campbell.

Comedies produced for Mutual

Some of the final films of the Mutual group are the most pointedly serious. In *The Immigrant* (1917) Chaplin comically recounts the problems of immigrants coming to the United States. *Easy Street* (1917) is the most bitter and mature of the group, a satiric deflation of utopias and idealistic clichés of social progress and human nature. In this film Chaplin comically demonstrates that the problems of living—poverty, hunger, drug addiction, animal brutality—are larger than any conceivable social solutions; the police who try to enforce the law fail, and the preachers who urge men to be better than they are, or can be, are mere dreamers. The irony inherent in the title of *Easy Street*, which is really a slum where life is very hard, is the kind that propelled Chaplin into his next creative state (see below *Comedies of the 1920s*).

Maturity of the U.S. film industry. Griffith, Sennett, and Chaplin all reached artistic maturity in about 1915. The same is true of the U.S. film industry as a whole. While the Europeans were more absorbed with World War I than motion-picture entertainment, the U.S. film industry pulled itself out of its infancy of commercial chaos. The Patents Company collapse began in 1915, defeated both in the courts and in the marketplace. And 1915, the year of *The Birth of a Nation*, was also the year when feature films seized control of the film industry and film audience. It was the year when Samuel Rothafel ("Roxy") first opened a plush "movie palace" on Broadway in New York City to show the new mammoth feature films. It was the period when the star system captured the public's imagination—as Chaplin's soaring commercial value and also that of Mary Pickford (she, too, signed a $1,000,000 contract) revealed. Other early stars included John Bunny (a fat comic whose distaste for propriety and the moralistic nastiness of his skinny wife, Flora Finch, foreshadowed the work of W.C. Fields), G.M. "Broncho Billy" Anderson (half owner of Essanay and the United States' first cowboy star), Theda Bara (the seductive sexual siren who added the word vamp to the English language), and Douglas Fairbanks (the energetic American go-getter who used his gymnastic talents to achieve the classic goals of the American Dream—love, money, and success).

The star system

The first fan magazines had appeared by 1915; so had the first motion-picture serials (*e.g., The Adventures of Kathlyn, The Perils of Pauline*), and the first reviews of films were published in the popular press. This was also the era of the first loud moralistic reaction against the sinfulness of screen stories and screen actors. It was the decade when Hollywood became the movie-production capital, when the first movie moguls became millionaires, and when the studio system became the standard means of film production. Thomas H. Ince was one of the first producers to organize a motion-picture factory, establishing shooting schedules, careful budgets, and approved shooting scripts before filming could begin. In 1916 Adolph Zukor assumed the presidency of the powerful organization that eventually called itself Paramount Pictures. In 1918 an outraged group of theatre-chain owners,

Rudolph Valentino as a romantic swashbuckling hero in *The Four Horsemen of the Apocalypse* (1921).
By courtesy of ©–1921, Metro-Goldwyn-Mayer Inc.

who found themselves pressured by the block-booking tactics of Zukor and the other powerful producers, formed the huge First National Exhibitors Circuit. In 1919, Chaplin, Griffith, Fairbanks, and Pickford combined their assets and talents to form the United Artists Corporation. And, by 1925, Goldwyn Pictures Corporation, Universal Pictures Company, Columbia Pictures, Warner Brothers, the Fox Company, and Metro-Goldwyn-Mayer, the biggest of Hollywood's studios, were all in business.

The aim of the studio system was to regularize production procedures, distribution methods, and the product itself. Films became less individual in style and theme; the Griffith days of improvising a whole film out of the creator's head were gone except in the work of Chaplin and a few others. Hollywood films tended to become increasingly categorized into recognizable genres: westerns (either with stars such as William S. Hart and Tom Mix or mammoth productions such as James Cruze's *Covered Wagon*, 1923, and John Ford's *Iron Horse*, 1924); romantic swashbuckling in faraway lands and times (the films of Valentino, Ramon Novarro, the later Douglas Fairbanks); idyllic, gentle rural romances (Mary Pickford's motion pictures, Henry King's *Tol'able David*, 1922); domestic stories of sexual seduction and marital temptation, either comic or melodramatic (von Stroheim's *Blind Husbands*, 1919, *The Devil's Passkey*, 1920, and *Foolish Wives*, 1922; deMille's *Male and Female*, 1919, and *Why Change Your Wife?*, 1922; Lubitsch's *Marriage Circle*, 1924, *Three Women*, 1924, and *So This Is Paris*, 1926); deMille's biblical spectacles produced after the sexual scandals of the 1920s when he was converted from the bedroom to the cross; war films with pacifist–humanist messages (King Vidor's *Big Parade*, 1925; Raoul Walsh's *What Price Glory?*, 1926); and comedies (the features of Chaplin, Keaton, Langdon, and Lloyd; two reelers from Sennett with Billy Bevan, Ben Turpin, and Harry Langdon; two reelers from Hal Roach with Charlie Chase, Will Rogers, "Our Gang," Snub Pollard, Stan Laurel and Oliver Hardy).

DeMille. Cecil B. deMille was one of the most successful of Hollywood directors at making hack formulas look very special. His bedroom comedies contained an air of naughtiness (many passionate stares) but very little bedroom activity and less comedy. His historical romances featured grandiosely unhistorical sets, costumes, and plot points. His religious spectacles featured spectacular sinfulness mixed with a dash of righteousness and a lot of self-righteousness. DeMille was a descendant of the Griffith tradition, and many of his films, like Griffith's *Intolerance*, began with the warning (on title cards and, later, from the booming voice of a narrator) that the film to follow was to be taken very seriously. The leaden pace, the huge sets, and the stilted seriousness of the acting styles in deMille's films continued to reassure the audience that what it was watching was "highly significant." In his blend of dramatic emptiness and overstated moralizing, deMille set a pattern for successful commercial film making that survived as long as he did. Significantly, his two periods of greatest popularity and influence, the 1920s and the 1950s, were the two decades most devoted to surface splash and bombastically ornate and ponderous production values.

Griffith's influence on deMille

Von Stroheim. Erich von Stroheim, on the other hand, was Hollywood's *enfant terrible*—a rebel in production values (decor, sets, costumes, lighting), moral assumptions, sexual attitudes, and personal temperament. Whereas deMille used passionate stares, von Stroheim captured genuine sexuality with shots of the details of the human body, and, where deMille turned desire into breast heaving and panting, von Stroheim consistently described human desires in animal terms using animal imagery. Unlike deMille, he insisted on absolute historical accuracy and minutely perfect atmospheric detail (much to the chagrin of his financial producers). Furthermore, while deMille's lighting was flat and even, von Stroheim's, echoing the character's passions, was grotesquely shadowed, with eye-shattering contrasts of dark and light. Von Stroheim acted in many of his own films, playing the central character from which the film's perversion and grotesqueness emanated. He played the elegant Prussian—fastidiously dressed, complete with military uniform, monocle, and white gloves, elegantly, suavely mannered, with complete knowledge of every social form and grace. But beneath the external elegance the man was a lecherous, sensual animal who assumed that other human beings were merely a means to his pleasure. For the film director to cast himself in such a role was central to the spirit of the films he directed.

Despite his bizarre style and themes, von Stroheim's sexual films for Universal made money. So did his strange version of *The Merry Widow* (1925) for Metro-Goldwyn-Mayer, which turned an operetta into a film of perversion suggesting the Marquis de Sade rather than Franz Lehár. But *Greed* (1924), von Stroheim's attempt to shoot a literal translation of Frank Norris' *McTeague*, a brutal novel of human corruption and the animal drive for wealth, was a catastrophe. Originally, von Stroheim wanted the film to run 42 reels (about eight hours); he agreed to cut it in half. Irving Thalberg, the new head of production at Metro-Goldwyn (Louis B. Mayer's name had not yet been added to the studio's), took the film out of his hands, ordered the film be cut to 10 reels and

Eric von Stroheim as the elegant Prussian in *Blind Husbands* (1919).

the remainder of the negative destroyed. The result is a film with powerful images, symbols, and episodes but one that is incomprehensible as a whole. After the silent era von Stroheim only acted in films, most memorably as von Rauffenstein in Jean Renoir's *Grand Illusion* (1938) and Max in Billy Wilder's *Sunset Boulevard* (1950).

The Motion Picture Producers and Distributors of America. The sensuality in the films of von Stroheim (and the pretense of sensuality in deMille's) was an indication of the mood and temperament of the audiences of the 1920s. Gone was the sentimental sweetness of Griffith's world of purity. The bizarre doings of the stars off screen—the Pickford–Fairbanks marriage three weeks after her divorce, the mysterious deaths of the actor Wallace Reid and the director William Desmond Taylor, Fatty Arbuckle's involvement in a rape and homicide—began to provoke as much public attention as the stars' activities on screen. In an attempt to avoid federal censorship and to placate moralistic critics, Hollywood created the Motion Picture Producers and Distributors of America in 1922, a public relations organization that sought to repair Hollywood's image in the press and Hollywood's activities both on screen and off screen. The man selected to head the organization, Will H. Hays, former postmaster general of the United States, served as Hollywood's moral leader for over 20 years. The "Hays Office" (as the MPPDA became colloquially known) took only informal and advisory censorship actions in the late 1920s; it would reach the height of its power a decade later.

Changes in the 1920s

Comedies of the 1920s. Hollywood's most vital and enduring product of the 1920s was comedy. Chaplin had been joined by three rivals—Buster Keaton, Harold Lloyd, and Harry Langdon—who surpassed him in productivity and equalled him in popularity.

Chaplin. Chaplin's longer films became much more conscious of exactly who the tramp figure was and how he contrasted with the social institutions and assumptions of the day. In the First National films of 1918–23 (varying in length from two to six reels), Chaplin plays several social roles (soldier, father, preacher) that are inconsistent with the character of his outsider tramp, in order to examine the differences between the tramp and the role. He compares the tramp's existence to that of a little mongrel named Scraps in *A Dog's Life*, showing that, for both Charlie and the mongrel, existence is an animal struggle for the necessities of survival—food, shelter, and companionship. In *Shoulder Arms*, the tramp attempts, without success, to adapt himself to the rigours of military routine and discipline. He eventually performs heroic military feats, though in his own unroutine, improvisatory way. He also awakens from a dream to discover that his heroism has been merely a romantic fantasy (a typical Chaplin motif). Charlie exposes in *Sunnyside* the dirt, selfishness, and dishonesty beneath the rural-U.S. ideal of small-town life. In *The Kid*, a rich film combining comedy and delicate pathos, Chaplin defines genuine familial love as opposed to society's definition of it with the tramp's relationship to his adopted child (Jackie Coogan). Chaplin burlesques both religious and legal definitions of righteousness in *The Pilgrim*, revealing that the tramp's personal moral system is superior to the assumptions of both church and state.

Chaplin's full-length features

When he began making full-length features for United Artists, Chaplin's control of cinematic distance (his awareness of the quiet intimacy of his style that required an equally intimate use of the camera), his knowledge of who he was, his awareness of societal assumptions, and his ability to make serious inferences with hilariously comic routines reached perfection. *A Woman of Paris* (1923), his first film for United Artists, was a daring departure. Chaplin directed it, and there was no tramp character; he played only a tiny walk-on part. The film starred Edna Purviance, the actress who had played Charlie's female foil for eight years, in the role of a woman who enjoyed the luxuries of the high life as the mistress of a sophisticated Parisian sensualist, acted by Adolphe Menjou. The film contrasted the purity of provincial life with the temptations of the city, the lure of materialism as opposed to the need for love. Remarkable about this much-repeated Chaplin theme of the conflict between love and prostitution was his refusal to moralize about the sinfulness of adultery; instead, he asks what other chance a poor woman has to enjoy the delights and comforts of opulence. Also remarkable was his building the film around concrete objects that implied so much more than they said—pipes, handkerchiefs, necklaces, napkins, a saxophone. The film's ironic restraint and clever comment became a major influence on the future direction of polite comedy—particularly on the films of Ernst Lubitsch.

In *The Gold Rush* (1925), Chaplin's favourite film and perhaps his best, Charlie prospects for gold in the frozen north. Despite the many hilarious scenes, every comic sequence is built around the question of human survival. The search for gold (a cold, dead metal) in a frozen desert (equally cold and dead) is a murderous, inhuman occupation. This coldness produces one of the great moments of pathos in all of Chaplin's films, when the woman of his dreams, who works in the dance hall, stands him up on New Years' Eve, leaving the sympathetic, gentle tramp completely desolate and alone. The tramp's gentleness and warmth are incongruous in the film's icy world. Similarly, *The Circus* (1928) contrasts Charlie's gentleness with the callousness of the circus owner and the romantic suaveness of the trapeze artist who steals the girl away from the tramp. The film also contrasts the spontaneous hilarity of the tramp's style of comedy to the usual circus-clown routines, which the tramp performs badly—as he does all routines.

Buster Keaton. Chaplin's opposite as a comic actor and director was Buster Keaton. He performed stunts with his whole gymnastic body rather than supple pantomime with individual parts of the anatomy. His little body was contrasted against the huge world of nature (forests, seas, rivers, rain, fire), unlike Chaplin's contrast of man and society, and Keaton played against huge objects that dwarfed him (locomotives, ocean liners, herds of cattle, an entire army, the entire police force) rather than the small objects that Chaplin manipulated and the individual opponents that Charlie fought. Keaton's films depended on driving, suspenseful plots, as opposed to the circular thematic structures in Chaplin's films. Keaton delighted in parodying other films, and he delighted in far-fetched gags, crazy machines, and bizarre tricks with the camera itself. Keaton's style of comedy was faster, zanier, and trickier than Chaplin's slow, subtle, intimate style. Charlie smiled and winked and sighed, all of which the camera recorded slowly and compassionately. Buster's face was a classically frozen mask of inexpression, producing its meaning from contrapuntal contrast with the huge, complex, bizarre world that surrounded the face and body.

Keaton's comic style

age of three), Keaton went to work as a supporting player for Fatty Arbuckle in 1917, much as Chaplin had served an apprenticeship with Mack Sennett. Between 1920 and 1923 Keaton made two reelers, among the most interesting of which are *The Playhouse* (a recollection of vaudeville days that exhibits Keaton's brilliant control of camera trickery), *The Paleface* (a parody of cowboy-and-Indian films), *The Electric House* and *The Scarecrow* (revealing Keaton's love of bizarre machines), and *Cops* (a driving film of cumulative mistakes in which Buster winds up the foe of the entire New York City Police Department).

From 1923 to 1929 Keaton made silent features that combined his sense of parody, his gymnastic stunts, his camera trickery, his crazy machines, and his understated character with a very strong sense of narrative drive and rhythm. Among his parodies of this period are *Our Hospitality* (1923), in which Keaton ridicules family feuds; *Sherlock Jr.* (1924), in which he mimics the famous detective; and *Go West* (1925), a parody of cowboy films, in which Keaton eventually succeeds in driving an entire herd of cattle to market, his sole aid in this achievement coming from "Brown Eyes," his lover in the film, who happens to be a cow.

Keaton plays a character who succeeds—despite his size, apparent insufficiency, and apparent effeminateness. He succeeds because his shortcomings are merely apparent. In *The Navigator* (1924), for instance, he succeeds in manipulating a huge ocean liner by himself; in *Battling Butler* (1926) he succeeds as a prizefighter; and in *Steamboat Bill Jr.* (1928) he succeeds in saving his tough father and soft sweetheart from a mammoth storm. His most striking success—as well as his best film—is *The General* (1926), in which Keaton singlehandedly defeats what seems like the entire Federal Army. He plays a Southern railroad engineer whose train is stolen by the enemy. He dutifully chases after his train because he loves it, and in so doing he accidentally performs romantically heroic deeds.

In the film's narrative suspense and its cynical deflation of heroism, war, and romance, Keaton creates his most unified comic epic. Keaton's apparent smallness and weakness are merely camouflage for his human potential, just as his apparently frozen face is merely camouflage for a pragmatic and active mind.

Harold Lloyd. Harold Lloyd is not a comic figure of camouflage at all. His internal personality shows on his face—in his smiles, his energy, and his horn-rimmed glasses. Lloyd plays the eager American who is energetic, anxious to succeed, and willing to compensate for his shortcomings with dash and speed. Lloyd's comedies put him in more familiar domestic situations than Chaplin's outsider looking at society or Keaton's elemental man fighting against the immensity of nature. Lloyd's goals are material success and romance, the typical goals of domestic comedy. His films are of various types. He is perhaps most famous for his comedies of thrills, his excitingly funny battles with gravity on the ledges and roofs of buildings, such as in *High and Dizzy* (1920), *Never Weaken* (1921), and *Safety Last* (1923). But Lloyd was also a master of a comedy of situations that built many laughs from either a reversal of character (in *Grandma's Boy*, 1922, he plays a coward who discovers courageousness) or a comic culmination of the character's supreme zeal and drive (in *The Freshman*, 1925, he pushes his way to eventual success in college). Although not as haunting and subtle as Chaplin, not as imaginative and surprising as Keaton, Lloyd comedies generate many laughs from lengthy, brilliantly constructed and developed gag sequences.

Harry Langdon. Harry Langdon, the fourth of the great U.S. comedians of the 1920s, was the opposite of Lloyd. Langdon was slow rather than fast, absent rather than aware, passive rather than active—a baby, not a man. Of the four famous clowns, Langdon was the stupidest, the least competent, the most effeminate, and the gentlest.

The plots of his comedies invariably plunge the male-fe-

male child-man into a dangerous or difficult environment where such foolish angels should fear to tread. He battles with desperadoes, vamps, tornadoes, gun molls, athletes, and gangsters, and he manages to win these impossible battles not because of his competence, like Keaton, or his push, like Lloyd, but simply because chance smiles on him. In *Tramp, Tramp, Tramp* (1926), for example, little Harry wins a cross-country walking race (despite such obstacles as virile male competitors, the vast countryside, the police, a chain gang, and a cyclone). In *The Strong Man* (1926) Harry rids a small town of its bootleggers and marries the girl of his dreams, who is blind (a suitable Langdon partner). He discovers in *Long Pants* (1927) that the girl of his dreams is a vicious, brutal gun moll, and little Harry crawls back home sheepishly to the comfortable reality of the small town (where this innocent really belongs).

The early documentary. An important development of the U.S. silent film was the birth of the documentary film. Robert Flaherty's *Nanook of the North* (1922), the first documentary to become a U.S. commercial success, was a close study of the life of an Eskimo. In its depiction of the way Nanook struggled daily to survive, the film also provided an awareness of the way it felt to be Nanook and the way life appeared to Nanook. The film's success allowed Flaherty to make other films for Hollywood, some alone (*Moana*, 1926), some with collaborators (*White Shadows of the South Seas*, 1928, and *Tabu*, 1931). Flaherty eventually found Hollywood antagonistic to his aims of observing and re-creating the experience of a unique way of life. He migrated to England, where he helped to steer the direction of that country's great documentary-film movement of the 1930s.

EUROPE

While Hollywood and the U.S. film dominated the commerce of the international film industry in the final 15 years of the silent-film era, the film industries of Europe began to recover after the devastation of World War I. European films during this period, rather than working for a conventional, standardized product, carried on many of the U.S. experiments of the Griffith era. Influenced by Griffith's composition and cutting, the Europeans compounded these cinematic techniques more complexly, personally, and innovatively than most U.S. producers and directors were willing or able to do.

Germany. The German film between 1918 and 1933 developed the effects of composition—the look, feel, and texture of the individual shot—so communicatively that many of the greatest German films contained the barest minimum of subtitles or none at all. German films demonstrated the emotional power of shadowy lighting, of architectural shapes and configurations, and of the subjective camera, often using the lens to mirror a character's inner vision of reality. Significantly, the German film was a studio film, shot indoors on a stage rather than outdoors in nature. Even outdoor scenes took place indoors, so technicians could perfectly control the effects of light, shadow, tone, and texture. This deliberate artificiality worked in favour of the most successful films of the era, contributing a feeling of stifling claustrophobia to stories of trapped people. These studio films necessarily put a heavy emphasis on decor, giving the designer great creative freedom in constructing his immense indoor cities—the sets of Hermann Warm, Robert Herlth, Walter Röhrig, and Walter Reimann were particularly notable. The emphasis on composition, however, put an equal aesthetic burden on the cinematographer, and Fritz Arno Wagner and Karl Freund consistently met the challenge by finding new and surprising ways of looking at the artificial universe they captured on film.

German studio system

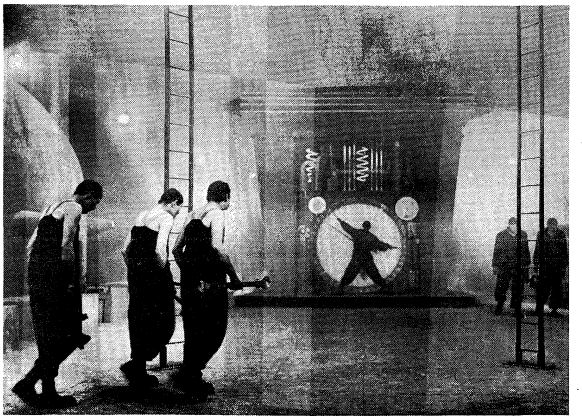
The German studio system was born in the late months of World War I, when the government sought a means of producing propaganda. After the Kaiser's fall, the huge studio Ufa (Universum-Film-Aktiengesellschaft) still stood. Just as there was a great burst of expression and creativity in German painting, poetry, fiction, and the drama after the fall of the monarchy and the birth of the Weimar Republic, creative expression in the German motion picture flourished. The German films thrived on the newfound freedom, but, when this freedom died in 1933 with the rise of Hitler and Fascism, the German film died as well, seemingly forever. The new excitement of the now mature motion-picture art attracted many talented artists to Ufa and its subordinate affiliates: Erich Pommer, a sensitive and intelligent producer; insightful and imaginative directors, including Ernst Lubitsch, F.W. Murnau, Fritz Lang, and G.W. Pabst; and a skillful group of repertory actors, such as Emil Jannings, Conrad Veidt, Asta Nielsen, Werner Krauss, Pola Negri, Lya de Putti, Henny Porten, and Lil Dagover. As early as 1918 Lubitsch had begun to direct his romantic historical spectacles with their clever and human premise that the great public moments of history were the products of intimate private moments. These films were especially distinguished for their careful control of decor and visual texture.

The beginning of the great German era of film making is marked by *The Cabinet of Dr. Caligari* (1919). Directed by Robert Wiene, the script was by Carl Mayer (who would become the greatest of the German scenarists) and Hans Janowitz, and decor was designed by Warm, Reimann, and Röhrig. *Caligari* is a multilevel story. On its first level, it is the story of a maniac, Dr. Caligari, who has hypnotized another human being, Cesare, subjugating the man totally to his own will and power. Though Caligari pretends to use his power merely for human amusement by displaying this human mannequin at fairs and circuses, he really uses his slave as an evil tool, sending him out to murder unsuspecting citizens at night. The film's hero follows Caligari and Cesare and discovers that the mad murderer is ironically the head of a mental hospital. The keeper of the insane is himself insane. The horror story of the film's first level clearly condemns bureaucratic social institutions (the incompetent police and the state asylum), official authorities, official definitions of sanity and madness, and the inhuman control of one man's mind by another.

But the film's second level gives it a completely different twist. Only at the end of the film does the viewer discover that the film's hero and narrator, who has been telling a listener as well as the spectator the whole horrifying story, is himself a patient in an insane asylum. And, further, the insane Caligari, whom he so viciously describes, is indeed the head of that asylum. Is the viewer, therefore, to believe the narrator's story of Caligari's murderousness or to interpret his story as the narrator–hero's paranoid fantasy?

Visual style of *Dr. Caligari*

The entire film has been designed in a visual style that defies objective reality: the walls are too white, the shadows too black; the houses, windows, and doors are not perpendicular with the Earth; there is no sunlight, merely painted black shadows on the walls. There are no streets, for the film seems to take place entirely indoors. The film raises many questions—is one to interpret the bizarre,



Metropolis (1926), directed by Fritz Lang.
By courtesy of the Museum of Modern Art Film Stills Archive, New York

psychotic unreality of the film's visual style as a mirror of the diseased brain of the narrator or as a metaphoric projection of the way an evil mind such as Caligari's casts its spell on reality? Is the film told in the first person or in a metaphoric third person? These two possibilities are as difficult to unsort as is the priority of the film's two plot levels (in fact, the uncertainty of the intention about the film's visual style is a perfect mirror of the uncertainty about its social and intellectual intentions). But, in the film's two levels—one mystical and fantastic, the other internal and psychological—the film points in the two directions of succeeding great German films.

Of the mystical descendants of *Caligari*, there was F.W. Murnau's *Nosferatu* (1922), the first of the film treatments of Bram Stoker's Dracula story, which uses many camera tricks and subjective devices to create a pure figure of horror (rather than the sexually attractive Dracula of later films). There were also Paul Leni's *Waxworks* (1924), a story of three figures in a wax museum who come to life to tell their stories, and the films of Paul Wegener and Henrik Galeen (*The Golem*, 1920, and *The Student of Prague*, 1926), who had begun making films of horror (an earlier version of *The Golem*) seven years before *Caligari*. The films of Fritz Lang, *Destiny* (*Der müde Tod*, 1921), a fantasy of the romantic past, and *Metropolis* (1926), a fantasy of the sterile future, are also in the *Caligari* tradition. *Destiny* is a romantic conflict between love and death (a conflict that also influences both *Caligari* and *Nosferatu*). When Death (personified in the film by a grim, black-clad man) takes away a woman's lover, he gives her three chances to redeem him, each of those chances symbolized by a flickering candle (the candle is used as a metaphor for human existence). Her three chances take her to a Muslim city, to Venice, and to a magical China, all of them distinguished by brilliantly textured sets, costumes, and architectural shapes, the last of them especially delightful in its use of camera tricks descended from those used by Georges Méliès. The woman fails at all three chances, but in the film's epilogue she performs a heroic action, saving an infant from death in a burning hospital. And, in dying herself, she joins her lover forever, conquering Death by dying. Although *Metropolis* claims to be about a world of science, the film is just as romantic. In his condemnation of the class system and the dehumanizing effects of industrial society, Lang builds a film that is visually magnificent but that, in its own way, is equally dehumanizing in its converting of men into dazzling architectural patterns. Lang's melodramatic plot, romantic social abstractions, and naïvely optimistic conclusion further reduce its power as social commentary (theoretically, its purpose) but cannot dull its effects as a kaleidoscopic visual experience.

Murnau's psychological realism

The greatest of the realist descendants of *Caligari* was F.W. Murnau's *Last Laugh* (1924), one of those half dozen or so representatives of the ultimate potential of the silent film as an art. The film's plot is extremely simple. A porter (played by Emil Jannings) at a posh hotel defines his self-respect and the value of his life in terms of this prestigious job, symbolized by his attachment to his ornate porter's uniform. Because he is old, the manager of the hotel strips him of that uniform and gives him another—the white linen jacket of the lavatory attendant. In losing his uniform, the porter loses his self-respect, as well as the respect of his neighbours, his friends, and even his own daughter. The story seems to end with the porter stooped in abject misery, a small, broken figure in the sterile whiteness of the hotel washroom (a man has been symbolically thrown into the toilet). But the film ends with a capricious reversal when Murnau inserts a subtitle, the only one in the entire film, to tell us that he has taken pity on the porter. In the film's epilogue, the porter miraculously inherits the millions of an eccentric American who died in the porter's arms in the hotel washroom. The now wealthy porter enjoys fancy food, cigars, and clothes; he showers the needy with gifts and money. Perhaps the contrived happy ending is needed to snap the absolute futility and despair of the porter's decline. Or perhaps the ending is a deliberate burlesque of the happy ending, also burlesqueing the Hollywood—and therefore American—notion that eventually poetic justice and good fortune will erase all social injustice and personal misery.

The remarkable feature of the film is its detailed care in the emotional rendering of every step in the porter's decay. The expressiveness of Jannings' performance—snappy, alert, vital in his porter's coat; broken, feeble, bent without it—partly creates the film's clarity and power; the expressive camerawork does the rest. Karl Freund, the photographer, frequently leaps into the porter's subjective vision of reality—his dreams of strength, his feeling that the world is collapsing on top of him, his drunken blurriness, his horror when the neighbours discover his dishonour. The camera both records how the porter appears from the outside and how he feels from the inside, constantly translating these feelings with the effects of lenses and the moving camera. Also remarkable about the film is its refusal to sermonize or draw facile moral conclusions. The porter's definition of himself in terms of a uniform is false but understandable. The same is true of his neighbours' false and surface definitions of the man's value. The hotel manager's decision to strip the porter is vicious but pragmatic. Perhaps the most vicious figure in the film is the hotel itself, the social institution that serves the wealthy few by sacrificing the human dignity of the many poor. The symbol of the hotel, a revolving door, underlies what Murnau saw as the inhuman, mechanical social process—as the old porter revolves out, another revolves in, a truly vicious circle.

Among the other psychological, social-realist films of the era was E.A. Dupont's *Variety* (1925), which also starred Jannings. In this story of desire, infidelity, and death among circus artists, the camera again plays a crucial subjective role in mirroring internal emotions; it swings aloft on a trapeze bar, spins around a room, tracks down a hallway.

The "street" films

The "street" films (a group of films that examined a whole social milieu) were more interested in the external problems of poverty, justice, and survival than in internal psychological states. Examples were Karl Grune's *Street* (1923) and Bruno Rahn's *Tragedy of the Street* (1927). These films frequently used the moving camera not for subjective views of experience but as an objective means of revealing a whole social pattern. G.W. Pabst's *Joyless Street* (1925) and *The Love of Jeanne Ney* (1927) are in this same realist tradition, combining melodramatic love stories with a carefully developed political, social, and moral background.

In a completely different direction, several of the German films of the 1920s tried to break the traditions of both fantasy and realism, as well as to break out of the restrictions of studio filming. Early in the decade Hans Richter and Viking Eggeling began making Surrealist, abstract films of form, shape, rhythm, and motion. In 1927 Walter Ruttmann combined these visual–musical principles with the documentary form of film in *Berlin: The Symphony of a Great City*, a candid study of Berlin

and Berliners at work and play, united by rhythms of editing and parallels and contrasts in visual forms. The ultimate intention of this "city symphony" (which started an international trend toward making other such city films) was to show the diversity of the Berlin experience, its joys and sorrows, warmth and coldness, without moralizing. The film also tried to use such kinetic effects of the cinema as rhythmic cutting and a dialogue of shapes and objects to make its points. These German experimental films of the 1920s were clearly a reaction and rebellion against the conventions of German studio films and their definition of nature as something built by a set designer, shaded by an electric light, and shaped by a camera lens.

Soviet Union. The Soviet cinema developed, defined, and ultimately codified the effects of editing—to which they gave the name montage. Like the Berlin symphony (which deliberately emulated the Russians), the Soviet film masters controlled the way that two shots could be joined together to generate meaning and feeling. Unlike the German cinema, the Soviets depended on the outdoors and nature, producing their interpretation of nature not by rebuilding it but by juxtaposing different views of it from shot to shot. In reproducing nature the Soviets also interpreted it, and that interpretation was a Marxist–Leninist view of history, social justice, and human necessities.

The Soviet cinema was created for the explicit purpose of propaganda and education rather than entertainment. Shortly after the Revolution of 1917, the state seized control of the scraps of the tsarist film industry that had been left behind. The Soviet discovery of montage was partly aesthetic—editing proved a very effective means of increasing intellectual awareness, creating social consciousness, and shaping emotional commitment—and partly accidental. Because of the many years of war and revolution, of blockades and counterblockades, there was very little raw film stock in the Soviet Union. So the potential film makers could work only at developing that potential in schools and workshops, doing film exercises rather than making films. Another significant accident is that one of the few Western films to pierce the blockades was Griffith's *Intolerance*, the finest example of the power of motion-picture editing that had yet been made.

Experimental editing in Soviet studios

In the workshop of Lev Kuleshov the future film makers performed countless editing experiments. They discovered that editing alone created the impression of unity of time and place in a film and could even assimilate a whole human being out of the individual parts of many different actors. The act of putting pieces of film together necessarily led the audience to connect the two pieces in time, space, meaning, or feeling. Even a face without expression could take on powerful significance depending on the emotion of the shots that preceded or followed it. For example, a preceding shot of a corpse made such a face appear sorrowful and a shot of a child at play made the same face appear quietly contented.

The experiments revealed that editing served three primary functions in a film. It could narrate, or communicate, the sequence of events, by shifting back and forth between the various figures in the sequence, cutting from a shot of one man to a shot of some force that would soon influence the man (Griffith's crosscut). But editing could also produce intellectual inferences. If the director cuts from a man standing in a pompous position to a statuette of Napoleon, the audience necessarily connects the two intellectually and applies the psychological and political implications of the statue to the man. Still further, editing generates a silent, undetectable energy and rhythm that work on the senses without an audience's being aware of them. A series of quick cuts or languid ones, a series of cuts of steadily darkening pictures or brightening ones, an exact metronomic rhythm of cutting, a series of cuts of larger and larger or smaller and smaller objects—these are all ways that an audience can be manipulated to feel something about the material without even realizing that it is being manipulated. The subliminal (or kinetic) use of cutting is very useful for underscoring a film's emotional effects as well as shaping an audience's moral responses to the action. Visual rhythms, like musical ones, are difficult to articulate because they work on the unconscious.

Eisenstein. Sergey Eisenstein was the greatest magician and musician of montage. He manipulated the kinetic rhythms of editing so successfully that an audience was never aware of manipulation, only of the film's tension, energy, and excitement. Eisenstein's theory of montage was one of collision—a crash of images from cut to cut, the images contrasting in light, shading, length, texture, size, speed, or emphasis. The result of this collision was an emotional experience of intense nervousness, a high level of anxious tension that never relaxed until the film ended. Eisenstein was remarkable for the intellectual thrust of his cutting. He also possessed a keen satiric sense that could produce comic intellectual inferences (juxtaposing a political leader with a shot of horses' buttocks) as well as serious ones. But Eisenstein was equally remarkable in his ability to handle visual images like musical notes and chords, for he was an orchestrator of visual images. His "music" was parallel to the dissonance in the compositions of the contemporary composer Sergey Prokofiev, and the later union of the two "musicians" for the film *Alexander Nevsky* (1938) was no coincidence.

Theme of brotherhood

Eisenstein's essential theme was human brotherhood, destroyed and betrayed by the vicious capitalistic system, eventually revealing itself as the brothers and comrades unite to take political action against the oppressor. Eisenstein consistently makes his protagonist the mass, not a single human being but a whole society. As opposed to the virtuous mass, Eisenstein personifies and individualizes his social villains. He either burlesques his villains (with animal faces as in *Strike* or with satiric, inanimate objects as in *October*) or turns them into the vicious stereotypes of melodrama (the smug officers and satanic priest of *Potemkin*). Eisenstein's social targets, the forces that oppress the people, are the "means of production" (the factory system of *Strike*, 1924), the military (*Potemkin*, 1925), the bureaucracy (*October*, 1928), and Christianity (which Eisenstein treats with either horrifying or comic ugliness in *Potemkin* and *October*).

Potemkin is probably Eisenstein's most unified, consistent, and controlled film. It is a simple story of a group of Russian sailors who seize control of a tsarist ship, build their comradeship and unity with the people of the Russian Black Sea port of Odessa, and eventually succeed in uniting all members of the fleet in brotherhood. Despite the story's simplicity, the flow of its rhythms turns each of its five sections into a musical movement, varying in tone but united in spirit. The sequences can be tensely expectant, chaotically violent, lyrically calm, horrifyingly brutal, or joyously triumphant. The most extraordinary movement in this visual symphony is the famed "Odessa steps" sequence, in which the vicious soldiers of the Tsar slaughter the defenseless men, women, and children, young and old, healthy and crippled, as these people respond joyfully to the harbour excitement of the liberated battleship. The emotional rhythms of the sequence's cutting perfectly mirror the brutality of the slaughter, providing an objective moral comment on the event as well as a subjective impression of how it felt to be there. But Eisenstein's aim is not despair but hope—the new spirit of the people that emerges with the slaughter. Among his subliminal symbols in the film are the battleship's guns, the sexual implications of which are intentional. At the beginning of the film, the guns are sheathed, impotent, lifeless; they are infertile servants of the Tsar. When the people seize the battleship as their own, the guns come to life, an expression of potency and fertility.

Eisenstein's most important rival

Pudovkin. Eisenstein's most important rival, Vsevolod Pudovkin, made films that were quieter, softer, more lyrical. They were also more obvious in their emotional effects and symbolism, using montage as a means of underscoring conventional dramatic effects rather than as a musical or intellectual element in itself. Like Eisenstein, Pudovkin's subject was Soviet political education and conversion, but, unlike Eisenstein, Pudovkin told a story of a single character's conversion, using that singularity to symbolize a mass movement: in *Mother* (1926), a

single woman discovers that revolution is the only means of securing justice in an unjust state; in *The End of St. Petersburg* (1927), a young man learns that to betray the revolution to the authorities in exchange for money is truly the act of a Judas; and in *Storm over Asia* (1928), a Mongol learns to rebel against his imperialist captors and to sweep them from his land. Underlining these gentler, more personal stories of people were Pudovkin's abilities with actors (he was a fine actor himself) and his tender natural imagery of fields, skies, earth, trees, and rivers, which also contrasted with Eisenstein's intellectual, inanimate, sarcastic, or brutal imagery.

Pudovkin's two greatest contributions to cinema technique were his theory of the "plastic material" and his awareness of camera angle. Pudovkin noted that concrete objects often are more effective at revealing a character's emotion or producing an audience's social and moral awareness than any piece of acting or human gesture. His theory of building a film around specific objects was really the summary of a cinematic axiom that had been unconsciously realized by such directors as Chaplin, Griffith, von Stroheim, and Lubitsch. In an external, surface medium such as the motion picture, which merely records what can be seen, the unique power of the objects the camera sees is undeniable. Pudovkin's camera saw such physical objects as the brutal dismemberment of a fish (*Mother*), the parallel vanity of religious statues and people (*Storm over Asia*), the heavy emotional weight of a single silver coin (*The End of St. Petersburg*). Pudovkin also realized that how the scene or object is seen is equally important. The particular camera position—high, low, eye level—shapes the reaction of both the characters and the audience to the scene. An extremely low angle makes a bureaucrat, soldier, or policeman seem overpowering and awesome. An extremely high angle makes an ordinary citizen seem very small and insignificant.

Other directors. Aleksandr Dovzhenko was the third of the great Soviet directors who realized that natural imagery, montage, human feelings, and political commentary can be mixed together in an exciting, personal way. Dovzhenko was the most poetic of the Soviet masters—the most fanciful, unrealistic, elliptical, and imagistic. In his greatest silent films, *Arsenal* (1929) and *Earth* (1930), there is no story at all, merely a series of isolated vignettes unified thematically by consistent natural imagery and by the flowing rhythms of montage. Among the other significant Soviet film makers in the silent era who similarly combined emotional experience and didactic lessons were Dziga-Vertov, a master of montage documentaries, Abram Room, a more conventional realist (*Bed and Sofa*, 1926), and the documentarists Victor Turin (*Turksib*, 1929) and Esther Shub (who combined montage with old newsreel footage).

Dovzhenko's poetic imagery

France. France in the 1920s was more significant as a place of apprenticeship, experiment, and innovation than as a centre of a mature film industry with a unified aesthetic and theme. The experimentation of the 1920s, however, would produce in France during the 1930s some of the best early sound films and directors (René Clair, Jean Renoir, Jean Cocteau, Luis Buñuel, Jean Vigo) who had begun to master the medium in the silent era. The French experimented in the ways that the motion picture can mirror a distorted, dreamlike, or surreal version of nature. The contemporary artistic movements of Dadaism, Surrealism, Impressionism, and other experimental "isms" produced the films of Man Ray, Jean Epstein, Marcel Duchamp, Fernand Léger, Alberto Cavalcanti, Louis Delluc, and Marcel L'Herbier. Perhaps the most impressive of the Surrealistic short films (the short form was most useful for formalistic innovation since a film of pure forms lacked the unifying element of plot and could easily become tiresome) were René Clair's dizzy romp *Entr'acte* (1924) and the Salvador Dali–Luis Buñuel intermixture of dream, sexuality, and *non sequitur*, *Un Chien Andalou* (*An Andalusian Dog*, 1928).

In the feature film, France produced the spectacular visual experiments of Abel Gance (*J'accuse*, 1919, and *Napoléon*, 1927), a Surrealist interpretation of the U.S. poet Edgar Allen Poe's "Fall of the House of Usher" (1928) by Jean Epstein, and Clair's devastating comic attack on bourgeois assumptions and social conventions, *The Italian Straw Hat* (1927). The most important French feature of the decade was *The Passion of Joan of Arc* (1928), directed by a Dane, Carl Theodor Dreyer, and designed by a German, Hermann Warm. This hypnotic, sensitive sketch of Joan's trial and execution was not so much a story as a visual tone poem of suffering and inspiration. Like Eisenstein's work, the film is a musical flow of images, but, unlike Eisenstein's dissonant symphonies, *Joan of Arc* is a hymnlike choral mass of vital faces and architectural compositions.

The feature film in France

Scandinavia. The maturity and control of Dreyer points to the final major film tradition of the silent era. The Scandinavian silent film combined the mystical, romantic view of nature found in the German film with the concrete, objective depiction of vast nature manifested in the U.S. film. The great Scandinavian directors such as Mauritz Stiller and Victor Sjöström developed the interrelation of men and nature, of emotional states and natural forces, and of human urge and natural setting with mystical intuition. Both Stiller and Sjöström made powerful silent films in the United States, where images of nature could also play a significant role in shaping the human story. The introduction of synchronized sound not only erected a linguistic barrier that forced the Scandinavians back to Europe but also temporarily banished the world of nature (where dialogue was difficult to record) from the U.S. film.

IV. The sound era

1928 TO 1945

Experimentation and the first "talkies." The idea of synchronizing sound and picture was as old as the motion picture itself. In the earliest Edison–Dickson experiments, Dickson achieved a rough synchronization of word and image. Many of the inventors of the first cameras and projectors, in fact, devoted their efforts to sound synchronization after this early equipment had been created. There were two technical obstacles to dependable, stable sound filming: synchronization (keeping the image and sound permanently and perfectly together) and amplification (filling a large auditorium with sound that would be audible to many people at once). The amplification problem was solved first, with the invention in 1906 by the American Lee De Forest of the audion tube, which drove the sound into loudspeakers rather than requiring it to trickle out of horns or earphones. The synchronization problem was solved in the years just following World War I by the discovery of the oscilloscope, which was based on the principle of converting sound into light beams that could then be recorded on celluloid alongside the visual image.

Early problems of synchronization and amplification

Although the eventual stability of sound filming would

owe its life to this sound-on-film principle, most early U.S. experiments used the more clumsy sound-on-disc method, attempting to keep film and recorded disc synchronized ("in synch") electronically. As early as 1912, the Edison studio produced a musical film based on nursery tales and characters that roughly synchronized phonograph disc and recorded image. In this very early musical picture, there is no editing at all. The camera statically records 15 minutes of singing and dancing without stopping or moving. This stasis would be a consistent trait of sound films until 1930. In the 1920s De Forest made a series of Phonofilms, filmed recordings of singers, entertainers, and lecturers, exactly parallel to the first novelty performances in Edison's movie studio. De Forest's Phonofilms used a sound-on-film principle. So did the Movietone, another sound process that recorded static performances of talking and singing. William Fox bought the Movietone in 1927 and inaugurated a series of conversations with famous people (George Bernard Shaw, for example). In 1927 Fox also produced the first newsreel that combined narration and picture—the Fox–Movietone News.

The first and most influential triumph of synchronized sound used the sound-on-disc process: the Western Electric Company's Vitaphone. After failing to interest any of the major Hollywood producers in the Vitaphone, Western Electric sold the device to Warner Brothers, who were struggling for survival in 1925. Warner Brothers first used the novelty exactly as their competitors did, by making sound-film recordings of opera stars, famous personalities, and vaudeville entertainers. In 1926 Warners added a recorded ("canned") musical score and sound effects to feature films, replacing the live orchestra or piano in the pit. In 1927, the Warners added four singing sequences and a little dialogue to an otherwise silent feature film with recorded musical accompaniment—*The Jazz Singer*. Contrary to myth, this Al Jolson vehicle was not the first talking picture and not the first film to use synchronized sound. But it was the first commercial feature film to combine the musical performances and "canned" orchestrations that had been used earlier with some dialogue that replaced title cards and helped to move the film's plot. Sound had been integrated, if only fleetingly, with plot and not used as an independent novelty in itself. *The Jazz Singer* was such an enormous commercial success that every studio had converted to sound within two years. And the Vitaphone quickly converted itself to the sound-on-film principle.

Commercial success of *The Jazz Singer*

The initial effect of Hollywood's conversion to sound filming was commercial, technical, and aesthetic chaos. Sound filming was enormously expensive. The new sound cameras and microphones were not the sole expense, for sound filming required completely soundproof studios, where only a single shot could be filmed at a time. In the silent era, six production companies could share a single, huge room, shooting noisily but easily side-by-side. The theatres also required expensive sound projectors and speaker systems, as well as wiring to link them. In addition to these commercial difficulties, many of the studios' old stars were suddenly worthless, their new voices no longer matching their old images, and the studios imported new stars, writers, directors, and plays from Broadway.

The technical difficulties of the ponderous sound machines imprisoned the camera in a soundproof glass booth, to keep its noisy apparatus away from the microphone. The active, mobile fluidity of the camera in the silent era came to a very abrupt end. The rhythmic freedom of the editing process also suffered the restrictions of sound, for it was very difficult to edit sound and picture without knocking the dialogue out of synchronization. Space and time reasserted their tyrannical control over the motion picture. Even the actors lost their ability to move, for dialogue scenes required them to sit, stand, or huddle together in a stationary position so that the single hidden microphone could catch their words.

The earliest sound films used static, dead pictures as accompaniment for the dialogue. There was no longer motion in the motion picture. In *The Jazz Singer*, for example, the sound sequences use long, frozen views of Al Jolson's singing with no camera movement and very little cutting. Whatever happens in these sequences is because of Jolson, not the camera. The silent sequences of the film, however, though fluid and active, are less entertaining, and that was the point for the audience. Despite the unimaginative stasis of the cinematic technique, the sound sequences provided a kind of entertainment that they had not seen before—the speech and song of a compelling personality combined with a complete motion-picture story. The problem for imaginative film artists was to integrate that kind of entertainment with the earlier principles of "motion" pictures. Film critics and theorists were certain that such integration was impossible, that Hollywood's commercial greed had swallowed a magnificent art, and that the motion picture was dead as an art form.

Role of pictures in early sound films

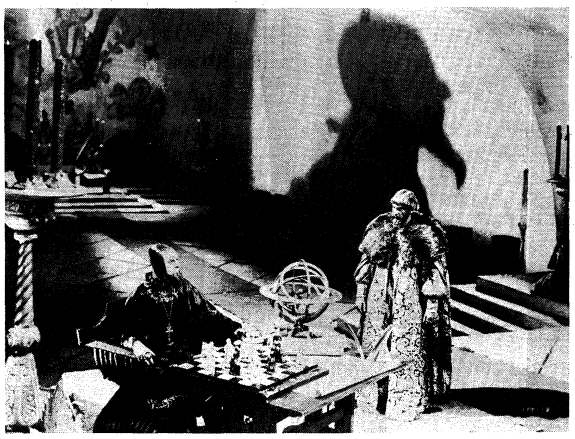
Ironically, that particular form of art was indeed dead. The introduction of sound did not simply add something to silent pictures; it also took something away—the way the juxtaposition of images and the texture of visual compositions themselves created social reality, human feelings, and thought. That reality, those feelings, and those thoughts would now have to communicate themselves, at least partially, in the same way they do in reality—with speech. The difference between the silent and sound film was the difference between a possible ballet version of *Hamlet* and Shakespeare's version. The aesthetics of the sound film and the silent film were as different from one another as the aesthetics of the theatre and the silent film or the theatre and the sound film. Once technicians had invented more serviceable sound equipment, the artists could discover the aesthetics of this new form—the way of integrating picture, word, cutting, noise, and music.

Some of the first interesting sound films were made in the United States, where sound produced its first complete revolution. Directors quickly learned that, although talking scenes had to be static, others without talk could be shot silently, using the old freedom of camera movement and cutting, then dubbing (adding) in the music and sound effects later. Ernst Lubitsch's *Love Parade* (1929) and *Monte Carlo* (1930), Rouben Mamoulian's *Applause* (1929), King Vidor's *Hallelujah!* (1929), and Lewis Milestone's *All Quiet on the Western Front* (1930) all reverted to silent principles for their active, nontalking, and musical sequences. Lubitsch was especially inventive at realizing that what is heard but not seen or seen but not heard could play very clever, ironic contrapuntal roles in a film. He also realized that, if one was going to make talking films, the dialogue ought to be good, and in his films (most of them written by Samson Raphaelson) the talk was very good indeed.

While directors of feature films tried to integrate the clumsiness of sound filming with their mirroring of the natural world, the animated cartoons of Walt Disney could indulge in all kinds of playful games, owing no allegiance to reality or nature. Disney used sound so cleverly in his second Mickey Mouse film, *Steamboat Willie* (1928), that he vaulted himself, Mickey, and the clever potentialities of sound to international attention. In the film Disney delighted in showing the surprising, ingenious sounds that could issue from cats, cows, pigs, and parrots. The climactic "Turkey in the Straw" number, in particular, is a visual–aural symphony of movement, rhythmic cutting, sound effects, and music. Symphony is an appropriate word for the effect, and one year later Disney inaugurated his series of "Silly Symphonies," which continued his experiments with abstraction, musical tone, rhythm, animated motion, and, by 1933, colour.

Early animation with sound

The early German sound films were among the best made anywhere. The German reliance on studio production and compositional style in the silents was especially suited to sound filming, which similarly required studio filming and relied on compositional style and texture for its primary visual appeal. *The Blue Angel* (1930), despite its U.S. director Josef von Sternberg, is a very Germanic study of a man's collapse (the man played by Emil Jannings). The careful control of visual contrasts, symbolic objects, musical motifs, and contrapuntal sound in the



Ivan the Terrible (filmed 1944–46), directed by Sergey Eisenstein.

film created a motion picture that seemed as cinematically free and emotionally satisfying as any of the German silent era. Fritz Lang's *M* (1931) was successful primarily because of the director's awareness of the power of subjective sound (and silence) as a means of tightening suspense. G.W. Pabst's early sound films, *Westfront 1918* (1930), a pacifist view of World War I, and *The Threepenny Opera* (1931), a heavy-handed but visually stunning version of Bertolt Brecht's play, also used the devices of sound—music, silence, asynchronous effects (sound and picture working in counterpoint, not together), subjectivity (the way the sounds feel to the character, not the way they really sound)—very effectively. When the Nazis gained control of the government and seized the film industry, the great German directors left the country, as did the spirit of creative freedom in German film making. After 1933 German films became remarkable instruments of propaganda, in which the "documentaries" of Leni Riefenstahl (*Triumph of the Will*, 1936; *Olympia*, 1936–38) and others were used as a means of allying the German mind with Hitler's objectives.

The early Soviet sound films were uninspired and clumsy. The great minds of the silent era had terrible troubles with the new equipment. Those troubles stemmed from several causes. Reliable sound machines were very slow arriving in the Soviet Union. The greatest silent film makers had all become politically suspect. And perhaps the very essence of the Soviet method, montage, was contrary to the demands of the sound film. Although both Eisenstein and Pudovkin wrote very perceptively on the theory of the sound film (they both argued that sound should work asynchronously with the visual), both deplored the idea of talking films—and most film critics feel that neither made sound films that measured up to his greatest silent work. Eisenstein did not complete a sound film until 1938, and his sound pictures (*Alexander Nevsky* and the two completed parts of *Ivan the Terrible*, made 1944–46) are more successful in their parts than in their entirety, and in their visual and intellectual conception rather than their execution.

France. The spirit of formal experiment and innovation among the French film makers in the 1920s led to their eager acceptance of the formal challenges of the sound film. Sensitive French directors quickly perceived the principle of asynchronous effects. In *Sous les toits de Paris* (1930; "Under the Roofs of Paris"), René Clair used a unifying street singer's song and cleverly integrated such sound effects as a repeating groove of a phonograph record into his story. In *Le Million* (1931), Clair juxtaposed a battle for a piece of clothing with the noises of a football game on the sound track. In *Boudu sauvé des eaux* (1932; "Boudu Saved from Drowning"), Jean Renoir used a shot of an etching—a military bugler blowing his trumpet—juxtaposed with the notes of a trumpet on the sound track to imply a seduction. In the same film, significant and symbolic musical motifs (the "Blue Danube" waltz, a brass band, a flute, an organ grinder's tune, a grunting song) underscore the film's action and ideas. Jean Vigo's *Zéro de conduite* (1933; "Zero for Conduct") and Jean Cocteau's *Sang d'un poet* (1931; "The Blood of a Poet") were predominantly silent films with musical accompaniment, functional sound effects, and a very sparing use of dialogue.

French use of sound

Having mastered the principles and procedures of sound filming so quickly and cleverly, the greatest French directors made some of the best films of the decade—indeed of any decade.

René Clair. Between 1930 and 1933 René Clair's career reached its peak with four sound films—two lyrical melodramas (*Sous les toits de Paris* and *Quatorze Juillet*) and two musical farces (*Le Million* and *À nous la liberté*). Clair's two greatest gifts were his feeling for music and his sense of decor. Songs, dance, musical interludes, and balletic chases dominate Clair's films, in which there was more singing than talking. In addition to evading reality by depicting a world where people sing, Clair handled the decor in an equally fanciful way, using visual shapes, patterns, and textures to echo his plot and themes rather than to mirror nature. In *À nous la liberté*, for example, a film that fancifully equates work (a factory) with slavery (a prison), every composition echoes the monotony and sterility of prisons by arranging people and sets in perfectly regular horizontal and vertical lines. Clair avoided the stifling demands of realistic talking pictures by avoiding reality and creating a world of fancy.

Injection of serious themes

Into this operetta world Clair injected serious themes. Central to most of his films is a male couple, who symbolize friendship or brotherhood in the abstract (*Sous les toits, Le Million, Liberté*). The plot of the film threatens to tear the friends apart, but they emerge victorious and friendly at the end. The foes of these friends become Clair's philosophic enemies: money, greed, possessions, social class, social propriety, societal assumptions about a meaningful and valuable life. Clair, heavily influenced by Chaplin, is the advocate of nature in its war with society, of people in their war with machines, and of fancy in its war with reason (hence, the unity of style and content in these fanciful films). Clair's ideal of happiness concludes *À nous la liberté* when the oppressive, prison-like factory continues to produce machines by itself, leaving human beings free to dance, sit by the river, and relax in the sun. Clair's sunny, optimistic view of man's innate potential was perfectly suited to the delicate, fanciful whimsy of his earliest sound films. But, when Clair's cleverness got heavy-handed (*The Last Millionaire*, 1934; *Beauty and the Devil*, 1949; *Beauties of the Night*, 1952) or when he tried to inject fantasy into a natural dialogue reality (*The Ghost Goes West*, 1935; *It Happened Tomorrow*, 1943; *Le Silence est d'or*, 1947), his delicate, uncomplicated ideas drowned in a sea of formalistic whipped cream.

Jean Renoir. Like Clair, Jean Renoir was also a proponent of nature, spontaneity, and freedom and the opponent of social form, convention, and assumption. Renoir's view of the conflict, however, was darker and more complex than Clair's, for he did not distill society into a

vague, impersonal "it" but showed quite clearly that malignant social forces were the products of men. His comedy is more bitter and caustic than Clair's and his serious films more gloomy and menacing. Whereas Clair denuded reality of its natural texture, Renoir worked oppositely, to provide as much realistic texture and depth as possible, even developing a unique shot that relied on depth of field to produce visual and emotional contrast between foreground and background.

Renoir was also a master of complex cinema structure, developing parallel lines of action, parallel events, and parallel symbols in each film that seem to speak to one another within a rich intellectual system. The Renoir films also rely more heavily on individual performances, using some of the most impressive and able film actors of the period: Jean Gabin, Erich von Stroheim, Michel Simon, Marcel Dalio. And, finally, Renoir was a master of a cold, distant irony that consistently showed human beings struggling blindly toward worthless goals, pitifully unaware of their own blindness and the worthlessness of their pursuits. In *Boudu sauvé des eaux*, for example, a bourgeois bookseller rescues a despairing tramp from the river and seeks to continue the rescue process by introducing the man of nature to the world of culture (a bourgeois home and edifying books). By the end of the film, the former tramp is so engulfed by respectable, bourgeois culture that he has a wife, fancy clothes, money (won in the lottery), a mistress (except that Boudu's mistress is, ironically, the bookseller's wife), and a job (in the bookstore). Boudu decides to turn his back on this life and "unrescue" himself. He pretends to drown in a boating accident, but he actually returns to the open road as a bum once more. The careful structural pattern comes full circle as Boudu ironically saves himself as a human being by pretending to drown.

Renoir's mastery of contrast

Renoir's mastery of contrast is evident in such films as *Toni* (1934), in which he contrasts the sensual, anarchic passions of Spanish peasants with civilized society's laws and regulations; in *The Crime of Monsieur Lange* (1936) the utopian happiness of a communal publishing house is contrasted with its previous stifling sterility and inhumanity under a tyrannical owner; *The Lower Depths* (1937) contrasts the suffocating life within a social microcosm with the freeness of life in the outdoors; and *A Day in the Country* (made in 1936) contrasts the artificiality of bourgeois city people with the natural feeling of the people who live outdoors in the country. *Grand Illusion* (1937) and *The Rules of the Game* (1939) climax the decade, indeed the entire prewar French cinema, with their studies of polite societal murder—the chivalric murder of World War I, in which everyone (prisoners and captors alike) is caught in the rules of wars and concentration camps, and the genteel murder of spontaneous emotions and natural vitality by the rules, codes, and assumptions of the ruling classes. The two films depict the death of the old aristocracy, blindly, ironically killing itself and everyone around it with its artificial, inhuman definitions of human value and social conduct.

Marcel Carné. Death is also pervasive in the films of Marcel Carné (with scripts by Jacques Prévert), not because of deadly social assumptions but simply because men die and they are not happy. The nihilism of these films takes several forms: a tragedy of fate in which death overtakes the man fleeing from it and in which love cannot triumph over death (*Port of Shadows,* 1938); a farce in which men make mistakes of interpretation because they are selfish and blind and in which even the comedy revolves about murder and death (*Bizarre, Bizarre,* 1937); a spectacular historical extravaganza in which the theatre is more satisfying than life, in which people achieve great success at what they do not really want and which does not satisfy them, and in which love and happiness always dangle just beyond man's grasp (*The Children of Paradise,* 1943–45).

To make their journeys into blackness entertaining and moving, Carné and Prévert built extremely complex film structures (like Renoir), rich in ironies, levels of interpretation, and ambiguities. They captured stunning visual images, saturated in the style and period of the particular story, and manipulated a heightened poetic dialogue with great effectiveness. Carné also used gifted actors such as Michel Simon, Jean Gabin, Jean-Louis Barrault, and Pierre Brasseur. The complex richness of a film such as *The Children of Paradise* or *The Rules of the Game* reveals how far the sound film had come from its clumsy introduction only a decade earlier.

United States. The sound film came a long way in the U.S. as well, but, unlike the poetic, personal films from France, the U.S. film was still made in the context of an industrialized studio system. The basis of the studio system was quantity, the need to produce over 500 feature films each year for the over 75,000,000 weekly customers who patronized the chains of theatres that the studio corporation itself owned. The Hollywood studio was, in effect, an entertainment factory. Like any factory, its goal was to produce a large number of products of consistent, dependable quality. Also, like any factory, its organizing principle was the division of labour—separate departments for writers, performers, technicians, film cutters, publicity men, etc., each of which contributed its piece to the finished whole. A film was not an individual artistic and commercial enterprise but one part of a whole year's output. Uniting all the studio departments were the men in the management who planned the year's production, managed all the budgets, and kept the assembly line flowing. The introduction of synchronized sound—with its mechanical difficulties, technical intricacies, and expense—gave even more power to the industrial system that had already existed for a decade. From 1930 to 1945, the studio system reigned supreme in the United States.

The commercialism of the studio system

That system created a very clear tension between art and commerce. Art defies mass production and assembly lines. Indeed, most films of the studio era were competent, conventional pieces of unimaginative entertainment, far more interesting sociologically (in defining the attitudes and expectations of the audience) than artistically. Most Hollywood films substituted craft for inspiration and familiar genres for individual conceptions. The director who could execute a script with professional polish, on schedule and within the budget, and the script that fit into some familiar film cycle—the gangster film (now that audiences could listen to tough talking), the musical (a genre that sound made possible), the western, biography, marital comedy, historical romance—were the studios' most valuable commercial assets. The dominant cinematic style in the studios of the 1930s was clean, bright lighting, along with smooth, functional editing and unobtrusive camera work that did not detract from the dialogue, for most studio films were "talkies."

The studios. Within the general pattern, the two giant studios, M-G-M (Metro-Goldwyn-Mayer) and Paramount, were stylistic and intellectual opposites. M-G-M was a studio with almost dictatorial central control by Louis B. Mayer and Irving Thalberg. Paramount under

Adolph Zukor was a much looser organization, allowing individual producers and directors greater freedom. M-G-M was a studio of stars (*e.g.*, Greta Garbo, Jean Harlow, Joan Crawford, Norma Shearer, Judy Garland, Clark Gable, Lionel Barrymore, Mickey Rooney, Spencer Tracy), while Paramount was a studio of directors and writers (*e.g.*, Ernst Lubitsch, Josef von Sternberg, Cecil B. deMille, Leo McCarey, Preston Sturges, Billy Wilder, Samson Raphaelson). In the early 1930s Paramount was the iconoclast's haven—the home of Mae West, who ripped up the sentimental clichés of femininity and romance; of W.C. Fields, who ripped up the sentimental clichés of propriety and conventional ethics; and of the Marx Brothers, who ripped up high finance, higher education, democratic government, and anything else they could get their hands on. Paramount permitted the sexual excesses of von Sternberg and the sexual snickering of Lubitsch. M-G-M, on the other hand, flattened all excesses into a shiny, respectable wholesomeness. When M-G-M inherited the Marx Brothers, it smoothed their chaotic clowning with elaborate production numbers and trite plots. Lubitsch films for M-G-M were heavier, shinier, and sweeter than his breezy films for Paramount. M-G-M gladly sacrificed vitality and energy for its glossy, pseudo-elegant style.

None of the other studios was as distinctive as these two at the extremes. Warner Brothers was remarkable for its gangster pictures, biographies, and musicals. It had directors such as William Wellman, Mervyn LeRoy, William Dieterle, Busby Berkeley, and Michael Curtiz and stars

Warner Brothers, 20th-Century Fox, and RKO

such as James Cagney, Edward G. Robinson, Paul Muni, Humphrey Bogart, Dick Powell, Ruby Keeler, and Bette Davis. The 20th-Century Fox Film Corporation excelled in historical and adventure films directed by John Ford, Henry King, and Henry Hathaway with Tyrone Power and Henry Fonda as stars; in show-business musicals with Don Ameche, Alice Faye, Betty Grable, and Dan Dailey; and in the comedies of Shirley Temple. RKO is most memorable for its musicals with Fred Astaire, smooth comedies with Cary Grant, and the adventure films and comedies directed by Howard Hawks. Universal excelled in the horror films—Dracula, Frankenstein, and the Werewolf—directed by James Whale and Tod Browning; in the comedies of W.C. Fields after he left Paramount; in the cheap comic films of Abbott and Costello, Ma and Pa Kettle, and Francis, the Talking Mule; and in the saccharine singing pictures of Deanna Durbin and Gloria Jean.

Most directors in the studio era were merely staff directors. These competent, proficient, unimaginative technicians took any script they received, shot it, and then passed the footage along to the editing department for shaping into its final form. The few directors who proved themselves particularly capable, who earned the right to shape the script before shooting and control the cutting after it, either transcended the Hollywood clichés or injected so much life into the cliché it was no longer recognizable as such.

Ernst Lubitsch. Ernst Lubitsch was Hollywood's most remarkable director at avoiding formulas and even at playing games with the formulas. His central subject was sex, quite a central subject in an era that produced a formal moral code in 1933 to eliminate sex from the motion picture. Lubitsch showed that even faithful husbands have their moments of rakishness and that women are not statues but sensual beings with powerful sexual drives of their own. In matters of sex, Lubitsch was a gentle European cynic, rather than an American idealist like most of his contemporaries. The primary battle in a Lubitsch film was between sexual attraction and the permanent definitions of a person's life. In *Forbidden Paradise* (1924), *The Student Prince* (1928), *The Love Parade* (1929), *Monte Carlo* (1930), *The Merry Widow* (1934), and *Cluny Brown* (1946), the characters felt their social positions pull them one way and their desires pull them another. In *The Marriage Circle* (1924), *Lady Windermere's Fan* (1925), *So This Is Paris* (1926), *One Hour with You* (1932), and *Angel* (1937), the characters felt their marriages (another kind of social position) pull them one way and their desires another. In *Ninotchka* (1939) and *To Be or Not to Be* (1942), political beliefs pull one way, passion another; and in *Trouble in Paradise* (1932) vocation (thievery) pulls one way and desire another.

Lubitsch's handling of potentially censorable material

Lubitsch handled the potentially dangerous or censorable material in such ironic and clever ways as to take all the passion out of it and turn sex into a matter of intellect. In his silent films Lubitsch revealed sexual attraction by concentrating on inanimate objects. In his sound pictures, however, he added another dimension to his sexual comedy by making the picture and soundtrack work in opposition. In *The Love Parade* Maurice Chevalier can tell a risqué anecdote—if the camera stays outside the window and reveals him talking about a lewd incident that one cannot hear but must imagine. In *The Merry Widow* Maurice Chevalier plays erotic games with Jeannette MacDonald's legs underneath a café table. Lubitsch, however, keeps his camera on the faces above the table. Only Jeannette MacDonald's "Stop that" and "Don't do that" inform one of what cannot be seen but must be imagined. According to Hollywood clichés, sex was either an all-consuming flame or a nonexistent feeling for the pure of heart. For Lubitsch, sex was merely one kind of natural human activity—no more or less important than intelligence, cleverness, manners, wit, taste, humour, and style.

Josef von Sternberg. Josef von Sternberg was the director who most successfully and powerfully depicted the reigning clichés. Von Sternberg's sound films—*The Blue Angel* (1930), *Morocco* (1930), *Shanghai Express*

Marlene Dietrich in a scene from Josef von Sternberg's *Shanghai Express* (1932).

(1932), *Blonde Venus* (1932), *The Scarlet Empress* (1934), *The Devil Is a Woman* (1935)—were stories of men and women bewitched by overwhelming desire. At the centre of these films was Marlene Dietrich, the supreme enchantress, who turned men into milk. Whereas Lubitsch made sexual relationships playful, natural, and ironic, von Sternberg made them terribly exotic, relying on strange foreign settings, esoteric symbolism, and a lush visual style with grotesque contrasts of light and dark, minutely detailed ornate settings, and a breathlessly moving camera (usually managed by Lee Garmes). Perhaps von Sternberg himself saw the excesses of the grand passions in his films; his later Dietrich films are so excessive in their visual styles and symbolism that the director may have been chuckling slyly to himself about the naïveté of an audience that could accept such bizarre posing as emotional reality.

Howard Hawks. Howard Hawks not only eliminated the appearance of sex from his films; he eliminated most of the Hollywood emotions. Hawks's characters are remarkable for their doing, not feeling. His films refuse to moralize and sentimentalize, a striking characteristic in a moralistic, sentimental era. The Hawks character is wrapped up in himself—his job, his interests, and his personal sense of integrity. The conflict in a Hawks film stems from the integrity of one character running up against the integrity of another: in *Red River* (1948) the older ego of John Wayne confronts the younger ego of Montgomery Clift. The male ego of Humphrey Bogart meets the female ego of Lauren Bacall in *The Big Sleep* (1946), and in *Bringing Up Baby* (1938) the scientist's ego of Cary Grant runs up against the feline ego of Katharine Hepburn. *Twentieth Century* (1934) is the most complete and successful comedy of ego ever made, in which two people of the theatre, John Barrymore and Carole Lombard—the Svengali and his ungrateful Trilby—fight to an egotistic draw.

Hawks's characters fight more than they love, but in that fight there is a kind of love; for, if they did not love, they would not fight. Love in a Hawks film is a matter of mind—one ego's perception of the strength and integrity of another. When Hawks added this ironic and insightful view of human interactions to his fast-paced rhythmic action and his sharp cutting and functional camera style, he proved himself one of the best storytellers of the studio years.

John Ford. Like Hawks, John Ford was interested in the civilizing of the old West. But, whereas Hawks's stories were of strong-willed men imposing their wills on weaker ones, Ford's were moral allegories of virtuous men bringing moral light to spiritual darkness. His villains were either uncivilized savages who had not yet received the light of morality or, worse, men of civilization who deliberately warped and perverted law and order for their own selfish purposes (the banker in *Stagecoach,* 1939; the murderous brothers in *My Darling Clementine,* 1946; or Liberty in *The Man Who Shot Liberty Valance,* 1962). Ford's ultimate belief, however, is in human kindness. In *Stagecoach* the kind people inside that social microcosm are also the virtuous people, regardless of their specific social and moral errors. Ford turns John Steinbeck's political novel *The Grapes of Wrath* (1940) into a personal epic of one family fighting vague social and natural enemies rather than Steinbeck's specific economic system. The Joad family survives because of its human strength in combatting the outside forces and because, despite the struggle, they never lose their human compassion and feeling for one another and for others in a similar plight. Ford's films are not nearly as tough and fast-paced as Hawks's, but they compensate with their genuine feeling for human compassion, suffering, and sacrifice.

Ford's moral allegories of virtuous men

Frank Capra. Frank Capra was John Ford's counterpart in comedy. For Capra, as for Ford, the centre of moral and political virtue was the heart, whereas for both Hawks and Lubitsch it was the brain. If people all loved each other, acted warmly toward each other, there would be no wars, no poverty, no tyranny, no dishonesty, and no unhappiness. The Capra hero is personified by Longfellow Deeds (*Mr. Deeds Goes to Town,* 1936), Jefferson Smith (*Mr. Smith Goes to Washington,* 1939), and John Doe (*Meet John Doe,* 1941), three unaffected, simple, folksy Americans who solve all moral problems with their personal warmth and who convert all the hardened cynics with their sincerity. The Capra villain (often acted by Edward Arnold) is personified by someone who uses his wealth to buy power and reduce other human beings to his pawns and puppets (*Mr. Smith*; *You Can't Take It With You,* 1938; and *John Doe*).

To reduce conflicting social and political ideas to matters of sentiment was absurdly naïve. But Frank Capra's view of politics harmonized with the hopes of his audience, who felt the Depression at their backs and World War II staring them in the face. Despite their political naïveté, the Capra films are very entertaining, particularly those with the least serious scripts and the most of James Stewart's or Gary Cooper's bumbling naturalness and Jean Arthur's or Barbara Stanwyck's energetic wit.

Other studio directors. Among the other distinctive studio directors were Leo McCarey (*Ruggles of Red Gap,* 1935; *The Awful Truth,* 1937; *Going My Way,* 1944), who made Capra-style comedies of sentiment that were less energetic and more plodding than Capra's; Preston Sturges (*The Great McGinty,* 1940; *The Lady Eve,* 1941; *Hail the Conquering Hero,* 1944), who combined sharp dialogue, Lubitsch wit, a cynical view of Hollywood clichés, and Capra's love for the "little people"; George Cukor (*Dinner at Eight,* 1933; *The Philadelphia Story,* 1940; *Adam's Rib,* 1949), who directed stylish dialogue comedies in the Lubitsch manner without the Lubitsch insight and attitude; and William Wellman (*Nothing Sacred,* 1937; *The Ox-Bow Incident,* 1943), who was a softer, sweeter version of Hawks.

Chaplin. Still other directors, particularly Walt Disney and Chaplin, were free of studio restrictions altogether, maintaining their independence and innovation throughout the decade. Chaplin made no conversion to sound at all in his first two "talkies" (*City Lights,* 1931; and *Modern Times,* 1936). He preserved his tramp in a world of mime and silence, underscored by music that Chaplin himself composed. The two films are deliberate burlesques of synchronized sound, using clever sound effects and a very rare dialogue sequence to show how freely one could handle sound in a film. For his final three U.S. films Chaplin adopted dialogue but still maintained much of his spontaneity, wit, and ironic iconoclasm: *The Great Dictator* (1940), which contrasted the egomaniacal urges of a Hitler with the natural, human responses of a little tramp-barber (Chaplin played both roles); *Monsieur Verdoux* (1947), which acidly and ironically showed murder to be as legitimate a means of making money as any; and *Limelight* (1952), a tender, personal summary of Chaplin's whole career and commitment to life and art.

Late Chaplin films

Orson Welles. Orson Welles was a film maker imported to Hollywood from outside the studio system. Unlike Hitchcock, Welles was never successful in Hollywood's

Orson Welles in *Citizen Kane* (1941).

terms. Like the earlier perfectionist and iconoclast Erich von Stroheim, Orson Welles lost more and more control over his films and eventually lost his job altogether. But *Citizen Kane* (1941), Welles's first and greatest film, ironically signified the death of the old Hollywood system even as Hollywood was trying to suppress it. The film aroused public controversy and contempt for its obvious and unflattering relationship to the life of the publisher William Randolph Hearst. Further, the film's structure was sprawlingly complex (yet completely controlled), its visual style idiosyncratic (shots using extreme depth of field, extreme shadowy backlighting, extreme upward angles), and its critical view of U.S. life and values was out of keeping with a nation engaged in a world crisis that threatened those values. For *Citizen Kane* showed the horrible destruction, emptiness, and deadness of a man who was supremely successful in the American terms of success.

Welles's influence

Charles Foster Kane was a man of fabulous wealth and possessions, but the one thing that he did not possess was love; for love, not being a material object, is not capable of possession. *Citizen Kane*, therefore, is a tragic story of the conflict between the material and the spiritual, possession and love. In the comic or romantic treatment of the American Dream (for example, Harold Lloyd's or Douglas Fairbanks'), the hero acquires both material success and love, the reward and the girl. *Citizen Kane*, however, shows that the two are mutually exclusive. If one devotes oneself to objects, one will come to treat people as objects and then will end up with nothing but objects. Ironically, Charles Foster Kane was dead before he died; his death began with the childhood decision to separate him from his family and natural environment all because of the rich metal (another object) on the family's property. The journey of Charles Foster Kane from vibrant, rebellious youth to dead tyrant and ogre was inevitable, the result of never knowing what was really valuable. In the individuality of its bitter theme, as well as the daring, innovative individuality of its cinematic technique, Welles pointed the way for a later generation of U.S. film makers. Although Welles's later work shows an occasional flash of *Kane*'s brilliance (*The Magnificent Ambersons*, 1942; *The Lady from Shanghai*, 1948; *Othello*, 1955; *Touch of Evil*, 1958; *Falstaff*, 1967), it never reaches that perfect integration of complex human statement, complex intellectual structure, and complexly rich cinematic style.

Documentaries. Also completely outside the studio boundaries and conventions was the U.S.'s struggling yet growing documentary movement. The most sensitive and effective U.S. director of documentaries in the 1930s was Pare Lorentz, whose *Plow That Broke the Plains* (1936), a study of the Depression's effects on the poor farmer in the "Dust Bowl," and *The River* (1937), a study of the beauty of the Mississippi River and its impact on the land and people surrounding it, combined factual photography, social criticism and commitment, compassionate human observation, poetic narration, effective musical scores, and a masterful control of editing. Lorentz was equally important as a producer and as an influence on the future direction of the U.S. documentary movement. He produced *Power and the Land* (1940), directed by the accomplished Dutch documentarist Joris Ivens, and brought Flaherty back to the U.S. to film *The Land* (1942). Lorentz also brought the power of documentary production—both in informing a people and shaping its values—to the attention of the United States government. The United States Film Service, which Pres. Franklin D. Roosevelt created specifically after seeing Lorentz' two films, was the first of a series of government film projects, eventually leading to the important government documentaries during World War II and the creation of the United States Information Agency after the war. On a more popular level, Louis de Rochemont's "March of Time" series, inaugurated in 1935, was a means of giving commercial film patrons a combination of interesting information on current issues and events as well as editorialized propaganda about those issues in the news-heavy years preceding the war.

England. The documentary movement in England played a much more central and vital role in the health of Britain's film culture. Whereas the commercial British film industry in the 1930s was primarily a colony of Hollywood, dominated in the era of sound by the common language that both nations shared, the most distinctive British products were documentaries. Funded and produced by the British government (the General Post Office or Crown Film Units), which accepted the principle of state production much more quickly than did the United States government, the most effective British documentaries were directed by John Grierson, Alberto Cavalcanti, Basil Wright, Humphrey Jennings, Harry Watt, Len Lye, Paul Rotha, and the Boulting brothers. The British historical epics produced or directed or both by Alexander Korda (*The Private Life of Henry VIII*, 1933; *Catherine the Great*, 1934; *Rembrandt*, 1936) were distinguished in their visual detail and texture and their smooth, realistic acting (notably by Charles Laughton).

Importance of documentaries in England

The commercial domination of Hollywood was so great in the 1930s in Great Britain that the government passed quota laws against U.S. films, intended to protect the native British industry. The laws only guaranteed that extremely cheap, incompetent "quickies" would be cranked out by British studios to satisfy the quotas, allowing the British cinemas to show all the Hollywood films they desired. England's greatest film stars (Laughton, Leslie Howard, Sir Laurence Olivier) went to Hollywood as soon as they were invited, as did England's one unique, imaginative director, Alfred Hitchcock.

Hitchcock's films

The Hitchcock film, both in England and the United States, was an exciting mixture of suspense and whimsy, murder and wry comedy, a driving narrative line and delightful digressions, social observation, and psychological aberration. Hitchcock's two dominant plots were the frantic chase for some vital "political" information (*The Thirty-nine Steps*, 1935; *The Man Who Knew Too Much*, 1935 and 1956; *The Lady Vanishes*, 1938; *Saboteur*, 1942; *North by Northwest*, 1959) or the psychological study of a single personality built with the same rhythms of the suspenseful chase (*Suspicion*, 1941; *Shadow of a Doubt*, 1943; *Spellbound*, 1945; *Strangers on a Train*, 1951; *Psycho*, 1960). As the Hitchcock films rush breathlessly toward their climactic solutions, the director weaves in bizarre interruptions that minutely examine an unfamiliar social milieu or wildly freakish occupation and that, ironically, prove not to be interruptions but vital strands of the plot. Hitchcock films succeed in making the completely incredible seem credible by piling one incredibility on top of another so that the incredible becomes logical, by developing the texture of each incredibility with great detail, and by moving from bizarre twist to twist with great speed and tension. If there is an essential Hitchcock theme, it would be the deception of surface appearances—that proper-seeming people can be very improper or those who seem mad are sane and vice versa. Because nothing is as it seems, the film's protagonist has

even more trouble solving the riddle, and the film's audience has even more fun watching the twists and turns.

As a technician, Hitchcock is a master of controlling the "plastic material." Hitchcock, like Lubitsch, manipulates concrete objects that mean so much more than they seem. Hitchcock is also a master of rhythmic, suspenseful cutting and particularly of intercutting sound and picture, underscoring the rhythm of his cuts with sound effects or using a sound effect to motivate a cut. He uses sound brilliantly by making many of his films revolve around musical motifs. Hitchcock, however, subordinates this technical control to creating a whole film world in which murderers, psychotics, and spies are no stranger than the little old lady next door, in which insanely exotic tales hang on the most trivial details, and in which the most unusual, abnormal settings became backgrounds for incredible chains of events that one accepts as credible because of their social detail, human comedy, and hypnotic rhythm.

1945 TO 1965

United States. During World War II, Hollywood contributed to the war effort both directly and indirectly. Many of the best U.S. directors—John Ford, Frank Capra, William Wyler, Garson Kanin, John Huston—made documentary films for the government. These films effectively mixed information and propaganda, combining newsreel and combat footage of battles and invasions with an editorial affirmation of the need to rescue the United States' freedom-loving allies and a warning about dangers to the United States' survival if those allies were to fall. The "Why We Fight" series, produced by Frank Capra and directed by Capra and Anatole Litvak, was the most notable group of war films to explain U.S. policy prior to the war and the necessity of fighting it after its brutal eruption (*Prelude to War*, 1942; *Divide and Conquer*, 1943; and *Battle of Russia*, 1944, were probably the three most effective films in the group). Other films combined combat footage of U.S. men in action with a stirring editorial tribute to human courage, personal sacrifice, and moral commitment (John Huston's *Report from the Aleutians*, 1943, and *The Battle of San Pietro*, 1944; John Ford's *Battle of Midway*, 1942; William Wyler's *Memphis Belle*, 1944). Whereas the propagandist "documentary" film played a minor and very tentative role in World War I, nations on both sides of the Atlantic had come to realize the power of film in shaping values and commitment by World War II.

Hollywood also contributed to the war effort by adding special taxes to theatre tickets. But Hollywood's greatest contribution during the war was probably its continuing to go about its usual business, producing the purely entertaining pictures that boosted the morale and spirits of both civilians and soldiers, taking their minds off the grim realities of the battlefield. The war, in turn, contributed to Hollywood's health, keeping the industry's profits up and the government's interference at a minimum. The U.S. industry's greatest commercial year was 1946, when box-office receipts climbed to just under $1,700,000,000. Box-office receipts fell every year thereafter (in an era of rising labour costs and inflation), sinking to about half the 1946 total by 1962.

Peak of Hollywood's success

The primary assault against Hollywood's audience came from television. More and more people stayed home every year to watch programs on their television sets. Gradually, the motion picture lost its role as the United States' primary means of mass entertainment. The United States courts were secondary assailants, finally ruling in 1949 (in the landmark Paramount case, which had begun in the courts 11 years earlier) that it was illegal for studios to operate their own chains of theatres for their films. The anti-monopoly ruling, however, was probably academic, like the legal ruling against the Patents Company trust in 1915. Commercial realities and audience demands preceded legal decision. There would be no audience to support either the huge theatre chains or the huge studios within less than a decade after the war. As the audiences shrank, the number of feature films, stars, contract players, technicians, executives, and publicity men also shrank. The studio system steadily lost its reason to exist as the yearly demand for large quantities of films steadily dwindled. Also, as the demand for feature films dwindled, the demand for the studios' supporting products—the comedy shorts, animated cartoons, travelogues, and newsreels—dwindled and died.

Hollywood's initial reaction was panic, which took several forms. In times of financial crisis, Hollywood had consistently imposed moral restrictions in the hope of luring the audience back with the support of the pulpit and the politician. The creation of the Hays Office in the 1920s and the Breen Code in the 1930s was succeeded by the industry's own witch-hunts as well as its subservient grovelling before congressional investigating committees in the late 1940s and early 1950s. Ironically, some of the very writers and directors who contributed to the war effort a few years earlier lost their jobs simply upon suspicion of being Communists, former Communists, Communist sympathizers, or "pinkish" leftists. Despite Hollywood's official piety, audiences continued to shrink.

Technical experimentation was another sign of panic. Hollywood introduced new cinematic gimmicks in the mid-1950s: 3-D, Cinerama, Smell-O-Vision, and others. Fortunately, several of the most gimmicky experiments were short-lived. Hollywood's intention was to provide a kind of entertainment that television could not. And television could throw neither props (3-D) nor smells (Smell-O-Vision) into the living room, nor could it successfully give the sensation of a roller-coaster or airplane ride (Cinerama) on an immense wide screen. The new devotion to mammoth spectacular films—*The Greatest Show on Earth* (1952), *The Robe* (1953), *The Ten Commandments* (1956), *Ben Hur* (1959)—was the result of the same panic. In these films, producers sought something grandiose that would stretch across the new wide screens and would overwhelm the puny inches of the image on a television screen.

Colour filming

The almost total conversion to colour filming in the mid-1950s can also be traced to the same source. Although a dependable Technicolor process had been perfected at about the same time as synchronized sound, only a very special studio offering (a lavish, historical film; a musical; the animated cartoon) could afford the additional time, care, and expense of colour filming. Technicolor originally required a very bulky three-lens camera, special technicians, and special artistic consultants. After the war, Hollywood needed colour to compete with a still black-and-white television. Several new and competing colour processes (Technicolor had previously been a monopoly supported by all the studios) lowered the costs and smoothed the difficulties of colour filming. Ironically, after television perfected colour in the 1960s, a motion picture had to use colour not to compete but to sell the suddenly valuable television rights to show the film on television.

Yet another reaction to the commercial chaos of the 1950s, in a completely different direction from Hollywood's preoccupation with size and dollars, was the birth and growth of America's "underground" film movement. The underground film maker rejected the huge, sophisticated equipment for his own portable, hand-held 16-millimetre camera; he rejected conventional plots for his own abstract, poetic, metaphoric, or satiric structures or non-structures; he rejected Hollywood's impersonal gloss for his own personal (if also technically rough) statement. The films of Stan Brakhage, Bruce Baillie, Ron Rice, Stan van der Beek, Kenneth Anger, Jack Smith, and Jonas and Adolfas Mekas rebelled against Hollywood's cinematic, social, sexual, intellectual, and psychological values. Although Hollywood and its patrons ignored the underground in the 1950s, the underground had ironically captured much of the aesthetics of commercial filmmaking by the late 1960s.

The U.S. commercial war between television and the motion picture was over in 1956, and the motion picture had lost it. Both motion pictures and motion-picture stars appeared on television, from which they had previously been banned. The studios began producing series and commercials for television, needing something to occupy

the vast sound stages and the large studio staffs. As the number of feature films dwindled each year, the sense of the U.S. film industry as a vital, fertile national movement also withered. Many of the greatest directors of the studio era had died in body or in spirit. Ford, Hawks, Cukor, and Hitchcock—the accomplished directors who survived—made films that deepened and broadened their own concerns but in no way blazed new trails in the possibilities of the motion-picture art. The new directors produced competent, entertaining, intelligent films in familiar, uninventive styles: George Stevens (*A Place in the Sun,* 1951; *Shane,* 1953), Fred Zinnemann (*High Noon,* 1952; *From Here to Eternity,* 1953), John Huston (*The Treasure of the Sierra Madre,* 1948; *The African Queen,* 1951), Elia Kazan (*Viva Zapata!,* 1952; *On the Waterfront,* 1954; *East of Eden,* 1955), William Wyler, Joseph L. Mankiewicz, Otto Preminger, and Stanley Kramer. These well-acted, clearly photographed dialogue films often merely used the camera and sound track to transcribe some hit play or best selling novel. Although many of these films yearned to say something socially, morally, and personally "significant," their social consciousness was extremely self-conscious and muted, strangled by fears of Hollywood political suppression, on the one hand, and by a devotion to Hollywood stylistic clichés, on the other.

Decline of comedies and musicals

The great comic films of the previous three decades withered into cheap, careless, formula entertainment with Abbott and Costello, Dean Martin and Jerry Lewis, Bob Hope, Red Skelton, Ma and Pa Kettle, and Francis, the Talking Mule. The dialogue comedies of Billy Wilder (*Stalag 17,* 1953; *Sabrina,* 1954; *Some Like It Hot,* 1959; *The Apartment,* 1960), however, effectively carried on the Sturges tradition of mixing satiric, unconventional comedy with a serious moral point. Another genre, the original musical comedies of M-G-M's waning years (directed by Vincente Minnelli, Charles Walters, Gene Kelly, and Stanley Donen), hit a peak of musical and visual imagination in the decade following the war, but by the mid-1950s Hollywood was producing mammoth, ponderous adaptations of Broadway musicals.

While both the U.S. film industry and film imagination decayed, the greatest contributions to motion-picture art came from smaller nations, the film industries of which were less dependent on quantity, where film making had always been more personal (if less slick) than in the United States, and where television took away the audience much more slowly. Indeed, the non-U.S. film saw its market expanding, not shrinking, for it found a new home on U.S. screens, which had been formerly very unreceptive to European "art" films, since sound erected its linguistic barriers. In contrast to the Hollywood film, the best films from Europe, India, and Japan were more sensitive to realistic social problems, to human psychological needs, and to flexible systems of moral values in a very complicated and rapidly changing world. The films translated into cinematic terms many of the intellectual and moral questions raised in the century's greatest novels, plays, and philosophic essays. These motion pictures were also more adventurous in their handling of the camera, editing, and the sound track—freeing themselves from the tyrannies of dialogue and of theatrical space and time that had begun to smother the U.S. film. The postwar European film, in particular, recaptured much of the visual freeness of the last decade of silent filming. And, just as the post-1918 European cinema helped the U.S. industry discover the fuller possibilities of its art, the post-1945 European cinema eventually gave the U.S. film its new direction and identity as well.

Neorealist movement

Italy. Italy's Neorealist movement showed human beings struggling with four basic problems of survival: against the war and the murderous political chaos that invaded their land, against hunger, against the poverty and idleness of unemployment, against the dissolution and corruption of the family. The Neorealist films straddled the boundary between fiction and documentary, emphasizing poverty rather than Hollywood glamour; ugly, bare hovels rather than tidy homes and chic apartments; and common, defiant, earthy people, such as Anna Magnani, as actors and actresses, rather than Hollywood's elegant gods and goddesses. The Neorealist films adopted the Marxist principle that unjust social structures pervert the essential human relationships and that both love and friendship become dangerous and elusive luxuries in a society in which there are not enough work, not enough money, and not enough food. Roberto Rossellini's *Open City* (1945) and *Paisan* (1946) were among the first Neorealistic statements, but the fullest and most moving of them were Vittorio De Sica's films, with scripts by Cesare Zavattini.

Scene from *Satyricon* (1969), directed by Federico Fellini.

Vittorio De Sica. De Sica's *Bicycle Thief* (1948) is remarkable in its ability to develop so much frustration and pathos from the simplest of stories. A worker, who needs his bicycle for the job that will support his wife and son, sees a thief steal that bicycle on his first day at work. The film becomes a desperate search for the bicycle, taking the man, his friend, and his son on a hopeless search through the slums and junk markets of Rome. When Antonio catches the thief, he discovers that the culprit is merely a starving young man like himself, a thief out of the same necessity that they all face. Unable to retrieve his bicycle, Antonio finally steals another (he is the film's second bicycle thief), only to be caught and abused by an unsympathetic and uncomprehending mob. The man's degradation is complete, and only the gentle affection of his young son provides him with a reason to continue to exist.

De Sica's later films (also with scripts by Zavattini) consistently examine human needs and desires with sensitive detail and compassion, juxtaposing the fervent human attempts to survive with the immense social, economic, and political chaos surrounding them: *Miracle in Milan* (1951), *Umberto D* (1952), *The Roof* (1956), *Two Women* (1961), *The Garden of the Finzi-Continis* (1971).

Luchino Visconti. The contrast of poor, humble man and malignant, impersonal society became the basis of hundreds of postwar Italian films. But, as the country (and the country's film industry) became richer, the Italian films drifted further from poverty, hunger, and social inequities. Whereas Luchino Visconti began with realistic, black-and-white films about the poor and squalid (*Ossessione,* 1942; *La terra trema,* 1948; *Rocco and His Brothers,* 1960), he soon drifted to historical films in colour (*The Leopard,* 1963), grandiose allegory in colour (*The Damned,* 1969), and mammoth literary adaptations in colour (*Death in Venice,* 1971), all of them adorned with sumptuous elegance and elaborate decor.

Change in Italian films.

Federico Fellini. Fellini also began with modest, personal studies of individual people and drifted toward the multimillion-dollar spectacle of *Satyricon* (1969). Fellini's journey from modest poverty to mammoth visual circus is quite understandable. The circus and variety hall had always been his favourite domains (which he proved in his intimate study of *The Clowns,* 1970), often forming

the backgrounds for the lives of the poor people he tenderly studied. Fellini's subject in his earlier films was not how the social milieu oppressed the poor and starving but how the poor and starving went about the business of trying to find love, the only necessity that made life worth living. Fellini's Cabiria (*Nights of Cabiria*, 1956), a prostitute who has plenty of money, gladly sacrifices it for the man who will take her off the streets. Gelsomina (*La strada*, 1954) is a foolish waif who requires affection more than food. Her death from the cold and snow is the fault of her brutal, callous lover-master, not of any social system in the abstract. Fellini's other early films (*Variety Lights*, 1950; *The White Sheik*, 1952; *Il bidone*, 1955; *I vitelloni*, 1953) are similarly close, personal, sensitive studies of love and rejection, human responsiveness and callousness, many of them featuring his own wife, the actress Giulietta Masina, as the source of their laughter and tears.

Fellini's later work expands the scope of his human circus. These films consistently reveal the director's urge to generalize, to convert his grotesquely compelling images of human faces and social events into intellectual symbols. *La dolce vita* (1960) contrasts the collapse of life's spiritual meaning (the commerciality and deception of the church, a constant Fellini theme; the impotency of the intellectual life) with the new vitality of sensual experience (the escape into riches, drink, and sex). The film *8½* (1963) is a bewilderingly complex study of the director's own life and art, a story in which a film director's imaginative fancies blend into his life and his life into his artistic creations, causing his agonized suspicion that he is a failure both as man and as artist. *Juliet of the Spirits* (1965) is Fellini's first colour circus, a hypnotic series of dazzling vignettes that contrast the stifling propriety of the bourgeois, conventional life with the lures of sensuality and amoral spontaneity. Fellini's devotion to flamboyant colour, grotesque faces and makeup, and sumptuously rich settings and costumes culminates in his *Satyricon*, a film that plunges the audience into a sensual Roman netherworld, where the spectator roams about aimlessly, like the film's protagonists, in a waking dream of colour, bizarre images, and sexual gratification, the only purpose of which is to be savoured and felt, like any circus.

Michelangelo Antonioni. Michelangelo Antonioni is far more introspective, more internalized, and much quieter than Fellini. The essential Antonioni theme is the anguish of modern life, and his essential human study is the way people (especially sensitive people) come to terms with that anguish. Contemporary life forms the backdrop for Antonioni's films: the world of the rich in *L'avventura* (1960), the literary world of *La notte* (1961), the stock exchange in *L'eclisse* (1962), the factory in *Red Desert* (1964), the chic world of fashionable success in *Blow-Up* (1966). Antonioni sets a sensitive human being (often the actress Monica Vitti) against these backdrops, using the camera and sound track subjectively to mirror the way she feels the hard, cold, intimidating world around her.

Antonioni's images and sound devices

Antonioni's favourite images are slick glass windows, white walls, shiny aluminum structures, polished terrazzo and stone, metal pipes, and barren, jagged rocks. His favourite sound devices are scraping, clanging, chugging, and thumping noises, as well as deathly silence. His films use little music and little dialogue, because they are about quiet people—sensitive characters who do not trust talk as a means of expressing their feelings. Also he finds talk less communicative than image, gesture, and noise. When Antonioni adopted colour photography in *Red Desert*, he used colour subjectively, to mirror the way the central character felt the world, not to present a dazzling Fellini circus for the eye. Most of Antonioni's films are not stories but circular journeys that leave the action at the end exactly where it was at the beginning, except for the increased awareness of the central figure. Though life does not look any brighter at the end of an Antonioni film, its betrayals, frustrations, and brutalities are more understandable and, hence, more bearable for both the central figure and the audience who has lived through the emotional experience with that character.

Other directors. The Italian film was extremely rich in the 25 years following the war—rich in imagination, in influence, and in profits, which have flowed into Rome's film studios from all over the world, especially from the U.S. Pier Paolo Pasolini began with the Neorealistic *Accatone* (1961) and progressed to biblical–Marxist spectacle, *The Gospel According to Saint Matthew* (1964); sexual–Marxist allegory, *Teorema* (1968); and sexual–allegorical spectacle, *Medea* (1970) and *The Decameron* (1971). Pietro Germi directs stingingly acid satires of provincial Italian hypocrisies and infidelities: *Divorce—Italian Style* (1962), *Seduced and Abandoned* (1964), and *The Birds, The Bees, and The Italians* (1966). Ermanno Olmi directs sensitive, Neorealist studies of sympathetic human beings caught in the gears of industrial, bureaucratic society—*The Sound of Trumpets* (1961) and *The Fiancés* (1963). Ironically, Italy capitalized not only on its sensitive artistic masterpieces but on the cheapness of its labour and film-production methods. In the 1950s and 1960s Italy sent Hollywood countless third-rate historical spectacles (often starring American musclemen) and cowboy films (called "Spaghetti westerns") as well as its "art" films by the De Sicas, Fellinis, and Antonionis.

France. *The continuing tradition.* Whereas the Italian cinema leaped off in a revolutionary direction after World War II, the French cinema first tried to repair the bridge to the past. Both *Les Enfants du Paradis*, which cost so much money, and *Zéro de Conduite*, which had been banned for its iconoclasm, could be released just after the liberation. René Clair returned to France to make sentimental, fanciful, occasionally effective films that were less innovative and much heavier than his earlier works. Jean Renoir also returned from Hollywood to make three of his greatest films, all of which were in colour: *The River* (1951), located in India; *The Golden Coach* (1953), set in early-19th-century South America; and *French-Cancan* (1955), which took place in 19th-century Paris. These films were magnificent in their visual splendour, in their saturation with the music of the particular culture, and in the director's own new sense of satisfaction with his life and art. As opposed to the bitter irony of his motion pictures of the 1930s, the late Renoir films develop the mood of "consent," that crucial term introduced in *The River* and developed specifically in his next two films, which are both about artists who have learned to consent to their lives.

Return of Clair and Renoir to France

Among the other postwar French directors who worked in traditional, graceful, almost literary cinematic styles were Jean Cocteau, who mingled realism and symbolism in *Beauty and the Beast* (1945), *Les Parents terribles* (1948), and *Orphée* (1950); Robert Bresson, who combined his quiet, sensitive attention to people and settings with his affirmation of both human values and religious faith (*The Diary of a Country Priest*, 1951; *A Man Escaped*, 1956; *Pickpocket*, 1959); and René Clément, who wandered from a delicately horrifying child's view of war in *Forbidden Games* (1952) to glossy, leaden, picture-postcard thrillers that were part Hitchcock and part parody of Hitchcock (*Purple Noon*, 1959; *Rider on the Rain*, 1970). Max Ophüls migrated from the U.S. to France, where he made several lavish spectacles that combined an ornately decorated society of turn-of-the-century Europe, an ironic view of romantic and sexual experience, and a dazzling control of camera, cutting, structure, colour, and composition. The Ophüls films, which contrasted the shams and artifices of society with the undeniable power of sexual lust and emotional need, were as intellectually subtle as they were visually hypnotic (*La Ronde*, 1950; *Madame de. . .*, 1953; *Lola Montès*, 1955).

Jacques Tati made a rather literal leap into the past with a series of essentially silent comedies that used music and brilliantly comic sound effects rather than talk, techniques such as those used in Chaplin's *City Lights* and *Modern Times*. Tati's Mr. Hulot, like Chaplin's tramp, punctures society's self-satisfied rules, forms, and values with his own natural spontaneity and with the director's miraculously clever visual gags. In *Mr. Hulot's Holiday* (1953), Tati's target is the bourgeois conventionality of a

stifling seaside resort; in *Mon Oncle* (1958), the inhuman sterility of a modern, bourgeois house full of maddening gadgets and plastic utensils. Life in the house is as plastic as its inanimate objects, for its owner also runs a factory that manufactures plastics. *Playtime* (1968) comically condemns the spread of U.S. culture in the form of both tourists and bureaucratic business procedures. Tati also condemns the non-Americans who surrender their own lives and culture so as to make money in the U.S. manner from those Americans. *Traffic* (1971) is a comic study of man's perverse attachment to his automobile, his conversion of himself into a machine, and his consequent divorce from both the world of nature and of spontaneous, natural feelings.

The New Wave. By 1960 an iconoclastic generation of French film critics and film makers rebelled against the classical, carefully written studio films that had dominated French film style since the introduction of synchronized sound. The young film makers applied to their own films the critical principles they had developed in writing for the magazine *Cahiers du Cinéma*. Jean-Luc Godard's *Breathless* (1960) officially marked the beginning of this New Wave; but several directors (Roger Vadim, Louis Malle, Claude Chabrol) had made New-Wave films before it, and two other extraordinary pieces of cinematic freedom, François Truffaut's *400 Blows* and Alain Resnais's *Hiroshima mon amour,* appeared in 1959. The parallel characteristics of all three films were the violation of linear time (huge leaps forward and backward and elliptical gaps in the story), an audacious mixture of varying cinema styles within the same film, and a spirit of spontaneity, improvisation, and freedom that was reflected in both the films' characters and in their cinematic style. For Truffaut and Godard especially, the spontaneous, irrational surprises and the breezy playfulness in the films of Vigo and the early comedies of Renoir and Clair served as models for the kinds of loose, buoyant films that they wanted to make.

Characteristics of the new films

Godard began as an Existentialist, passed through a period as Brechtian comic parodist, and then came to regard himself as a Marxist–Maoist lecturer. From the breezy Michel Poiccard in *Breathless*, a gangster in the Bogart mold who was charming, pleasant, warm, and completely committed to life as a series of spontaneous impulses rather than as a planned program, Godard switched to characterless, humourless, political debates in which his figures mouth banal platitudes (*La Chinoise*, 1967; *Le Gai Savoir*, 1968; *One Plus One*, 1968). Godard's spontaneity, humour, and human observation produced his best films, which either juxtaposed elusive and irrational feelings with the mechanical, rational repetitiveness of daily life (*Breathless*; *Vivre sa vie*, 1962; *Masculine/Feminine*, 1965) or became little parables of human and social existence that mixed parody of other films as well as literature with brutality (*Les Carabiniers*, 1963; *Weekend*, 1967).

Truffaut remained consistently committed to spontaneity, to human interaction, to a comic view of life in which love and sincerity are very difficult but still very possible.

Jean-Pierre Léaud as Antoine Doinel (centre) in *The 400 Blows* (1959), directed by François Truffaut.

His *400 Blows* shows the adolescent Antoine Doinel's breaking free from the stifling confinement of his childhood—his family, his school, a reformatory. Truffaut traces Antoine's later life in *Stolen Kisses* (1968), another story of Antoine's breaking away—from the army, from stifling (and comic) jobs—until he finally blunders into love. And in *Bed and Board* (1970), Antoine still loves his wife but also craves his freedom to experience. He wriggles free and then wriggles back to the marital relationship that really means something to him. Truffaut's art and the story of Antoine Doinel are intimately bound up with Jean-Pierre Léaud, the young actor Truffaut found for the first film and who continued to perform so vigorously and engagingly in the remaining Doinel films. Truffaut's non-Doinel films are equally committed to human sensitivity, spontaneity, and sincerity—in their cinematic styles as well as their plots: *Shoot the Piano Player* (1960) is a story of a honky-tonk pianist who cannot run away from his ability to love, and *Jules and Jim* (1961) is a story of three spontaneous people who love each other very much but cannot do so without also hurting each other and confining themselves and their own feelings. *The Wild Child* (1970), dedicated to Léaud, is a story of the film maker's own determined commitment (Truffaut plays the main role) to educating and to love. Truffaut's films are works of both education and love or, rather, education about love.

The films of Alain Resnais are much colder, quieter, and hollower than those of Truffaut and Godard, the works of a much more skeptical, older man. *Hiroshima mon amour* reveals the deadness of two people, their inability to love and respond to each other because of the deadness of their atomic world and the deadness of their own horrifying pasts. The Japanese architect and French actress are already dead inside, and Resnais uses images of cold, hard sterility to reveal that these people are stones. *Last Year at Marienbad* (1961) is another dazzling exercise in cinematic deadness, a series of flat, cold, gleaming images so confusingly interwoven, so bewilderingly arranged in space and time that it is difficult to make any rational story out of the film. It is a nightmarish experience of people frozen into statues, nature crushed into a painted landscape, and experience paralyzed into a series of photographs. *La Guerre est finie* (1966) is a much clearer and warmer story of a man who is virtually dead and whose life's work does not exist any more. He, too, is a prisoner of the past. In order to give his life meaning in the present, he must continue living as if his past were not dead and the war were not over.

Resnais's film world of living death

In the years since 1959, the New Wave has swept up many other directors. Claude Chabrol directed thrillers and case studies of psychological perversity (*Les Cousins*, 1958; *Les Bonnes Femmes*, 1959; *Les Biches*, 1968; *Le Boucher*, 1971), while Roger Vadim's films seem to fulfill the United States' stereotyped view of French sexiness (*And God Created Woman*, 1956; *Les Liaisons dangereuses*, 1959; *Barbarella*, 1968). Louis Malle jumped eclectically from classical, "literary" films (*The Lovers*, 1958) to irrational, incongruous comedy (*Zazie dans le métro*, 1960) to a combination of the classical world of sex and money with the child's world of spontaneity (*Murmur of the Heart*, 1971). Costa-Gavras combined political commitment with satiric comedy, exciting suspense and chases, and spontaneous cinematic tricks (*Z*, 1969; *The Confession*, 1970). The introspective, reflective, intellectual films of Agnes Varda (*Cleo from 5 to 7*, 1962; *Le Bonheur*, 1965) and Eric Rohmer (*My Night at Maud's*, 1969; *Claire's Knee*, 1970) have further enriched the French postwar cinema.

Sweden. The mid-1950s also brought the Swedish film industry to international attention, particularly through the films of Ingmar Bergman. Like the great Swedish silent films, Bergman's developed the interrelation of man and nature and of the reality of human existence with the metaphysical reasons for that existence. His films are dominated by men who have fallen out of touch with nature because of organized religion (*The Seventh Seal*, 1956), bureaucratic, bourgeois laws and assumptions (*The Magician*, 1958; *The Ritual*, 1969), a deadening

Bergman's interrelation of man and nature

and insensitive routine (*Wild Strawberries*, 1957), falsely idealized and romanticized notions of love and human relationships (*Smiles of a Summer Night*, 1955), and a loathing for an existence that cannot be rationally explained (*Through a Glass Darkly*, 1961). Many Bergman characters, feeling the total chaos of an inexplicable universe, escape from reality into a neurotic, selfish, fractured vision of people and the world (*Persona*, 1966; *The Passion of Anna*, 1969). Nature, however, reasserts itself in these films, with images of sunlight, trees, fields, skies, and flowers, showing the faltering, anguished humans its potential warmth and beauty if they will only allow themselves to see it. In his intelligent dialogue, glowing natural images, grimly ironic comedy, careful handling of music and the sound track, and capriciously clever manipulation of occasional cinematic tricks, Bergman combines his Existential quest with cinematic power.

Other contributions to postwar cinema from Scandinavia include the films of Alf Sjöberg (Bergman's mentor), *Torment* (1944) and *Miss Julie* (1951), the romanticism of Bo Widerberg (*Elvira Madigan*, 1967), and the titillating, inexpensively produced "stories" of ladies named Inga, Helga, and the like that are among the most popular entrées in the theatres devoted exclusively to films that in an earlier day would have been banned as pornographic.

Britain. The British film acquired a new individuality in the years following the war. The authenticity and realistic detail of the documentary tradition carried over into the fiction films, adding realistic texture and understated, realistic acting to genres as diverse as polished adaptations of literary classics directed by David Lean (*Great Expectations*, 1946; *Oliver Twist*, 1947), taut thrillers directed by Carol Reed (*Odd Man Out*, 1947; *The Third Man*, 1949), and quiet, realist comedies produced by the Ealing Studios, many of them with Alec Guinness (*Tight Little Island*, 1948; *The Lavender Hill Mob*, 1951; *The Man in the White Suit*, 1952). The year 1959, as significant a cinematic year in Britain as in France, was the year of both Jack Clayton's *Room at the Top* and Tony Richardson's *Look Back in Anger*. For the next several years, the British specialized in these "angry young man" films, which combined the British feeling for realistic acting and for the detailed textures of documentary reality with the foreign influences of cinematic freedom from France and of Neorealistic observation of human and social behaviour from Italy. Behind the new British movement was also the shift in the British class system: the angry but intelligent appeal of the former proletarian who had acquired an education. As the 1960s progressed, the British film, like the Italian cinema, lost its feeling of grimy, working class, black-and-white poverty and began producing colour studies of historical eras and existential rebellions of self-expression that were almost indistinguishable in style from films from the United States (*If . . .*, 1968; *Oliver!*, 1968; *The Lion in Winter*, 1968; *Nicholas and Alexandra*, 1971).

Eastern Europe. Exciting films and film makers also emerged in the postwar era in the eastern European countries of Poland, Czechoslovakia, Hungary, and Yugoslavia. In the 1960s the Pole Roman Polanski and the Czechs Jan Kadar and Milôs Forman all demonstrated personal commitment and artistic control within a small but healthy national tradition, just as DeSica and Rossellini had done in postwar Italy. Because of political and artistic suppression in Communist eastern Europe, most of these film makers migrated to Hollywood, where they shifted from national, personal, and social themes and modest styles to international casts, Existential questions, and tricky cinematic styles.

Japan. The international film festivals led to the Western discovery of the films of Japan, particularly of Kurosawa Akira. The thriving Japanese film industry, which by 1953 produced more feature films yearly than Hollywood, also demonstrated the artistic maturity and sensitivity of its product in the 1950s. Kurosawa's films were of two types: historical epics of the golden age of Japanese warriors called samurai (*Rashomon*, 1950; *Seven Samurai*, 1954; *Yojimbo*, 1961) and stories of contemporary Japan (*Drunken Angel*, 1948; *Ikiru*, 1952). Kurosawa's stories of old Japan are modelled on John Ford's and Howard Hawks's studies of the old West; Kurosawa uses western motifs, plot twists, a reliance on scenery and the outdoors, and even the western's means of building suspense and tension. Behind the violent action of these films and the heroic self-assertion of their central characters, however, Kurosawa has posed serious and significant

Influence of U.S. westerns on Kurosawa

Rashomon (1950), directed by Kurosawa Akira.

human questions. *Rashomon* remains one of the most powerful film treatments of the 20th-century idea that truth is in the eye of the beholder and that no single objective, factual explanation for a human event can ever be found. Ironically, after Kurosawa copied the U.S. western, U.S. westerns copied Kurosawa, turning both *Seven Samurai* and *Rashomon* into cowboy films (*The Magnificent Seven*, 1960; *The Outrage*, 1964).

Among the many other Japanese films that have been acclaimed in the West are Mizoguchi Kenji's *Ugetsu* (1953); Kinugasa Teinosuke's *Gate of Hell* (1954), Japan's first film to use colour; and Teshigahara Hiroshi's *Woman of the Dunes* (1964), which used the subjective, impressionistic camera with great beauty and success. Because film production was so inexpensive in Japan, the U.S. also imported many cheap, commercial films in which various prehistoric reptiles (*e.g.*, Godzilla, Rodan) reawoke to devour plastic models of Japan's major cities.

India. Although the Indian motion-picture industry is as productive as Japan's, very few of its films have been seen in the West. Most Indian movies have been produced for the subcontinent's populous domestic audience and therefore use local themes, settings, music, and actors. Satyajit Ray's "Apu" trilogy (*Pather Panchali*, 1954; *Aparajito*, 1956; and *The World of Apu*, 1959), the story of a boy's growing up and becoming part of Indian society, has been India's most impressive export. Striking glimpses of the Indian settings, actors, and culture can also be seen in Jean Renoir's *River* and in the films of James Ivory (*e.g.*, *Shakespeare Wallah*, 1965), an American who directs in India. The growing popularity of Indian culture, art, music, and thought in the West since the 1960s may eventually lead to more international distribution of that country's films.

V. Recent trends

Internationalism a major trend

If nationalism was the major trend of the first two decades following World War II, internationalism would seem to be the trend after 1965. Not only does international distribution play a major role in the film industry of every country, but the international production (for example, an Italian director using British, Italian, French, and Swedish actors to film a German story) has levelled national and cultural boundaries. Perhaps this cinema internationalism was foreshadowed by the 45-year career of the wandering film director Luis Buñuel—a man without a cinematic country. He has made films in France (*Un Chien Andalou*, 1928; *L'Age D'or*, 1930; *Belle de jour*, 1966), in Spain (*Las Hurdes*, 1932; *Viridiana*, 1961), and in Mexico (*Los Olvidados*, 1950; *The Exterminating Angel*, 1962). The unity of this lengthy career stems neither from nation nor from a consistent cinematic style (Buñuel travels between total Surrealism and total social realism) but from the energy of the director's brutal, savage attack on social proprieties, on the Christian–Humanist interpretation of the needs of man, and on the pretentious falsity of any philosophical system that refuses to recognize the animal, bestial centre of human motivation.

The vitality, creativity, and commercial strength of film activity outside the United States eventually made their impact on the U.S. film industry. In the early 1960s, the attrition of both the art and the industry ended when Hollywood redefined its audience, its function, and, hence, its product. Since the motion picture was no longer the primary source of mass entertainment, it no longer needed to cater to the general tastes of the public—rich and poor, old and young, urban and rural. The industry addressed itself to the minority who were willing to see something they could not see on television. The new motion-picture audience was predominantly young (under 30), urban (or suburban), educated, and affluent enough to afford a high-priced ticket. Films could cater to even smaller minority audiences, such as urban blacks, devotees of rock music, homosexuals, "skin flick" addicts, and those interested in the documentary. Still other films were specifically designed for the whole family—a special attraction for a family outing. No longer did every family spend its weekly movie night at the "Bijou" (a U.S. colloquialism for old movie palaces often so named). There was no more Bijou, but, in its place, there arose smaller "art cinemas." A few anachronisms also remained, such as the Radio City Music Hall, New York City.

Influence of the elite audience

The catering to an essentially elite audience determined the content and styles of the films. The industry's uniform restrictions against sexuality, perversion, brutality, and unpleasantness disappeared. The Hollywood Code completely crumbled in 1966, to be replaced by a more flexible system of rating films according to their "level of maturity." In the new films, poetic justice did not always triumph; life did not always appear to be just and good; and virtue did not always defeat injustice. In fact, the new cinematic convention seemed to be the reversal of good and evil and the horrifying triumph of injustice. The members of the new elite audience were skeptical about social institutions and social justice and cynical about the idealistic beatitudes they heard in the mouths of politicians and saw in the movies of a previous generation.

The new hero was iconoclastic, rebellious, unsatisfied; he valued sincere emotional and sexual experience over moral platitudes and sanctimonious hypocrisies.

Along with their rebellious themes and characters, U.S. motion pictures adopted the rebellious, innovative styles of the European cinema. Films were no longer rational, linear stories but kinetic, emotional almost metaphoric experiences. Directors played as freely with space, time, and logical continuity as had the most fluid silent films. Tricks with the camera, the sound track, and editing techniques became the obligatory conventions of the new films: flashes forward and backward in time, kinetic uses of colour, split-screen effects, intrusive zooms, discordant and startling cutting, asynchronous sound effects, musical interludes that were metaphorically related to the feeling of the film but not its story. Many of the visual tricks of the U.S. underground films had been incorporated in the new commercial films. The most influential and impressive U.S. films of the 1960s inevitably combined an iconoclastic social statement with innovative cinematic devices. Such films included Stanley Kubrick's *Dr. Strangelove* (1964), *2001: A Space Odyssey* (1968), and *A Clockwork Orange* (1971); Robert Rossen's *Hustler* (1961); Sidney Lumet's *Pawnbroker* (1965); Arthur Penn's *Bonnie and Clyde* (1967); Sam Peckinpah's *Wild Bunch* (1969) and *Straw Dogs* (1971); Peter Yates's *Bullitt* (1968); George Roy Hill's *Butch Cassidy and the Sundance Kid* (1969); Peter Fonda–Dennis Hopper's *Easy Rider* (1969); Bob Rafelson's *Five Easy Pieces* (1970); John G. Avildsen's *Joe* (1970); Peter Bogdanovich's *Last Picture Show* (1971).

Commercial and artistic revolution

By 1970 the U.S. film industry and the industries of the rest of the world (they had become almost inextricable) had accomplished an immense commercial and artistic revolution. Hollywood was no longer the centre of the U.S. industry; more U.S. films were shot in New York, in Mexico, in Europe, and in various other locations than in the former film capital (indeed, the motion-picture industry in Hollywood became almost exclusively devoted to television production). Quantity film production had been transformed into a more individualized, personal, independent concern with quality. No longer considered the star's vehicle but the director's, audiences, critics, and even directors themselves had become conscious, indeed self-conscious, of the motion picture as an art form rather than as an entertainment medium. The art and history of the motion picture, therefore, had become subjects for serious study, and the film as a medium was accorded an equal cultural position with the older, traditional arts of the novel, drama, poetry, painting, and music. It is from such premises that the past history of the motion picture will evolve into its future. (Ge.M.)

(1960), two influential histories now dimmed by age and lack of critical perspective; PIERRE LEPROHON, *Histoire du cinéma*, 2 vol. (1961–63), useful reference work of names, dates, titles, and events; GERALD MAST, *A Short History of the Movies* (1971), a history of significant films and film makers presented in the context of the entertainment industry; RICHARD SCHICKEL, *Movies: The History of an Art and an Institution* (1964), a lively study of the entertainment industry.

Historical studies of specific periods: C.W. CERAM (pseudonym of K.W. MAREK), *Eine Archäologie des Kinos* (1965; Eng. trans., *Archaeology of the Cinema*, 1965), authoritative, well-illustrated study of cinema prehistory; PENELOPE HOUSTON, *The Contemporary Cinema* (1963), a survey of international trends after World War II; RICHARD DYER MacCANN, *Hollywood in Transition* (1962), personal observation of Hollywood's collapse in the 1950s; TERRY RAMSAYE, *A Million and One Nights* (1926, reprinted 1964), classic study of the cinema's infancy, with emphasis on American film between 1890 and 1915; GEORGES SADOUL, *Histoire générale du cinéma*, 6 vol. (1946–54), a mammoth, detailed study of the epoch of silent film.

Historical and critical studies of national film movements: JOSEPH L. ANDERSON and DONALD RICHIE, *The Japanese Film: Art and Industry* (1959), authoritative study of Japan's cinema history, directors, and major films; ROY ARMES, *French Cinema Since 1946*, 2nd ed., 2 vol. (1970), a survey of both the classical tradition and New Wave; ERIK BARNOUW and S. KRISHNASWAMY, *Indian Film* (1963), an authoritative study of India's industry, film art, and the relationship of film and society; KEVIN BROWNLOW, *The Parade's Gone By* (1968), nostalgic, well-illustrated study of American silent films and film stars; PETER COWIE, *Swedish Cinema* (1966), a survey from silents to Bergman; BOSLEY CROWTHER, *The Lion's Share* (1957), on the rise and fall of M-G-M; LOTTE H. EISNER, *L'Écran démoniaque*, rev. ed. (1965; Eng. trans., *The Haunted Screen: Expressionism in the German Cinema and the Influence of Max Reinhardt*, 1969), a study of the influence of the arts of painting, drama, and the novel on German cinema; DAVID STEWARD HULL, *Film in the Third Reich: A Study of the German Cinema, 1933–1945* (1969), Hitler's and Goebbel's use of the film as propaganda; LEWIS JACOBS, *The Rise of the American Film* (1939, reprinted 1968), a detailed study of American films through 1938, with emphasis on film trends and audience tastes rather than on individual works of art; SIEGFRIED KRACAUER, *From Caligari to Hitler: A Psychological History of the German Film* (1947, reprinted 1966), a psychological, sociological, and political study of German cinema, arguing that films unconsciously prepared the way for Hitler's accession; JAY LEYDA, *Kino: A History of the Russian and Soviet Film* (1960), an authoritative study from tsarist beginnings to 1958; RACHAEL LOW and ROGER MANVELL, *The History of the British Film*, 3 vol. (1948–51), a detailed study of the British silent film; GEORGES SADOUL, *French Film* (1953), a concise survey; ANDREW SARRIS, *The American Cinema: Directors and Directions, 1929–1968* (1968), classic definition of the "*auteur* theory" and its critical application to American films and film makers; PARKER TYLER, *Magic and Myth of the Movies* (1947, reprinted 1970), studio films seen as myth and dream, with a psychological analysis of the relationship of audiences to films of the 1930s; EDWARD WAGENKNECHT, *The Movies in the Age of Innocence* (1962), nostalgic reminiscences of silent films and stars.

Genre studies: RICHARD MERAN BARSAM, *Nonfiction Film: A Critical History* (1972), analysis of the art, themes, and values of primarily British and American documentary films; RAYMOND DURGNAT, *The Crazy Mirror* (1970), a sociological study of American comedy, reflecting audience values and tastes; JIM KITSES, *Horizon's West* (1970), Anthony Mann, Budd Boetticher, and Sam Peckinpah as representatives of the western; KALTON C. LAHUE, *Continued Next Week: A History of the Moving Picture Serial* (1964) and *The World of Laughter: The Motion Picture Comedy Short, 1910–1930* (1966), two surveys of significant stars, dates, producers, and titles; GERALD MAST, *The Comic Mind: Comedy and the Movies* (1973), thematic study of sound and silent comedies and the relationship between intellectual content and comic form; SHELDON RENAN, *An Introduction to the American Underground Film* (1967), a survey of significant films and film makers; PAUL ROTHA, with SINCLAIR ROAD and RICHARD GRIFFITH, *Documentary Film*, 3rd ed. rev. (1963), a classic study of the genre, written by one of its most influential practitioners, now somewhat dated and rigid, however.

(Ge.M.)

Motion Pictures, Technology of

The technology of motion pictures, based on the prior invention of still photography, developed rapidly after 1900 to meet the expanding needs of professional and amateur moviemakers. The technology, a complex one, consists, in fact, of several more or less independent technologies; that is, camera and projector design, film manufacture and processing, sound recording and reproduction, and lighting and light measurement.

This article is divided into the following sections:

I. History
- Early history
- Introduction of sound
- Introduction of colour
- Wide-screen and stereoscopic pictures
- Amateur motion pictures

II. Professional motion-picture photography
- Cameras
- Film
- Lighting
- Film processing and printing
- Sound-recording techniques
- Special effects
- Projection techniques and equipment
- Animation
- Motion-picture films in television

III. Motion pictures for scientific purposes
- Time-lapse cinematography
- High-speed cinematography

IV. Amateur motion-picture photography

Other articles in which specialized aspects of the subject are treated include SOUND RECORDING AND REPRODUCING; PHOTOGRAPHY, TECHNOLOGY OF; and OPTICAL ENGINEERING. Motion pictures as an art form are treated in MOTION PICTURES, ART OF; MOTION PICTURES, HISTORY OF.

I. History

EARLY HISTORY

The conditions necessary for generating the illusion of motion in a picture were set forth with remarkable clarity in a French patent of April 25, 1864, granted to Louis Ducos du Hauron.

> My invention consists in substituting rapidly and without confusion to the eye, not only of an individual but when so desired a whole assemblage, the enlarged images of a great number of pictures when taken instantaneously and successively at very short intervals. . . . The observer will believe that he sees only one image, which changes gradually by reason of the successive changes of form and position of the objects which occur from one picture to the other. Even supposing that there be a slight interval of time during which the same object was not shown, the persistence of the luminous impression upon the eye will fill this gap. There will be as it were a living representation of nature and the same scene will be reproduced upon the screen with the same degree of animation. . . . By means of my apparatus I am enabled especially to reproduce the passing of a procession, a review of military manoeuvers, the movements of a battle, a public fête, a theatrical scene, the evolution or the dances of one or of several persons, the changing expression of countenance, or, if one desires, the grimaces of a human face; a marine view, the motion of waves, the passage of clouds in a stormy sky, particularly in a mountainous country, the eruption of a volcano . . . . (From Terry Ramsaye, *A Million and One Nights*; © by Simon and Schuster, Inc., 1926.)

Persistence of the impression

Earlier devices, such as the Daedalum (later called Zoetrope—"wheel of life"—shown in Figure 1) had shown the possibilities of the principles set forth in the patent of Ducos du Hauron.

In carrying out these principles it is necessary to have the picture to view. At first, such pictures were drawn or painted by hand. In 1872 Gov. Leland Stanford of California, who was interested in the gait of racing horses, engaged Eadweard Muybridge, an English photographer, to take action photographs of a running horse. After many tries Muybridge was able to get successive pictures of a horse as it ran beside a wall. He used a battery of cameras facing the wall, and a picture was made as the horse went by each camera in turn. This was the first time that motion was recorded photographically.

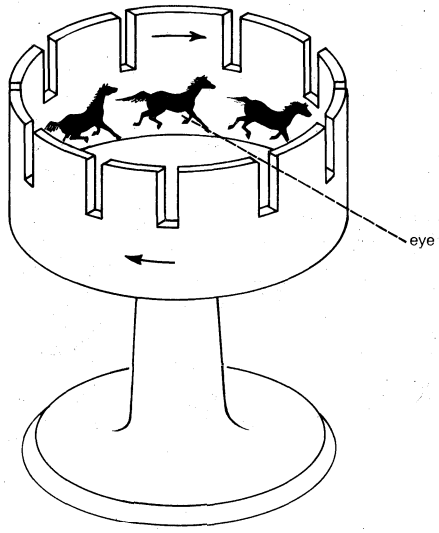

Figure 1: Zoetrope.

But, as long as photographs were made on glass plates, the pictures remained too bulky and fragile for even elementary cinematography. A few years later Émile Reynaud demonstrated a wide band of celluloid film, hand drawn and coloured, in his Théâtre Optique in Paris; and Thomas Edison, working with film made by George Eastman of much the same size as the present-day 35-mm standard width (see Figure 6), exhibited the Kinetoscope (Figure 2), an elaboration of the Zoetrope. The

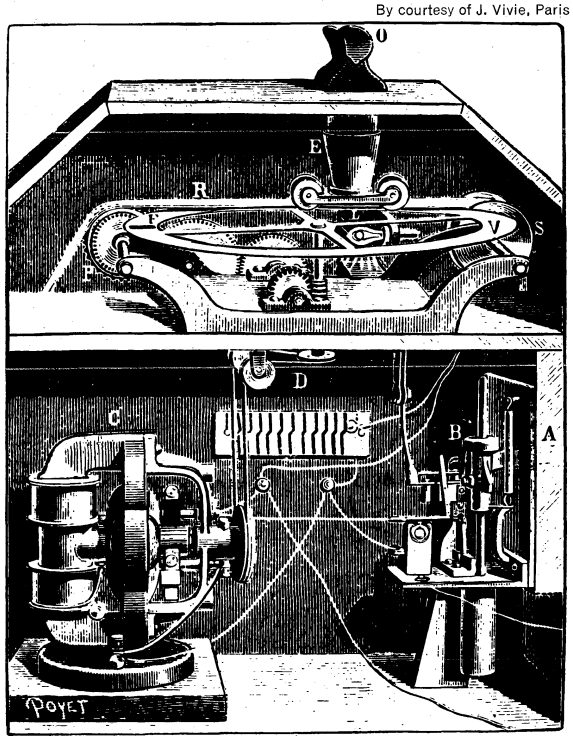

Figure 2: Edison's Kinetoscope, a device permitting one viewer to watch an illuminated strip of moving film one frame at a time through a narrow slit in a fast-moving shutter wheel. (A,B) Switching gear, (E) lens, (O) peephole, (R) film in continuous motion, (V) shutter wheel with slit (F). Engraving by Poyet.

pictures have been recorded on an extended film strip, R, which moves continuously in front of a light, L. They are viewed from a peephole, O, and lens, E, through a fast-moving shutter wheel, V, that has a narrow slit, F. This gives a short momentary view of each picture in turn. In the device, 46 separate pictures were viewed per second.

The pictures themselves were taken in a camera (the kinetograph) on a film that was drawn past an aperture.

Intermittent motion

The arrangement permitted the film to be exposed while it was stationary; it was then covered with a shutter while it was moved, and the sequence was repeated for another exposure. Several devices for obtaining the intermittent motion were used. At first the film at either end of the mechanism was stowed loosely inside the lighttight camera box. This became inconvenient as longer films began to be used, and the intermittent jerk was isolated to a relatively short loop between two continuously moving sprockets. Outside the sprockets the film moved uniformly and in time was wound neatly on reels.

At first most of the film exposed by Edison was photographed in a barnlike studio covered with black tar paper and called the Black Maria. It had large, movable pane windows at one end to let in appropriate natural light. The structure was mounted on a circular railroad track so that it could be turned with respect to the prevailing light. A sketch of the interior that appeared in 1894 showed a phonograph electrically connected with the camera, suggesting the possibility of a recording of sound pictures. Many years of arduous development and experience were needed, however, before acceptable sound pictures could be achieved.

The Edison camera and peephole Kinetoscope endured for a surprising time, remaining a feature of peepshow arcades as late as 1909. The device's great weakness was that it was wasteful of light, since the continuously moving film was cut off from the light for such a large fraction of the time. The small amount of light available made it impossible to project the picture onto a screen. One cause of the delay in the introduction of projectors was that the earlier so-called intermittents were very noisy, a situation that was intolerable in an auditorium.

In Paris in 1895, Auguste and Louis Lumière presented the *cinématographe*, in which the film was intermittently moved in both camera and projector. A special device incorporated a pin mechanism both to advance the film and to hold it in a firm position when stationary. Many designs for such devices were presented, ranging from complex machinery to the much simpler claw mechanism of the type shown in Figure 3.

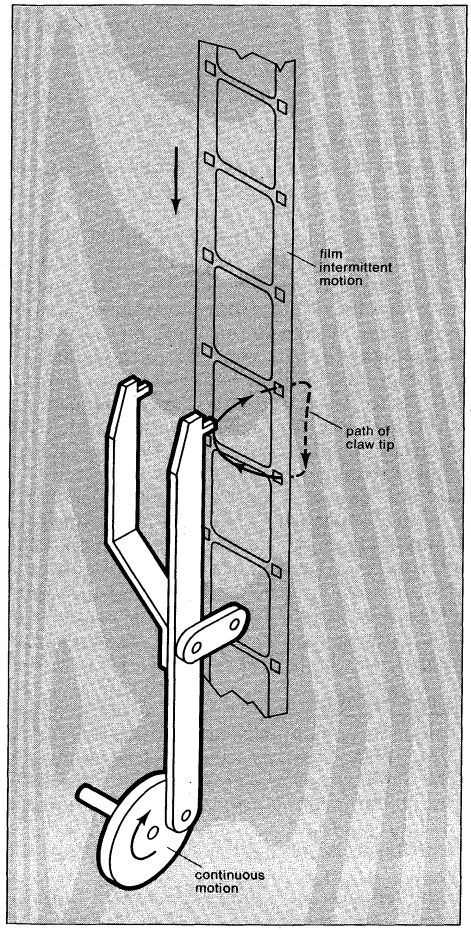

Figure 3: One type of the claw pull-down intermittent mechanism.

The intermittent was connected to a shutter. For projectors, the shutter was designed with two or three blades so that each picture frame was exposed two or three times and blanked out between these exposures for an interval equal to that required for the film motion from one frame to the next. This multiple exposure, with some light loss, reduced the flicker on the screen and made it possible to drop the frame rate from Edison's 46 to 15–18 frames per second. Since there was no flicker problem in the camera, the single-blade shutter was used there.

Growth of popular interest

Avid popular interest stimulated exploitation. The first naive titles, *The Baby's Meal, A Game of Cards, Street Dancers*, were followed by the more sophisticated *Cupid's Barometer, The Course of True Love*, and *Modern Brigandage*. News events appeared, such as *Moscow: The Crowning of Nicholas II; Stockholm: The King Arrives at the Exposition* (1896); *The Dreyfus Affair; London: The Crowning of Edward VII* (1902); and *Wall Street* (1896). Georges Méliès, in France, produced fantasy stories of the Jules Verne type, such as *The Voyage to the Moon* (1902); *Gulliver's Travels* (1902); *The Arabian Nights Palace* (1905); and *The Conquest of the Pole* (1912). Other narrative films included E.S. Porter's *Life of an American Fireman* (1903), and the very famous *Great Train Robbery* (1903).

When the art of projection was established, the importance of a bright screen picture was appreciated. Projectors used an arc lamp, at the time the brightest known light source. The machines ushered in the era of the nickelodeon (from Odeon, a theatre of ancient Athens and, much later, modern Paris, and the U.S. nickel, or five cents). Admission soon rose to $1.50 for *Quo Vadis* in 1913, as the auditorium grew from a vacant shop to a new theatre built for motion pictures.

INTRODUCTION OF SOUND

The popularity of the motion picture inspired many inventors to seek a method of reproducing accompanying sound. Two processes were involved: recording and reproducing. Further, the sound reproduction had to be presented in an auditorium and had to be quite good. This could not be achieved without a good amplifier of electrical signals. The invention of the Audion (triode electron tube) by the United States inventor Lee De Forest in 1907 made such an amplifier feasible and made possible an undistorted sound of sufficient loudness.

Next came the problem of synchronization of the sound with the picture. A major difficulty turned out to be the securing of constant speed in both the recorder and reproducer. Many ingenious ideas were tried. In 1918 in Germany, the use of a modulated glow lamp in photographically recording sound and a photocell for reproduction were studied. In Denmark in 1923, an oscillograph light modulator and selenium-cell reproducer were developed. De Forest tried a gas-filled glow discharge operated by a telephone transmitter to record a synchronized sound track on the film. For loudspeakers he experimented with a variety of devices but finally chose the speaker with horn. The operating signal was obtained from a light shining through the film soundtrack and detected by a light-sensitive device (photocell). These were used in a system called Phonofilm, which was tried experimentally in a number of theatres. In 1927 the Fox Film Corporation utilized some of these principles in the showing of Fox Movietone News.

Meanwhile, the Western Electric Company laboratories in the United States had been making extensive studies on the nature of speech and other sounds and on techniques for recording and reproducing such sounds. They experimented with recording on a phonograph disk and developed a 16-inch disk rotated at 33⅓ revolutions per minute; they improved loudspeakers, introduced the moving-coil type of speaker, and generally improved the entire electronic amplification system. The Warner Brothers movie studio became interested in all these de-

velopments and formed the Vitaphone Corporation to market the complete system. The first picture released was *Don Juan* (with music but no speech), in August 1926, followed by *The Jazz Singer*, featuring Al Jolson, with speech, in the fall of 1927. These two films introduced the era of sound pictures.

The first sound pictures

Further improvements were made in the disk system, but with time it became clear that recording on the film itself would be much more convenient. A serious problem was the distortion of the signal introduced by the glow lamp when recording the sound track on film. The Western Electric Manufacturing Company devised a mechanical light valve, in which the output from the amplifier causes a double-ribbon valve system to open and close by magnetic means. The light valve is arranged to modulate the light beam coming from a fixed lamp; the beam is projected optically onto the edge of the film to record the sound track. In 1930 the film recording supplanted the disk in the Warner Brothers Vitaphone system, and all other motion-picture makers adopted it.

There are two possibilities in the way the track can be recorded. The valve ribbons can be aligned either horizontally or vertically. In the first case, the optical track on the film will appear to be of varying density according to the modulation. In the second case, the densities will always be the same (black-and-white), but the track will vary in width. The two arrangements each have their advantages and disadvantages, and both have been used successfully.

INTRODUCTION OF COLOUR

The use of colour in photography and motion pictures is based on the fact that any arbitrarily selected colour can be produced by a mixture of red, green, and blue. In 1869 Ducos du Hauron outlined the principles of the two basic methods of colour photography, the "additive" and the "subtractive" methods. White light is composed of all the spectral colours, in equal intensities. It can also be composed of the red, green, and blue components, also in equal intensities. Light other than white can be composed of various proportions of these primary colours; for example, cyan can be composed of blue and green. In an additive system the colours are formed by the addition of specific amounts of light of the three primary colours. In practice, three pictures are taken behind a red, green, and blue filter, respectively; these are made into black-and-white slides, and each is projected by a separate projector through the appropriate filter, thus producing three images superimposed on a screen. Each spot on the picture is made up of added components of the red, green, and blue light in the proper proportion to give the colour of the original scene.

In a subtractive system the undesired components are subtracted from white to obtain the desired colour. By subtracting, say, the red from white light, the residual colour of cyan is obtained. By subtracting both red and green, the remainder of the spectrum, or blue, results. Subtracting all three colours yields black. In practice, the red-positive slide is converted into a "minus red" dye slide, so that the dark areas take away all red colour (and are cyan). Similarly, the green slide turns into a "minus green" slide, and the blue into a "minus blue" slide. The three slides are bound together into one so that each slide in turn subtracts its share from what has come through the preceding ones. When the composite slide is projected, it reproduces the colour view of the original scene. This is essentially what a colourist does in painting a slide by hand with transparent colours; transparent blue paint, for example, is simply a pigment that absorbs the red and green of the spectrum and lets the blue through.

Both systems have been used in colour motion pictures. Projection is simpler for the subtractive system because of the need for only one projector. Modifications in the additive system, however, can be used. The three projections can be made in quick succession, with a rotating set of colour filters. For motion pictures, this requires three times the picture speed for the one projector; or the picture space may be subdivided into many very small areas, so small that they will not be distinguishable on the projection screen, with very small filters of three classes in front of them when making an exposure. The emulsion is then processed, and, keeping the right filters in front of the small picture elements, the complete picture is projected. The essential difficulty here is that the slide will be dark because each colour will use only one-third of the slide area.

In 1906 Charles Urban and G. Albert Smith in the United States initiated an additive system of colour cinematography, which they called Kinemacolor. It used the system of successive colour projections, but to avoid extreme frame speeds it used only a two-colour process, namely orange red and blue green. The frames were exposed at 32 per second (giving 16 complete pictures per second) behind rotating colour filters. The film was processed in black and white and projected through rotating colour filters. Because of the two-colour process, the colour rendering was only fair. Also, because the two colours were exposed in succession, they did not cover exactly the same image. Thus, a white horse's legs in motion appeared successively orange red and then blue green. The system had some vogue; its outstanding film was *The Durbar of Delhi* in 1911 in London.

Around 1910 Louis Dufay made an additive-colour film that used fine-ruled areas on the film for the three colour elements; it was not put on the market until 1930. Eastman Kodak in 1928 produced Kodacolor 16-mm motion-picture film. This was also an additive process and used film with lenticular embossing that separated the rays of light according to where on the objective lens the rays came through. Thus, by putting three filters at the objective, the light on the emulsion was effectively separated into three small colour areas. After processing the emulsion in black and white, the film was used in a similar optical system for the projector. Both this and the Dufay process involved some loss of resolution and light-transmission capability. The Kodak film enjoyed a certain degree of commercial success, the name Kodacolor was later applied to an entirely different process.

After early starts with two-colour systems, a three-colour subtractive process (Technicolor) was introduced in 1932. This used a beam-splitting optical cube, in combination with the camera-objective lens to expose three black-and-white films. The three films individually registered the red, green, and blue tones of the scene being photographed. After processing, three film surfaces (red, green, and blue) were formed with gelatin layers that would retain more or less dye. After the surfaces were dyed, the films were contact printed on the final film base, the dyed images being superimposed to form the colour picture. Early famous pictures made by the Technicolor process were *Becky Sharp* in 1935 and *Gone with the Wind* in 1939. This system enjoyed a wide and durable commercial success.

WIDE-SCREEN AND STEREOSCOPIC PICTURES

Many people have felt that, while vision at the extreme sides of the vision field does not usually contribute much information to the eyes, it does add substantially to the illusion of reality when it is present. In 1929 Grandeur films were presented using 70-mm instead of the standard 35-mm film to give a wider field of view. Other film producers also experimented with wide films that showed a distinct improvement in realism, but they were introduced during a period of rapid development in sound pictures and did not last commercially.

In 1952 a radical attack was made on wide-field projection in the form of the Cinerama, using three projectors giving a field of view of some 70° or 80° (versus a more usual 40° or so) for most of the audience. An outline of the auditorium arrangement used is shown in Figure 4. This gave a remarkable increase in the illusion of reality, especially with such exciting and spectacular subjects as a ride down a toboggan slide. There were technical problems, including the necessity of carrying three cameras bolted together at the correct angles on the toboggan or other carrier, synchronization of the three separate films, and matching of the image structure and brightness at the joining edges on the screen. In spite

Heightening the illusion of reality

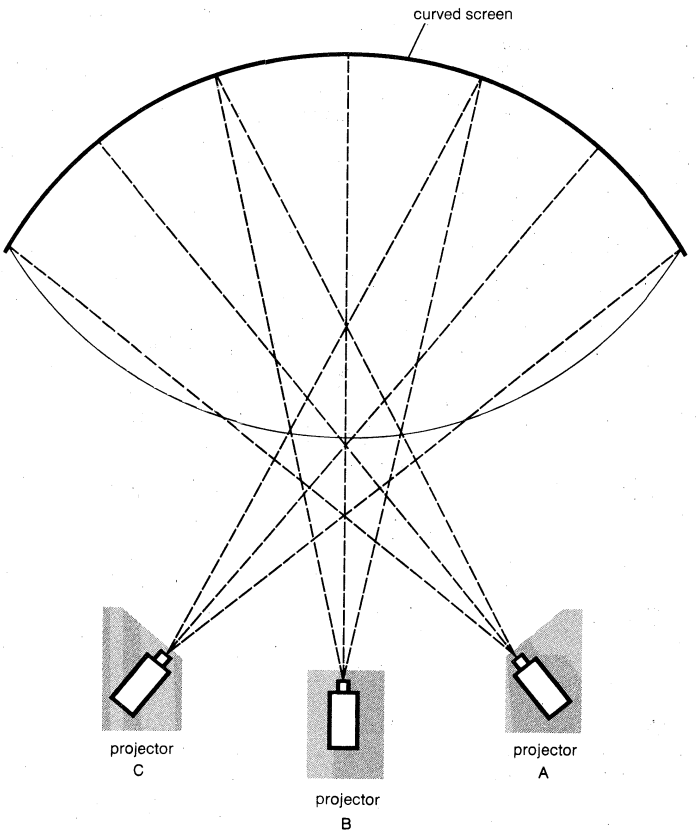

Figure 4: Cinerama auditorium.

of these problems and in spite of the difficulty of continually finding suitable subject matter, the presentations enjoyed a great vogue. A fourth film carried entirely separate sound tracks, which were connected to loudspeakers distributed throughout the auditorium.

A full circle of vision was presented by Walt Disney in a 360° projection at the Disneyland amusement park in 1955. At first, the projection involved 11 16-mm projectors and screens and, later, nine 35-mm projectors. The audience stood on a low platform in the middle. The result was extremely realistic. In one scene, showing the view from a cable car in San Francisco, the viewers were seen involuntarily to lean over on the curves, as if they were actually on the cable car. Such views, however, are not particularly adapted to general storytelling.

A less spectacular form of wide-screen system, introduced by CinemaScope in 1953, employed a special optical system to give a different magnification horizontally from that given vertically, thus changing the proportions of the picture on the 35-mm film to a relatively much wider one on the screen. This requires that the original picture be taken with a similar lens, used in reverse, to compress the picture on the 35-mm film. Such lenses are known as anamorphic optics.

In 1955 Todd-AO introduced a wider film (65-mm for the camera and projected on 70-mm film), with several sound tracks added (see Figure 6). It also used five sprocket holes per frame instead of the previous four. The wider film permitted projecting the picture on a wide screen with a single projector instead of the three used by Cinerama. In recent times wide-screen systems have tended to use a single wide film because of the complexities of the multiple films and screens of the Cinerama and similar systems.

Stereoscopic cinematography

Another project that has been introduced to improve the illusion of reality in motion pictures has been the development of stereoscopic, or three-dimensional, cinematography. Very simply, this consists in projecting (via the screen) to each eye of the viewer the different picture (that is, comparing one eye with the other) that it sees in normal vision.

One stereoscopic system uses two films, exposed side by side in a camera. The optical system is somewhat like that of a prism binocular and permits adjustment of the interocular (between-lenses) separation, to correct for differences in perspective as the scene is taken in close-up and somewhat longer shots, to make the final viewing seem natural. The system uses polarized light; that is, light that is vibrating in one specific plane. One projection lantern has a filter that polarizes its beam in one direction, and the other polarizes its beam at right angles to this. The projectors are adjusted so that the two images superimpose exactly on the screen. The observer in this system has to wear special viewing glasses that polarize light in the same relative directions as do the filters on the projectors. Thus, the left eye sees only the projection from the left lantern, and the right eye views only the right projection; together the two eyes see the projected image in the same way as they would have seen the original subject.

This process can give very realistic projections and has had some commercial success. A drawback is the need for the special glasses. Other systems have been devised to avoid this, but they are more complicated, have delicate adjustments, and are generally more expensive. Another problem is that only relatively few subjects presented in motion pictures gain substantially from the special depth perception given by the stereoscopic effect.

AMATEUR MOTION PICTURES

The public acceptance of motion pictures became so great in the 1920s that impetus arose to adapt the art to amateur use. One step was to devise means of reducing the film cost. A reduction in the size of the film was one approach. Various sizes, ranging in width from 28-mm to 9.5-mm, were explored in both the United States and Europe. Another approach was to study the overall process that required making and processing both the original negative and a positive print.

Reversal processing

This last gave rise to an exploration of reversal processing to obtain a positive rather than a negative from the original film. There are a number of processes that

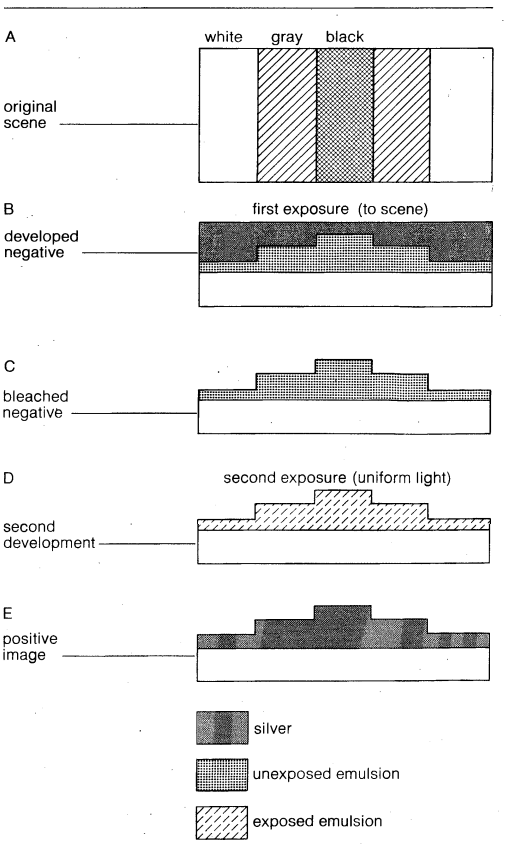

Figure 5: Principles of reversal processing of black-and-white film (see text).

can be used, but the one that has become almost universal is that developed in 1923 and outlined in Figure 5. An original scene (A) is represented by bars of various tones. It is developed as a negative, at B, in the usual fashion. Then the developed silver image is bleached away, leaving the unexposed silver halide, as at C. This is given a second and uniform exposure at D, which develops as a positive silver image at E. The first point that was noted in using this process was that it seriously reduced the latitude in exposure; *i.e.*, the exposure had to be correct for the particular lighting condition. This was especially unfortunate for inexperienced photographers. After some experimentation it was found that an appropriate adjustment of the second exposure improved the latitude. It was further found that this could be regulated automatically by exploring the image at D with infrared light, to which the emulsion was not sensitive. The total infrared light transmitted was detected by an infrared photocell. The more infrared that came through, the more light the second exposure was given. The reversal process not only saves the cost of an extra positive but also gives less graininess than when the positive is printed separately.

Amateur motion-picture photography soon became very popular, and other firms introduced their products. In 1923 Bell and Howell in the United States brought out equipment to use 16-mm film. In the same year Pathé introduced a 9.5-mm film camera that, along with the corresponding projector, became very popular in France. The 16-mm reversal film was introduced subsequently by a number of other manufacturers.

The Kodacolor film mentioned earlier was an improvement introduced in 16-mm amateur film in 1930. The later Kodachrome colour film was also introduced in 16-mm amateur film.

In 1929 a sound track was proposed for 16-mm film by omitting the perforations on one side, and a projector for it introduced on the market by Radio Corporation of America (RCA) in 1930. Narrower film was explored, and 8-mm film with cameras and projectors for it were put on the market by Eastman Kodak in 1932.

II. Professional motion-picture photography

CAMERAS

Principles of operation. The principles of operation of modern professional motion-picture cameras are much the same as those of earlier times, although the mechanisms have been refined. A film is exposed behind a lens and is moved intermittently, with a shutter to stop the light while the film is moving. In the process, the film is unrolled from a supply reel, through the intermittent to the gate where the exposure takes place, and then on to the take-up reel. Optionally, the film, after exposure, is passed through a sound-recording mechanism between the intermittent and the take-up reel. Currently, however, it has often been found more practical to record the sound on an entirely separate film or tape that is kept synchronized in some fashion with the picture film. The sound-recording stage is omitted in such cases.

Principal parts. *Body.* The principal difference between current cameras and the earlier ones is in the matter of sturdiness and rigidity. It was found that in order to maintain a high quality of picture it was necessary to eliminate vibration, so that the picture would remain sharp and also the film would not move about in the film frame. In some designs, the film chambers are separate from and attached to the camera body; in others, they are integral with the body.

Lens. Lenses have gone through a continuous evolution in the last half century, for both still and motion-picture photography (see OPTICAL ENGINEERING). The two major objectives have been to focus properly all the colours of the image at the film plane (*i.e.*, to make the lens achromatic) and to focus portions of a beam coming from different portions of the lens, the centre or the edges, at the same point on the film (*i.e.*, anastigmatic). Both objectives require solution for as large a lens opening as possible, in order to capture maximum light for the exposure, and for as wide a field of view as will be needed in the use of the lens. In order to solve these problems, lenses have been made with more and more components. Also, more types of glass have been discovered and developed, to give better achromatic performance. It was found, about 1939, that a special coating of the glass-to-air surface of a lens component could greatly diminish reflections from this surface without affecting other properties of the lens. The use of such coatings improved image contrast by reducing the stray rays that were produced by reflections in a multiple-component lens. Coatings also reduce loss of light by reflection in the desired rays. Coating developments have permitted making lenses with many more components than had previously been possible.

Achromatic and anastigmatic lenses

Long experience with both motion-picture and still cameras has shown the need for a variety of focal lengths (ranging from ultrawide angle to telephoto) to photograph scenes under the best conditions. To make changing focal lengths more convenient, the lenses have been mounted on a turret, so that one out of a set of three lenses may be quickly selected. For motion pictures this would mean an interruption in the action depicted. A continuous change would be more desirable.

When two lenses are used in a tandem combination, the focal length of the combination varies according to the separation between the two components. For example, when two thin converging lenses are mounted close together, the combined focal length is shorter than when they are separated a certain distance. Thus, the focal length of the combination can be continuously varied over a range merely by changing the separation.

This observation has led to the conception of camera lenses of variable focal length in which the variation is obtained by moving one or more elements. One simple design consists of two fixed convex (converging) lenses of unequal power with a movable concave (diverging) lens between them. When the central concave lens is located close to the front convex element, the combination focal length can be shorter (and the image therefore smaller) than when it is located close to the rear convex element. The design can be made such that, with the two convex elements remaining fixed, a distant view can remain almost in focus on the film as the middle element is moved. Exact focus for this arrangement, however, could not be attained. Thus, for lenses of this design, a cam device has in the past been provided to move the front convex element a short distance as the middle element is moved over its range, to keep the focus exact. This kind of lens has come to be called a zoom lens.

The zoom lens

By increasing the number of elements, the focus can be kept exact without the need of a correcting cam. Other improvements include increasing the range of focal lengths covered, increasing the effective lens aperture, increasing the angular field of view seen by the film, and improving the colour correction with radically new glass materials.

For a long time the change in focus was carried out manually. More recently, the use of an electric motor drive has allowed a smoother change, with less distraction to the cameraman.

The resolving power (in general, the ability to record fine detail) of the zoom lens has not in the past been equal to that obtainable from lenses of fixed focal length, and for this reason they were little used in professional feature motion pictures, being reserved rather for news and amateur pictures. The performance is improving, however, and some studio cameras now use zoom lenses.

Transport system. The general principles utilized in the film transport system have remained much the same over recent years, at least for the 35-mm film. The films are usually preloaded in lighttight reel cases, with an exposed loop between the supply and take-up reels. This loop is quickly fitted into the camera mechanism when loading.

The intermittent is usually a claw-type mechanism, somewhat more sophisticated, however, than that in Figure 3. Some cameras are equipped with pin-registering mechanisms, which hold the film firmly in place in the exposure gate, with the pins engaging sprocket holes.

In the early days of sound films, the noise made by the

intermittent and other moving parts in the camera was loud enough to interfere with the sound picked up by the microphone. Cameras were sheathed ("blimped") with outer, separate sound-absorbing materials. The sound insulation is now usually self-contained in the camera.

The film drive

Before the introduction of sound, the film and intermittent were driven by a large crank operated by the cameraman. With sound, considerably more uniformity in the speed of the film drive became necessary. For this and other reasons, the film drive in modern cameras is provided by an accurately controlled electric motor.

Shutter. This component keeps light from striking the film while it is moving from one frame to the next. A variable shutter opening can also be used to reduce exposure when it is necessary or desirable to do this without reducing the lens aperture. The shutter is rotary and is synchronized with the intermittent. In some cases (see below *Viewfinding and focussing*) the interval when the shutter is closed is used for viewfinding through the same lens that produces the image on the film. Here the shutter cuts the incoming light beam at an angle, and the front face of the blade has a mirror surface to deflect the light beam to one side toward the viewfinder.

Viewfinding and focussing. Viewfinding has always been a problem for both motion-picture and still cameras. If a separate viewfinder is attached to the camera, its line of sight to the scene is different from that of the taking lens, so that the picture seen is not exactly the same as the picture photographed. One solution to this problem consists of mounting the viewfinder in such a way that its angle can be adjusted so that the finder and the taking lens point at exactly the centre of the subject. Still another method is to use a partially reflecting mirror (beam splitter) in the path of the beam of light that is used to take the picture. This is objectionable because it takes away part of the light that would be used for the exposure, and, in addition, there is some possibility that the light beam containing the image to be photographed will be impaired.

Another possibility is to use a mirror to divert the taking light beam while the film is moving and the shutter is covering the film. This arrangement is not wholly free from objections. The arrangement opens a return path for light from the viewer's eyepiece to reach the film. The eyepiece must fit snugly around the eye while the viewfinder is in use, and the finder must be closed completely while it is not in use. In addition, since the camera shutter is closed only once per frame, the image will be subject to a distinct flicker, to which the cameraman must adjust himself.

Focussing has also been a perennial problem for the motion-picture camera. On the camera the position of the lens is precisely indicated on a calibrated scale. The actor's location on the set was formerly marked on the floor and the exact distance to the camera measured with a tape. The actor moved to previously marked places, and an assistant to the cameraman, called a focus puller, or follow-focus assistant, kept the lens in adjustment. Various electrical devices have now been introduced for remote adjustment by the assistant.

Distance measurement

Where a through-the-lens finder is used, focussing can be done directly, using the viewfinder image. Also, experienced cameramen can estimate distances quite closely.

Miscellaneous features. It is usual to generate some kind of signal in synchronism with the intermittent when an auxiliary, magnetic-tape sound recorder is used, so that the sound record can later be synchronized exactly with the picture. Where a separate film is used for the magnetic sound record, the sprocket holes are electronically locked with those in the picture film, maintaining the synchronization.

The camera is often supplied with electric motors to perform miscellaneous functions, such as to provide smooth rotation (panning) of the camera or to change the magnification in a zoom lens (or change lenses in a turret).

The camera is normally provided with footage indicators to indicate the amount of film left unexposed and frame counters where it is desired to superpose a second exposure. There can also be an "inching knob" to reposition the film to a given frame for multiple exposures. When the camera is used at a speed different from standard, a tachometer may be provided to indicate the actual speed.

The cameras that have so far been described are for the standard 35-mm film. Cameras for 65-mm film are generally quite similar, though heavier. The quality of 16-mm and 8-mm film has improved so much that a good deal of professional work is now done in these sizes. The 16-mm professional camera may differ from the 35-mm in the form of its case, in its use of a spring-operated film drive, and in its method of film loading, as a result of its development from a former amateur camera. On the other hand it may be a smaller version and have the same features as the 35-mm model by the same manufacturer.

Stereoscopic and Cinerama cameras. Three-dimensional cameras differ from standard cameras chiefly in being arranged to expose two films simultaneously side by side, using a twin optical system with prism arrangement.

CinemaScope cameras use a special 35-mm film with somewhat smaller sprocket holes and a lens or attachment that makes the reduction ratio from scene to film different in the horizontal dimension from what it is in the vertical dimension.

Camera supports. The camera must be mounted on a substantial support. In its simplest form this is a heavy tripod structure, with sturdy but smooth-moving adjustments and casters, so that the exact desired position can be quickly reached. Often a heavy dolly, holding both the

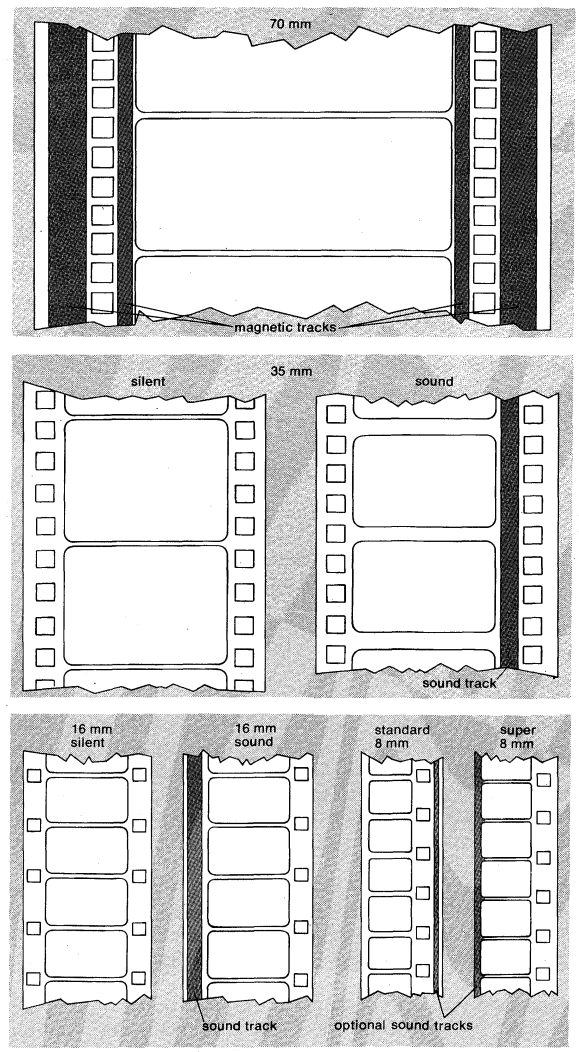

Figure 6: *Film formats.*
The sizes shown are approximate; the overall width of 70-mm film is 70 mm, etc.

camera and a seated cameraman, is used. This can be pushed or driven around the set. When shots from elevated positions are to be used, both camera and cameraman are carried on the end of a crane, also on a dolly. In some cases the assemblage is smoothly driven to follow the action being pictured, such as movement along a street.

FILM

Format and support. The more frequently encountered film formats are illustrated in Figure 6. The silent 35-mm film, however, is seldom used. There are some minor differences in the shape of the sprocket holes in 35-mm film between negative and positive film. The first 8-mm film was made by using 16-mm film, punched with twice as many sprocket holes of the same size and shape. One side, to the middle line, was exposed in one direction. The supply and take-up reels were then interchanged in the camera, and the other side was exposed in the other direction. After processing, the film was split into two strips, which were spliced into one. Experience with this format indicated that the sprocket-hole structure was unnecessarily sturdy, and a so-called Super-8 film was designed with the idea of reducing the sprocket-hole size and employing the space thus made available for a larger picture area. Both formats are in current use, but the Super-8 is becoming predominant.

Originally, the film base was some form of celluloid or cellulose nitrate. This material is highly inflammable, and extensive precautions were required in projection rooms to avoid film ignition because of the proximity of the projector arc lamp to the film.

In 1923, when 16-millimetre amateur film was introduced, cellulose acetate (or safety film), much less inflammable than the nitrate, was used. It was not considered desirable to adopt it for professional 35-millimetre film, largely because it was inferior in strength and dimensional stability. By the late 1930s an improved cellulose acetate safety film was introduced, and by the early 1950s it had generally replaced the nitrate film.

Black-and-white emulsions. The film base is coated with a light-sensitive layer of silver halide emulsion. Emulsion manufacture is quite complicated and delicate. The earlier emulsions were most sensitive to violet and blue light, as shown schematically in Figure 7, curve *a*.

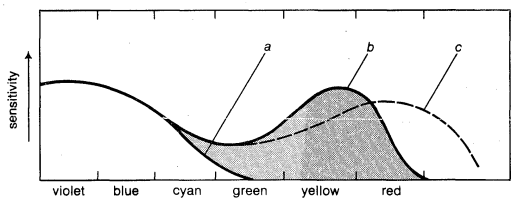

Figure 7: Sensitization of photographic emulsions (see text).

Toward the cyan and green, sensitivity drops rapidly. Such an emulsion is called natural, or ordinary. The result of such a characteristic is that in a natural scene reds and yellows appear black in the positive, and green appears too dark.

As early as 1873 it was found that dyes introduced into the emulsion could increase the sensitivity in the yellow and green, Figure 7, curve *b*. The change increased the natural appearance of the reproduced picture, and the emulsion was called orthochromatic. Later (1904) dyes were found to prolong the sensitivity into the red, and this emulsion is called panchromatic, Figure 7, curve *c*. The dates are fairly early for motion-picture application, but the development had importance in the general technology.

The overall sensitivity for picture taking has been increased greatly, from below about ten ASA before 1930 to several hundred and even several thousand. The ASA (American Standards Association) scale is an arbitrary rating of film speed; that is, the sensitivity of the film to light. If everything else is kept constant, the required exposure time is inversely proportional to the ASA rating.

Negative films designed for original picture exposure are usually faster (*i.e.*, have higher ASA ratings) than those for prints and are apt to be somewhat coarser grained.

Colour emulsions. The modern subtractive colour, which is so easy for the cinematographer to use and which gives such generally satisfying results, is sometimes thought to be one of the minor miracles of the 20th century. First introduced in 16-millimetre amateur films, it is now used in all sizes of motion-picture film and has largely replaced black and white.

The development of modern colour film

There are two major steps involved in making a dye image on motion-picture film. The first is to convert the negative silver image that is obtained from a normally exposed film into a positive dye image. The clue to how this can be done came from experience with a developer known as pyro (pyrogallol), once very popular with still photographers. A negative developed with pyro developer has not only a silver image but also a brown stain. Study of the process showed that the stain was caused by oxidation products given off locally by the developer in the development process. A substance in the developer reacts with these oxidation products to give an insoluble brown dye. The substance is called a dye coupler. Since the dye is not soluble, it does not wash off in the subsequent film treatment.

This suggested the possibility of bleaching to take away the silver image, leaving the dye image on the film. The first step was to find a developer and dye couplers that would produce the three dye colours that give a faithful three-colour picture rendering. The second step was to carry out the process in the film coating with three separate colours and keep them separate, all the way from exposure to the final three-colour image on the completed film.

The first portion of this second step is carried out by obtaining three emulsions that can be laid on top of one another and are sensitive, respectively, to the red, green, and blue of the exposing image without interfering with each other and that give corresponding silver layers that similarly do not interfere with each other.

It has been observed above that normal silver halide photographic emulsion is particularly sensitive to blue light and that one of the early problems was to obtain a more natural pictorial rendering by extending the sensitivity of the emulsion to green and finally to red light. The problem was solved by inserting appropriate dyes in the emulsion. The dye adds a peak of increased sensitivity, respectively, to green and red light, as in Figure 7. The triple-layer film then consists of, on the top, an ordinary blue-sensitive emulsion; below this, a yellow filter to cut off blue light; next below this, an emulsion with a sensitivity peak in the green, with the yellow filter cutting off blue sensitivity; and finally an emulsion with a peak sensitivity in the red, a valley in the green, and blue sensitivity cut off by the yellow filter. The sensitization can be chosen to locate and enhance the sensitivity peaks.

Thus, the blue layer responds to the blue light in the original, the green layer to the green light, and the red layer to the red light. These can be given a first development together, so that the individual responses will be indicated as silver deposits in the respective layers. The developer used is one which leaves no dye-coupler stains.

In what is called the nonsubstantive subsequent process, the dye couplers are introduced in a second development. Each colour layer is treated separately. Uniform red light is applied (from the bottom up) to expose the undeveloped silver halide in the red layer. It has no effect on the other layers because of their insensitivity to red. The film is processed with a developer containing a minus-red (or cyan) dye coupler. This leaves a silver and minus-red dye deposit wherever there was newly exposed silver halide in the red layer. Similarly, the blue layer, newly exposed with blue light from above and processed with a developer containing a minus-blue (or yellow) dye coupler, leaves a silver and minus-blue dye deposit wherever there was newly exposed silver halide in the blue layer. In the remaining green layer, a white-light exposure and development with a minus-green (or magenta) dye coupler converts the residual silver halide into a silver and minus-green dye deposit.

All the silver deposits and the yellow filter are finally bleached out. The remaining dye deposits serve to subtract from white light, in the manner that was described earlier, the correct part of the spectrum to leave the colour of the initial exposing light. For example, where this light was red, the final dyes absorb blue and green. Of the spectrum, this therefore leaves red light to go through the film.

The substantive process

In a modification called the substantive process, the appropriate dye couplers are suitably embedded in the emulsion in the appropriate colour layers to prevent their moving about during processing and contaminating the colours (an important problem). It is then possible to carry out the second exposure and development on all three layers in a single step with white light and with only one developer.

Examples of the nonsubstantive type of film are Kodachrome and Fujicolor. Examples of the substantive type are Ektachrome, Anscochrome, and Ferraniacolor.

The processes described can be modified to give a negative (or complementary-coloured) image by omitting the reversal step. This can then be printed to give a positive image on another film. This process can be useful when it is desired to make a large number of prints from a single matrix. The matrix can also be made as an internegative from an original positive film.

In professional commercial motion pictures, final exhibition prints can be made by a variety of combinations of these several processes, according to convenience, quality, and economic requirements. The combinations can include films in a variety of sizes, so that 16-mm projection prints can be made from 35-mm originals, or 35-mm prints can be made from 16-mm originals (for example, news films), and other sizes (such as 8-mm and 70-mm) may be involved in the operations.

LIGHTING

Equipment and techniques. One of the earliest problems encountered in motion-picture photography was the need for sufficient light for exposure. In contrast to still photography, the exposure duration was limited to something like half the time between one frame and the next. With the low-speed films and the relatively small-aperture objectives then available, a good deal of light was needed. At first, only sunlight and skylight were used. Artificial lighting had to be very strong to be effective and involved several problems. Incandescent-lamp lighting is rich in red rays but poor in blue, the reverse of what was desirable for the natural films shown in Figure 7, curve *a*. As with projection, in which a great deal of light was also needed, it did not take long to apply the brightest light source then available, the electric arc lamp. The term klieg light (arc made by Kliegl) became widely recognized in motion-picture production. Specialists developed a systematic technique, the general principles of which continue to this day and extend in their application from studio to location shots or other outdoor shots where preparation is possible.

First, a general level of illumination is established throughout the set to approximate daylight conditions. Actual outdoor daylight requires only a touching up procedure. Second, concentrated beams of light are shot onto people or areas that need to be clearly set forth in the picture. The shapes of the beams and their intensities depend upon the nature and shape of the area to be filled in. In the case of a travelling shot, in which the camera follows the action along a defined path, the fill-in light may have to be turned on and off as needed by the photographer. As a result of these different needs, a great variety of designs and intensities of lighting equipment have been produced.

Colour requires that much greater care be taken with the colour of the light directed onto the set. It is, for instance, much more of a problem to fill in general arc-light illumination with incandescent lights. These latter tend to be yellower and need filtering or a very cautiously selected location to avoid giving an unnatural appearance to the set on the colour film.

New tungsten-halogen lamps have been developed, using a quartz envelope. The halogen compound is included inside the envelope, and its purpose is to combine with the tungsten evaporated from the hot filament. This forms a compound that is electrically attracted back to the tungsten filament. It thus prevents the evaporated tungsten from condensing on the envelope and darkening it, an effect that reduces the light output of ordinary gas-filled tungsten lamps. The return of the tungsten to the filament means that the incandescent lamp can be run at a higher filament temperature and still have a long life. These lamps are now sometimes provided with a special multilayer filter to give a bluish light that approaches arc light.

Tungsten-halogen lamps

The lamps usually are now also provided with lenses to concentrate the light beam somewhat and prevent excessive light loss around the sides. They can also, when suitably focussed, give a relatively sharp beam. In a studio there are racks above and stands on the floor on which lamps can be mounted. The primary considerations are that they direct the light where it is wanted and that they not impede floor traffic around the set.

Light measurement. The measurement of the light is a development that took some time to come into the photographic art. It was not until the 1930s that a photoelectric device was developed that could be used easily to measure light intensity. Since that time there has emerged a body of knowledge on how the intensity is to be most effectively measured. This has been especially desirable since the advent of colour, which is more sensitive to exposure than is black-and-white film.

There are three approaches to this measurement: incident light, reflected light, and spot.

Incident light. Readings of this type measure the overall illumination on the scene. This is not always practical, as when the subject being photographed is distant, such as a remote building. These measurements require some adjustment for the general reflectance of the subject being photographed.

The meter for this type of measurement can be the usual portable meter used by amateurs, but it may be desirable to have the photocell covered by a translucent dome so that light coming from the side is included in the measurement. A more sophisticated meter is occasionally used with a photocell separate from a more sensitive indicating meter.

Reflected light. Readings by this kind of meter measure the average light coming toward the camera from the scene being photographed. This works well for average subjects but gives wrong exposures if the background contains either many bright areas, as in a beach scene, or very dark areas, as in front of a dark building. In such cases the photocell must be held not at the camera but very close to the subject of interest, to eliminate the effect of the background. This is also the case when the scene contains a good deal of backlight.

The meter here can also be the simple, portable, amateur exposure meter, but it is desirable that it have a relatively narrow acceptance angle for the light, to reduce the effect of the background. The procedure is the simplest and most popular with amateurs.

Spot measurement. These readings measure the light coming toward the camera from selected spots in the subject being photographed. The meter for this purpose has an optical system that covers measurement of a spot of about one degree. Such readings must be checked against the overall lighting on the set to assure that the distribution of light values fits the characteristics and range of the film being used.

Colour. With colour photography it has become necessary to measure not only the intensity of the light on the scene but also its colour. The meter used in this case is called a colour-temperature meter. A standardized and fairly accurate measurement can be obtained by taking the ratio of light intensities in the red and in the blue, which is what a colour-temperature meter does. More recently it has been found desirable on such meters to sample the intensities of three, rather than only two, colours to obtain the best results on colour film with artificial light.

FILM PROCESSING AND PRINTING

Processing. In the early days of motion pictures, films were processed by winding on flat racks and then dipping in tanks of solution. As films became longer, such methods proved to be too cumbersome. It was recognized that the processing system should have the following characteristics: it must run continuously; it must be lighttight and yet capable of being loaded in daylight; and it must be as compact as possible to provide a minimum air surface for the processing solutions. A general form evolved that is still in use (see Figure 8).

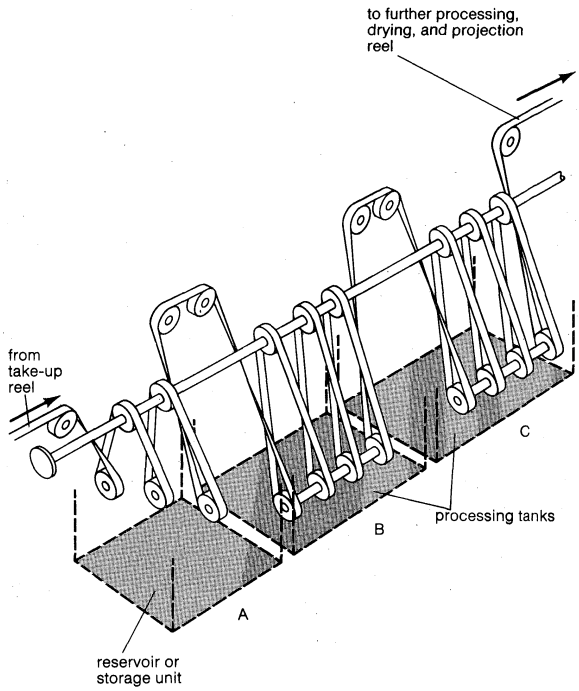

Figure 8: Basic steps in the continuous method of film processing.

For continuous operation the film must be passed continuously through the solutions and folded back over rollers that do not touch the emulsion surface. It must be handled very carefully, as the impregnation with solution weakens the support, and the sprocket holes should preferably not be engaged. Drive should, therefore, be accomplished by a light friction force at the edges.

Splicing on a fresh film without affecting the motion of the part of the film being processed is handled by using a storage unit or reservoir, as at A in Figure 8. This reservoir has a variable capacity so that the output end can be giving out film while the input end is stationary as the new film is spliced. Lighttight gates prevent all but a short length of film being light-struck at the very beginning or end of the film (and leaders may be used). The take-up-reel case is fastened in a lighttight way to the storage unit so that after splicing, the film is unreeled into the storage and processing units until the other end is reached, ready for splicing to the next film after changing cases.

Passing the film through solution

Many tank shapes have been tried. The long vertical tanks (as at B and C in Figure 8) provide for several passes of the film through each tank. The spools are designed so as to hold the film at the edges by friction. There are a number of types of drive, but all function gently to avoid strain. Sometimes the spools have multi-stepped edges to accommodate various film widths. The lower spools (or "diabolos") are more or less free but guided in a loose fashion so that they will not jam or tangle. The long vertical tanks give a minimum of air surface to the solution. The motion of the film through the liquid can be sufficient for proper contact of the film with the solutions, but sometimes submerged sprays with small jets of fine nitrogen bubbles are provided to increase the agitation.

Processing solutions age in continuous operation. They must be constantly checked by chemical or other analysis, and fresh replenishing solutions must be added as necessary. Lengths of processed film are examined to make sure that the processing is continuing normally.

The last receptacle in the processing sequence is a drying oven. There are several designs, some of which generally resemble the tank but without solution and are provided with heating elements. This receptacle does not need to be lighttight.

A variety of methods are used to make sure that processing is dust free.

The processing steps for the many different types of film are similar in principle, though there are variations in specific solutions and treatments. Reversal film requires a second exposure step, accomplished between trips through solution tanks. The introduction of sound track requires a much closer control of the development process to maintain the sound quality, for both variable density and variable area tracks. Colour film materially increases the number of processing operations and extra exposure steps and lengthens the size of the machine. It also further increases the need for close control of the processing operations. In cases in which the sound track is carried by the silver deposit instead of the colour dyes, special processing for the track is required.

Film prints to be used for projection are given a coat of wax over the sprocket-hole areas. This eases the film passage between the pressure plates at the projection aperture.

Processing solutions have been devised in viscous form, which are more rapid in operation than the liquid and permit the use of more compact equipment. These have been employed for special applications but have not been used generally.

Printing. The preparation of exhibition prints for sizable numbers of theatres is a large-scale operation. Printing takes a number of different forms.

In contact printing, the master film (or negative) is pressed against the raw stock; this combination is exposed to light on the master filmslide.

In optical printing, the master film is projected through a lens to expose the raw stock.

In continuous printing, the master film and the raw stock both run continuously. Continuous printing is usually contact printing but could be optical, through a projected slit.

In intermittent, or step-by-step, printing, each frame of the master film is exposed as a whole to a corresponding frame space on the raw film.

It is possible to print from one size master film to another size raw stock, such as 35-mm to 16-mm, or vice versa. In such cases the printing must, of course, be optical, and in the examples cited must be intermittent if there is a sound track. This is because, as indicated in Figure 6, 35-mm sound film has a spacing between frames which 16-mm does not. The sound track must be printed separately.

SOUND-RECORDING TECHNIQUES

The art of sound recording for motion pictures has developed dramatically. Apart from a continuous improvement in sound quality, two particular developments have markedly affected the technology and practices. The first was the discovery that there was no need to record the sound on the same film and in the same camera as the picture. On many occasions several pictures are taken from different points of view of the same scene, which has only one sound record. Or several sound records may be taken. It is far more flexible for subsequent handling (starting with the developing, which can be specialized) to take the sound recording or recordings in a separate box under the care of a specialist. In later editing processes, the editor can cut in such segments of the picture film as best fit the development of the story, but they are all anchored to the same time sequence of the sound tracks. For this it is necessary to have absolute synchronism between the various picture films and the sound recordings. When the last are on a sprocket-holed support, the

Separate sound recording

sprockets are all driven synchronously from a common power supply. A common starting point can be established at the beginning by a "clapper," or set of wooden jaws about a foot long, snapped together in the picture field. The instant of clacking then appears in both picture and sound tracks.

The second change in technology was the advent of magnetic sound recording. The big advantage of this technique is that it provides improved sound quality, thus permitting greater flexibility in editing procedures. When a sound track is copied, the copy is not as good as the original, and a copy from the copy is poorer yet, and so on as successive copies are made. The amount of degradation at each step, however, is less if the process gives a more faithful rendering in the first place. Thus, magnetic recording permits the use of successive copies in the editorial process while still giving a final copy of adequate quality for exhibition purposes. Also, magnetic tape or film does not need to be developed but can be used as soon as made and does not need to be protected from light. The result is that most of the present original sound recording for motion pictures is done magnetically. On the other hand, most of the 35-millimetre film projected in theatres carries a photographic sound track, as most theatre projectors in current use are equipped with optical sound reproducers, thus requiring the magnetic sound track to be converted to an optical sound track in the exhibition print.

Much of the equipment and procedures in motion-picture production is more or less the same whether the process used is optical or magnetic (see also SOUND RECORDING AND REPRODUCING). The microphone is an example. Microphones of many different types have been used for sound recording. These may differ in sound quality, in directional characteristics, in practical convenience of use, and in other characteristics. Conditions that may dictate the choice of a particular microphone include the presence of minor echoes from objects in the set or reproduction of speech in a small room, as distinct from that in a large hall. Painstaking adjustments are made by careful attention to the choice of microphones, by the arrangement of walls and furniture on the set, and by the exact positioning of the actors. For recording a conversation the preferred microphone is sensitive in a particular direction to reduce extraneous noises; it is moved toward each actor in turn. The boom used to hold the microphone in these cases resembles that used for small lights. Microphones can also be mounted on a variety of other stands. If necessary, a chest microphone that is hidden under clothing may be used.

Choice of microphones

When several microphones are used on the set, their outputs are often mixed and reproduced on a single film or tape. The mixing is done at a small console, and the operator must use a high degree of skill. Sometimes this is done in the later editing or dubbing process.

Magnetic recording. As far back as 1900, Valdemar Poulsen, a Danish electrical engineer, devised means of recording sound on a steel wire. Around 1928 the German firm Allgemeine Elektricitäts-Gesellschaft (AEG) experimented with a thin iron oxide layer deposited on paper or plastic tape. It was not, however, until well after the end of World War II that its advantages were recognized for sound motion pictures.

The system makes use of a magnetic iron ring with a wire winding around it. In the recorder this carries the electrical signal. The ring has two gaps in it, filled with shims of nonmagnetic material. The plastic tape with magnetic iron oxide coating is drawn past one of these gaps at a constant speed. The current in the winding causes a magnetization of the ring, which in turn leaves a permanent magnetization in the iron oxide coating. The wave shape of the permanent magnetization follows the wave shape of the signal current. The recording of fine details on the track depends upon the fineness of the nonmagnetic gap in the ring and on the speed of the tape.

In the replay condition the tape is passed over a similar ring with nonmagnetic gap, and the magnetization in the iron oxide coating induces a current in the winding. A measure of the quality of the reproduction is the fidelity with which the wave shape of the current follows the wave shape of the original current that was supplied to the recorder and the amount and nature of the noise that was added.

It has been found that, if a certain fixed amount of current (usually called "bias") is added to the recording signal, the quality of the reproduction is distinctly improved, both as to faithfulness in wave shape and as to noise. The amount of bias added is usually adjusted to a value giving the greatest improvement. With this improvement the quality of the reproduction obtainable in practice is higher than that usually provided by the use of the photographic sound track.

The tape base is available in two forms. One is with sprocket holes of the kind used for picture recording. Usually this is without emulsion, since no picture is carried. Occasionally, however, especially with the 16-mm format, it is desired to record the picture also, and for this the film carries both picture emulsion and magnetic track. Sometimes, if there is no picture emulsion, the base is made of different material from that used for picture film.

Tape bases

More compact recording apparatus is possible with a straight quarter-inch-wide tape having no sprocket holes. In this case, a second magnetic track is necessary to maintain synchronism with the camera.

Optical recording. Among new developments in optical sound recording is a technique using a fast-acting galvanometer rather than the double-ribbon light valve to control the amount of light reaching the sound track. The record on the film is a variable-width track.

The principal present use of this type of recorder is to make a master optical negative for final exhibition prints after all the editing and dubbing have been finished. From this optical negative the sound track can be printed photographically on the exhibition release prints. Sometimes the release prints are printed as positives directly from the final magnetic track, rather than from a negative made from this track. This is known as electronic, or electrical, printing, and it may have advantages from the standpoint of quality.

Dubbing. This is a term used to indicate a sound track that was added during an editing stage rather than recorded at the same time as the picture. It can include the addition of incidental background noise to add to the realism of a scene. It can also provide for the substitution of a voice recording made under more favourable conditions than those prevailing during picture taking and can be made before or after the picture is taken. In pictures that present singing of operatic quality, for example, the singing may be accompanied by facial expressions that are not attractive in close-up (which in an opera would not be noticeable to an audience). Such scenes can be prerecorded or postrecorded, due care being taken to assure exact synchronism between the sounds and the lip movements. In musical productions in general, a better recording of the music can be obtained in a separate session in a sound studio than on the picture set, with the result that filming is made with only a token orchestra. Sometimes an addition dubbed in can be only a commentary on the action in a picture. In all of these cases the sound and the picture recordings are merged in an extra editing session of the production film.

There is a further use of the dubbing procedure. It is often desired that a film made in one language be translated into another, for an entirely different audience. If the actor cannot speak the other language, it is possible to dub the speech in that language from another speaker. In such cases, if this is to be done credibly, it is necessary to make the speech in the other language fit the character and cadence of the original. If the actor's face is visible in the picture it is also necessary to fit the words of the translation so that the lip movements are not too disparate. Dubbing of this sort done skillfully can be remarkably credible.

Translation dubbing

SPECIAL EFFECTS

Perhaps the simplest special effect is the gradual dissolving of a scene by a slow reduction of contrast until it

disappears into either a uniform field or another scene. This is frequently carried out in a preparation of the final film negative. Another method involves "wipe" patterns, in which the scene grows from a small part of the frame until it encompasses the whole frame. This is accomplished by the use of a "travelling mask" on an auxiliary pair of films (one the negative of the other). On a first printing through the positive mask the first scene is exposed on the fresh film. On a second printing through the negative mask the new scene is printed on the unexposed part of the fresh film.

To print conveniently and simultaneously from several films requires a special-effects printer, which is usually a specially designed optical printer. The machine becomes relatively complicated when several films are involved in the special effects.

Another type of special effect is the projected background. If, for example, it is desired to photograph the actors before a remote background, such as a street in Paris or the Pyramids, an ordinary shot of the location, perhaps taken from stock, is projected in the studio onto a translucent screen. Necessary precautions involve synchronizing the taking film with the projected one and adjusting the colour. It is usual, also, to use a pin-registered intermittent for the projected film so that the background scenes do not show vibration with respect to the actors. Some very convincing pictures can be taken in this way.

The term special effects also includes more ambitious simulations. A background can be painted on a backdrop, as in the live theatre. Sometimes a large glass sheet is used; the actors and the immediate surroundings are photographed with built-up scenery, but the more distant objects are painted on the glass, with the junction merged into a feature of the locale.

It may even be desirable to compress the actual distance in a condensed background by falsifying the perspective with exaggerated building and street angles that merge with the foreground. In this technique the camera point cannot be changed, as it would reveal the false perspective at the merger.

Use of models for special effects

A practice that is not really a special effect but can be noted is the use of full-scale models of heavy stone, brick, or other materials made in cast plastic foam. Some remarkably convincing structures, inexpensive and light to handle, can be built in this way. Scale models often require changes in the time scale and a great deal of care about perspective. A disaster at sea, for example, or an automobile plunging off a cliff can be simulated with scale models and a speeding up of the frame-taking speed.

PROJECTION TECHNIQUES AND EQUIPMENT

Apart from the addition of sound, the most notable change in projectors has been the progressive introduction of automation. Automatic feed for the arc-lamp carbons, automatic film changeover from one reel to another, and other automatic features have been developed.

Picture projection. In projection practice, a cue mark is placed on the film, consisting of a small ring scraped in the film emulsion at the upper right-hand corner of the picture as seen on the screen. This is put near the end of the film at about the time the second machine should be ready. A second cue mark, somewhat later, indicates that the first machine should be faded out and the second machine faded in. The film is usually edited so that the changeover corresponds with a fade-out–fade-in sequence in the narrative. Three machines are often installed, the third being a spare in case of a breakdown (or during maintenance) in one machine.

Lamps. An important element of picture quality on the screen is brightness. The introduction of the arc lamp initiated a constant effort to increase the brightness. A typical lamp design is shown in Figure 9. A fairly large concave-mirror condenser concentrates the light from the most brilliant part of the arc (the crater on the positive carbon) onto the film aperture, and from there to the objective lens. The arc lamp is operated with direct current to avoid the periodic brightness variation every 60th second that would occur with alternating current. A double screw feed moves the carbons together as they burn. The brightness was first increased by increasing the arc current. In time, it was found that if the positive electrode was "cored" with a softer carbon mixture, as in Figure 9B a greater stability and higher crater brightness could be obtained. Then if the core were impregnated with fluoride salts the crater and the immediately surrounding gas became phosphorescent, the brightness increased, and the light became whiter. This was called the flaming arc. The current was then further increased but at the cost of crater stability. The stability was restored by rotating the positive carbon and inclining the negative, as in Figure 9C. This is now called the high-intensity arc. All these developments have improved picture quality, especially with colour film and have also permitted larger screen pictures.

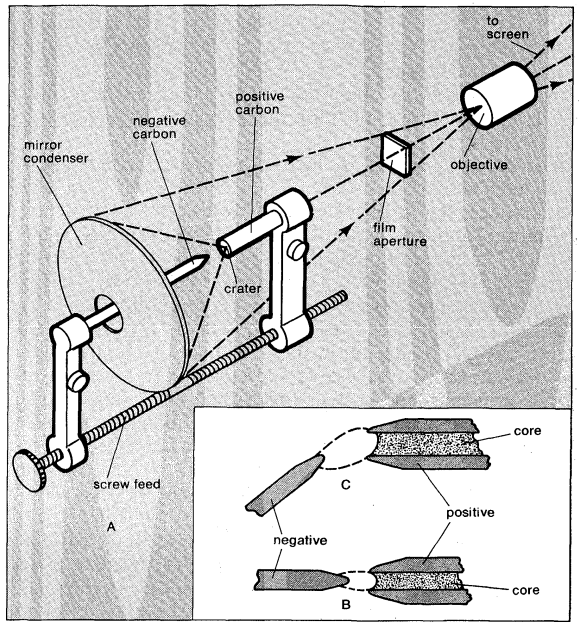

Figure 9: *Typical projector-lamp design.*
(A) Principal parts. (B) Coring of positive electrode with a softer carbon mixture. (C) Rotation of positive carbon and inclining of negative carbon to stabilize the crater, resulting in a high-intensity arc (see text).

Meanwhile, other developments have been studied. A high-intensity form of incandescent lamp, with halogens as noted for studio lighting, and high-intensity xenon glow lamp have been developed.

As the light on the film aperture has increased, so has the heat. To some degree this is abated by the use of a heat-absorbing filter. But the darker areas of the emulsion still tend to expand over the short exposure in the aperture, causing the film to bow in the interval and go out of focus. The film is cooled by a small jet of air to mitigate this.

The intermittent mechanism used in current projectors is generally of the Geneva-cross design (see Figure 10), sometimes called the Maltese cross, machined to close tolerances to give steady pictures and minimum noise.

Screens. The screen used in projection has itself been the subject of development. As screen and picture grew larger, it became necessary to keep the viewed image bright. Light from the screen is wasted if it comes back over the heads of the audience, is too low down, or is too far to the sides. With an ordinary matte-white screen, the return light comes back in a wide cone, less intense as the angle between the incident and reflected beams increases. A good deal of light is wasted at larger angles. Screen surfaces have been developed that are somewhat more specular, or mirrorlike, in their reflection. The design involves a choice between saving light and keeping a wide, usable audience area. One recently developed screen surface is embossed with shaped indentations to form the return light in narrow up-and-down angles, with wider angles from side to side.

Innovations in screen surfaces

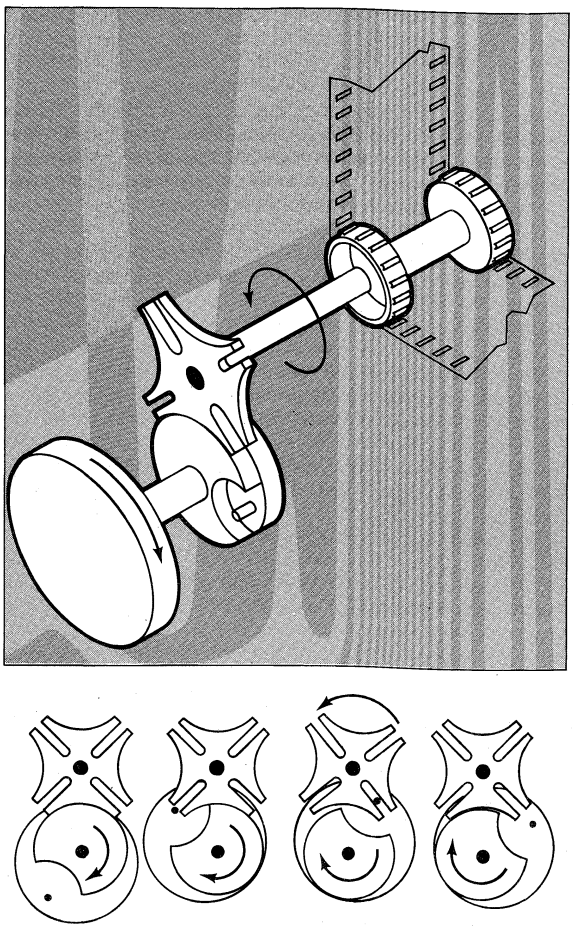

Figure 10: Full Geneva-cross intermittent. Bottom shows successive positions of the intermittent mechanism.

Greater image brightness permits a slightly higher illumination level in the audience without sacrifice of contrast. A moderate level of illumination in the audience is less tiring during prolonged viewing. With sound (see below *Sound reproduction*) it is necessary to perforate the screen with fine holes that reduce reflecting surface and therefore image brightness.

Rear projection (that is, through a translucent screen to an observer on the other side) is occasionally used for exhibition purposes, as well as for special effects. The directional characteristics of a translucent screen are more pronounced than those of a reflecting screen, and a "hot spot," or extra-bright local region, is often observed directly in line of projection from the incident beam; some provision is usually necessary to mitigate this. Another problem is the lateral scattering of light within the thickness of the translucent screen itself, which shows as a haze around the sharp edges in the image, giving loss of crispness or definition. Because of these effects, special lenticulated plastic screens have sometimes been used.

Stereoscopic projection. Stereoscopic projection requires two projectors running in synchronism. In some, the two projectors are incorporated in one machine, but it is also possible to use two machines with interlocked drive. When light polarization is used for image separation, the screen reflection must not destroy the polarization, as would a plain-white matte screen. Aluminized screens are frequently used.

Sound reproduction. The sound track on the film is usually picked up by a "sound head" on the projector. On full-sized film (35-mm or wider), when the track is optical, the recording is placed earlier on the film than the corresponding picture material. Consequently, the sound head must be placed later in the film path so that the two will be projected at the same time. Since the film travels down through the projector, the optical head is located below the picture aperture. When the sound track is magnetic, on full-size film, it is recorded later on the film than the picture and consequently must be scanned earlier in the film travel path. Thus, the magnetic head is located above the picture aperture on the projector.

In 16-mm and 8-mm film (standards are not completely set on the Super-8), both optical and magnetic tracks are located ahead of the picture. Consequently, both optical and magnetic heads are located past the point where the film has passed the picture gate.

Sound amplification

The sound signal, whether from an optical or a magnetic track, is suitably amplified and fed to loudspeakers. In general, modern speakers reproduce with fidelity a fairly wide band of sound frequencies. For theatrical use the speakers embody two or even three parts. The low notes involve a mechanism different from the high notes, and the third, when used, is an intermediate device. These are usually all mounted on one structure. In the case of a relatively large screen, the most realistic sound from one speaker is obtained when it is mounted directly in back of the middle of the screen. To give good-quality sound, the screen must be perforated.

Room design (especially as the room becomes quite large) requires a certain amount of acoustic sophistication. The nature and geometrical shape of the wall and ceiling surfaces become important, as does the general shape and arrangement of the room. The reverberation time (the time for a sound to die down once the source stops) has to be appropriate for the room size.

All these factors become even more important when stereophonic sound, from two or more tracks, is used. The location of the loudspeakers must be planned with care, and their total acoustical power output must be in proportion to the size of the room. In some systems, five loudspeakers are used behind the screen, and special effects are obtained from speakers over the auditorium, all on separate magnetic tracks.

ANIMATION

The picture in motion-picture film does not have to be a photograph; it may be drawn or painted. A start in the technique was made in France about 1908 by Émile Cohl, when he depicted white matchstick figures on a black background. Later developments employed cartoon figures, a concept highly developed by Disney in the United States in the period from 1928 to 1940. Employing a technique of exaggeration in proportions of figures and motion, Disney created feature-length movies with great commercial success. In more recent times, the animation technique has been used on shorter films, such as television commercials or occasional short comic films. The principles are also found to be very useful in teaching films, since they can show exaggerated forms or motions that would not be obvious enough in their natural proportions and can show exploded views of intricate assemblies, with motions added to bring out interrelations that might otherwise be obscure.

Use of animation in teaching films

The practical technique leans heavily on the use of clear-plastic sheets on which the drawings are inked or painted. Sometimes each frame is completely drawn and coloured. Stationary parts may, however, be reproduced on a succession of sheets in which the moving parts are completed as they occur, or various parts may be moved with respect to each other to form the action. The clear plastic permits the lower sheets to be viewed as distinctly as the upper sheets. The final result is convincing largely because of the skillful depiction of the successive steps in the motion shown. It is not always necessary for each frame of the final film to represent the exact status of the motion at that instant; especially in the case of fast or erratic motions, it is often possible to use the same picture for each group of two or more successive frames.

The frames are photographed in a so-called animation stand, which supports the camera at the desired height over the plastic sheets. The sheets can be moved about on calibrated, screw-operated platforms. Very complex stands are needed to depict perspective by separating the plastic sheets by suitable distances and moving the nearer sheets faster than the farther ones.

Another animation technique consists of the use of puppets in a three-dimensional scene. The puppets are moved or changed between the successive frames.

MOTION-PICTURE FILMS IN TELEVISION

Films have been used in connection with television in a variety of ways. The most important is the use of previously made films as program material. The second is the taking of a film during a television program to serve as a recording for further use or possibly for exhibition directly with a projector.

Problems of using films in television

The principal complication arises from the different frame rates in the two arts. The 24-frame-per-second rate was adopted as standard for films when sound was introduced, and, for a variety of reasons, this has proved to be a wise decision. In the United States, the electrical-power supply operates at 60 cycles per second. In the early days of television there were a number of points in the complete television system, from studio to broadcasting station to home receivers, where the power supply could cause interference (cross talk) with the television equipment. It was possible to minimize the effects of this on the received picture by setting the frame frequency at 30 frames per second, and this was done. It had the advantage that the brightness of the received picture could be raised without making flicker apparent. Cross-talk-prevention techniques have improved, and the power supply is no longer a valid reason for the 30-frame-per-second standard, but because of the flicker advantage this has not been changed.

In Europe the power supply operates at 50 cycles per second. In the early days this was the justification for a 25-frame-per-second standard. It is no longer so, and the difference between 24 and 25 cycles per second gives only a very small flicker advantage, but the television standard has not been changed.

In using films made at 24 frames per second on a television transmitter operating at 30 frames per second, advantage is taken of the fact that because of interlace in the television picture the picture is scanned at 60 fields per second (two fields make up one complete picture). Then alternate frames on the film are scanned three times and the intervening ones twice. Thus, the total time taken to scan two frames is $^3/_{60} + {}^2/_{60} = {}^5/_{60} = {}^1/_{12} = {}^2/_{24}$ seconds. This is exactly two frames on the 24-frame-per-second standard. To work this out practically requires a special "limping intermittent," of which there have been several designs.

In Europe, 24-frame-per-second films are run at the 25-frame-per-second speed without perceptible visual effect. The sound pitch is raised by slightly over 4 percent, about a third of a whole tone interval. This is perceptible to a musician but not particularly objectionable to most hearers. More recently in Europe, film intended for television use is often taken at 25 frames per second.

The second important complication arises from the fact that the pull-down time for film (the time during which the film is moving from one frame to the next, with shutter closed, in camera or projector) is much longer than the field retrace time (the time from the end of one field to the start of the next, when the electron beam is blanked out) in television.

The solution makes use of the storage capabilities of the camera tube. The image is projected in a short flash on its sensitive surface during the field retrace time, after which it is scanned by the tube's electron beam. The instants have to be picked carefully because of the relation between fields and frames, though this is less important now that the new tubes permit overlap between the light incidence and the beam scanning without causing interference.

The problems occur also in film recording of a television picture from a cathode-ray screen, but recording of television pictures is now usually by means of magnetic tape.

Besides these more or less mechanical problems, there were also problems in contrast and colour reproduction, in the use of film both as source material for television and as a recording medium for received television pictures. These have required considerable and continuing study, and some reasonable compromises have been reached (see also TELEVISION).

III. Motion pictures for scientific purposes

As soon as motion pictures were invented, they were applied in the recording of scientific phenomena. The recording of an experiment in which a number of things happen at about the same time is especially appropriate for motion-picture recording.

TIME-LAPSE CINEMATOGRAPHY

There are many occasions on which the cinematography can be carried out at normal speeds, and these need no further discussion. There are other situations in which the changes occur very slowly, so slowly that the eye does not discern the change. One example is the opening of a flower blossom. In such a situation the technique used is to take successive pictures at intervals of, for example, an hour, taking great care not to move the camera or the plant and to project the resulting film at normal motion-picture speed. The projected picture will disclose many details in the development from the bud to the completed flower that are not apparent in ordinary visual observation. Other phenomena can be studied in this way. These techniques require merely a standard camera that can take single exposures, plus a timed triggering device that can take the exposures at the desired intervals. The rest of the technique is mostly a matter of preventing undesired motions of camera and subject.

HIGH-SPEED CINEMATOGRAPHY

Motion pictures have also been used to study phenomena that occur so fast that they cannot be recorded on normal cameras. An immense amount of ingenuity has been applied to the solution of many problems in this field, and a short discussion can only summarize the techniques used.

Optical systems outside the camera. *Shadowgraph.* The film can show sharp shadows of fast-moving bodies, indicating their speed and any changes of attitude they undergo. With a rapid enough exposure this procedure can also show the sharp shadow of a wave front in air.

Schlieren optics. The procedure shows changes in the condition of a test area of space in the optical path, even when it remains fully transparent. A simplified outline of

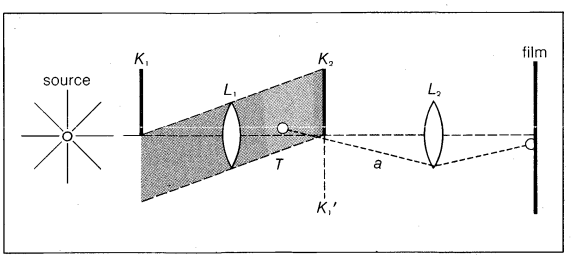

Figure 11: Schlieren optical system (see text).

the arrangement is shown in Figure 11. A source sends out a beam of light through the apparatus to a film. Half the field is cut off by a knife-edged screen, K_1, which is imaged by a lens, L_1, to a position, K_1', in the same plane as a matching screen, K_2. The knife-edges of image and screen exactly coincide. A test position, T, is sharply focussed on the film. Thus the light flow past K_1 to K_2 is all cut off from the film if the space at T is completely uniform. Any nonuniformity, such as caused by a wave front in the air at T, causes a scattered light beam to evade the screen, K_2 (path a), and reach the film.

Schlieren interferometer. This is a modification of Figure 11. Apparatus that is too complex to describe here but that polarizes the light beam—separating it into two slightly different paths and then reintegrating it into one path—is inserted before and after the area T, to bring out details of the phase of the light as it progresses from left to right. These details appear in the form of light and dark phase bands, or fringes. They outline the disturbance of the wave by any nonuniformity existing at T. Counting the number of fringes displaced gives a measure

of how great the nonuniformity is. The arrangement is especially adaptable to detecting and measuring irregular flow phenomena and wave fronts in the air (or another fluid) at *T*.

Time variation of spectrum. A spectrum of a self-luminous subject is often obtained. Sometimes the spectrum varies quickly, as in an explosion, and it is desired to study the variation. The light output from the spectrometer is led into a motion-picture camera that can handle the speed needed, and a film record is taken. The film can then be studied at leisure.

Framing. The normal-speed camera records on the film a succession of frames, each showing a complete picture but taken at successive instants of time. Not all high-speed cameras record in this way, but some do, and the various methods of separating the frames and recording them represent key elements in the technology. As a framing method, the intermittent mechanism has limitations, since it is not capable of being pushed very much beyond the normal speeds. Even if the mechanism itself could function, the sprocket holes in the film are not strong enough for the necessary accelerations.

Rotating prism. When a cube (or many-sided prism) is rotated in the optical path in a camera, it moves the image periodically past the picture aperture. If the film is moved in the same direction at the same speed, the image, while it is appearing, is fixed on the film. The problems are that, during its appearance, the image does not move with an exactly constant velocity, and the prism introduces some optical distortion of the image. These can be partially remedied by a variety of modifications, but there are still residual imperfections. The device is used, however, up to about 10,000 frames per second. A variation, in which an internal mirror drum with many facets is used instead of a glass prism, is usable up to some 40,000 frames per second. In evaluating the performance of the system, the size of the frames and sharpness of the images must be considered, as well as the number of frames per second.

Rotating-mirror system. Such systems take a number of forms, but Figure 12 shows a reasonably typical arrangement. The objective lens forms a primary image at

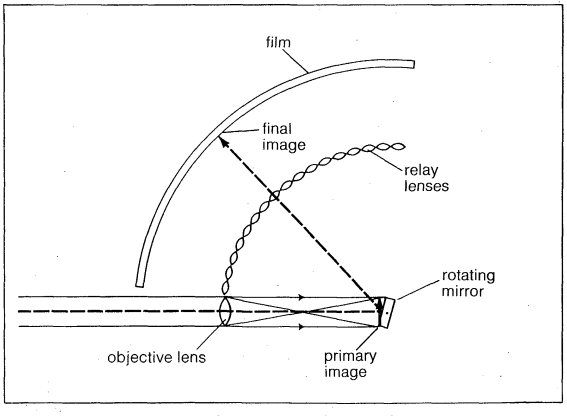

Figure 12: Arrangement of the principal parts of a rotating-mirror system (see text).

the rotating-mirror position. The mirror reflects this image through an arc of fixed, individual relay lenses in succession on the stationary film. The relay lenses having the primary and final images both in focus keep the final image fixed at each place in succession on the film as the beam traverses each lens. With some rotating-mirror systems it is possible to go to some 5,000,000–10,000,000 frames per second (again keeping in mind that frame size and image sharpness are important as well). The arrangement wastes light, so that bright original subjects are necessary for a satisfactory exposure. The system has been used to study explosions and plasmas and to study subjects by reflected light with very high intensity illuminants.

Image dissector. The central idea of this technique is to cut up a picture in the same way a television picture is cut into horizontal scanning lines. The bright lines are made very narrow, with black or empty space between, which permits superimposing other, similar pictures—also in fine lines separated by empty spaces. A number of pictures can be superimposed in this way without the lines interfering with each other. Lenticulations (embossed lenslike shapes) on the film form the scanning lines and concentrate the incoming light into fine lines on the film, according to where the light comes from on the objective lens.

The method will also work with two sets of lenticulations, one horizontal and the other vertical and superposed. This permits the storing of more pictures on the record film—in this case, as dots instead of thin lines. A number of devices based on these general ideas have been used. The frame speeds achievable vary with the specific arrangements but are generally lower than with the moving-mirror mechanisms.

Streak camera. The number of frames in Figure 12 may be increased to infinity by changing the optical system to put the primary image on the film and leaving out the relay lenses or, more simply, to replace the mirror with the film on a rotating drum. This requires compressing the individual frame from a two-dimensional into a one-dimensional image or slit. The equipment becomes a "streak camera." It is useful when there are one or more distinct demarcations in the one-dimensional view of the subject, and it is desired to record their motion along a more or less straight line. This is useful, for example, in recording the motion of the front of an explosion cloud or of a projectile. It leaves no unexplored areas of time, as does a framing record.

Illumination. The need for sufficient light is a most important requirement in high-speed cinematography. This need is so great that it is often undesirable to keep the light on longer than absolutely necessary, so that in many cases the light being turned on and off acts as a shutter. High-intensity, short-time sources have been studied extensively. Most sources consist of electrical discharges or, in some cases, arcs in air or a gas. In most cases they involve sophisticated electronic control methods.

Separate shutter. In cases in which the original subject is sufficiently self-luminous, such as in explosions, a fast shutter may be required. Since mechanical shutters do not go to very high speeds, various types of electro-optical shutters are used. Typical is the Kerr cell, in which a substance between electrodes can be made opaque or transparent according to the voltage on the electrodes. It can be made extremely fast acting in response to a sharp voltage pulse. Sometimes a relatively slow but positive "capping" shutter is required, to cut off light before and after an experiment. This is usually a mechanical shutter.

Electro-optical shutters

Image converter. On some occasions it is necessary to amplify the light after it has left the subject and before it reaches the film. In recent years "image converters" have been developed that can do this. Such devices usually project the light image onto a photosensitive surface that emits electrons. The electron beam is amplified and projected by electron optics onto a luminescent surface, which is then photographed optically on a film. These devices can also act as shutters by the use of a triggering pulse on one of the electrodes.

X-rays. X-rays are sometimes used as the source of illumination, but these rays do not permit the usual optical procedures. Slits in lead screens must be used instead of lenses and mirrors. As is the usual practice with X-ray films, both sides of the film are coated with emulsion. Also, an intensifier is used, consisting of a suitable fluorescent screen backing the film.

IV. Amateur motion-picture photography

Throughout the world the number of amateur cinematographers has increased steadily since the 1920s. As the quality of amateur equipment and the performance of the narrower film have improved, this equipment has been used on more and more professional tasks. News events can be covered more effectively with a compact amateur camera than with cumbersome professional equipment.

In addition, there is a growing number of semiprofessional makers of motion pictures. Their products include teaching films, used by schools of all types. Such specialized topics as geography, history, and archaeology can be effectively treated. Also involved are business and commercial films, such as promotional movies of various kinds. A new field that has become very popular is the making of amateur entertainment films by budding actors and directors.

The field of amateur-motion-picture technology is quite varied and forms a substantial part of the overall industry.

Camera. The need for simplicity of operation, lightness and compactness, ruggedness to withstand amateur abuse, and low cost have brought many camera developments that are gradually finding their way into the professional field.

The external shape of the camera has gone through a number of changes since its introduction in 1923. The present-day amateur camera takes a variety of forms. It is generally (but not always) hand held and often has a large pistol-grip handle to improve steadiness. Film reels are carried inside the body, and loading is possible in daylight. Loading has been so simplified that it sometimes consists merely of inserting a cassette, without the need for threading the film.

Modern amateur cameras

The lens most popularly used is of the zoom type, with a ratio of effective focal lengths running in some cases up to 10:1. In some instances this is manually moved; in others it is battery-motor operated. Exposure is nearly always automatically controlled. A choice of frame speeds is often available on the camera, usually from 16 to 20 frames per second.

Film. At one time 16-mm film on safety base was the most popular amateur film. In recent times, however, 16-mm has become a professional and semiprofessional film and has been replaced in the strictly amateur field by the 8-mm and Super-8-mm. The reasonably good quality of these latter and their lower costs and greater compactness have been the chief causes.

The 8-mm and Super-8-mm colour film is available in several emulsion speeds for daylight and also artificial light use and packaged in rolls, magazines, or cassettes.

The processing, carried out by a laboratory, involves the same general type of equipment as described above for professional film. Editing is done in a much more informal way, and some relatively inexpensive equipment for this is available for amateurs.

Very little printing is done for the home-movie amateur, although sometimes extra copies are made from original film. Printing for the semiprofessional, however, is another matter. Films for promotional or sales use or for teaching may be printed in fairly large quantities. Special printing machines are available that can print and process several copies at the same time, often on wide stock prepunched with sprocket holes. After processing, the wide stock is slit into the several copies. The choice of specific arrangement is almost entirely a matter of economics. One problem has been the lack of final standardization in packaging of the amateur film, which influences some automation steps. This sort of printing is mostly done as a reduction from 16-mm original, inasmuch as printing from 8-mm original to 8-mm stock does not give the highest quality results.

Machines for multiple printing

Lighting and light measurement. This is generally much more modest than for the professional. The semiprofessional, however, uses some of the smaller lighting equipment of the professional. The home-movie amateur is still more modest; for artificial light he has used 65-volt lamps on 110-volt supply to give intense light with a relatively short (but reasonably adequate) life. Special 650-watt tungsten-halogen lamps are now available for this purpose, in some cases held in reflectors that can fit on the camera.

Light measurement is currently nearly always accomplished automatically with a photocell in the camera. In many recent cameras it is combined with the viewfinder, and readings are taken through the lens by using a bypassing, partially reflecting prism in the taking beam. Some one-third of the light is used for viewing, together with a range-finding prism, and for a photocell; an amount that does not seriously reduce the amount of light available for film exposure.

Sound recording. All of the three small film sizes carry an optional sound track, optical or magnetic. The way in which the sound track is used, however, varies a good deal with the nature and interests of the photographer.

Semiprofessionals by themselves cover a wide range of interests. The makers of serious teaching films and of promotional films generally use much the same sort of techniques used by the full professionals, with some simplifications and a greater degree of informality. They almost always use 16-mm film and record the sound on a separate film (or tape), registering magnetically. There are some cameras, however, that ordinarily record picture only but in which a sound-recording magnetic module can be inserted to record both picture and sound. It can be used even with a recording amplifier having built-in mixing to be done on the set. The final exhibition print of the film usually has an optical sound track.

The film as finally used is likely to be 16-mm, but there is some tendency to reduce the format in printing to 8-mm, particularly to Super-8 and in general with the magnetic track. There are occasions when the 16-mm original is enlarged to 35-mm, but this is hardly in the amateur category.

Reduction in format

The home-movie amateur generally restricts himself to 8-mm film. Few 8-mm cameras, whether standard or Super-8, include provision for simultaneous sound recording. If sound is used, it is dubbed on the magnetic track afterward. There are some cameras, however, that include a special contact to send a pulse at every frame over a wire connection. This can be used with a tape recorder, on a separate track, to synchronize picture and sound. The film is projected on a special projector that has an arrangement to lock the speeds of the projector and tape recorder (and start the two in phase) so that the recorder sound matches the picture on the screen. These devices are not yet generally standardized.

Projection. The projection installation varies with the nature of the amateur and the use involved. For the serious semiprofessional, the 16-mm film is projected, with a sound track (usually optical) pickup from the film. This is usually the situation with teaching films, amateur entertainment films, and some forms of promotional-film uses. The equipment includes a moderate-sized screen and usually a single loudspeaker, and installation can range from permanent to portable. The projector itself in such cases is very much reduced in size from the professional projector and usually uses a high-power incandescent lamp (frequently of the tungsten-halogen type) or an enclosed tungsten arc lamp. For some promotional uses the projector is compact and throws the light on a small integrally mounted rear-projection screen.

For both teaching and professional use, Super-8-mm projectors have been designed to employ the semi-professionally produced sound track on the film and project onto moderate or small-size screens using a tungsten-halogen lamp. These have been designed for cassette-packaged film with many automatic features. There are several forms of cassettes and of sound pickups, and the field is only partially standardized.

Finally, for the home-movie amateur, projectors are offered with or without sound pickup—often permitting up to seven frame speeds (arranged with special frame repetition at low speeds to avoid flicker)—with zoom lenses to permit quick adjustment of projected picture size and accepting films in reels or various cassettes (but not on the same machine). Some machines accept only standard 8 and others Super-8; some accept either with a small adjustment. Many machines use tungsten-halogen lamps, and some use standard high-power incandescent lamps. Some machines, as noted earlier, are specially designed to be synchronized with a double-track tape recorder. The possibilities are quite varied.

The screens used run all the way from small portable screens to fixed moderate sizes installed in a small audito-

rium. Some amateurs still use a white cardboard or a white wall, but these do not generally give a high light effectiveness.

BIBLIOGRAPHY. R. SPOTTISWOODE (ed.), *Focal Encyclopedia of Film and Television* (1969); and L.A. MANNHEIM (ed.), *Focal Encyclopedia of Photography*, rev. ed. (1969), are two fairly complete one- and two-volume encyclopaedias on their subjects, for the nonspecialist. TERRY RAMSAYE, *A Million and One Nights*, 2 vol. (1926); and LEWIS JACOBS, *The Rise of the American Film* (1939), are two extensive, chatty, and unusually detailed stories of the development of the motion picture. RAYMOND FIELDING (ed.), *A Technological History of Motion Pictures and Television* (1967), reprints collected landmark papers from the *Journal of the Society of Motion Picture and Television Engineers* on the history of these two arts; the SOCIETY has also compiled *The Technique of Motion Picture Production* (1944), that covers many then-current details of this art. D.V. KLOEPFEL (ed.), *Motion Picture Projection and Theatre Presentation Manual* (1969); and JEAN VIVIE, *Projection des images animées et reproduction des sons* (1968), are projection manuals on the modern technology of motion-picture projection. GEORGES SADOUL, *Cinéma d'Aujourd'hui*, vol. 1, *Georges Méliès* (1961), vol. 29, *Louis Lumière* (1964), are two little volumes describing the early experiences of these pioneers, mostly in terms of their pictures, rather than the technology. There are also others in the series. JEAN VIVIE, "Motion Pictures and Education in France," *J. Soc. Motion Pict. Telev. Engrs.*, 78: 950–955 (1969), is a chatty story about the development of the narrow-gauge film for educational use in France. J.S. COURTNEY-PRATT, *A Review of the Methods of High-Speed Photography* (1957), and *Proceedings of the Fifth International Congress on High-Speed Photography* (1962); WILLIAM G. HYZER and WILLIAM G. CHACE (eds.), *Proceedings of the Ninth International Congress on High-Speed Photography* (1970), include detailed techniques in high-speed and scientific cinematography. R.J. ROSS, *Television Film Engineering* (1966); H.M. TREMAINE, *The Audio Encyclopedia* (1959); R.W.G. HUNT, *The Reproduction of Colour* (1967); Y.N. GORokhovskii, *Spectral Studies of the Photographic Process* (1965; orig. pub. in Russian, 1960); C.E.K. MEES and T.H. JAMES, *The Theory of the Photographic Process*, 3rd ed. (1966); and RUDOLF KINGSLAKE, *Applied Optics and Optical Engineering*, 5 vol. (1965–69), are more extended discussions of specific portions of motion-picture technology. A. BONI (ed.), *Photographic Literature* (1962), is merely a bibliographic listing, but useful to hunt up occasional articles. Periodical literature (all monthly): *Journal of the Society of Motion Picture and Television Engineers*; *British Kinematography, Sound and Television*; *Popular Photography*.

(P.Me.)

Motion Sickness

The term motion sickness was proposed by J.A. Irwin in 1881 to provide a general designation for such similar syndromes as sea sickness and train sickness. This convenient term, imprecise for scientific purposes, has nevertheless gained wide acceptance.

Definition. Manifest, or frank, motion sickness comprises a constellation of symptoms resulting from sudden exposure to periodic unnatural accelerations, and its course is self-limited through the mechanisms of adaptation. The nonacoustic part of the inner ear must function if the symptoms are to develop, but secondary factors, tending either to increase or decrease susceptibility, always are present. Normal persons are inherently susceptible, and susceptibility in the same person may differ in different gravito-inertial force environments. Overt manifestations include pallour, sweating, salivation, drowsiness, and (most important from a practical standpoint) the nausea syndrome. First-order responses give rise to second-order responses and complications of ever-increasing diversity, which may lead to prostration. The diagnosis of frank motion sickness is so easy that it is not a matter of professional concern, but mild symptoms may pose a diagnostic problem. In addition, confusion may arise because similar symptoms may be elicited in the absence of "motion"; *e.g.*, by syringing the ear with cold water, or by manipulating the visual input. Prevention is the key to good management in all cases. Motion sickness, theoretically, is preventable, but countermeasures may be impractical in many circumstances. Once symptoms are well established, quick relief may require intensive therapy.

Despite the prevalence of motion sickness and its age-long challenge to the investigator, most of the events and processes underlying the manifestations of motion sickness have not been elucidated. Some of the elements of a conceptual framework are discernible, however, and will be presented here in truncated form.

Vestibular systems. The nonacoustic portion of the inner ear comprises the otolith apparatus and semicircular canals, collectively termed the vestibular organs. In each ear the sensory receptor mechanisms in the three mutually perpendicular canals are stimulated normally by rotary motions of the head or head and body. The paired otolith organs, their receptor mechanisms in the shape of four curved plates constituting *in toto* a significant portion of a sphere, are stimulated continually by gravity and also by sudden linear accelerations. The vestibular organs are encased in a bony labyrinth and, while protected from external mechanical stimuli, must react slavishly to accelerative forces insofar as their response characteristics permit. The important point to be made here is that vestibular stimulation eliciting motion sickness may result from exposure to motions in conveyances either by virtue of (1) linear oscillations (as when a ship rises and falls); (2) angular oscillations (as when a ship rocks); (3) Coriolis acceleration (as when a ship pitches and rocks simultaneously); (4) Coriolis accelerations generated by two angular velocities, one contributed by man and one by machine, as when nodding the head on a carrousel; and (5) passive rotation at constant velocity in the laboratory when rotated in the "barbecue spit" or earth horizontal axis.

Types of motion causing motion sickness

The vestibular organs have a large representation in the brain stem, cerebellum, and spinal cord. By virtue of an extensive and complex neuronal circuitry, mainly at subcortical levels, the vestibular systems participate in such functions as the maintenance of postural equilibrium and in the coordination of eye-head-body motions. Although evolutionary adaptation has ensured that such participation is effected in elegant fashion in naturally occurring accelerative environments, this guarantee does not hold true for exposure to all types of artificially generated accelerations. This limitation accounts for the great individual and intraindividual differences in susceptibility to motion sickness but, of course, explains nothing.

Mechanisms and manifestations. When a susceptible person is exposed to an adequate accelerative stress, the resulting abnormal pattern of impulses to the vestibular system exceeds the capacity of the vestibular systems to maintain a state of equilibrium, or homeostasis, with two distinguishable consequences. The first consequence is confined to the vestibular systems proper and is manifested by disturbances in normal responses. The second consequence involves a "failure" in homeostasis, allowing the irradiation of vestibular activity to reach foreign servation systems; the manifestations evoked include the typical symptoms of motion sickness and are superimposed on any manifestation of the first. The fact that, in this case, manifestations appear that have their immediate genesis in nonvestibular systems implies a linkage of a temporary nature with the vestibular systems. Thus the main chain of events involves the vestibular systems, a facultative linkage, and the nonvestibular systems that will be considered in turn. Through selection of subjects and control of stimulus it is possible to bring about vestibular perturbations without causing motion sickness. Typical responses include nystagmus (rapid involuntary eye movements), disequilibrium, and "sensations" of turning that have the characteristics of reflex phenomena. Continued exposure to a constant level of accelerative stress leads to their disappearance through the mechanisms of adaptation; a specific mechanism involves the establishment of new central nervous system integrative patterns, and a general mechanism may involve activity arising from the vestibular systems. Adaptation both to these sensorimotor perturbations and to motion sickness takes place in the vestibular systems proper. Vestibular aberrations and hence motion sickness can be avoided when an otherwise intolerable level of stress is reached by incremental steps; indeed, this is one of the keys to the prevention of motion sickness.

Perturbed vestibular responses without motion sickness

Little is known concerning the facultative linkage. The

fact that irradiating vestibular activity is demonstrably open to modulating influences points to the use of common pathways in the brainstem reticular formation. The sometimes long delay in appearance of motion sickness suggests that a chemical linkage also may be involved.

Response of nonvestibular systems

The manifestations having their immediate origin in nonvestibular systems are far more widespread than the overt signs and symptoms of motion sickness mentioned earlier. These responses do not have the characteristics of typical reflex phenomena and are absurd in terms of the needs of the organism. Unfortunately, there has been no systematic attempt to categorize these manifestations as first-, second-, or third-order effects and their complications. The release of antidiuretic hormone (which reduces the output of urine), and the appearance of stress hormones (catechols and corticoids) in the urine testify to the general nature of the signs and symptoms when the stress is sufficient and sufficiently prolonged.

The recovery from motion sickness during continual exposure to the stressful accelerations is complicated. The nonvestibular systems must first be freed from outside influences (vestibular activity, chemical agents), after which restoration takes place spontaneously through homeostatic events and processes. Curves depicting the time course of these events overlap, but as yet these curves have not been clearly defined.

The responses evoked on sudden return to a stationary environment depend on the level of adaptation acquired in the vestibular systems and upon whether restoration was complete in nonvestibular systems. If adaptation is incomplete, one experiences both a loss of muscular coordination and motion sickness; if complete, motion sickness is absent.

The roles of vision, distraction, illness

Secondary influences. It may be concluded that any factor tending either to evoke or inhibit a response characteristic of motion sickness will affect susceptibility accordingly. Vision plays an important role. A pilot, for example, free of symptoms in the cockpit, may experience motion sickness in the navigator's closed compartment. Mild symptoms of motion sickness have disappeared under the influence of experimenter-directed tasks that may have preempted central nervous system pathways used by irradiating vestibular activity. Illness may raise susceptibility greatly; indeed, a provocative test may bring out the symptoms of the disease before they would otherwise have appeared.

Prevention. The prevention of motion sickness is a highly individual matter. Persons differ not only in their inherent susceptibility to unusual accelerations but also in the roles played by secondary factors, in the acquisition and decay of adaptation effects, and in the effectiveness of drugs. Assessment of these factors could be made in the laboratory, but for the great majority of persons it is a matter of self-appraisal under travel conditions by land, sea, or air. The more complete this assessment and the more precise the knowledge of the duration and conditions of travel, the greater the opportunity to exploit preventive measures. It is particularly important to guard against the false security that may be engendered by the delay between the onset of exposure and the onset of overt symptoms.

It will be apparent that certain options suggested in the following discussion are not available to everyone and that certain trade offs are "judgment" decisions.

Minimizing accelerations. The single most effective measure is to fix the body, especially the head, with reference to the vehicle. Minimizing accelerations in a particular vehicle involves such things as seat location and time of day in an aircraft and cabin location and time of year in a ship. Choice of vehicle for a given mode of travel may be important; *e.g.*, flying above turbulence in a jet aircraft and use of stabilizers in a ship.

Incremental exposure. This measure is at once highly effective and highly impractical except in using private conveyances. Any incremental exposure to stress on a particular trip in common carriers is a fortuitous matter. The traveller does have the option of gradually increasing the duration of trips and, to some extent, choosing favourable conditions. On long ocean voyages, during an initial period of calm at sea, moving about would increase the rate of adaptation; and this might even be extended to less favourable conditions under the protection of drugs. This is a bit risky, however, for the inexperienced.

Secondary factors. Unless vision is used to "lock" onto the horizon or to engage in activities resulting in competitive inhibition (distraction), there is less tendency to motion sickness if the eyes are closed. Certain illnesses, especially those with gastrointestinal symptoms, may increase susceptibility to motion sickness. Susceptibility is lessened if the most pleasant atmospheric conditions are sought or arranged and if the thought is kept in mind that the very motions evoking symptoms also result in adaptation, which may be near at hand.

Drugs. Persons who are in the passenger category do well to test a "new" drug for its side effects prior to travel. A combination of l-scopolamine hydrobromide and dextroamphetamine sulfate, taken 40 minutes before departure, affords some protection for several hours. Four hours later the dose is repeated unless the trip will soon be over. There is need of caution both in continuing the prescribed dosage and in using larger doses that afford increased protection. Promethazine hydrochloride, with minimal risk of side effects, is a good substitute for scopolamine. Ephedrine is only a fair substitute for amphetamine but has minimal side effects.

Several drugs in the antihistamine category decrease susceptibility to motion sickness, including diphenidol, dimenhydrinate, cyclizine, and meclizine. The last named is effective over periods up to 24 hours.

Today many persons are under therapy with drugs that may cause nausea. It is highly desirable, therefore, to seek professional advice with regard to continuing these drugs.

Therapy. The inexperienced person with motion sickness needs the best available professional help. Once symptoms of motion sickness are established, appropriate preventive measures are taken, as have just been described; but drugs taken by mouth may either remain in the stomach or be regurgitated. The most effective measure, recommended only for long trips, may involve injection or rectal administration of a soporific drug in an amount to ensure sleep.

BIBLIOGRAPHY. K.E. MONEY, "Motion Sickness," *Physiol. Rev.*, 50:1–39 (1970), provides the most recent comprehensive review in which motion sickness is treated mainly as a medical syndrome. The conceptual approach in the present article represents essentially a condensation of a report by A. GRAYBIEL, "Structural Elements in the Concept of Motion Sickness," that appeared in *Aerospace Med.*, 40:351–367 (1969). Anti-motion sickness drugs are considered at some length by S.C. WANG, "Emetic and Antiemetic Drugs," in *Physiological Pharmacology*, 2:255–328 (1965). Recent evaluations of representative anti-motion sickness drugs are described in two articles by C.D. WOOD and A. GRAYBIEL in "Evaluation of Sixteen Anti-motion Sickness Drugs," *Aerospace Med.*, 39:1341–1344 (1968); and "Effective New Motion Sickness Remedy," *ibid.*, 41:932–933 (1970).

(A.G.)

Motivation

The term motivation popularly refers to the causes of behaviour; *i.e.*, whatever it is within the individual that incites action. The term motive is commonly applied to fairly specific causes. Thus, it often is said that someone is highly motivated for success and, more specifically, that success serves his motive for achievement or for power, status, recognition, or some other more specific motive. Yet, motivation can hardly be the sole basis for success; one must have ability, training, knowledge, and many other characteristics to achieve specific goals. What this popular definition effectively implies would seem to be the mainspring of success: the characteristics that drive one person to achieve a particular end that another individual with similar endowments apparently lacks.

The word motivation comes from the Latin term *motivus* ("a moving cause"), itself derived from *motus* ("moved"). The implication that it refers to the springs of action seems evident in such phrases or words as motive power, motive force, automotive, and the like. Not until the 20th century, however, did "motivation" seem to enter

the vocabulary of philosophy and psychology. The concept was not in the *Dictionary of Philosophy and Psychology*, publication of which was completed in 1911; the word motive was listed, but in the sense of an awareness of desire or purpose rather than as a moving force.

HISTORICAL OVERVIEW

According to the hedonistic principle, human actions are governed by a calculus or combination of pleasure and pain. Although hedonism in this sense is a motivational factor, the full advent of motivational ideas among psychologists was not to come until the latter part of the 19th century, following the development of Charles Darwin's theory of evolution (*Origin of Species*, 1859).

Among the significant effects of Darwin's theory were these: first, that man and more primitive animals were seen as being parts of the same continuum, rather than as sharply demarcated from one another as rationalist ideology had held; second, that the structural and behavioural characteristics of all animals, including man, were regarded in terms of their survival value or of their usefulness for adaptation to a particular environment. These effects were far reaching. As to the first effect, it suggested that if less completely evolved animals have instincts, so also does man (and if man has reason so also may other animals). This has been summarized as leading to the "brutalization" of man and to the "humanization" of animals. The effect led to the development of comparative psychology and to an emphasis on instincts in the control of human behaviour.

Impact of Darwin's evolutionary system

The second effect was equally, if not more, important. It made relevant the study of behaviour as a means of adaptation to situations and environments. Prior to this time there had been little interest in the empirical study of behaviour, and psychological approaches to the study of man largely had been confined to determining the contents of consciousness, the elements of which these contents were constituted, and the rules for the combination of the elements into larger units. This view of the task of psychologists (held by Wilhelm Wundt [1832–1920] and Edward B. Titchener [1867–1927], for example) had no room for motivational determinants as they are defined by contemporary theorists. But evolutionary theory produced functional psychology, whose adherents were mainly interested not in what *is in* awareness, as Wundt and Titchener were, but rather in what consciousness *is for*; *i.e.*, how awareness functions in the organism's adaptive interactions with the environment. Functional psychologists also broadened the task of psychology to include not only conscious functions but the whole range of the behavioral repertories of animals. (Behaviourism, a later development, simply eliminated the study of conscious states from the functionalist program.)

For the study of motivation, the first consequence of evolutionary theory, then, was a primary stress on notions of instinct, man's behaviour being interpreted as the manifestation of many instincts. William James (1842–1910) wrote that human beings have more instincts than do any other animals, and many other writers attributed instinct after instinct to man. One writer facetiously went so far as to propose that there is an instinct to believe in instincts. Almost any behaviour came to be called instinctive. Unfortunately, instincts were proposed without empirical support or with only the most casual sort of evidence. There was little scientific value or gain to this uncritical, proliferative invention of instincts, and there was such a powerful reaction against this trend that the word instinct came into disrepute, almost disappearing from the psychological vocabulary for a number of years. The term began to return to popularity in the 1950s, however, the earliest reappearance with some frequency being found in the writings of certain European zoologists known as ethologists. (Ethology is the scientific study of animal behaviour.)

Motivational concepts survived, however, and it is to three individuals that this survival may be attributed: William McDougall (1871–1938), Sigmund Freud (1856–1939), and Robert S. Woodworth (1869–1962). All of them wrote of instincts, but the real emphasis of these men lay on energetic sources of conduct, by whatever names they might be called.

Instinct as the driving force

McDougall identified his point of view as hormic psychology, the term hormic being derived from the Greek word *hormē* ("impulse" or "striving"). He defined the instincts as being the prime movers of conduct, stating that without them the organism would be inert. Purpose, goals, and striving he saw as the hallmarks of human conduct. He wrote that the instincts in human beings determine not only perception of and attention to relevant objects but also generate emotional excitement when such objects are perceived and produce impulses to act toward the objects in some way. McDougall saw mankind essentially as driven by irrational instincts, and he posited a need to control these as the main reason for socialization. In his theory of personality he provided for the control of instincts through the concept of what he called the sentiment, much as Freud did in his theory when he invented the notions of the ego and the superego. McDougall's contributions are important, especially in the history of academic psychology, because his stress on impulse and striving had to be acknowledged. While his extreme emphasis on instincts was later abandoned by others, his concern for impulsive sources of action was not, being incorporated into the contemporary concept of drive.

Like McDougall, Freud emphasized the irrational, impulse-driven aspects of human conduct and proposed that it rested on an instinctive basis. Freud was most especially concerned with the unconscious character of these motivational factors (McDougall was not) and suggested the existence of fewer specific instincts than did McDougall. Since Freudian theory has survived as a pervasive influence, it will be treated more fully below.

Woodworth, who brought the term drive into the psychological lexicon, regarded instincts as useful concepts but distinguished two features in the preparatory and consummatory behaviour of which he said they were composed. One of these features he called the mechanism, the other the drive. The automobile is an illustration of what Woodworth meant: it has mechanisms for imparting motion to the wheels and mechanisms for steering them, and all of the structures are present, whether the machine is moving or at rest. The mechanisms require a supply of energy or a force to make them go. It was this force that Woodworth identified as drive. Thus Woodworth performed the service of distinguishing between mechanisms and drive as two important components of action. His neutral term drive served in lieu of the more controversial term instinct.

THEORIES OF MOTIVATION: MOTIVES AND GOALS

Although there are a number of theoretical views of motivation, it seems fair to say that no one of them can be considered as fully adequate. In a number of respects these theories are not directly comparable. To some extent, the adequacy and comparability of the theories are difficult to judge in that they tend to define the problem and function of motivation differently, especially since their origins lie in attempts to cope with differing sets of phenomena. Before entering into descriptions of particular theories of motivation, it will be helpful, first, to comment on the following three general issues that pervade the subject.

Homeostatic mechanisms. Homeostatic regulation is a familiar concept when exemplified by the thermostat in a residential heating system. Such a device is sensitive to temperature variations, and, when the temperature falls below a selected point, it will switch on the furnace; likewise, the thermostat is set to turn off the source of heat energy when the temperature has risen to some designated value. The thermostat serves thus so to regulate the production of such energy by means of the furnace that the temperature of a room or of a house remains relatively constant within a narrow range of variation. The tendency for such an arrangement to produce more or less constant temperature can be referred to as homeostatic, although the term homeostasis ordinarily is applied to biological systems. In physiology there are constant levels that regu-

latory processes function to maintain. For example, when a person's body temperature rises, perspiration increases, functioning to regulate the level through the loss of thermal energy through evaporation. When body temperature falls, other regulatory processes (*e.g.*, shivering, increased muscular activity) come into operation to generate more heat.

Many writers have depicted behaviour as a regulatory process, called into play by some imbalance in bodily or psychological forces, and functioning to restore a state of equilibrium. Imbalances are considered as being motivational states and as ranging in kind from such conditions as deficiencies of food or water in the body to deficits or excesses in the external stimulation that impinges on the body's receptor structures. Homeostasis can be used as a relatively precise physiological term, but often it is employed in such a loose way that it can be made to fit a much broader set of circumstances. The notion of homeostatic regulation runs through much of the theorizing about motivation; depending on the set of assumptions that characterize any given writer, however, it has been disputed and denied.

External and internal determination. In some theories (McDougall's for example) motivation seems to be treated as having an internal bodily locus and as being an impulse that propels the organism into action. In other theoretical systems, however, the emphasis is on sources in the surrounding environment that may be said almost to pull or push the organism toward them or from them.

Role of motivation in behaviour. Behaviour varies in many ways; it occurs or it does not; it is produced in varying amounts and at different speeds; it is initiated slowly or rapidly; it may be intense or weak, broad or narrow in its scope. These variations are essentially *quantitative*; *i.e.*, any given behaviour (such as eating) can be described in terms of its different degrees as being strong or weak, fast or slow, and so on. Behaviour also may be seen to vary in *kind*: there may be eating, drinking, or mating; approach or withdrawal; concentration on one goal rather than on another. Such qualitative differences are commonly employed to indicate what usually is termed the direction of behaviour; the quantitative variations mentioned first in this paragraph reflect an energetic component in any kind of behaviour.

To some theorists it is the direction of behaviour that requires the motivation concept. Direction implies qualitatively different goals, purposes, choices, preferences, and decisions; it is such processes that these theorists hold to require motivational factors for their explanation. By contrast, other writers suggest that motivation is not a necessary notion in accounting for direction, preferring to rely on other concepts (such as habit) to explain qualitative behavioral variation. In the view of such authors it is the quantitative dimensions, reflecting changing levels of energy expenditure, to which the motivation concept is pertinent. In their view, motivation serves not to direct but to energize behaviour.

In what follows, the three issues just summarized will be apparent in the exposition of representative theories; the discussion will focus on classes of theory, giving an account of a specimen typical of each. No effort will be made to detail or even name the richly diverse variants within these classes.

Psychoanalytic theory. Classical Freudian theory emphasized internal determinants and was homeostatic in character. It seemed to ascribe to motivation both the functions of energizing and of directing behaviour, perhaps emphasizing behavioral *qualities* most.

Freud modified his theory from time to time, so that the version summarized here represents his last formal efforts. In his accounts he postulated two major sources of instinctual energy: *Eros* (so-called life-giving instincts) and what he referred to as death or destructive instincts (sometimes collectively called *Thanatos*). These instincts were said to be located in a presumed, large unconscious part of the personality known as the id, from which other parts of the personality (what he named as the ego and the superego) were held to emerge. The personality was portrayed as providing a structure for the discharge of the instinctual energy, but the instincts themselves had directional components as suggested by their names.

Freud postulated death-destructive instincts in the light of observations of a general prevalence of aggressive and suicidal acts among his patients and in the rest of the world about him. He seems, however, never to have set forth the detailed nature of these instincts as clearly as he did for Eros. (In passing, it may be noted that other psychoanalysts have not always accepted the instinctive character either of Thanatos or of Eros. Some of them have indicated that the German word *Trieb* in Freud's writings could have been translated by the term drive as well as by the word instinct.)

Any infant was seen by Freud as containing a relatively undifferentiated amount of so-called psychic energy (named libido) that, in the course of each child's development, underwent successive changes in the parts of the body where it achieved the most pleasurable discharge. Psychosexual stages

Freud spoke of erogenous zones (the mouth, the anus, and the genital area); if all proceeded properly, the libido was first to be expressed through the mouth (oral stage), next via the anus (anal stage), and then, in the period of infantile sexuality, was to focus on the genitals (phallic stage). The phallic stage was held to be followed by a latency period during which sexual expression was at a minimum; the eventual genital stage, if reached, would occur in the psychosexually mature adult.

Freud characterized instinctual energy as requiring discharge and as accumulating if not vented. It seems obvious that there was a limit to the amount of energy that could be accumulated before discharge was necessary. (This formulation has been interpreted as following a hydraulic model.) Discharge was described as often being delayed, since the environment rarely can be so arranged as to meet the young child's needs immediately. Hence, frustrations in dealing with the environment were expected to be experienced by the child at a very early stage in life. These frustrations are seen by some psychoanalytic theorists as essential for initiating the development of the ego.

The unbridled discharge of libidinal energy at any stage (especially in the Victorian society of Freud's middle-class, turn-of-the-century Vienna) was described as meeting with disapproval and punishment. Yet, it was felt, discharge must be arranged, and another reason for the development of the ego was theorized to make this possible.

The ego was depicted as a kind of executive of the personality structure. It was said to serve the id, tending to reduce or to prevent frustration by permitting discharge of libido while also carefully acting to disguise the ways in which the discharge was permitted so that punishment and disapproval would not follow. The ego could be said to follow what Freud called the reality principle in its operations, whereas the id was described as following only the pleasure principle. The ego was supposed to react by producing anxiety when punishment or disapproval were foreseen to be in the offing. Anxiety in Freudian theory is a major activity for keeping expressions of libidinal energy in check through the ego. Another part of the personality, the superego, was offered as an internalized set of parental (and other social) prohibitions and standards, having the ability to punish the ego and to induce anxiety via a threat to diminish self-esteem.

According to Freud the ego then must mediate among the demands of the id, prohibitions and threats of environmental reality, and the moralistic functions of the superego. The ego was presumed to employ a number of devices, sometimes called dynamisms, or defense mechanisms, that permit discharge of energy from the id yet disguise the nature of the discharge to avoid censure by the superego and the anxiety that this would bring. Among these so-called ego-defense mechanisms were named such dynamisms as repression, sublimation, reaction formation, regression, isolation, undoing, projection, introjection, turning against the self, and reversal. Two of these many different mechanisms can be sketched here as illustrative. Defense mechanisms

When a young boy reached the phallic phase, his libidi-

nal energies typically were to be directed to his mother as the object suitable for gratification of his phallic wishes. (Freud named this the Oedipus complex.) The boy was said to be threatened, however, by the fear of what his father would do to him (castration anxiety) were he to follow through sexually on his impulses toward his mother. This anxiety commonly was expected to be so great that to overcome it he was supposed to repress (forget, become unaware of) his impulses and the memories associated with them and to enter what Freud called the latency phase. Presumably, the maintenance of this severe repression (by which Freud accounted for the amnesia people commonly report concerning their first years of life) requires the expenditure of a great deal of energy. At any rate, the repression was seen as protecting the ego from the anxiety it would have without such unconscious forgetting.

The ego also was empowered to channel energy into behaviour that counteracted behaviour the id instincts would generate if left unmodified. For example, if expression of anal tendencies were the basic impulse, the ego was held to channel this energy into the behaviour of excessive cleanliness; *i.e.*, to employ the mechanism of reaction formation, thus avoiding the anxiety that direct expression of the anal impulse would engender, while still permitting some discharge of energy. When successful, all of the dynamisms of defense were understood to have the function of permitting discharge to a greater or lesser degree while avoiding anxiety.

This brief summary has been designed to underscore the all-important roles that Freud attributed to instinctual energy and to anxiety in the production and control of behaviour. There are few theories of behaviour that have been so firmly committed to and dependent upon motivational determinants as Freud's. Later psychoanalysts, as well as some of Freud's contemporaries, such as C.G. Jung, O. Rank, and A. Adler, disagreed with Freud in many respects. But the emphasis on unconscious motivational determinants of conduct remained a central core in the thinking of most of them.

Drive theory. It will be recalled that Woodworth characterized drive as the force of energy that activates the mechanisms that subserve behaviour. As the term instinct began to fall from fashionable use in the 1920s, "drive" emerged as the major motivational concept of the functionalist tradition in psychology. There were two primary interpretations of drive. The first was that of drive as an internal, bodily stimulus condition epitomized in the theory of the U.S. physiologist Walter B. Cannon (1871–1945) that the experience of hunger arises from the contractions of the empty stomach and that the feeling of thirst stems from dryness in the mouth and throat; other drives (such as that said to energize sexual behaviour) were understood to have similar sources in local stimulation involving appropriate bodily structures. The organism was described as being goaded into regulatory acts by these uncomfortable stimulus conditions, the relief of which was to occur when consummatory behaviour took place. This formulation clearly emphasizes internal sources and has a homeostatic character; and it was actually Cannon who coined the term homeostasis.

While a substantial body of empirical data supported Cannon's local, peripheral conception of drive, there were many contrary results as well, so that the theory began to lose favour. Behaviour that commonly is interpreted to signify hunger persists in experimental animals whose stomachs have been removed or have been denervated; similar findings are obtainable for evidence of sexual behaviour and for signs of thirst. Human beings, for example, may report that their feelings of hunger persist even when the stomach remains full of food while passage to the small intestine temporarily is blocked. The hunger experience persists with no notable change according to ulcer patients who have been vagotomized; that is, those in whom a branch of the vagus nerve has been cut to alter the actions of the stomach. Men who suffer desert thirst persist in drinking even after wetting their mouths and throats. Sexual desire continues to be reported by humans who have undergone castration and other operations involving the genitals (including denervation). Although there are clear experimental grounds for attributing partial validity to the theory, evidence of these kinds patently is incompatible with it.

Drive as a central state

A second interpretation characterized drive as a central state. The basic idea here was that in some way depletion or (in other instances) repletion of body tissues sets up more or less diffuse internal conditions that instigate the organism into activity. Such activity was seen as regulatory, since it was thought that the more active an animal is the more likely he is to find the goal objects necessary to relieve the internal tension arising from depletion or repletion of tissues.

Several types of evidence were compatible with this interpretation. For example, as the length of time that an organism is deprived of food or water increases, eating or drinking is observed to increase in amount and rate when food or water becomes available. Similarly, animals tend to cross an electrified grid to reach an appropriate incentive more frequently after prolonged deprivation (within limits) than after short periods of deprivation. Hormonal states seem to be important to the readiness with which some activities are likely to occur in many species; seasonal sexual behaviour, heat in females during only a part of the sexual cycle, seasonal migrations, and maternal behaviour are examples. These suggest a diffuse, internal, hormonal basis for the instigation of the activities in question. When animals have food available at all times, periodicity in eating also suggests internal regulation, as does evidence for such specific hungers as in the preference and heightened intake shown for dietary substances (*e.g.*, sodium salt compounds), of which deficiencies have been established experimentally.

It is understood that in all of these instances, an incentive (food, water, a potential mate, for example) is present at the time the behaviour indicative of drive occurs. Another source of evidence for the central-state interpretation is general activity, studied extensively by the U.S. physiologist Curt P. Richter and his students who found, for example, an activity rhythm in laboratory rats over 24-hour periods. Activity was low following feeding, remained low for some hours, and increased to a peak as the next feeding time approached. This rhythm clearly seemed to support the notion that internal factors instigate nonspecific activity; the general principle seems to be that as drive mounts activity increases.

Internal conditions, then, leading to homeostatically regulatory behaviour, were the prime notion of drive theory (as far as biological needs or drives are concerned). It was recognized readily that unmodified biological drives alone were an insufficient basis to account for all of animal motivation, and the concept of secondary or learned drives was added to complete the picture. In the development of a learned drive, a stimulus situation (or, particularly in humans, a symbolic process) was thought to gain motivating power by becoming associated through experience with a biological drive state. As an example, consider the learning of fear among laboratory animals. A two-compartment box that has a hurdle between its two sides may be employed. If a rat is placed in one compartment and shock is applied to his feet by electrifying the floor, he is quite prone to escape to the other (shock-free) compartment. If the administration of the shock is signalled ahead of time by flashing a light or by a buzzer tone, the animal will begin to learn to avoid the shock by jumping into the electrically safe compartment before the shock is given. Learning to escape the shocks presumably is motivated by the rat's painful experiences, but learning to avoid them is inferred to be motivated by the animal's anticipation of the pain, this posited anticipation being referred to as fear. In this situation fear is a learned drive, and the anticipatory avoidance developed by the animal is quite persistent. It was believed that the addition of many such learned drives based on a full range of biological motives (such as hunger) would help provide a full account of the complexities of human motivation.

As drive theory developed and was incorporated into a general behaviour theory, it was suggested that a drive contains two components, only one of which was consid-

ered motivational. One component was identified as embracing the stimuli associated with the drive and as being correlated with such factors as the local sources of the stimuli and the length of time the organism is deprived of consummatory behaviour. The other component was the energizing factor; *i.e.*, it was posited that any internal state corresponding to drive somehow could prime into readiness any learned habit or unlearned behaviour of which an animal was capable. The drive stimuli were thought to impart selective direction to behaviour, but this function was said to be associative rather than motivational. The energizing function, however, was conceived as being motivational and nonspecific; it would prime for action any and all behavioral tendencies. Thus a particular habit originally may have been learned under the impetus of one drive but was held to be subject thereafter to activation by other drives as well. In this form of drive theory, drive was described as being internal and was homeostatically conceived but was not assigned a directional function for behaviour; direction was attributed either to habit or to unlearned stimulus-response connections.

In this formulation the promptings of drive were held to be stilled by consummatory behaviour, and activities followed by such consummatory behaviour were represented as what animals learned. In other words, learning was supposed to occur as a consequence of reward or reinforcement, conceived by theorists as drive reduction or tension relief.

Together with psychoanalytic motivation theory, to which it has some strong resemblance, drive theory dominated the study of motivation by North American psychologists from about 1920 to about 1950. After 1950 drive theory declined in influence. There are several reasons for the waning of the theory, and these reasons have led to the suggestion of alternative theoretical views of motivation. The summaries of alternative accounts in the following sections incorporate some of the reasons for the decline of drive theory.

Arousal theory. Arousal or activation theory came to prominence in the early 1950s. It arose primarily from studies of emotional behaviour in conjunction with selected neurological findings. A number of other discoveries or findings that appeared at about the same time, independently of arousal theory, not only offered challenges to drive theory but also seemed to fit well with the notion of arousal theory.

The electroencephalogram (EEG) is a record of the electrical activity of the brain. Such records for humans and other animals exhibit a number of patterns. Readily identifiable variations in these electrical rhythms were interpreted as reflecting inner states by a number of investigators. For example, it was suggested that a pattern of rapid, low-amplitude fluctuations in electrical potentials recorded from humans and other mammals corresponds with alert, excited, and emotional states; regular, slower, and larger amplitude fluctuations in potential tend to appear when a subject seems to be in a relaxed state; even larger and slower fluctuations are likely to be observed when a subject shows signs of sleep. The suggestion was that there is a continuum covering the range from low to high arousal, and that several different levels of arousal could be inferred from their characteristic patterns of EEG activity. It had been suggested that emotional states correspond to a relatively high degree of arousal. It also had been proposed that behavioral efficiency is greatest at intermediate levels of arousal, being low both at the relaxed-sleep end and at the excited or emotional extreme. Evidence accumulated showed that, to a substantial degree, arousal of the cortex (outer surface) of the brain was a response to activity in the ascending fibres of a structure (the reticular formation) found in the brain stem. Stimulation or destruction of these reticular activating tissues was found to produce signs of arousal or of a decline in the bioelectric evidences of cortical arousal. Although some data were obtained empirically that behavioral performance was more effective at intermediate levels of arousal than at the extremes, this evidence was neither very clear nor unequivocal. It further was posited that intermediate levels of arousal would be perceived by the individual as desirable or pleasant, so that both increases from low levels of arousal as well as decreases from high levels of arousal could be rewarding. The incorporation of the idea that increase in arousal would be a rewarding state clearly seems inconsistent with theories that hold all reinforcement in learning to require drive reduction or tension relief.

Empirical discrepancies with drive theory

Meanwhile, a number of findings were being reported that were interpreted as posing difficulties for homeostatic drive theory. One of these groups of data provided evidence for curiosity as manifested in the behaviour of a variety of animals. Thus, animals in the laboratory were found to explore their environments, to manipulate objects, to evince orientation and attention to novel stimuli, and to exhibit preferences for situations and objects that the observers judged to be novel or unfamiliar. In all of these cases, there seemed to be no obvious way in which these behaviours could be attributed to the operation of the postulated primary (or biological), homeostatic drives. Further, it was shown that animals would learn when the reward seemed to be simply an opportunity to explore or to encounter novelty, a kind of reinforcement that is not readily attributable to tension reduction. Direct, experimental investigation also showed that moderate increases in the degree of stimulation often have reinforcing effects. One consequence of this work was that postulated new drives such as curiosity and exploration were added to the list. Theorists also were led to question whether reductions in drive and tension were necessary conditions for reinforcement in learning.

An additional set of evidence was obtained from laboratory work with human subjects who had volunteered to be confined under conditions of sensory deprivation. For example, they might stay in a small, sound-deadened room, wearing goggles and special cuffs over their limbs to further reduce the amount of sensory stimulation they received, and they were given nothing in particular to do. Environmental stimuli were substantially eliminated under these conditions, and, according to some interpretations of drive theory and psychoanalytic motivation theory, it might have been expected that the subjects would enjoy this ostensibly tension-free situation. (Indeed, typically they were being paid well for their service as subjects.) Yet, after a time (usually within a day or so), most of them had found the situation intolerable to the point that they urgently left to find higher levels of sensory stimulation. Many said they experienced hallucinations and showed other abnormal symptoms while confined under these circumstances. The results were interpreted to mean that people have a need for stimulation, perhaps at some optimal level.

Other findings during the 1950s that did not seem to accord well with a tension-reduction view of reinforcement included the discovery of so-called pleasure centres or reward centres in the brain. Electrodes were permanently implanted in various parts of the brains of such animals as rats, and stimulation from the electrodes in some of the tissues served to reinforce and maintain behaviour on the part of the animals. A rat would work to the point of exhaustion to obtain the stimulation. Other parts of the brain that seem to produce unpleasant or aversive responses under electrical stimulation also were identified.

While there is a similarity between the concept of states of arousal and the nonspecific drive as posited in drive theory, arousal theorists proposed a much more inclusive set of antecedent conditions. According to drive theory, on the other hand, time of deprivation is the chief factor for manipulation in eliciting motivated behaviour. There is an unquestionable degree of vagueness in arousal theory, since the state of arousal is not tied to specific antecedent circumstances. Nevertheless, arousal theory in some form has had a wide appeal and serves to provide a popularly acceptable basis for interpreting stimulation and information seeking, curiosity, and the like as motivational factors. It stresses factors that are external rather than internal, and to the extent that the theory is homeostatic, stimulation is the variable that is held to be

maintained at an optimal level. Arousal does seem to be offered as a general, energizing state, rather than as acting to direct the organism's behaviour.

Incentive theory. It long has been observed that incentives (that is, goal objects such as food or sexual partners) exert a powerful influence in behaviour. For example, laboratory rats were found to perform better in maze learning when particular incentives were used than when others were offered (efforts being made to hold drive constant). Selective preferences among food substances are manifested by these animals, even when they are not judged to be hungry.

Incentive theory came to prominence in the 1960s on the basis of evidence that appeared to be embarrassing to drive theory. Though major support for drive theory had been found in an observed increase in an animal's general activity as the duration of deprivation was prolonged, clear evidence now available indicates that the relationship is the result of functions that are neither automatic nor innate but learned.

In the animal experiments conducted through which the relationship was demonstrated, feeding occurred at predictable points in time. When animals are deprived of food for the first time (say, for three days) activity does not appear to increase substantially; but when subjects are fed regularly every 24 hours they appear gradually to become active in anticipation of feeding time (*i.e.*, apparently they learn to anticipate the appearance of the goal object or incentive).

Other evidence that clearly fails to conform to drive theory and that points to external incentives comes from studies made of such hormonally based activity as sexual behaviour. For example, male rats show no sexual behaviour (even though they are hormonally primed for it) in the absence of a female in heat. Even in her presence a considerable amount of mutual stimulation seems to be necessary before the threshold for actual copulatory behaviour is reached. Consummatory behaviour and crossing an electrified grid to reach an incentive require the presence of exhibited incentives. Such behaviour is not reliably elicited when the incentive is obstructed or screened from view. Specific hungers (*e.g.*, under calcium deprivation) also do not function as automatically and as efficiently in regulating dietary imbalances as earlier research had suggested. There is evidence for apparently inappropriate choice of foodstuffs under some circumstances. Periodicity in feeding, reported for groups of animals when food is always available, has been demonstrated to hold only when the average behaviour of a group is considered. Episodes of eating and noneating in individual animals were observed to be ordered randomly rather than periodically.

Incentive theory in the 1970s was not fully developed. It relied on a general process of arousal or activation that was seen to be instigated by incentives. The U.S. psychologists Charles N. Cofer and Mortimer H. Appley suggested two mechanisms in describing such instigation. In their anticipation-invigoration mechanism (AIM), animals learn to be aroused by the presence of or the imminent occurrence of a given incentive. In their sensitization-invigoration mechanism (SIM), which applies to behaviour not obviously learned, arousal appears (as in sexual behaviour) in the presence of an incentive and a suitable hormonal condition. In some way not yet understood, the latter is held to sensitize the animal to be responsive to the incentive object without learning. Cofer and Appley identified the motivational aspect of the incentive mechanism as being the general arousal, holding that direction of behaviour is supplied by the stimulus conditions of the situation through learning or innate relationships. (These conditions include the incentive itself.) External factors possess an obvious importance in this analysis and, in general, some optimal level of arousal would be postulated.

Hedonic theory. Hedonic theory is similar to arousal theory and incentive theory in rejecting the notion of drive and in emphasizing external objects and situations. It differs from them in specifying that the arousal is affective: pleasant, unpleasant, or neutral. In hedonic terms, behaviour is conceived as being ordered on a continuum of approach and withdrawal. Approach is described as being manifested toward goals, situations, or outcomes that are anticipated by the organism as pleasant, avoidance being shown when the individual's anticipation of contact with the incentive condition is that it will be unpleasant. The theory reinstates the principle of hedonism, long considered significant in the control of conduct (*e.g.*, Epicurus).

The idea was offered that pleasantness and unpleasantness represent departures from a level of adaptation to prevailing conditions, small deviations being perceived as pleasant and large discrepancies being experienced as unpleasant. The concept formalized as adaptation level (AL) was interpreted to mean that at any given time either an individual has adapted or must adapt himself to past and prevailing levels of stimulation. Movement toward or away from specific objects is held to change the individual's AL. Given an AL for some situation, then, one view was that motivation of approach or avoidance will arise on the basis of one's anticipated deviations from that level if he moves with respect to the objects.

This hedonic theory represents a break with drive theory; it was distinguished by its proposition that all motives are learned and by its reintroduction of affective (emotional) processes as factors in motivation. The theory did not generate a great deal of empirical work and seemed difficult to test unequivocally. One problem was with its definition of the conditions for pleasantness and unpleasantness; it seemed likely that these reactions are not ordered well by deviations from AL alone, but that they are determined by favourable or unfavourable outcomes, whatever the deviation from AL. Hedonic theory, however, clearly identified a learned, general arousal state, instigated by anticipation of contact with incentives. It was homeostatic in the sense that the AL is a homeostatic concept; in this respect hedonic theory resembled arousal theory.

Conclusions with respect to theory. Theories of motivation, as the foregoing survey reveals, were in a rather unsettled state in the 1970s. Drive theory seemed to have fallen, leaving no single, systematic alternative that had yet risen to replace it. The trend, however, seemed to be in the direction of emphasizing external factors (or their surrogates), toward reliance on some notion of arousal, and toward supporting a postulate that there is an optimal level of arousal. In addition to this incomplete picture of alternatives, further suggestions of developments will be made below.

In passing, it may be mentioned that psychoanalysis had changed, too. The direction of the change was to provide for ego functions that, while they may be said to use the energy of the instincts, are, or may become, independent of the conflicts originally proposed as the reasons underlying their development. It would no longer be pertinent to say, as some psychoanalytical theorists once did, that a conception of reality would never develop without conflict and frustration. Ego structures, it now seemed, would develop anyway.

HUMAN MOTIVATION

With the exception of psychoanalysis, the viewpoints surveyed in the preceding sections constitute general theories. These systems are applicable in principle both to humans and to the behaviour of other animals, taking work with both human and infrahuman subjects as their empirical base and, in several cases, relying more on the latter than on studies of humans. Since it shares common elements with other theories (*e.g.*, drive theory), and, in view of its historical importance, psychoanalysis was included in the discussion above. Attention must also be given to formulations developed largely in conjunction with human beings, ideas that do not seem to have the general sweep of the theories already reviewed.

In general, these more limited notions may be divided into two classes; one focusses on specific human motives or needs; the other looks to situational factors or to their interaction with need factors as providing motivational support for human behaviour.

Needs and motives. In 1938 the U.S. psychologist Henry A. Murray published a catalogue of human motives, or what he called needs. These needs were distinguished as being either primary (biological, innate) or secondary (learned, acquired); they were seen as impelling behaviour and giving it a goal-related cast. Among the motives that Murray discussed were what he identified as needs for achievement, affiliation, power, dependence, and succor (the need to be taken care of), these being selected from among many more in the list.

Work on the needs listed by Murray largely has been limited to those called achievement, affiliation, and power; inquiry also has been directed selectively to other motives such as anxiety and aggression. Anxiety has been studied both in its own right and as a factor that might underlie other apparent needs, such as affiliation. Brief accounts will be given here of needs that Murray labelled achievement, anxiety, and aggression.

Achievement. By the 1970s achievement had been explored more fully than any of the others had been. The study of the need for achievement (abbreviated as nAch) can be considered under three headings: measurement, relationship to behaviour, and development.

Measurement: A kind of quantification of nAch was accomplished by having people write a story in response to each of several pictures (selected from Murray's Thematic Apperception Test, or TAT) and scoring the stories for imagery of achievement and for achievement-related themes. Achievement was scored when a story gave evidence that the person felt concern over competition against some standard of excellence. The scoring system was empirically based; *i.e.*, the elements to be scored were those features that had been found to distinguish stories written under experimental conditions designed to arouse competition with a standard of excellence from stories produced under relaxed circumstances or other competition-free conditions. The scoring system is not perfect from a psychometric standpoint but does seem to have acceptable reliability. (That is, measures obtained from the same story by different scorers tend not to differ markedly.)

Thematic Apperception Test

Relationship to behaviour: People vary in their nAch scores under ordinary conditions; *i.e.*, when no attempt to arouse achievement motivation has been made. Scores reflecting nAch have been found to be related positively to performance on an anagrams test and an arithmetic test, although the degree of relationship has not always been high and the evidence has not always been consistent. Similar findings have been reported for the validity of nAch scores in predicting college grades, recognition times for achievement-related words presented for brief visual intervals, estimates of the individual's level of aspiration, ability to recall the names of tasks that one has and has not successfully completed, and measures of risk-taking behaviour (as in gambling games or tests of skill). Some of this work has shown that the nAch score reflects elements of positive achievement as well as those relating to the person's fear of failure. In risk-taking studies, for example, people with high nAch scores have been found prone to take moderate risks when their chances of success are reasonable; such people do not seem to be interested in choices for which the chance of accomplishment is practically assured or virtually nonexistent. Risk-taking behaviour among subjects who are judged to fear failure differs from this pattern; such people tend to choose alternatives for which success appears certain or for which success seems so unlikely that they can hardly be blamed for failure.

One outcome of efforts to relate nAch scores to different kinds of behaviour is the conclusion that such relationships have complex sets of determinants. For example, the need for achievement is not always manifested; the situation apparently has to be identifiable by the individual as one involving competition with a standard before the need will be aroused.

Development: Evidence has been offered that the need for achievement is learned, and its origins have been identified in a general emphasis on independence training in the early childhood of those who make high nAch scores. There remained some uncertainty in the 1970s, however, as to exactly which prior experiences are related to the development of nAch.

Anxiety. Anxiety has been given considerable importance in some of the theories of motivation discussed earlier, but it has been given extensive empirical attention in research conducted only in a limited number of contexts. One of these involves anxiety as a basis for affiliative behaviour. It has been reported that when subjects were threatened with electric shock certain female subjects (those who were first-born children or only children) were prone to seek an opportunity to spend a waiting period in the company of others; later born subjects were markedly less likely to show this affiliative behaviour. Thus, at least among some people under given conditions, fear or anxiety seems to motivate such forms of social behaviour, and it does not appear necessary to postulate an affiliation motive in such cases.

In other contexts anxiety has been studied by making quantitative estimates of the levels of anxiety among people and then comparing the performance on selected tasks of highly anxious subjects with the task behaviour of those found low in anxiety. One measuring instrument for this purpose is the Manifest Anxiety Scale, which includes true-false statements concerning symptoms of anxiety; *e.g.*, My mind wanders; I have many headaches; I am easily embarrassed; I have frequent nightmares. Proponents of the view that anxiety is a drive have been especially prone to use this scale. These investigators tested people with the Manifest Anxiety Scale and then had them perform in other situations (such as classical conditioning routines and complex verbal learning tasks) in the expectation that level of anxiety would affect performance in accordance with theoretical predictions. The derivation of the predictions is technical and complex, but it can be noted that theoretical expectations usually have been verified in classical conditioning situations; results have been less consistent for the more complex tasks.

Another instrument, the Test Anxiety Questionnaire, also has been used to quantify anxious reactions under selected conditions. People judged to be highly anxious on the basis of this scale are reported to compare poorly with others on tasks in which they experience feelings of failure or threats of failure. On the other hand, the anxious subjects were observed to do as well as or better than did the so-called low-anxiety people in situations where there seemed to be no threat or in which they had experienced success.

Aggression. Aside from Freudian theory (and later contributions by such ethologists as Konrad Lorenz), most theorists have regarded aggression as a learned pattern for getting one's way. Hence, these theorists either do not consider such behaviour as expressing an aggressive drive or they have conceived of aggression as a learned drive expressive of anger or frustration. The frustration-aggression hypothesis (that frustration leads to aggression) is difficult to entertain as an accurate generalization since its validity is not always supported by observation. It appears that frustration does not lead to aggressive behaviour when the frustrating condition is not perceived by the individual as threatening, as emotion arousing, or as arbitrary. Neither is aggression the only consequence of frustration, and alternative responses among frustrated people have been observed. If aggressive behaviour has instrumental value in a situation or if it is frequently rewarded, it seems more likely to follow frustration. There are wide individual differences, however, and some people are said to have considerable tolerance for frustration, while others seem to have very little ability to resist frustrating stresses. Aggression may arise in a context of anger that is instigated by annoyances, insults, or attacks from others but tends to be short-lived under these conditions. Aggressive behaviour can be suppressed by punishment and augmented by permissiveness. Clear demonstrations of displacement of angry aggression (*e.g.*, the angry man who kicks his innocent dog) and of catharsis (emotional release) through angry aggression have yet to be made in the laboratory, although Freudian theory predicts that both should occur.

The psychological literature of aggression indicates the difficulty, as it does also for other human motives, of separating aggressive acts held to arise from anger from those said to occur because they are instrumental in reaching specific rewards. Anger-instigated aggression, however, would be the one of motivational significance as far as the possible existence of a motive of aggression is concerned. Yet, it is remarkable that the research literature offers only marginal support for the notion of an enduring motive of aggression based on anger, despite the heavy emphasis on aggressive expression in popular accounts of war, crime, and other social disturbances.

Aggressive behaviour, of course, need not require a specific motive for its appearance. Modern neurophysiological work may show (see EMOTION) that there are neural centres or more or less diffuse neural systems that mediate aggression. If their existence is substantiated, it could turn out that activation of aggressive behaviour depends less on anger than on properties of stimuli and situations that engage these structures in the nervous system.

A hierarchy of human motives. Three posited human motives, those to which major research attention has been devoted, have just been discussed. They have been considered, however, independently of one another. The question remains: are such motives organized in any way? The U.S. psychologist Abraham H. Maslow (1908–70) suggested the existence of a hierarchy of motives. In his formulation, the so-called physiological needs (such as hunger) were at the bottom of the hierarchy. Above them were the needs for safety and higher still were needs for belongingness and love; needs for esteem came next. At the top of the hierarchy he placed needs for self-actualization and for various cognitive and aesthetic goals. Maslow suggested that self-actualization was the ultimate and desirable goal but that it could not be reached until what he called lower needs were relatively well satisfied. Such lower needs were seen to dominate conduct unless they were satisfied or unless the individual felt no concern over their satisfaction, and it was held that higher needs cannot be expressed adequately in the unsatisfied presence of dominant lower needs. Of the motives discussed above, achievement probably should be classified as one of the esteem needs, and anxiety is probably to be related to the safety needs—that is, to a lack of safety. Maslow did not regard aggression as an innate need, as he did the others, holding it to be a reaction to frustration and to other conditions.

Maslow's hierarchy has had much appeal, but, although there are some data that support the idea that lower needs may dominate conduct at the expense of higher needs, there is little direct evidence for the notion. Maslow perceived the human personality as typically being caught in conformity to the demands of society. He wrote that such conformity is not necessary, proposing the idea of self-actualization as a condition that can be reached by everyone if he eschews the conformity brought upon him by the dominance of those needs at the lower levels of the hierarchy.

Situational and interactional factors. So far, this discussion has emphasized internal needs or motives (except in the case of incentives); this inner orientation has pervaded thinking about motivation. It is possible, however, to conceive motivation not as involving a list of stable motives but, rather, as embracing needs that arise from situation to situation. The theorizing of the German-U.S. psychologist Kurt Lewin (1890–1947) to a large extent represents this way of looking at motivation, and investigators that he influenced have stressed cognitive aspects of motivation. Lewin's orientation stemmed from Gestalt psychology, a movement in which the prime concern was with the process of perceiving.

Gestalt psychologists regarded perceptual experiences as the outcomes of a stimulus field in which there are stresses. An unbalanced visual figure, for example, was said to contain dynamic forces or stresses that would tend to make it be perceived or remembered in a regular, symmetrical, or balanced way. This is a dynamic theory, but the forces were posited not as arising from internal agencies (*e.g.*, the Freudian id) but from the stimulus field as imposed upon brain processes said to correspond (to be isomorphic) with the organization of the external, environmental field. In a sense Lewin applied these interpretations to the dynamics of action.

Lewin conceived of the person as existing from moment to moment in a life space with regions that could be in states of tension; when these states occurred, forces were supposed to be created that instigated symbolic or actual movement or attempts to move from one region to another. While the tension was depicted as being internal, it was held often to be created by the circumstances in the field at the moment, in interaction with the goals that the individual saw the situation as permitting him to reach. Thus, task completion was offered as one such goal, and failure to complete a task was expected to lead to a continuing tension that would make it easier to remember incomplete tasks than would be the case for completed tasks (this is the so-called Zeigarnik effect, in honour of its discoverer). It also was predicted that there would be a tendency for work on the uncompleted tasks to be resumed at the first opportunity. Lewin also pointed to the importance of the person's cognitive evaluation of any given situation. Much study was devoted to the individual's level of aspiration for performance on a number of tasks, the subject being asked to state at what level he hoped to achieve the next time he attempted to perform a task. It was found that subjects do not typically give perfect performance as their expectation; yet, if achievement of success is a major goal, chances are that they should do so. These empirical findings suggested to Lewin that goal setting is a complex process, being affected not only by the positive valence of success but also by the negative valence of failure. He proposed that subjects are affected by how they estimate the probability level at which they expect to succeed or to fail in performing at a given degree of effectiveness. Lewin added that the valences of success and failure are weighted by these subjective probabilities in determining the actual goal the person says he will strive to achieve.

To an extent, then, Lewin saw the tasks themselves as creating motivation, and he characterized behaviour as occurring because of imbalances in the stimulus field. He also depicted cognitive evaluations as interacting with valences in determining the behavioural outcomes in a given situation. Lewin was especially influential in outlining presumed conditions of conflict and in describing methods held likely to resolve them. His interest in conflict was an understandable one, since conflict of goals, for example, was depicted as creating imbalance in the field, the resulting behaviour tending to restore equilibrium.

A number of theories, especially in social psychology, appear to have been influenced by Lewin's conceptualizing. At any rate, these theories have little to say about standard motives but rather look to motivation as arising from imbalances in a situation. Balance theory and congruity theory are among the major viewpoints of this type. Discussion here will be limited to the most well-known system in this group: the theory of cognitive dissonance. In its career since the U.S. psychologist Leon Festinger proposed it in 1957, the theory of cognitive dissonance has stimulated a great deal of investigation. Although it is not without problems, this theory as presented here will serve to illustrate another way of looking at motivation.

Festinger proposed that a tension state (that seems to be much like a drive) would be created when two or more cognitive elements exist but are dissonant with one another in that they are perceived to be incompatible or inconsistent. For example, if it is supposed that one regards himself as an excellent golfer but that on a given day he earns an unusually poor score, there are two cognitive elements: the man's high estimation of his skill and the conflicting evidence of his relatively inept performance. The two elements are said to be dissonant, and dissonance was depicted as a state of tension that must be resolved. This situation assumes that the elements are related to one another, as the two in the example are, and that they are perceived to be important, as the elements involving golf would be in one who prides himself on his skill at playing this game.

Festinger applied his theory to dissonance that arises after one has made a decision. He saw the resolution of the dissonance in the individual's behaviour relative to the conflicting elements. If it is supposed one has just bought a new automobile after carefully considering two models and having perceived both of them to have positive and negative features, the positive features of the rejected alternative are said to be dissonant with the fact that it was rejected, the negative features of the vehicle that was purchased being dissonant with the fact that it was selected. A prediction that follows from the dissonance formulation is that, after the car was bought, one would be prone to read advertisements that stress its positive features and to avoid advertisements for the rejected automobile, and to do both for the same reason. Partial support was obtained in a study conducted to test this prediction. In another experiment, college girls were invited to participate in group discussions concerning sexual behaviour. As a precondition for participation, some of these girls underwent what was designed to be an embarrassing interview; another group of them were interviewed under comparatively bland conditions. Both groups then listened to a taped recording of what most people would judge to be a dull discussion of sexual behaviour among subhuman animals. The girls who had gone through the embarrassing preconditioning tended to rate the discussion as much more interesting than did those who had been subjected to the neutral preparatory interview. The cognitive elements here are those of the embarrassment of the initial conditioning procedure and the dullness of the ensuing discussion; they are interpreted as being dissonant. According to Festinger's theory, the embarrassed girls evaluated the discussion favourably to resolve the cognitive dissonance.

A great deal of research that has been generated by the theory of cognitive dissonance has tended to support the principles that Festinger enunciated. The lustre of this theory, however, seemed to fade in the years following the first surge of interest it attracted. This dimming may be attributable to difficulties that arise in defining and measuring dissonance and in the rather elaborate and contrived experiments that had to be undertaken in efforts to test the theoretical formulations. Results of a number of the experiments failed to replicate earlier findings. Although the theory was not regarded as favourably in the 1970s as it once was, it clearly was most provocative and stimulated a wealth of empirical work. It exemplified an approach to the study of human motivation that is rather different from those theories in which there is a dependence on the controversial existence of relatively permanent or stable motives or needs.

LATER DEVELOPMENTS

A discussion of motivation written in 1950 in all likelihood would have been more positive in its evaluation of the status of the field and of the systematic integrity of its concepts than one written in the 1970s. By 1970 motivation theory was in a state of flux, partly in view of a decline in the cogency and acceptability of the notions of drive and acquired drive. There was a growing uncertainty that motivational concepts were needed at all. For example, it has been suggested that notions of motivation may not be needed in accounting for behaviour; that the phenomena popularly listed under the rubric motivation can be encompassed readily by considering the operation of the general phenomenon of learning called reinforcement.

Reinforcement refers to an increase in the probability that an organism will exhibit a given kind of behaviour (in a situational context) through some consequence of the behaviour itself. It is well known that laboratory animals will learn mazes, solve puzzles, and develop the ability to discriminate among sensory stimuli, for example, if they are rewarded (reinforced) for such behaviour with food if they seem hungry, with water if they appear thirsty, and so on. Learned rewards (*e.g.*, approbation) also have been found to be effective and may be supposed to function as the typical reinforcers for human learning. It was tentatively suggested that close analysis of the conditions under which reinforcement occurs will reveal these conditions (rather than motives or incentives) to be the factors that control the behaviour. It was too early at that time for a rigorous evaluation of this notion, although a number of investigators were not optimistic concerning its chances for success. Reinforcement itself is a complex concept and is not well understood; it becomes a nice question whether some condition of motivation is necessary for many reinforcers to be effective.

Another trend in the 1970s was seen in the re-emergence of the term instinct in the writings of ethologists. The ethologists distinguished appetitive behaviour (*e.g.*, copulation) from instinctive acts (*e.g.*, the courtship of some birds), a distinction somewhat like that made by Woodworth between consummatory and preparatory behaviours. They pointed to these species-specific, innately generated acts and to the stimuli that apparently can release such species-specific behaviour (or instinctive acts) without the need for learning. Since much of the work of ethologists concerned birds and lower mammals, the extent to which their conclusions could be generalized to other species was uncertain. They emphasized such factors as territoriality (as observed in birds that drive interlopers away) in the determination of behaviour. While some ethologists seemed willing to extrapolate their conclusions to human beings, others were more conservative. In general, however, it did seem that stress on innate determiners of behaviour had grown and received acceptance since about 1960, in contrast to the radical environmentalism of earlier decades. It should be added that the evidence offered for innate factors in behaviour was much more specific and was obtained under much more carefully controlled conditions than was the case in McDougall's time during the earlier period of the dominance of the instinct concept. The instincts postulated in the 1970s also were to be understood as behavioral acts rather than as urges or purposes. It seemed more modest or objective to speak of unlearned acts and their innate determinants than to refer to such activities as reflecting instincts.

PRACTICAL APPLICATIONS

Despite the uncertainties that have been indicated concerning definitions and the theoretical status of motivational concepts, what might be called a technology of motivation has developed. There is, however, little theory that may be extended in socially or economically useful ways. Indeed, applied efforts that are successful may turn out to have desirable effects for reasons that are not motivational, despite their having been undertaken in the name of motivation.

In the control of animal behaviour, for example, it is clear that depriving an organism of food is a powerful means for accomplishing reinforcement. Appropriate use of food under these circumstances is an effective procedure for shaping an animal's behaviour, maintaining it, and controlling the rate of its occurrence. This is not to say that any act can be controlled by such procedures; such methods, however, are widely applicable. Likewise, it is clear that animals have preferences (within, for example, the range of foodstuffs) and that their behaviour can be controlled with relatively greater effectiveness by the proper selection of preferred substances for use in training.

In many cultures, deprivation cannot be used so readily with human beings as it can be with other animals, although there are many human examples. Thus, some success has been reported in effecting desired behaviour in the classroom by depriving children of some of their recess time when they behave in ways deemed undesirable by the school authorities. Economies based on the use of tokens (*e.g.*, poker chips) have been set up in wards in psychiatric hospitals and in institutions for retarded people. The result typically has been an improvement in the inmates' behaviour and personal care and in the ease with which they may be managed. In such economies, tokens can be exchanged for privileges and commodities (*e.g.*, candy, toys). The individual's ability to obtain tokens is made contingent on socially desirable acts, such as mak-

ing beds, being personally clean, being cooperative, and generally acceptable to others. There have been reports of marked improvement in scholastic achievement among institutionalized juvenile delinquents who have been placed in such token economies.

The effectiveness of these and similar procedures has been most easily demonstrated in institutions, in which the situation permits a great deal of control over the inmate's conditions of life and over his activities. In society at large, of course, this degree of control is effectively not feasible. There also are widely endorsed moral or ethical concerns about the desirability of instituting such control even if it were possible. The use of particular kinds of motivational devices in the control of human behaviour seems to many to be incompatible with the ethical idea of personal freedom and to be fraught with potentials for immoral misuse in the hands of those who seek to manipulate others for ends that are politically or socially conformist. To some, the disarray of motivational concepts and the constraints that limit the effectiveness of such motivational devices as advertising and political propaganda in society at large come as welcome antidotes to rising concern. Hopefully, the development of society, as grimly outlined in George Orwell's novel *Nineteen Eighty-Four* or in Aldous Huxley's *Brave New World*, may not come to pass as readily as many people have feared.

On the other hand, it often is observed that many of society's problems are motivational. This observation usually means that the goals and values of economically affluent groups in the Americas, Europe, and Asia are not shared by members of deprived urban ghetto populations or by millions of poor people in industrially less developed countries. Or, it may mean that the goals of those who own or control profit-seeking enterprises (to make a product or deliver a service for the investors' profit) are not shared by workers below the level of middle management. Many techniques have been tried both in capitalistic and socialistic forms of business and industry to effect so-called motivational involvement with production on the part of ordinary employees. Some of them have had success, in Soviet tractor factories as well as in West German automobile plants. Incentive systems, employee participation in company planning and decisions, and human-relations training exemplify the procedures used. A substantial corps of specialists throughout the world provides programs to industry designed to improve the motivation, morale, and satisfaction of workers at all levels. Although these programs have wide acceptance, most of them have received very little objective evaluation. All of them must, of necessity, be designed ultimately to orient the worker to identify his interest, goals, and values with those of management. As complex a process as such identification is, it no doubt contains motivational elements.

BIBLIOGRAPHY. The most comprehensive treatment of the topic is the one by C.N. COFER and M.H. APPLEY, *Motivation: Theory and Research* (1964), although R.C. BOLLES, *Theory of Motivation* (1967), gives an excellent historical introduction and offers a thorough analysis of most of the theoretical issues. R.S. PETERS, *The Concept of Motivation* (1958), presents a rationalistic approach to motivation; V.H. VROOM, *Work and Motivation* (1964), surveys the industrial applications. R.A. HINDE, *Animal Behavior: A Synthesis of Ethology and Comparative Psychology*, 2nd ed. (1970), summarizes the ethological position; B.A. CAMPBELL and J.R. MISANIN review recent literature on special topics in "Basic Drives," *Ann. Rev. Psychol.*, 20:57–84 (1969). Work on token economies is indicated by T. AYLLON and N. AZRIN in *The Token Economy: A Motivational System for Therapy and Rehabilitation* (1968). Specific human motives are discussed in J.W. ATKINSON and N.T. FEATHER (eds.), *A Theory of Achievement Motivation* (1966); and by L. BERKOWITZ in *Aggression: A Social Psychological Analysis* (1962). A comprehensive source for balance theories, including the theory of cognitive dissonance, is *Theories of Cognitive Consistency: A Sourcebook* (1969), ed. by R.P. ABELSON *et al.*

(C.N.C.)

Motor Sports

Motor sports cover a multitude of different types of events, the majority of which are races. The basic idea of a race is, of course, simple: drivers of automobiles or motorcycles run as fast as they can over a given course. The man and machine combination that has covered the prescribed distance in the shortest time (or covered the greatest distance within the prescribed time) wins.

Rules and regulations for competitions are made by international governing bodies, national sanctioning bodies, or both, and supplementary regulations are issued by the organizers of a given individual event. The rules spell out in great detail the type of vehicle eligible to race so as to assure equality among the competitors. There may be restrictions on engine type and size, body dimensions, fuel supply, number of driving wheels, and number of vehicles built to the same specifications. Though automobile racing and motorcycle racing are under completely different rules, passed by different organizations, both types of vehicles often race at the same places, and occasionally, in competition with each other.

Types of races and other motor-sports events

There are several types of races held on a great diversity of racing sites, or venues. Road races are staged on public roads (closed to the public for the occasion) or on simulated road circuits. Other races are held on speedway tracks, mostly oval, with or without banked turns. Acceleration races are held on straight and level strips called drag strips. Certain kinds of races are held in rough terrain (off-road racing). Speed-record events are held on beaches or the beds of dry lakes.

Motor-sports events that are not races include rallies, of which there are numerous categories. Driving-skill tests (gymkhanas) and historical car meets are also considered motor-sports events.

For speed records and records of principal automobile and motorcycle-racing events and championships see also SPORTING RECORD in the *Ready Reference and Index*.

Popularity. Motor sports constitute one of the most popular spectator sports in the world. Crowds of 300,000 and more have been claimed for such automobile racing events as the Le Mans (France) 24-hour Grand Prix d'Endurance and the Indianapolis (Indiana) 500 Miles Sweepstakes. In the United States, statistics show auto racing to have higher attendance than football and baseball, running second in popularity only to horse racing. Participation in motor sports has increased to new proportions since the end of World War II, and enthusiasts worldwide have formed clubs and stage local events.

The racing calendar is overcrowded. Ranking international events compete for the fixed dates of their choice, and sanctioning bodies have a hard task trying to accommodate all interests. On any given weekend there are countless minor car and motorcycle races, rallies, and other events. Many of these do not cater to spectators but are organized for the participants alone.

I. History of motor sports

MOTORING AND AUTO RACING

First automobile races

Motor sports began at 8 AM, July 22, 1894, when 21 cars set off from Paris to Rouen, France, in a reliability test run organized by the *Petit Journal* newspaper. The first true automobile race was held on June 11, 1895, over a 732-mile (1,178-kilometre) route from Paris to Bordeaux, France. Town-to-town French races on public roads became the norm as other events followed: Paris–Marseille–Paris, Paris–Dieppe, Paris–Trouville, Paris–Amsterdam–Paris. The Course de Périgueux, the first race held on a closed-road circuit, took place on May 1, 1898. The circuit was 90 miles (145 kilometres) long, and competitors covered only one lap.

Other organizers took up the idea and circuits were improvised in the Ardennes Mountains and in the Auvergne Mountains. Town-to-town events dominated the sport until 1903, when the high number of accidents occurring during the 1903 Paris–Madrid race caused it to be halted at Bordeaux. After that, road racing became confined almost entirely to closed circuits.

The Automobile Club de France defined racing rules and the classification of cars and functioned as a governing body for the sport in its formative period, but the man who did most to make motor racing international was an American, James Gordon Bennett, owner of the *New York Herald* newspaper. Automobile racing in North America started on November 28, 1895 with a contest over a 54-mile (87-kilometre) road course near Chicago, organized by the *Chicago Times Herald*.

In 1899 Bennett presented a trophy for a race, not between the drivers or the manufacturers but between representatives of the national automobile clubs, using cars built entirely from parts manufactured in the country represented. Each nation could enter a maximum of three cars. The Automobile Club de France was to organize the first Gordon Bennett Cup Race. As other countries became more active in motor racing, the Gordon Bennett went to the Circuit of Ireland in 1903, the Taunus Rundstrecke in Germany in 1904, and to France's Circuit d'Auvergne in 1905.

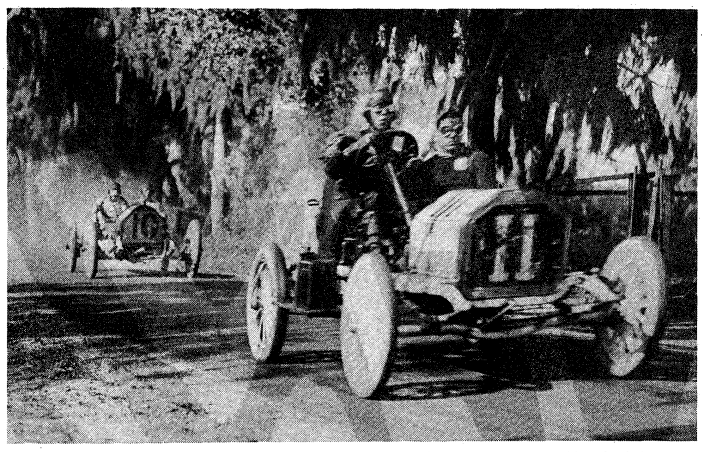
By 1906, the French automobile industry was no longer willing to be restricted to only three cars as was required by the Gordon Bennett races, and a new type of event with no limitations on the number of cars that might be entered from any nation was inaugurated. The new event was known as a Grand Prix (see below) and the first Grand Prix race was held that year at Le Mans.

During the 1906–14 period, the French Grand Prix was the main event of the year, and no other nations held Grand Prix races during this period.

The Vanderbilt Cup and racing in America

William K. Vanderbilt, Jr., was the next American to offer a motor-racing trophy. The first Vanderbilt Cup Race was held on Long Island, New York, in 1904. The rules were patterned on French practice; and America became an important factor in road racing, although at first most competing cars were imported.

PHOTOWORLD—FPG



Two of the competitors in an early U.S. road race, the Vanderbilt Cup Race of 1906.

The Vanderbilt Cup Race was held annually on Long Island until 1911, when it was moved to Savannah, Georgia; then to Milwaukee, Wisconsin; then to Santa Monica, California. The 1915 race took place in San Francisco, and the 1916 event was back at Santa Monica. Then the cup was retired and not revived until 1936.

Italy moved into the forefront of international racing in 1906 when the first Targa Florio was organized in Sicily by Conte Vincenzo Florio. It was a 90-mile course in the hills of sparsely populated Sicily where crowd control was less of a problem than near the big cities. It was, and is, run on public roads (theoretically closed off) and has been renewed annually (with interruptions) to this day.

Up to World War I the same type of car was used in most races. The racing car began as a prototype for the following year's production model. Later, racing cars became too specialized for quantity production. At the same time, many high-performance touring cars were turned into racers by the removal of the bodywork and the fitting of special seats, tanks, and extra tires. After World War I, Grand Prix racing became a tightly regulated sport with strict rules, and sports-car racing and endurance racing gained in popularity. Other forms of racing also sprang up, including production car (stock-car) racing, maximum-speed or maximum-acceleration events (drag racing), hill climbs, and others, each catering for a particular type of vehicle.

Development of Grand Prix racing. In all of automobile racing, Grand Prix events are the most elite. Grand Prix automobiles are commonly the ultimate in design, speed, and horsepower and are regarded as the purest racing cars. They are painted in national colours (British green, Italian red, French blue, German white, U.S. blue and white, etc.). They are entered in events by their manufacturers or by private owners as teams, usually consisting of two or three cars, and driven by professional drivers. Races are held on closed circuits, usually three or four miles (five or six kilometres) to the lap, with the total distance varying from 150 to 400 miles (250 to 650 kilometres). All modern Grand Prix cars conform to one of various formulas or sets of specifications, laid down by the Fédération Internationale de l'Automobile (FIA), to govern the size, weight, and other specifications of the vehicles that may compete.

Grand Prix racing, interrupted by World War I, resumed in 1920 with an engine-displacement limit (intended to equalize power and promote technological advance). Engines became smaller and lighter, and cars became lower and faster. All leading industrial countries produced Grand Prix racing cars, though Italian and French makers dominated until 1934.

Up to 1925 a riding mechanic had occupied the passenger's seat. He had been needed in earlier days to pump oil, help change tires, and so on; but in 1925 the riding mechanic was outlawed.

European Grand Prix circuits and speedways

Most western European countries soon began to organize Grand Prix races on road circuits. Some built speedways. The Belgian Grand Prix was first held at the triangular Spa–Francorchamps course in a wooded Ardennes valley in 1925. Italy built its Monza track (outside Milan) in 1922, and France followed with Montlhéry (outside Paris) in 1924. Italy also organized Grand Prix races at Mellaha Circuit in Tripoli, Libya, from 1925 to 1940.

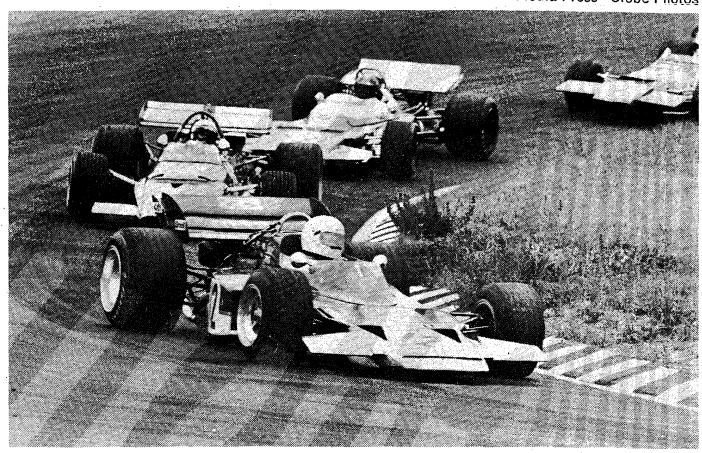
Germany created the Nürburgring road course in the Eifel Mountains as a make-work project to relieve unemployment in 1927. The circuit is 14.2 miles (22.8 kilometres) long and has an altitude span of 2,400 feet (about 700 metres). Germany also built a speedway between Potsdam and Berlin in 1926. It was called Avus (Automobil-Verkehr-und Übungs-Strasse, automobile test and training road).

Many local clubs organized races for Grand Prix cars through city streets. The most famous is Monaco (Monte Carlo), which began in 1929. Nice and Marseille followed. Others were Albi, Pau, Rome, San Remo, Turin, Cremona, and Florence.

The displacement limit, having proved detrimental to competition, was abandoned in 1928, and only a weight

limit (550 kilograms [1,200 pounds] minimum, 750 kilograms [1,650 pounds] maximum) was left in effect. The maximum-weight limit was abandoned for 1929–30, and the minimum raised to 900 kilograms (2,000 pounds).

Media Press—Globe Photos



Cars rounding a curve during the 1971 Grand Prix of The Netherlands

During the 1931–33 era, there was a free formula (no restrictions). From 1934 through 1937 there was a 750-kilogram maximum-weight limit that produced some of the fastest, most spectacular cars ever built. During the 1934–39 period German cars (Auto-Union and Mercedes-Benz) dominated completely. The 1938–39 formula reverted to a displacement limit. Racing resumed after World War II under a free formula. For the 1947–53 period, there was a new and still lower displacement limit.

The World Championship for drivers

The World Championship for drivers was instituted in 1950; it is based on points earned in major Formula I events (those open to the biggest, fastest cars) each year. The qualifying events, called *grandes épreuves*, are customarily the Grand Prix of Monaco, Belgium, The Netherlands, France, Great Britain, Germany, Italy, Mexico, South Africa, Canada, and the United States (Watkins Glen; the Indianapolis 500—for track-type cars—no longer qualifies for championship points). The first world champion was Giuseppe Farina (driving with the Alfa Romeo company team). An Argentinian, Juan Manuel Fangio, was champion five times (1951 with Alfa Romeo; 1954, Maserati and Mercedes-Benz; 1955, Mercedes-Benz; 1956, Ferrari; and 1957, Maserati). For the 1954–60 period, displacement limits went up for unsupercharged engines, and superchargers were further penalized. (From 1922 through 1937 no distinction had been made for superchargers; a sliding scale was introduced in 1938 and modified for later formulas.)

The 1961–65 Grand Prix formula again reduced the displacement limit. Speeds fell but racing-car design was revolutionized. In the course of this five-year period all racing-car builders who had not yet placed the engine in the middle of the chassis (behind the driver) did so. Beginning in 1966, engine displacement limits were doubled, and cars became larger and heavier again.

Development of speedway racing. The first speedway especially for automobile racing was constructed in 1907 at Brooklands, near Weybridge, Surrey. The Brooklands track consisted of a 2.766-mile (4.450-kilometre) circuit with a minimum width of 100 feet (30 metres) and two curves banked up to one in 1.6 and a height of 27½ feet (8½ metres). Brooklands became the scene of sprint races, relay races, endurance races, handicap races, and long-distance record runs. A 24-hour race was held in 1929, another in 1930, and another in 1931. These were followed by a 1,000-mile (1,600-kilometre) race in 1932.

The importance of Brooklands can be fully assessed only when it is realized that for many years it was the only place in England where any form of motor racing was legal. Road racing was barred from England until 1932 when a circuit was opened at Donington Park. Brooklands closed in 1939.

Oval, banked speedways on the European continent, such as Monza (Italy) and Montlhéry (France), were attached to road circuits and mostly used for Grand Prix racing, with the cars completing only half of the oval between laps of the road course. Montlhéry was also the scene of many long-distance international speed records.

Possibly the best known speedway in the world is a 2½-mile (four-kilometre) track at Indianapolis, Indiana, scene of a 500-mile sweepstakes. The Indianapolis Speedway opened as a dirt track on August 19, 1909. The first 500-mile race was run on May 30, 1911, after the track had been paved with bricks.

The Indianapolis 500

The Indianapolis races did not follow Grand Prix formulas, but the rules also restricted engine displacement, though far larger engines were admitted. The Indianapolis rules closely followed Grand Prix displacement limits between 1921 and 1930, and the result was total domination by two U.S. makes: Miller and Duesenberg. This led to a radical change in the formula. A so-called junk formula took effect in 1930; it encouraged the use of stock-block engines, and superchargers were banned. In 1938 a new displacement-limit formula was adopted, coinciding with the contemporary Grand Prix formula. The entry was limited to 33 cars in 1934, and this rule still stands. Helmets have been required since 1935. Fixed roll bars to protect the driver of an overturned car became mandatory in 1959.

Part of the track was resurfaced with asphalt in 1935, and in 1962 the whole track was asphalt-covered except for a 36-inch (91-centimetre) strip of bricks at the starting line. In 1957 a new formula restricted engine displacement to 255 cubic inches (4,180 cubic centimetres) without supercharger and 171 cubic inches (2,800 cubic centimetres) with supercharger. This formula was in effect through 1968.

American-built Indianapolis-type cars are not produced by the major auto manufacturers but by small specialist establishments. Established European racing-car builders have also competed with success at Indianapolis.

Beginning of stock-car racing

Oval-banked board tracks were popular in the U.S. during the 1920s. Rules generally catered to the Indianapolis type of cars, although some 24-hour events were staged, mainly for stripped-down touring cars. Stock-car racing, limited to American production-model passenger cars with suitable modifications, began at Langhorne, Pennsylvania, on July 4, 1939. Langhorne is an oval track, and stock-car racing has been primarily identified with oval speedways although stock cars regularly appear at road-racing circuits in various parts of America.

Stock-car racing did not become organized until the formation of the National Association for Stock Car Auto Racing (NASCAR) in 1948. The first NASCAR race was held on the Daytona Beach (Florida) road course on February 15, 1948. A Grand National division was started in 1949, and the first Grand National race was held on the Charlotte (North Carolina) speedway. There were nine Grand National races that year, including Heidelberg, Pennsylvania; North Wilkesboro, North Carolina; and Hamburg, New York.

Racing, conducted in several classes—grand national, modified, sportsman, and others—depending upon the type of automobile and the degree of modification allowed, has flourished, with annual attendance in the United States alone estimated at 10,000,000. Premier events are held at Charlotte and Daytona, and at Atlanta, Georgia, Darlington, South Carolina, Talladega, Alabama, and Ontario, California.

Development of endurance racing. Endurance racing started at Le Mans in 1923 when the Automobile Club de l'Ouest organized its first 24-hour race. The event took place on a road course of 11.4 miles (18.3 kilometres), partly paved, partly dirt, outside the city of Le Mans in western France. Racing went nonstop from 4 PM on Saturday to 4 PM on Sunday. Only cars in series production were admitted. Four seats were required (except for small cars with engines under 1,100 cubic centimetres), and the seats had to carry ballast to simulate a full complement of passengers. Cars were disqualified for failing to maintain minimum average speed, based on their engine size.

In the second year, convertibles were required to stop on the 12th lap and put up the top, run a minimum of 20 laps, then fold it again. Self-starters and headlights were required.

The rules were relaxed, year by year, in the interest of obtaining more entries, faster cars, and bigger crowds. By 1931 sports cars with two-seater bodies were eligible. The circuit was modified over the years (straightened, widened, resurfaced, and shortened). Since the resumption of this event after World War II the circuit has been 8.4 miles (13.5 kilometres) per lap. The most successful cars over the years have been, in succession, Bentley, Alfa Romeo, Bugatti, Jaguar, Ferrari, Ford, and Porsche.

Le Mans running start

The so-called Le Mans start requires the drivers to run across the road at the drop of the flag, get into their cars as lined up in order of engine size along the pit front, start them, and drive off as fast as feasible. This rule was not changed until 1970. Now the drivers sit inside their cars, with harness fastened, but are not allowed to start the engines until the fall of the flag. Race average speeds have gone from under 60 miles (100 kilometres) per hour to over 120 miles (200 kilometres) per hour for the full 24 hours, with no time out for refuelling or tire changes.

Belgium started its own 24-hour race in 1924, on the Spa–Francorchamps road course. It was an annual event, with average speeds rising from under 50 miles (80 kilometres) per hour the first year to over 90 miles (145 kilometres) per hour by 1953. The race was cancelled for 1954 and was later reorganized as a touring-car race.

The first step toward endurance racing in Great Britain was the Tourist Trophy (TT), the premier motor racing event until Britain got its own Grand Prix in 1948. The first Tourist Trophy race was held in the Isle of Man in 1905. It was a 205-mile (330-kilometre) road race for touring cars. Distance went to 338 miles (544 kilometres) in 1908 and to 600 miles (965 kilometres) in 1914. The TT was suspended between 1914 and 1922 and from 1923 to 1928. For 1928 it was moved from the Isle of Man to Ards, east of Belfast, in Northern Ireland. Distance at Ards was 410 miles (660 kilometres), except for 1933 and 1934, when it was 478 miles (769 kilometres). The series terminated in 1936, not to be revived until 1950.

In 1927 Italy revived point-to-point road racing with a 1,000-mile (1,600-kilometre) event called the Mille Miglia, starting at Brescia, running down to Rome and back again over another route to Brescia. The first race was won at 48.27 miles (77.67 kilometres) per hour. The 1955 race-winning average was just short of 100 miles (160 kilometres) per hour. The race was open to sports cars of all descriptions, with full road equipment. No codriver was required, but most drivers chose a navigator or driving partner. The Mille Miglia was entirely dominated by Alfa Romeo throughout the 1930s and by Ferrari from 1948 to the end in 1957.

Opposition to the race (for its lack of public safety precautions) had been rampant ever since Premier Benito Mussolini had closed it down after the death of 23 spectators in 1938 and directed it to be held on a shorter, closed circuit. In 1957, a single-car accident took the lives of 15 spectators, and the Mille Miglia was outlawed.

The Sports Car World Championship

The Sports Car World Championship, which is awarded not to a driver but to a make of automobile, started in 1953, adding up points for each make on the basis of results in the premier endurance races across the world: 12 hours of Sebring, 1,000-kilometres at Nürburgring, 24 hours of Le Mans, Mille Miglia, Tourist Trophy, Targa Florio, Carrera Panamericana de Mexico, the 24-hour race at Spa, and the Grand Prix of Sweden. (When the term Grand Prix is used in this context it refers, not to the type of car raced but to the fact that the race is a major automotive event in the nation in which it is held.) The list of qualifying races has changed from year to year, as some events are cancelled and new ones come into prominence.

The Mexican road race was from Tuxtla Gutiérrez in the south to Ciudad Juárez on the U.S. border, held from 1952 through 1954. The Grand Prix of Sweden was taken off the list in 1955 and has not been on the calendar since 1957. The 24 hours of Daytona was added in 1964, using part of the speedway and a flat, simulated road course in its infield. Ferrari was a consistent winner in the 1950s (except for Mercedes-Benz in 1955 and Aston Martin in 1959). The Ferrari domination lasted until conquered by Porsche in the late 1960s.

Evolution of hill climbs. Hill climbing started in France with the Nice–La Turbie event of 1897, covering four miles (six kilometres) of hard-surface public roads. Britain's first hill climb was the 1905 Shelsley Walsh, a rough, dusty or muddy, narrow track running steeply uphill through wooded terrain for 992 yards (907 metres).

On the Continent, hill climbs tended to have longer distance, such as Austria's Klausen (13.3 miles [21.4 kilometres]) and Semmering (6.15 miles [9.90 kilometres]), and they became a substitute for point-to-point road racing. France's Mont Ventoux (13.5 miles [21.7 kilometres]) ran from 1902 to 1936 and Grand Prix cars were eligible. Italy had a variety of hill climbs, starting from the northern lakes and running as high up in the Alps as the roads went (Stelvio, Susa-Moncenisio, Aosta-Great Saint Bernard), and a number of shorter events in the Apennines. The most famous hill-climb scene in the New World is Pikes Peak in Colorado, an unpaved hill of 18 miles (29 kilometres) length.

Evolution of drag racing. Drag racing as an organized sport started on the dry lake beds of southern California. Unofficially, drag racing had been going on in the streets of California and other American states for several years. A drag race might take place whenever young men driving cars especially tuned for acceleration met at traffic lights and gave each other the signal to "drag" (*i.e.*, race to the next stoplight). The first moves to get the sport off the street and channelled into safer surroundings were made with the foundation of the National Hot Rod Association (NHRA) in 1951 and the scheduling of races at a drag strip in Madera, California.

Drag race safety regulations

Safety regulations are strict. Steel safety shields completely surrounding flywheel housings became mandatory in 1955. Parachute braking devices were first used in 1959 and were soon made mandatory for all vehicles running over 150 miles (240 kilometres) per hour. Twin V-8-powered dragsters became popular in 1961. Fireproof clothing became mandatory for drivers of fuel dragsters (cars that burn mixtures of alcohol-benzol [or methanol] and nitromethane) in 1963 and later extended to drivers of all supercharged open-bodied machines. On-board fire extinguishers became mandatory for all vehicles in 1971.

NHRA sanctioned its first drag strip in Europe in 1961, but drag racing has not reached any degree of popularity outside the U.S.

The American Hot Rod Association, started in 1954 as a rival to NHRA, sanctions drag races on a national scale.

Evolution of rallies. Rallies are thought to have originated as a competitive version of motoring for pleasure, a popular pastime early in the 20th century. The basis of rally events is the attainment of regularity, by means of an average speed that has to be maintained not merely over the route as a whole but on every section of the route between control points. Legal speed limits have to be observed, high speeds being achieved at specified stages on unrestricted roads and on special sections (private land) and race circuits. Special tests of driving skill are held in difficult terrain en route. Consistent driving is needed as these tests and others at the finishing point are made against the stopwatch; and the results are used, in combination with a penalty marking system for general timekeeping, in assessing the winners in the different classes. In the United States rallyists follow a more or less complicated course—unknown to them until the start of the run—on public roads and under prevailing traffic regulations, the object being to maintain specified precise average speeds between checkpoints. All cars entered in a rally must pass careful inspection. Ordinarily each car is driven by a team consisting of a driver and a navigator who follows the directions for the route and calculates elapsed time, mileage, and speed.

Early tours and rallies

Not counting the Paris–Rouen event of 1894, the first rally was England's 1,000 Miles Trial of 1900. It was a tour from London to major cities such as Bristol, Manchester, Edinburgh, and Leeds, and return to London, with one-day exhibitions of the competing cars at these stops. Of 65 starters, 51 finished.

In 1904 the American Automobile Association sponsored a tour from New York City to St. Louis, Missouri, to visit the St. Louis world's fair. Charles Jasper Glidden, an enthusiastic participant, offered a $2,000 trophy to the AAA. Mr. Glidden then decided to sponsor a tour annually. The first Glidden Tour (1905) went from New York City through the New England States. The American Automobile Association continued to sponsor the Glidden tours until 1913, when the series ended.

Many early competitions that would now be called rallies used the name trials while the word trials today has a different meaning.

The first trial was staged at Edinburgh in 1904, including a road rally from London and back, and a hill climb in Scotland. This event was followed by two English events, the Land's End Trial in 1908 and the Exeter Trial in 1910. A form of rally more oriented to speed and regularity started with the Herkomer Trials of 1905–07 in Germany. The results were not determined on a basis of speed but of correct-route following and regularity. These events, sponsored by a wealthy painter, Hubert von Herkomer, led the Royal Automobile Club of Prussia to institute the Prince Henry Trials in 1908, held annually through 1911. Eligible vehicles were touring cars of certain minimum weights and dimensions, and the trial included special speed events along the way. Prominent cars were Benz, Mercedes, Adler, Opel, Austro-Daimler, and Laurin-Klement. The Monte-Carlo Rally started in 1911 and soon became the premier event of its type. Staged in midwinter, with starting points as far afield as St. Petersburg (Leningrad), Oslo, Athens, and Lisbon, it introduced the realities of extreme differences in climatic conditions to motor sport. The French Hotchkiss dominated the Monte-Carlo Rally in the 1930s and 1950s, giving way to Sunbeam, Austin, Citroën, Lancia, Panhard, Porsche, and Renault in later years. Smaller-scale rallies also became popular after World War II and led to the creation of an international rally championship, under Fédération Internationale de l'Automobile rules.

Long-distance tours

Extreme long-distance tours such as the Peking–Paris of 1907 and New York City–Paris of 1908 were races rather than rallies (with the outcome more dependent on road conditions and reliability than on speed potential). Such events were revived in 1953 with the staging of the Coronation Safari in Kenya. This became an annual event as the East African Safari Rally and developed into an extremely tough event with heavy emphasis on speed. In the mid-1950s Australia had its long-distance RedeX Round-Australia Trials (since discontinued). The most recent events have been the London–Sydney Rally of 1969 and the London–Mexico City Rally of 1970.

MOTORCYCLING

The development of motorcycling largely paralleled and often coincided with the development of automobile sports. There was a class for motorcycles in many of the old town-to-town automobile road races: Paris–Vienna, Paris–Nice, Paris–Cabourg (France), and Paris–Madrid. The de Dion tricycle dominated the sport in 1897, but two-wheelers like the Werner soon set the stage for an entirely different form of racing. Prior to 1901 the Werner carried its engine above the front wheel, but later versions had the engine mounted low in the frame, between the two wheels, with belt or chain drive to the rear wheel.

The international cup and the TT

After the turn of the 20th century, other makes came to the forefront: Griffon, Buchet, Sarolea, Adler, and Laurin-Klement. In 1904 the FIM (Fédération Internationale du Motocyclisme) created the international cup, uniting five nations: Austria, Denmark, France, Germany, and Britain. Each nation was to enter a team of three machines manufactured entirely in the country they represented, as in the Gordon Bennett automobile races. The first international cup race took place in 1905 at Dourdan, France.

The race for the Tourist Trophy (TT) was inaugurated in 1907 and was to become the most famous of all motorcycle races. The first TT race took place in the Isle of Man, and the winning machine was a British Norton powered by a Peugeot (French) engine. The victory gave a new impetus to Norton and the entire British motorcycle industry. Norton was in the front rank of motorcycle racing until 1951, when the Italians (Gilera, MV Agusta, Moto Guzzi) and Germans (NSU) took the lead. The 1960s were years of Japanese domination (Honda). The TT is still held every year in the Isle of Man, and a victory there carries more weight than any other motorcycle race.

Motorcycle racing in North America began in 1903 with the formation of the Federation of American Motorcyclists in New York City. By 1924, this society evolved into the still-active American Motorcycle Association, with headquarters in Chicago.

In the early days, motorcycles raced at the same tracks as automobiles: Elgin, Illinois, Savannah, Georgia, La Grande, Oregon, and Marion, Indiana, were among the most important.

Since 1937 the Daytona 200 miles (320 kilometres) race has been the leading race in the U.S. The race is held on the same road circuit used for the 24-hour Daytona auto race. Grand Prix racing (in the sense of being a major event in the country in which it is held) for motorcycles started soon after auto racing resumed after the end of World War I.

The Belgian motorcycle racing Grand Prix dates from 1921 when it was held at the Francorchamps circuit. The first event covered 188 miles (302 kilometres) on roads consisting of stones rolled into a mixture of sand and clay. The roads have been improved, but, except for one meeting held on a circuit near Dinant in 1923, one at Floreffe in 1936, and the interruption occasioned by World War II (1939–46), it has remained as an annual event at the traditional Francorchamps site. Germany began motorcycle Grand Prix racing in 1925, at the Avus track on the outskirts of Berlin. The event was moved to Nürburgring, back to Avus, and then to Sachsenring where it remained from 1934 through 1939. Resumed in 1949 at Nürburgring, it is now held at Hockenheim.

The Dutch Grand Prix started in 1925, for Dutch riders only, on a circuit near Assen in the northern part of The Netherlands. In 1927 the meeting, held on a different course in the area, became international. Switzerland's motorcycle Grand Prix started in 1934 on a short circuit outside Geneva (Genève) and moved to Bremgarten in 1936. The last Swiss Grand Prix for motorcycles was held in 1954.

There are about as many forms of motorcycle racing as there are of automobile racing—trials, speedway, hill climbs, rallies, moto-cross, drag racing, and ice racing. Trials date back to pre-World War I days, and speedway racing (dirt track) came into being in the early 1920s in Australia. Moto-cross—cross-country races consisting of a specified number of laps over a closed course laid out on rough, natural terrain—was successfully introduced in Great Britain and on the Continent in the late 1940s and early 1950s and by the 1960s had become a popular spectator sport. It was demonstrated in North America in the 1960s and the first regularly scheduled series of moto-cross events there was held in 1970.

Also beginning in the late 1940s, increased interest developed in events known as scrambles, which are similar to moto-cross but less regulated.

Motorcycle drag racing is an American phenomenon, dating from about 1950. Motorcycle ice racing started in Scandinavia in the 1930s and has spread to other temperate-climate countries. (For history and description of both of these events see below.)

II. Modern automobile sports

RACING

The various participants in automobile racing have different reasons for competing. Racing drivers are motivat-

ed by competitive spirit, and the promise of wealth, fame, and glory. Racing-car builders compete because the sport offers (a) publicity for all products bearing the same name, and (b) the acquisition of technical knowledge, trained specialists, and facilities that can be utilized for product improvement and associated commercial purposes.

Reasons for racing

Organization of the sport. There are two principal categories of race organizers: national and local clubs, which are nonprofit organizations, and private promoters, who are motivated by financial gain. The clubs participate partly for reasons of prestige, partly to gain power and weight in the organizations that govern motor racing.

Governing bodies. The world governing body of automobile racing is the International Automobile Federation (Fédération Internationale de l'Automobile, or FIA), a voluntary association of the national automobile clubs of 17 countries. It was founded in 1904 as the AIACR (Association Internationale des Automobile Clubs Reconnus) and acquired its present title in 1946. The motor-racing department of the FIA is the Commission Sportive Internationale (CSI). The CSI has delegates from 12 countries with permanent members from England, France, Germany, Italy, and the United States. The other seven members are elected annually from other FIA member countries. The CSI is responsible for the international sporting code, the international competition calendar, and various international championships.

The first duty of the CSI after its creation in 1922 was to establish an international sporting code for motoring sport. The first such code, developed, with modifications, from a draft code of the Automobile Club de France, was adopted in 1926. Since that time it has been continuously amended and brought up to date.

The Automobile Competition Committee for the United States (ACCUS), established in 1957, is the permanent representative of the CSI and the FIA in the U.S. Its board of directors includes representatives from the Sports Car Club of America (SCCA), the United States Auto Club (USAC), the National Association for Stock Car Auto Racing (NASCAR), and the National Hot Rod Association (NHRA). The primary responsibility of ACCUS centres on coordinating the schedule of international races held in the United States.

Finance. The question of finance has two parts: (1) How the race organizers finance their events. (2) How the makers (*i.e.*, builders or manufacturers of automobiles) finance the building and operating of racing machinery.

The functions of race organizers

The race organizer is traditionally a major or national club but increasingly of late has been a company formed to operate a racetrack. This is big business: the construction of a superspeedway with various ancillary facilities may cost $25,000,000, and to operate it takes a permanent staff, promotion and public relations officers, maintenance staff and crew. The organization and management associated with any major event requires large numbers of specialized personnel in a variety of branches. Some are volunteers, some paid by other organizations, but fees and wages can run into very important figures.

To attract a competitive field, the race organizer must offer starting money or prize money, or both. Starting money is a sum paid to an entrant when the machine and its driver are presented at the starting line. This sum can run from $1,000 to $20,000. Prize money paid by the race organizer can run to $750,000 in a single event, with an individual entrant (winner) collecting up to $125,000. The biggest purses are paid at Indianapolis Motor Speedway and in the Canadian-American Challenge Cup races.

The organizer's income is from ticket sales, fees, or profits from food, refreshment, or other concessions, advertising on the track, program sales, and advertising in the program. Most racing-car constructors are also entrants. The manufacture of a competitive Grand Prix or Indianapolis car may cost up to $100,000. Builders have found various ways to finance the building and operation of a team of cars: (1) If the constructor also makes touring cars, some of the racing-car development costs can be billed to the touring cars (and built into their prices). (2) The maker may produce racing cars for sale to private teams and professional stables. (3) He may seek a sponsor. This amounts to using the race car as an advertising medium, and painting the sponsor's name (or that of his product) on the cars that are raced officially by the constructor. Such sponsors may belong to associated industries (tires, oil, gasoline, spark plugs, antifreeze) or completely unrelated businesses (tobacco, beer, liquor, cosmetics, banks and credit institutions). (4) Starting money and prize money.

Motor-industry associations have occasionally given financial assistance to a constructor in order to extend the benefits of favourable publicity to the entire membership. National governments have rarely subsidized motor racing, but when they have, it has been with the double objective of increasing national prestige and to bring about a rise in national export trade.

Race management. The primary requirement for a race is that the track or site be approved by the sanctioning body in respect to safety for both participants and spectators. A substantial staff is needed for the organization and management of a major event: (1) The clerk of the course is responsible for conducting the event in accordance with the program. (2) The stewards are responsible for enforcement of the international sporting code. (3) The secretary is in charge of the race preparation and administration. (4) Scrutineers are responsible for vehicle inspection. (5) Timekeepers are responsible for the lap scoring and timing. (6) Pit observers and road observers are agents of the clerk of the course. (7) Flag marshals are in charge of signals to be given to the drivers (to warn of accident ahead, oil on the track, other dangers, or disqualification). (8) The starter gives the official starting signal (by flag, or signal lights).

A host of other services are required for various purposes (crowd control, safety, plant protection, communications, revenue). In addition to the presence of a regular police force, most events call for a special security force. With 250,000 spectators, a staff of 500 security men may be needed. Ticket and program sales require cashiers, supervisors, and assistants. A telephone-telegraph service requires operators; official communications depend on messengers; and the public address system must be staffed. Emergency medical service may call for ambulances, doctors, and nurses, with possibly a helicopter or a mobile hospital unit standing by.

Safety. Over the years, hundreds of drivers and spectators have been killed in racing. The risks are implicit in the nature of racing. Accidents are caused by pilot error, mechanical defects, and random hazards. They will continue to happen. The problem is to protect the drivers and spectators when they do occur.

Safety measures for drivers

The wearing of crash helmets has been common since 1950 and mandatory in most events since 1954–56. Seat belts or harnesses, pioneered by USAC and the SCCA about the same time, are now universally required.

Fireproof fuel tanks came in the early 1960s; automatic fire extinguishers in the late 1960s. Roll bars have been mandatory in SCCA and USAC events since the 1950s, in Grand Prix racing since 1961. The Motor Racing Safety Society, formed in New York in 1969, is internationally active as an advisory and information-collecting organization, with the goal of reducing injuries and fatalities in racing accidents.

The best protection for spectators is distance. Modern crowd-control methods place them in public enclosures, behind barriers or fences, separated from the road, track, or speedway by an open area. Guardrails are installed if distance is judged inadequate.

Classes and events. *Grand Prix.* Grand Prix racing comprises cars built under a variety of formulas, the most important of which is Formula I. Supporting formulas (such as Formula II, Formula III) were created to form a training ground for drivers prior to their acceptance into Formula I racing. All Grand Prix racing is for open-wheeled single-seater racing cars. Engine size and many other dimensions are limited by FIA rules.

Formula I limits engine displacement for supercharged and unsupercharged engines, specifies minimum weight, and prohibits aerodynamic devices that are not part of the body structure proper. Specifications cover camshafts, valve gears, and other components for various types of engines. Engines with more than 12 cylinders were outlawed in 1972.

Only FIA graded drivers of "A" standing are permitted to enter Formula I races and also have the right to participate in all international events listed on the FIA calendar. The qualifications for a new driver to obtain "A" standing include finishing at least twice in the top three in a race for the Manufacturers' Championship or winning the European Trophy for Formula II drivers (in addition to winning at least three nongraded events). In the 1970s there were only about 30 "A" graded drivers in the world.

The Formula I Grand Prix races

The countries that have their own Grand Prix (Formula I) races are the traditional ones: France, Italy, Germany, Spain, Monaco, The Netherlands, Belgium, and England. In addition, South Africa, Canada, and the United States are now included. Mexico was excluded after 1970 because of the lack of safety precautions. France's Grand Prix changes its scene from Reims to Rouen, Circuit Paul Ricard at Le Castellet to Clermont-Ferrand. Italy's Grand Prix rarely leaves Monza. Germany usually stages its Grand Prix at Nürburgring but occasionally goes to Avus. Spain alternates between Jarama (Madrid) and Montjuich (Barcelona). The Monaco circuit is the same as when it began, through the city streets. The Dutch Grand Prix is held at Zandvoort in the sand dunes on the coast outside Haarlem. The Belgian Grand Prix has its home at Spa-Francorchamps (but was banned in 1971 by the Grand Prix Drivers Association as unsafe). England's race goes from Brands Hatch to Silverstone and back. The South African Grand Prix is held near Cape Town. Canada uses Mont Tremblant or Saint-Jovite. The U.S. Grand Prix is firmly embedded at Watkins Glen in New York state. The Mexican race, when it was held, took place in the streets of Mexico City.

Formula II also limits engine displacement, but, since 1972, minimum vehicle weight has depended on the number of cylinders. Both the motor block and cylinder head must be derived from an engine used in a touring car or a sports car manufactured in a quantity of at least 1,000 units during 12 consecutive months. No restrictions are imposed on type of cylinder head or number of camshafts. Four-wheel drive is not allowed, and no more than five forward speeds are permitted.

Formula III also limits engine displacement. The number of cylinders is restricted to four. Engine block and cylinder heads must be those of a series-production car manufactured in quantities of at least 5,000 units during 12 consecutive months. The intake manifold must be fitted with a throttling flange through which all air fed to the engine must pass. Minimum wheelbase, minimum track (width between wheels), and minimum weight are specified.

Formula A was devised to encourage competition between the American and European continents. Formula A/5000 calls for open-wheeled single-seater cars using stock-block engines with pushrod valve gear of up to 5,000 cubic centimetres (305 cubic inches). Chevrolet and Ford-based units are preferred by most makers. Formula A has gained popularity in the U.S. and dominates the Tasmanian series (run during the Northern Hemisphere off-season). Formula A also enjoys a great following in Argentina, where the cars compete against Formula I cars on even terms (as they also do in the Questor Grand Prix at Ontario, California). There is also a supporting Formula A with a displacement limit of 1,600 cubic centimetres (100 cubic inches). Only production engines are admitted. This category is seen as a low-budget way of entry into Formula II racing.

Two championships are in existence for Formula A cars: the SCCA Continental Championship in the U.S. and the Guards Formula 500 championship organized by the British Racing and Sports Car Club.

Formula-V racing is for Volkswagens, and the engines and all major chassis components are basically those of the 1961–65 Volkswagen. The body is single-seater, and the wheels are open. No component of engine, power train, front suspension or brakes may be altered, modified, or replaced. Wheelbase and overall length are limited. Any size tire is permitted as long as it fits the standard VW wheels. Formula V is known as the lowest cost form of open-wheel racing.

Small-car formulas

Formula Super-V allows use of the Volkswagen "1600" engine and poses no restrictions on wheelbase. Still, no engine, drive line, brakes, or suspension components may be altered. Minimum weight is fixed, and wheel sizes are restricted.

Formula Ford was an English formula for cars using Ford of England four-cylinder production engines up to 1,600 cubic centimetres displacement (Cortina, Capri, Escort).

Formula 100 took the place of Formula Ford in the U.S. under regulations of the International Motor Sports Association. Cars powered by 1,600 cubic-centimetre Renault and Volkswagen engines can compete with the Ford-powered cars.

Formule Renault is an edition of Formule France, for cars equipped with 1,135-cubic-centimetre (70-cubic-inch) Renault engines, and a minimum weight of 425 kilograms (935 pounds). A number of French makers have built cars under Formule Renault rules, but the cars have not gained international recognition.

Manufacturers' Championship. The major races that count for the Manufacturers' International Championship follow closely on Formula-I events in importance. They are the 1,000 kilometres of Buenos Aires; the 24 hours of Daytona; the 12 hours of Sebring; the BOAC (British Overseas Aircraft Corporation) 1,000-mile race at Brands Hatch; 1,000 kilometres of Monza; 1,000 kilometres of Spa; Targa Florio; 1,000 kilometres of Nürburgring; 24 hours of Le Mans; 1,000 kilometres of Österreichring; six hours of Watkins Glen; and 1,000 kilometres of Canada at Saint-Jovite.

The championship racecourses

At Buenos Aires, the race is staged at an autodrome (speedway) near the city. The Daytona event uses part of the speedway plus a road course in the infield. Florida's Sebring is a track made up of airfield runways and access roads. Brands Hatch is a road circuit in rolling country in Kent, near London. Monza is a road course (with part of a speedway) near Milan, Italy. Spa-Francorchamps is a 5.6-mile (9.0-kilometre) road circuit in southeastern Belgium. Targa Florio is run on mountain roads in Sicily, as always. Nürburgring is a 14.2-mile (22.8-kilometre) course, with 176 curves, in western Germany. Le Mans permanent circuit is 8.3 miles (13.4 kilometres) long and has a straightaway of over three miles (five kilometres), on which some cars exceed 200 miles (320 kilometres) per hour. Österreichring, better known as Zeltweg, is a short 3.7-mile (six-kilometre) circuit in Austria. Watkins Glen is a fast, difficult road course in New York's Finger Lake region. Saint-Jovite is a relatively new facility with a good many interesting features, in the Laurentian Highlands in Quebec Province.

The eligible cars for the Manufacturers' Championship are grand touring cars, sports cars, and sports-car prototypes, as defined by the Fédération Internationale de l'Automobile. There are nine groups of cars, ranked according to production levels and purpose of operation. The groups admitted to the Manufacturers' Championship are 4, 5, and 6. Group 4 is defined as special grand touring cars with a minimum production of 500 identical models in 12 consecutive months. Group 5 is defined as sports cars with a minimum production of 25 a year and group 6 as prototype sports cars with no minimum production figure.

In this series of races, Group 4 cars enjoy unlimited engine displacement. Group 5 cars are restricted to 5,000 cubic centimetres (300 cubic inches), and Group 6 cars to 3,000 cubic centimetres (180 cubic inches). FIA specifies that the races must cover a minimum distance of 1,000 kilometres (620 miles) or have a duration of at least six hours. Some races exceed these requirements by a substantial margin. Supplementary regulations specify which parts may or may not be replaced during the race,

what tools may be used, conditions for replenishment of fuel and oil, and the number of mechanics who may work on a car in the pits.

Each driver is limited to four hours at a stretch in races over 12 hours or more. Time at the wheel is further restricted for shorter races. In a 24-hour race, maximum total driving time is 14 hours and minimum total rest time is seven hours.

The Canadian-American Challenge Cup. The Canadian-American Challenge Cup, popularly known as the Can-Am series, is an annual series of races in North America staged jointly by the SCCA and the Canadian Automobile Sports Club (CASC). Eligible cars are known as Group 7 (two-seater racing cars with no engine displacement limit and sports-car type bodywork without headlights and bumpers). Cars must run on commercial fuel and be equipped with self-starters (though the races are run with a "flying start" behind a pace car and not from a standing start). The races are short (from one hour and 20 minutes to two hours) and speeds are extremely high. Race averages range from 95 to 130 miles (150 to 210 kilometres) per hour, and the cars (with upwards of 600 horsepower) are capable of top speeds approaching 200 miles (320 kilometres) per hour. Minimum seating dimensions are specified by the rules, which also prohibit the use of movable body parts (airfoils, for instance), and set forth specific requirements for safety equipment (roll bars and belts).

The Can-Am series

The Can-Am series includes ten events. Points are awarded to the finishers in each race and added up so that the vehicle and driver with the highest number of points at the end of the season wins the cup.

American track racing. The United States Auto Club sanctions racing in various categories of single-seater open-wheeled racing cars on oval tracks from one-fourth of a mile to 2½ miles (one-half to four kilometres) in length, plus certain special competitions, such as the Pikes Peak Hill Climb. USAC's premier event is the Indianapolis 500 Miles Sweepstakes. The championship division of USAC governs the national championship for drivers on a points basis for a total of 21 events staged all over the United States.

Championship races cover a distance of 100 to 200 miles (160 to 320 kilometres). Most tracks are paved ovals, though some road courses are also used. Championship cars are subject to the same design measurements laid down for cars that compete in the Indianapolis 500. Engine displacement is restricted according to type of construction: overhead-camshaft power plants, without supercharging and supercharged; stock-block engines with pushrod overhead valves, unsupercharged and supercharged; diesel engines, unsupercharged and supercharged. Gas-turbine engines are outlawed. Minimum wheelbase and maximum width are specified. Front or rear-wheel drive is optional but four-wheel drive cars are barred.

The sprint-car division of USAC sanctions short-distance speedway races at a number of second echelon speedways throughout the U.S. Sprint cars are front-engined single-seaters of simplified design and construction compared with championship cars. They are heavier and slower.

Sprint and midget cars and races

The midget-car division of USAC governs dirt-track races with midget cars. Sprint cars are regulated by the same engine-displacement limits that apply to championship cars. Midget cars are scaled-down versions of sprint cars.

Touring-car racing. Touring-car racing takes different forms in different parts of the world, but the most important categories are run on European road circuits under FIA rules. The FIA has created an International Touring Car Championship for production-type touring cars of Group 1, Group 2 and Group 3. Group 1 cars are series-production cars manufactured in a quantity of at least 5,000 units of identical specifications. Group 2 cars are special touring cars manufactured in a quantity of at least 1,000 units of identical specifications. Group 3 cars are series-production grand touring cars manufactured in a quantity of at least 1,000 units of identical specifications.

The cars are further subdivided into 13 classes according to engine displacement. The use of optional equipment is restricted, and all parts (springs, wheels, tires, shock absorbers, and so forth) must conform to rules set forth for each category.

Championship races are usually four-hour events for Group 2 cars. They take place from March to October on circuits such as Monza (Italy), Brands Hatch (Kent), Jarama (Spain), Nürburgring (Germany), Spa-Francorchamps (Belgium), Zandvoort (The Netherlands), and the Paul Ricard Circuit (Le Castellet, near Toulon, France). Lesser events with cars of Groups 1, 2, and 3 are held throughout the season on other road circuits.

Touring-car racing in the United States takes two distinct and separate forms. One type of car is used for races under The National Association for Stock Car Auto Racing (NASCAR; see below *Stock-car racing*) and United States Auto Club (USAC) rules; another type is used in the Trans-Am (Trans-American) races sanctioned by the SCCA.

Eligible cars for the Trans-Am series are fixed-roof production cars built in a quantity of at least 2,500 units of identical specifications (except for the engine and transmission). Engine displacement and wheelbase are limited. At least 500 of the engines must have been built and installed. There are four classes, depending on engine displacement.

The Trans-Am series

This is one of the few forms of racing in which American, European, and Japanese production cars compete on equal terms. Trans-Am races are held from May to October.

Touring-car racing as performed in Japan, Australia, and South America is not subject to the same strict rules that govern the sport in Europe and North America. Competitors generally have carte blanche for modifications. Such races are not listed on the international calendar and are not included in any but local championships.

Stock-car racing. Stock-car racing is a unique American form of racing modified production cars. Stock-car events are sanctioned either by NASCAR or USAC.

NASCAR sanctions competition in five distinct categories of stock-car racing: grand national, grand American challenger series (formerly grand touring), late-model sportsmen, modified late model, and Pacific-coast late model. The so-called stock cars are anything but stock, being specially built and prepared in expert speed shops and supplied with special nonproduction components by the auto manufacturers. The external bodywork remains identifiable as a production-type passenger car. Grand national cars can be no more than three years old. Minimum wheelbase and minimum weight are specified. There are two classes based on engine size. A requirement that a restrictor plate be installed between the carburetor base and the intake manifold was discontinued in 1971, but carburetor-base openings were limited, depending on engine design and displacement. All engines are stock-block V-8s with four-barrel carburetors, and the restrictor plate has four lobes with size limits according to engine type and size. There is also a sliding scale for race-ready vehicle weight without driver and minimum dimensions concerning ground clearance.

Stock-car categories

The Grand American category was instituted for cars in the Trans-Am category. The same engine-size limits apply. Late-model sportsman cars are three to 13 years old, with minimum wheelbase and weight. Engine modifications are allowed, but only one carburetor can be fitted. Modified late-model stock cars have a minimum wheelbase and weight, but there are no restrictions on engine and chassis modifications. Re-bored blocks, superchargers, fuel injection, and any number and type of carburetors are authorized. The Pacific-class rules differ only in detail. Most NASCAR stock-car races are held on superspeedways such as Daytona (Florida), Talladega (Alabama), Atlanta (Georgia), and Ontario (California); but many older speedways are still in use, such as Darlington (South Carolina), and Charlotte and Rockingham (both North Carolina). The cars approach 200 miles (320 kilometres) per hour and race averages exceeding 150 miles (240 kilometres) per hour have been recorded.

The stock-car division of USAC, which sets different rules

than NASCAR, sanctions races in which greatly modified late-model American production-model passenger cars are eligible. A third series of stock-car races is sanctioned by the Automobile Racing Club of America, mostly on short oval tracks, both dirt and paved.

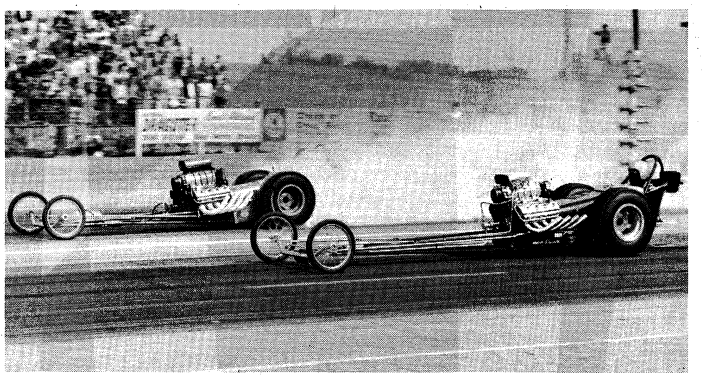
Sports-car racing. Races for production-type and modified sports cars are held all over the world. Sports-car racing is essentially an amateur sport, in contrast to the heavily professional manufacturers' championship races. Sports-car races are, of course, road-circuit races, often conducted concurrently with touring-car races. All major and many minor courses are in regular use throughout the season.

The most regulated form of sports-car racing takes place in the United States, where the SCCA directs a road-racing championship for production-type and modified sports cars. The SCCA lists a classification of all current or popular sports cars, grouping them in categories according to proved performance so as to accommodate all competitors on an equitable basis.

There are eight classes, from A through H, A being for the fastest machinery and H for the slowest. There are no engine-displacement or vehicle weight limits, but strict limitations govern modifications allowed from standard trim. The SCCA sanctions about 350 events per year, from drivers' schools, regional, and restricted-entry events, to national, interdivisional, national open, and international races.

Drag racing. Drag races are standing-start acceleration races over a quarter-mile with both elapsed time and terminal speed being recorded. Most events are match races between two vehicles, starting side by side and running parallel to each other on a straight and level roadway or drag strip. The loser of each race is eliminated, the winner returning to face other winners in his class. Starts are made by countdown-type signal lights, and performances are usually recorded electronically.

By courtesy of the National Hot Rod Association



"Slingshot" design cars at the start of their run for top gas eliminator title.

The largest drag-race sanctioning body is the National Hot Rod Association (NHRA), with an annual schedule of more than 3,000 events. The principal races are strictly professional and cover a multitude of classes, from those for special vehicles capable of covering the standing quarter-mile in about six seconds, with a terminal speed of about 230 miles (370 kilometres) per hour, to practically stock family sedans. The American Hot Rod Association (AHRA) is a rival organization, also sanctioning more than 3,000 events annually. Rules closely parallel those of the NHRA.

Off-road racing. Minor off-road events have been held all over the world, at least since the 1920s, but the sport has been organized and regulated in recent years with the formation of the National Off-Road Racing Association in America. NORRA stages two major annual events: the Baja 500, which starts and ends in Ensenada, Baja California, Mexico; and the Mexican 1000, which starts in Ensenada and ends in La Paz, Territorio Sur de Baja California, Mexico. Eligible cars fall in nine categories. Two-wheel-drive categories include: production two-wheel-drive passenger cars; production two-wheel-drive utility vehicles (pickup trucks, etc.); single-seat two-wheel-drive vehicles and two-wheel-drive vehicles with only one occupant; and modified and nonproduction two-wheel-drive cars with two occupants. Four-wheel-drive categories are: production-type four-wheel-drive vehicles and modified and nonproduction four-wheel-drive vehicles. Motorcycle categories are: motorcycles of 125 cubic centimetres (7.6 cubic inches) displacement and motorcycles over 125 cubic centimetres displacement. The ninth category is for "Baja Bugs," (modified Volkswagen sedans).

The Baja 500 and the Mexican 1000

The Mexican 1000 course includes long, straight stretches of open desert, some sudden detours, rock-strewn washes, and low, blind hillocks, boulder-covered rockbeds, sandy beaches, and tufted dunes.

A popular type of off-road event in Great Britain is the Rally-Cross, which is a short-distance cross-country race with production cars, with a minimum of rules. France has two main off-road races, the Rallye Infernal and Rallye des Cimes, which cover longer distances and allow production cars, dune buggies, and four-wheel-drive utility vehicles, as well as sports cars.

RALLIES

Rallies are point-to-point driving events taking place on public roads, with a common meeting point for routes from a number of different starting points, often in different countries. A rally is a reliability trial, not a race. The average speed is limited, and the highest speed attained under way is not a factor in the competition. Most rallies do, however, have special stages (divisions, or sections, of the route that follow a stretch of road that is closed to other traffic) over which each competitor races against the clock. The winner is decided on the basis of regularity on the road sections, speed on the special stages, and performance in extra tests held after arrival at the finishing point. The exact evaluation and allocation of points are set for each rally in the supplementary regulations issued by the organizer.

A secondary form of rally, officially called Touring Concentration, has as its aim the assembly of travellers at a certain point or points. Road stages have no speed schedules, and special stages are confined to additional trials (not speed tests) at the point of assembly.

Duration ranges from about six hours to more than a week, depending on the category of the event. Minimum distances are specified for all major international events to qualify for an FIA-sanctioned championship. The most important rallies are the events that count for the International Rally Championship for Constructors (points are given to the car, not to the driver).

Championship rally events

Eligible cars are specified by the FIA as series-production touring cars (Group 2), series-production grand touring cars (Group 3), and special grand touring cars (Group 4). The exact definitions are spelled out in the International Sporting Code.

The events are the Monte Carlo Rally, the Swedish Rally, the San Remo-Sestriere Rally in Italy, the East African Safari, the Rally of Morocco, the Austrian Alpine Rally, Greece's Acropolis Rally, France's Alpine Cup Rally, and Britain's RAC (Royal Automobile Club) Rally.

The rallies are usually organized by the national automobile clubs in the various countries, and the cars are entered either by the manufacturer or by a private competitor. Most drivers are professionals. The factory-team cars especially are extensively modified (within the rules of the class they are competing in). They may be equipped with larger fuel tanks; extra wheels with special tires, racing seats and steering wheels; a battery of fog lamps; special lights and auxiliary headlights and adjustable spotlights; plus reinforced suspension systems; super-tuned engines; heavy-duty cooling systems; and roll cages (steel tubes or bars to prevent body collapse in a roll-over accident).

There is also a European Rally Championship for Drivers, in which drivers and codrivers are allotted points for their performance in each event in the series, and the points are added up at the end of the series of 21 rallies,

including The Netherlands' Tulip Rally, Finland's Rally of the 1,000 Lakes, Tour de France, and Tour de Corse (Corsica). Eligible cars include all those allowed in the manufacturers' rally championship, plus sports cars and prototype sports cars, at each organizing club's discretion.

Rallies in America are governed by the SCCA. There are many types of rallies in the United States. Michigan's Press-On-Regardless Rally most closely conforms to the European rallies. The MG Car Club's International 1,000-Miles Rally stresses navigation and split-second timing. The Rebel Yell Rally is mainly a test of route-following ability. Other rallies are endurance events. Many local rallies are mere touring concentrations.

Long-distance events such as the 1968 London–Sydney and the 1970 London–Mexico City World Cup Rally are not true rallies in that they are not governed by FIA rules, nor do they conform to the traditional concept of multiple starting points and one finishing point. They were organized not by the national automobile clubs but by newspapers. Both routes included long sea voyages.

HILL CLIMBS AND TRIALS

Hill climbing. Hill climbs are short-distance races against the clock on mountain roads. Only one car races at a time, from a standing start to a flying finish. The roads are usually part of a public-road system, closed to traffic for the occasion. The most important hill climbs are the events that count for the European Mountain Championship: Austria's Semmering, Spain's Montseny, Germany's Rossfeld (Berchtesgaden), France's Mont Ventoux and Le Mont-Dore, Italy's Cesana-Sestriere and Trento-Bondene, Switzerland's Ollon-Villars.

The European Mountain Championship

Eligible cars are special touring cars (Group 2), special grand touring cars (Group 4), and sports cars (Group 5). The minimum distance is five kilometres (three miles), with a minimum altitude difference between start and finish lines of 350 metres (1,150 feet) and a minimum average gradient of 5 percent. Each competitor must run a minimum of ten kilometres (six miles), which means that he must make two runs on hill-climb courses shorter than that. In such cases, times are simply added and speeds averaged. The winner is determined solely by speed. Great Britain has its own hill-climb championship, with such venues as Shelsley Walsh and Prescott. The British events admit open-wheeled single-seater racing cars and sports cars but not touring cars.

Hill climbs in the United States are organized by local auto clubs, and entries range all the way from touring cars to open-wheeled single-seater racing cars. The U.S. number one hill climb is Pikes Peak, Colorado. Minor events are staged in all mountain areas (Rocky Mountains, Alleghenies, Poconos, and Adirondacks).

Hill trials. The word trials in this context has a very special meaning: a "trials" is a particular British event consisting of an off-road hill climb for two-wheel-drive sports cars. The "Trials Special" vehicle is usually a small, lightweight chassis powered by a mass-production engine, with thin front tires and fat rear ones. The Royal Automobile Club (RAC) has set rules for Trials Specials that demand that the distance between the front axle and the foremost spark plug can be no more than one-fifth of the car's wheelbase. The seating compartment must not extend beyond the rear axle. Maximum rear-wheel rim width is five inches (13 centimetres). Limited-slip differentials, chains, studs, and cleated tires are outlawed.

SPEED-RECORD TRIALS

Speed record trials do not constitute a popular spectator sport, as these record-breaking attempts usually take place far from population centres and last too long for public interest. The world land-speed record is a competition for the highest possible average speed over a measured mile, measured over two runs, one in each direction. There are no limitations on power plant, vehicle size and weight, fuel type or consumption. This kind of competition has progressed to the jet or rocket propulsion state (as opposed to mechanically driven wheels).

In the unlimited engine size class, a world land-speed record of 394.2 miles (634.3 kilometres) per hour set by Englishman John Cobb at the Bonneville Salt Flats, Utah, in 1947, stood until July 17, 1964, when Donald Campbell, son of a former British record holder, drove a jet-powered (rear wheels driven) "Bluebird" 403.1 miles (648.6 kilometres) per hour at the Lake Eyre salt flats in Australia. This record for wheel-driven vehicles was broken by Robert and William Summers of the United States on November 13, 1965, with 409.28 miles (658.53 kilometres) per hour at Bonneville. Driving pure-jet-thrust vehicles, Craig Breedlove of the U.S. became the first human to be officially timed at more than 400, 500, and 600 miles per hour, all at Bonneville. He set a record of 407.45 miles (655.59 kilometres) per hour in a three-wheeled jet in 1963, sanctioned by the Fédération Internationale du Motocyclisme. The FIA qualified jet-thrust propulsion for the land-speed record but still required that the vehicle have four wheels. In 1964 Breedlove in a four-wheeled jet was timed at 526.28 miles (846.78 kilometres) per hour (in 23 days during October 1964 the records were: October 2, Walt Arfons/Tom Green [U.S.], 413.20 miles [664.84 kilometres] per hour; October 5, Art Arfons [U.S.], 434.02 miles [698.34 kilometres] per hour; October 15, Breedlove, 526.28 miles [846.78 kilometres] per hour; and October 27, Art Arfons, 536.71 miles [863.57 kilometres] per hour). Art Arfons set the record at 576.553 miles (927.674 kilometres) per hour November 7, 1965; and on November 15 Breedlove pushed it past the 600 mark with an average of 600.601 miles (966.367 kilometres) per hour for two runs through the measured mile.

World land-speed record attempts

World land-speed record attempts can only be made one or two places in the whole world (Bonneville Salt Flats, Utah, and Lake Eyre, Australia) because of the tremendous speeds and distances required. There are also one-hour and 24-hour world-speed records for vehicles of unlimited engine size. International class records cover average speeds over distances from one kilometre to 100,000 kilometres for cars in ten different classes, based on engine displacement. International class record runs are usually made at banked speedways where nearly constant speeds can be maintained throughout, such as Montlhéry, Monza, and Miramas.

A variety of especially made cars compete annually at the Bonneville Salt Flats, during the Bonneville Speed Week, for top speeds on the dry lake. They follow NHRA classification (not FIA) since most active competitors come from the ranks of drag racing.

OTHER EVENTS

Gymkhanas. The gymkhana is a driving skill and manoeuvrability test with obstacles, usually including a selection of slalom S-bends, short straights, a reversing test, U-turns, and other elements of similar nature. Each car goes through alone and is timed. Gymkhanas are popular with local automobile clubs, one-make clubs, and other associations not involved with professional racing. There are no international rules, and most clubs set their own regulations.

Historic (Classic or Antique) car meets. Historic car meets are held all over the world, and competition exists on three levels—racing, road-driving regularity, and *concours d'élégance*. Very few events include racing. Most are route-following events or touring concentrations, with the main competition centred on the *concours*—*i.e.*, the condition (quality of restoration, authenticity, rarity, and overall desirability) of the vehicles.

Classifications of cars

Under British rules, all automobiles manufactured prior to or during 1904 are Veteran cars. Vehicles from the 1905–15 period are Edwardian, and 1915–30 cars are Classic. Under American rules, all cars manufactured prior to 1930 are Antique. Newer cars of special appeal are Classics, which overlap with the Special-Interest cars. Classics stop about 1948, while Special-Interest cars have no limit in time.

Most famous of the route-following events is the British Veteran Car Club's London to Brighton Run, which has been held annually (with interruptions for the war years) since 1896. Cars start at brief intervals from Hyde Park in London and congregate at the end of the 57-mile (92-

kilometre) trip on Madeira Drive in Brighton on the Channel coast. The only true historical car race is the Vintage Sports Car Club annual race meeting at Silverstone, England.

The FIVA (Fédération Internationale des Voitures Anciennes) sanctions nine rallies in Europe: the Westfalen-Rallye at Siegen; the Grand Prix Internationale de Restauration et Conservation at Verona, Italy; Automobilhistoriska Rallyt at Göteborg, Sweden; Gran Premio Barcelona-Alicante in Spain; Internationale Deutschlandrally at Travemünde; Rallye International des Ancêtres in Brussels; Rallye Monte Carlo des Ancêtres in Monaco; Tour du Luxembourg; and the Internationales Motorveteranenrally in Vienna. The Antique Automobile Club of America has a full calendar of events, topped by such functions as the AACA Spring Meet in Dearborn, Michigan; the AACA Glidden Tour; and the AACA National Fall Meet in Hershey, Pennsylvania.

III. Modern motorcycle sports

MOTORCYCLE RACING

Governing bodies. The International Sporting Code for motorcycle racing is the creation of the International Sporting Commission of the Fédération Internationale du Motocyclisme (FIM). The sporting code is continually revised and brought up to date. The International Sporting Commission has several subcommittees, such as the Standing Sub-Committee for Track Racing and the Moto-Cross Sub-Committee. FIM members are the motorcycle associations of more than 40 nations. Each country has only one national club that can be elected to FIM membership. These clubs sanction international, national, and regional events in their respective countries.

Classes and events. *Road racing.* Motorcycle road races are held on closed courses, parts or all of which may be public roads. The motorcycle road-racing world championships, established in 1949, have categories for both riders and machines. The machines are divided into two classes, A and B. Class A is for pure racing motorcycles, class B, for sports motorcycles. There are no formulas, such as in automobile racing, but Class A is divided into five groups, based on engine displacement, from 50 cubic centimetres (three cubic inches) and under, up to 350 to 500 cubic centimetres (20 to 30 cubic inches). Class A includes the Grand Prix motorcycles, which have supertuned engines and aerodynamic bodywork enveloping the handlebars, front wheel, and suspension system. Class B is limited to 500 cubic centimetres.

World-championship motorcycle road races

World-championship races are held on road courses or on speedways. There are 12 races that count for the championship with bonus points allotted to each machine and rider on a basis of performance in each event. The Austrian Grand Prix is held on Salzburgring; the German Grand Prix at Hockenheim; the Tourist Trophy (TT) on the Isle of Man; the Dutch Grand Prix at Assen; the Belgian Grand Prix at Francorchamps; the East German Grand Prix at Sachsenring; the Czechoslovakian Grand Prix at Brno; the Swedish Grand Prix at Anderstorp; the Finnish Grand Prix at Imatra; the Ulster Grand Prix at Dundrod; the Italian Grand Prix at Monza; and the Spanish Grand Prix at Montjuich (Barcelona). The Isle of Man TT, staged by the Auto-Cycle Union since 1907, is the world's oldest and its mountain road-racing course, site of the Senior (500-cubic-centimetre class) TT since 1911, is the world's most famous. It consists of well-surfaced highways running through the countryside and parts of two towns; hairpin corners and steep rises and falls abound, the highest point being 1,400 feet (425 metres) above sea level. The international events cover seven laps, or 264.13 miles (424.99 kilometres).

In addition, there are races with a Grand Prix title that do not count for the world championship, such as the Grand Prix of Canada, Grand Prix of Greece, and the Adriatic Grand Prix (Opatija, Yugoslavia).

Local clubs and organizations all over the world have their own international road-race meetings throughout the year. The FIM calendar shows over 100 such events sanctioned by national clubs and run in accordance with FIM rules and regulations.

Endurance and sprint races

Endurance races are road races with machines that are eligible in Grand Prix events, plus production-type sports models. Six races are selected as qualifying events for the FIM Endurance Cup: the Southampton 500 Miles Cup (England), six hours of Österreichring, 24 Hours of Montjuich, International six hours at Zandvoort (The Netherlands), Bol d'Or at Montlhéry, and the International six-hour race at Schwenningen (Germany).

Sprint races are short road races with Grand Prix type motorcycles. They do not qualify for any championship. The two principal sprint races on the calendar are both held in The Netherlands (Uden and Zandvoort).

Speedway racing. Speedway motorcycle racing is conducted on short, flat, oval dirt tracks for short distances. The machines are ultralightweight, with small tanks and small brakes.

The Speedway World Championship is not decided on a points basis but by elimination (as in drag racing). The finals decide the eventual winner(s). There are 11 qualifying events (one each in Germany, Italy, Yugoslavia, Hungary, East Germany, Sweden, Denmark, Poland, and Czechoslovakia, and three in England; but finals are held in a different country each year (which is then omitted from the following year's list of qualifying events). The national clubs sanction about 50 international speedway races organized by themselves or by local clubs under FIM rules. In addition, local clubs stage local events.

Grass- and sand-track speedway meetings are medium-speed events for machines of all types and sizes, with and without sidecars, competing within their respective classes. One-kilometre sand tracks (as used in harness [horse-and-sulky] races) are used in Scandinavia and Germany. The four World Sand Track Championship races are run on one-kilometre tracks. Shorter sand tracks and grass tracks are used for lesser international events.

Reliability trials. Motorcycle trials are slow, on-and-off-highway events of long duration, with machines in "production" trim; as in automobile rallies, speed is not the determining factor, but a time schedule must be maintained. There are classes for solo riders and machines with sidecars. The most famous are Britain's International Six-Days Trial, and the Scottish Six-Day Trial. A series of five two-day trials, each in a different country, forms the European Reliability Trial championship. The venues are Eschwege in West Germany, Zschopau in East Germany, Krkonosska in Czechoslovakia, Bergamo in Italy, Barcelona in Spain. The national clubs (under FIM rules) sanction a number of other international trials that do not count toward any championship. The Scottish Six-Day Trial is one of these.

Moto-cross. Moto-cross is a type of motorcycle race popular in Great Britain and Europe that takes place off the road, in rough terrain or open plains, of short distance and duration. Courses typically include steep up-and-down grades, sharp turns, straight stretches, bumps, stretches of loose sand or dirt, and mud holes. A race consists of a specified number of laps. The machines are equipped with knobby tires for off-road traction, high ground clearance, and extra-low gearing for pull power at low speeds.

Moto-cross racing has been formally organized in Europe since 1952. The moto-cross world championship is for motorcycles up to 500 cubic centimetres (30 cubic inches), and each participating nation has its own event that gives points toward the championship. There are 12 qualifying events: the Italian Championship Moto-Cross; the Austrian Moto-Cross Grand Prix at Sittendorf (Vienna); the Swedish Championship Moto-Cross; the Finnish Moto-Cross Grand Prix at Tikkurila; the Czechoslovakian Moto-Cross Grand Prix; the Soviet Moto-Cross Grand Prix at Kishinev; the East German Moto-Cross Championship; the British Moto-Cross Grand Prix; the German Moto-Cross Grand Prix; the Belgian Moto-Cross Championship; the Moto-Cross Grand Prix of Luxembourg; and the International Moto-Cross at Sint Anthonis (The Netherlands).

Championship moto-cross events

A minor league of moto-cross is restricted to 250-cubic-centimetre (15-cubic-inch) engines, and FIM has 12 such events counting for a secondary championship. The

Contestants manoeuvring over rough terrain in International Moto-Cross Championships of 1969, held at Kishinev, U.S.S.R.
London Daily Express—Pictorial Parade

most important venues are Payerne in Switzerland, Karlovac in Yugoslavia, Bergharen in The Netherlands, and Launsdorf in Austria. FIM and the national clubs also sanction a series of international moto-cross events organized by local clubs. These do not count toward any championship. In addition, local clubs everywhere organize national or regional events throughout the season.

With the approval of the FIM the American Motorcycle Association introduced an eight-race moto-cross series called the Trans AMA in the United States in 1970.

Drag racing. An outgrowth of the speed record trials included in the program of the Bonneville (Utah) Speed Week, motorcycle drag racing is patterned after automobile drag racing and, like it, is an American innovation. It consists of a series of acceleration, or top speed, contests, each between two racers, over one-quarter mile (one-half kilometre) on a straight, smooth-surfaced course. As in the case of auto dragsters, there are no restrictions as to frames, wheels, tires, engines, or most other components; the vehicles are raced in many classes; and there are both gas (gasoline-powered) and fuel events (see also above *Modern automobile sports: Off-road racing*).

Ice racing. Ice racing is the arctic equivalent of speedway racing. The machines resemble each other, except that spiked (studded) tires are used in ice racing. Instead of dirt tracks, ice races are held on ovals from which the snow has been plowed on frozen lakes, or on ice-covered stadium tracks.

The ice racing world championship is a six-stage duel between Sweden and the U.S.S.R. In addition to the championship events, Austrian clubs and the Motorcycling Federation of the Soviet Union stage a number of international ice races.

OTHER EVENTS

Rallies. Motorcycle rallies fall into two categories: first, events where route following and regularity count; and second, touring concentrations with low emphasis on competition. There are 23 important international rallies in Europe (often called reliability trials but not to be confused with off-highway trials). They include the Norddeutsche 2-Tagefahrt, the Austrian Aplenfahrt, the Saale Cup (East Germany), 24-hours of Liège at Zolder, the Cannes–Geneva–Cannes rally, and the Coupe de l'Armistice.

International rallies and touring concentrations

Touring concentrations have become the special preserve of the Italians, the Dutch, and the Belgians, and ten major rallies are held each year in towns such as Modena, Rimini, Alessandria, and Rome, Italy; Gand (Ghent) in Belgium, and Eefde in The Netherlands.

Hill climbs. Motorcycle hill climbs are uphill-road races for Grand Prix and sports-model machines in which each rider races against the clock. Only one machine is in motion at any time. The European Mountain Trophy is decided by points gained in a series of five events: the International Alpland Bergrennen at Mürtzal (Austria), Cernobbio-Bisbino in Italy, Mont Ventoux in France, Monte Generoso in Switzerland, and the Sauerland Bergpreis (Germany). The national clubs also sanction and organize five secondary international hill climbs: Behamberg and Stainz in Austria; Mont Verdun (Lyon) in France; Orsières in Switzerland; and La Rabassada in Spain.

Speed-record trials. Just as there are World Speed Records for automobiles, there are World Speed Records for motorcycles. Only one machine is running at any one time and, as a rule, there are no challengers present. The runs are made in a straight line, one kilometre and one mile in opposite directions, and the average speed for the two runs becomes the official record. In addition to the absolute speed record, there are one-hour and 24-hour world speed records for motorcycles, with and without sidecars. International class records cover distances from one kilometre to 100,000 kilometres with classification according to engine displacement and whether or not a sidecar is used.

Annual maximum speed runs for motorcycles are part of the program of the Bonneville Speed Week on Utah's dry lake. Classification is in accordance with NHRA rules (not FIA). These events led to an outgrowth in the form of the dragster motorcycle and motorcycle drag racing, often using automobile engines.

BIBLIOGRAPHY. GEORGE MONKHOUSE, *Grand Prix Racing: Facts and Figures* (1950), covers the premier events of road racing from the start up to modern times. GRIFFITH BORGESON, *The Golden Age of the American Racing Car* (1966), is a thorough account of U.S. constructors and drivers between 1921 and 1931. EARL HOWE, *Motor Racing* (1951); and S.C.H. DAVIS (ed.), *Motor Racing* (1957), are anthologies covering the state of the art. LAURENCE POMEROY, *The Grand Prix Car, 1906–1939* (1949), is an articulate technical thesis. JACK C. FOX, *The Indianapolis 500* (1967), details the history of the speedway in great statistical detail. ROGER LABRIC, *Les 24 Heures du Mans* (1949), covers all pre-World War II events at the Sarthe circuit (in French). ALFRED NEUBAUER, *Männer, Frauen und Motoren* (1958) and *Herr über 1000 PS* (1959), give an insider's view of the racing world in the period 1919–55 (both in German). WILLIAM BODDY (comp.), *The Story of Brooklands,* 3 vol. (1948–50), is a chronology of events at Britain's first motor speedway from 1907 through 1939. SIR MALCOLM CAMPBELL, *Speed on Wheels* (1949); and S.C.H. DAVIS, *The John Cobb Story* (1953), relate the quest for the World Land Speed Record prior to the arrival of the gas turbine. STIRLING MOSS and LAURENCE POMEROY, *Design and Behaviour of the Racing Car* (1963), is well described by its title yet is written to be fully understandable to the layman. PIERO TARUFFI, *Tecnica e practica della guida automobilista da corsa* (1958; Eng. trans., *The Technique of Motor Racing,* 1959), is an illustrated manual for would-be racing drivers. ENZO FERRARI, *Le Mie gioie terribili* (1962) and *Le Briglie del successo* (1970), are autobiographies of the famous constructor that throw considerable light on his drivers, engineers, friends, and enemies. NORMAN SMITH, *Case History* (1958), covers the career of all leading Grand Prix cars from 1927 through 1957. COUNT GIOVANNI LURANI, *Nuvolari* (1959), is a biography of one of the world's greatest drivers. RONALD HANSEN and FEDERICO B. KIRBUS, *The Life Story of Juan Manuel Fangio* (1956), is a smaller work of the same genre. STIRLING MOSS, *In the Track of Speed* (1957), reviews the early years of his career. GRAHAM GAULD, *Jim Clark: Portrait of a Great Driver* (1968), pays tribute to the Scottish champion. RUDOLF CARACCIOLA, *A Racing Driver's World* (1961), is a personal report on his life and activity. JOHN FITCH, *Adventure on Wheels* (1959), is the story of Fitch's racing career and also an account of the revival of road racing in America after World War II. GERALD ROSE, *A Record of Motor Racing, 1894–1908* (1949), is generally regarded as the most authentic description of motor racing for this period. The *British Racing Drivers' Silver Jubilee Book* (1952), is an anthology covering the history and technology of racing, with contributions by Sir Algernon Guinness, J.D. Benjafield, John Eason Gibson, Lord Brabazon of Tara, Rodney L. de Burgh Walkerley, Georges Roesch, R.R. Jackson, and Desmond Scannell. CHRISTIAN LACOMBE, *La Moto* (1970), is the most complete record of motorcycle racing in all its forms and the evolution of the racing motorcycle published so far (in French). MICHAEL COSTIN and DAVID PHIPPS, *Racing and Sports Car Chassis Design* (1961),

is a handbook for racing car engineers and constructors. MICHAEL HENDERSON, *Motor Racing in Safety* (1968), outlines the need for safety improvements and proposes areas and directions of action.

(J.P.N.)

Mo-tzu

Mo Ti (Mo-tzu; 470?–391 BC?) was an important philosopher and founder of a school of thought bearing his name that, with Confucianism, was, for 200 years, one of the dominant schools in ancient China. Although his name was Mo Ti, he is popularly referred to as Mo-tzu (Motze, Motse, Micius), meaning Master Mo or Teacher Mo. His school was Moism.

Born a few years after Confucius' death, Mo-tzu was a contemporary of Socrates. Mo-tzu attacked the most pressing problem confronting all thinkers in the 5th century BC, when the feudal hierarchy instituted at the beginning of the Chou dynasty (1122–221 BC) was swiftly disintegrating and the country was divided into small, constantly warring, feudal states: how to bring political and social order out of chaos.

According to tradition, Mo-tzu was originally a follower of the teachings of Confucius, until he became convinced that Confucianism laid too much emphasis on a burdensome code of rituals and too little on religious teaching, at which time Mo-tzu decided to go his own way. Confucius, from all accounts, was aristocratic by temperament and orientation and dreamed of a return of the calm and peaceful days of pomp and splendour at the beginning of the Chou dynasty. Mo-tzu, on the other hand, was drawn to the common people and looked much farther back to a life of primitive simplicity and straightforward human relations.

Mo-tzu's life, however, resembled that of Confucius in many important respects. He was widely read and well versed in the tradition of the Chinese classics. Except for a brief period when he held public office, Mo-tzu, in contrast to most Chinese thinkers, lived very simply. He spent most of his life travelling from one feudal state to another in the hope of meeting a prince who would allow him to put his teachings into practice. In the absence of such a prince, he had to be content with maintaining a school and recommending his disciples for administrative positions. He commanded respect partly because he was a teacher who took his own teachings seriously. He not only condemned offensive war but journeyed to distant states to prevent the outbreak of a war whenever he heard of such a possibility.

The *Mo-tzu*

The *Mo-tzu*, the principal work left by Mo-tzu and his followers, contains the essence of his political, ethical, and religious teachings. The gist of it is found in the three sets of chapters of its second section, which give an overview of the ten major tenets: exaltation of the virtuous, identification with the superior, universal love, condemnation of offensive war, economy of expenditures, simplicity in funerals, will of heaven, on ghosts, denunciation of music as a wasteful activity, and antifatalism. Since, following Mo-tzu's death, Moism split into three schools, the three sets of chapters may well represent the three sets of texts preserved by the three schools. The other sections might be listed as follows: I, summaries and abstracts of Mo-tzu's teachings; III, discussions on logic and physical sciences; IV, records of Mo-tzu's doings and sayings; V, a manual of military defense.

As a thinker Mo-tzu is distinctive in his insistence on methodology. He insisted that standards of judgment be established, and his criteria may be summarized as the threefold test and the fourfold standard. The threefold test reminded thinkers that the basis, verifiability, and applicability of any proposition must be analyzed; the fourfold standard reminded thinkers that one should always assess the benefits any proposition could bring to the country and the people. Benefits were defined as enrichment of the poor, increase of the population, removal of danger, and regulation of disorder. To Mo-tzu the tests and standards were indispensable. Generalizing further, Mo-tzu declared that before anything could be said to be good, it was necessary first to demonstrate what it was good for.

The cornerstone of Mo-tzu's system was universal love. If the world is in chaos, he said, it is due to man's selfishness and partiality, and the prescribed cure—in striking parallel with Christianity—is that "Partiality should be replaced by universality," for "when everyone regards the states and cities of others as he regards his own, no one will attack the others' state or seize the others' cities." The same principle was to be applied to the welfare of the family and of the individual. The peace of the world and the happiness of man lie in the practice of universal love. Many objections—its impracticability, its neglect of the special claims of one's parents—were raised against this new doctrine, but Mo-tzu demonstrated that the principle of universal love had in it both utilitarian justification and divine sanction. He spoke of "universal love and mutual profit" in one breath, and he was convinced that this principle was both the way of man and the way of God.

Mo-tzu's stand on religion makes him exceptional among Chinese philosophers. His call to the people is for them to return to the faith of their fathers. He might be said to be a revivalist, a champion of religious orthodoxy with a personal god. To Mo-tzu, there is heaven, heaven has a will, and this will of Heaven is to be obeyed by man and accepted as the unifying standard of human thought and action: "What is the will of Heaven that is to be obeyed? It is to love all the people in the world universally." Heaven not only "desires righteousness and abominates unrighteousness" but also metes out reward and punishment accordingly. The system of Mo-tzu, with its gospel of universal love and the ascetic discipline as exemplified by his own life, soon after the master's death, was embodied in an organized church with a succession of Elder Masters and a considerable body of devotees. The religion prospered for several generations before completely disappearing.

Influence

The teachings of Mo-tzu, however, continued to be held in high respect for several centuries. Down to the beginning of the 2nd century BC, writers referred to Confucianism and Moism in one breath as the two leading schools of thought. But from that time, Moism suddenly disappeared from the intellectual scene. Critics have generally agreed in admiring the high-minded character of Mo-tzu himself but considered his teachings overdemanding and contrary to human nature. It was not until the 20th century that Mo-tzu was rediscovered and his teachings reappraised.

BIBLIOGRAPHY. *The Mo-tzu*, ed. by SUN YI-JANG (1908; in Chinese), is generally recognized as the earliest and also the definitive edition of the text in the modern age. This is an indispensable work to all students of this subject. Other works include: Y.P. MEI, *Motse: The Neglected Rival of Confucius* (1934), a general study of the man and his age, his works, and his teachings, and (trans.), *The Ethical and Political Works of Motse* (1929), the only English translation of the text available; BURTON WATSON (trans.), *Basic Writings of Mo-tzu* (1967), a handy paperback from a series on ancient Chinese philosophers.

(Y.P.M.)

Mountain-Building Processes

A mountain is an area of land that is relatively much higher than the land surrounding it; thus, the so-called hills associated with great ranges such as the Himalayas would be mountains in a less formidable setting. In geology, the technical name for mountain building, orogenesis, is applied not only to the way in which existing mountains attained their high relief and elevation but to the processes that deformed the rocks of ancient mountain regions. Individual mountain elevations evolve in belts or ranges, with a succession of ranges forming a mountain system. Thus, the Himalayas constitute a mountain system within which are many ranges—such as the Karakoram Range—each of which has discrete mountain peaks —such as Mountain Godwin Austen, or K2 (28,380 feet [8,600 metres]).

Kinds of mountains

Structurally, mountains are of several kinds. They include isolated volcanic mountains constructed from accumulated lava flows and extruded igneous rocks. These may rise in only a few years (as Paricutín began to

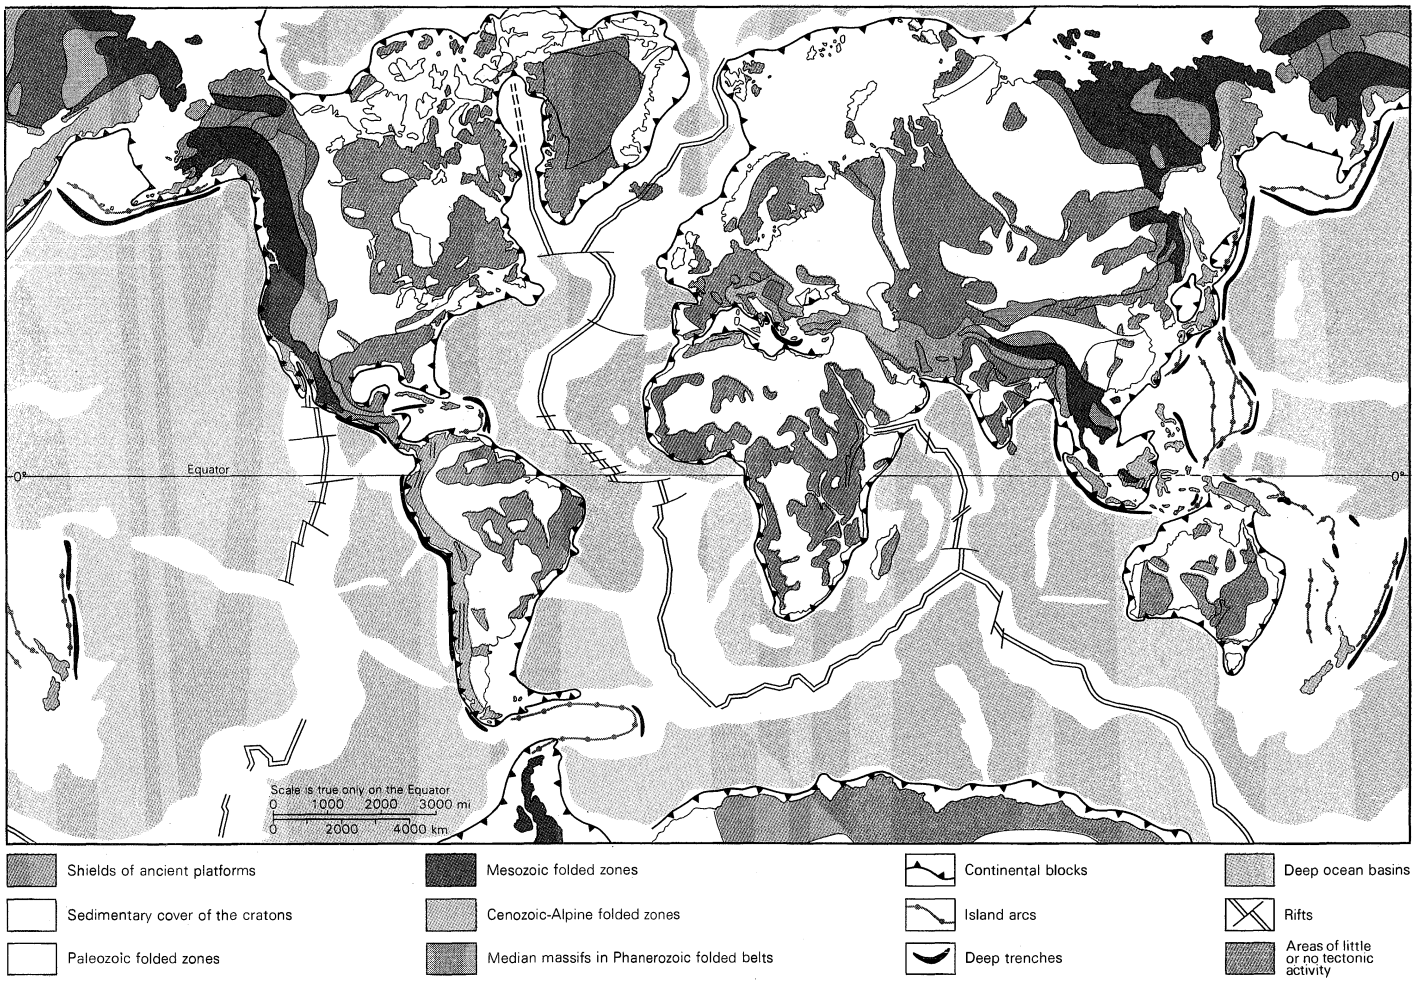


Figure 1: Structural features of the Earth's crust, particularly the regions of folding and faulting.

emerge on a plain in Mexico in 1943) or may grow over thousands or even millions of years. The broad Mauna Loa in Hawaii is built principally of lava flows; more conical mountains, such as Vesuvius in Italy and Fujiyama in Japan, contain a greater proportion of fragmental rocks that represent the explosive ejection of ash and other debris. Volcanoes (*q.v.*) are most abundant in narrow bands, particularly in the island arc areas that rim the Pacific Ocean. Recognizing the origin of volcanic peaks is not difficult; however, understanding the reasons for their distribution in particular areas and for the volcanic activity that caused them creates a project that requires much scientific research and study.

Another kind of mountain is formed by the tilt of blocks along such areas of separation as the rifts and fractures of the earth's crust. The structure of such a range can be simple, as in the tilted volcanic rocks bounded by fractures of the earth's crust along which movement has occurred (faults), exposed in the basin ranges of Oregon or those along the rift valleys (*q.v.*) of East Africa. In other ranges, though the topographic elevations appear to be similar, ancient mountains had to be reduced by erosion to subdued topography before faulting and elevation could produce the present ranges. The Sierra Nevada in California is of this sort.

The great mountain systems of the world comprise broad belts of varied rock types and structural patterns. Erosion through time tends to transform deformed and altered sedimentary and volcanic rocks into curved, elongated, continuous ranges, whereas plutonic igneous rocks (those formed by crystallization deep within the earth's crust) evolve as irregular elevations. Such rocks have distinctive compositions and structures that are recognizable even when only the roots of the ranges have avoided erosion. Processes that lead to rock deformation (*q.v.*) occur deep in the earth because the high temperatures and pressures required occur only at great depth. This fact encourages speculation on the nature of the earth's interior. Though volcanoes and block mountains contrast markedly with mountains produced by other tectonic processes of uplift and deformation, there are significant relationships among them; all the mountains are thought to represent aspects or phases of larger crustal movements.

Knowledge of the origin of mountain systems is derived from analysis of geologically young mountain ranges of high elevation, such as the Himalayas and the Alpine ranges of Asia and southeastern Europe, as well as from older and more deeply eroded ranges, such as the Appalachians of eastern North America and the Caledonian Belt of northwestern Europe. This article deals with mountains in terms of their basic origins, their reason for being. Additional details on the kinds and distribution of mountains are covered in MOUNTAIN RANGES AND MOUNTAIN BELTS. Related information on the processes involved in mountain building and their causes and effects is contained in EARTH, STRUCTURE AND COMPOSITION OF; ISLAND ARCS; RIFT VALLEYS; OCEANIC RIDGES; ROCK DEFORMATION; and SEA-FLOOR SPREADING. EARTH, GEOLOGICAL HISTORY OF contains a summary of mountain building through time.

DISTRIBUTION OF MOUNTAIN BELTS

Relation to global tectonics. The younger mountain belts of the earth appear to be related to global tectonics —that is, to the movements of large plates of the earth's crust on the underlying mantle (Figure 1). The conti-

nents and the oceans exhibit thicknesses of crust that are different from each other. The density of rocks in the continents is less than that of those in the crust below the oceans, and the crust above the Mohorovičić Discontinuity (a zone separating the crust and the denser underlying mantle within which the velocity of seismic waves changes) is relatively thicker in continental areas (40 kilometres or less) than it is below ocean basins (*q.v.*; 10 kilometres or less). It has been a basic tenet of earth scientists that elevations of the earth's surface are related to isostasy (compensatory balance of low regions of dense crust and lighter crustal segments). The gravity, and presumably the density, below oceanic trenches is unusually low. Although geophysical measurements are somewhat variable, the thickness of crust beneath the North American continent is generally greater beneath the mountains than beneath the plains. The thickest continental crust, nearly 70 kilometres (40 miles), is reported to lie beneath the Alps.

Crustal plates, rift systems, and subduction zones

Continental and oceanic crust is separated into plates that are bounded by fracture zones. The plates separate along zones of spreading; it is these zones that form the world rift system. Rift zones classically are exemplified by the Mid-Atlantic Ridge, but some, such as those of the East African Rift Belt, pass into continents. The East Pacific Rise is also of this type; it enters North America at the Gulf of California and passes beneath continental rocks in the western United States. These rift zones are the sites of relatively shallow-focus earthquakes (*q.v.*)—that is, those tens of kilometres deep or less. The plates descend into the mantle and disappear along margins termed subduction zones. These zones are represented by the distribution and concentration of deep-focus earthquakes, which increase in depth along planes that emerge in ocean trenches and are tilted toward and beneath continents or island arcs (*q.v.*). Such seismic bands are called the Benioff zones. On the western margin of South America, these earthquake focuses descend from the Andean Trench under the Andes mountain chain to a depth of 700 kilometres (430 miles).

Most of the world's volcanoes are in the islands or continents bordering the trenches of the Pacific Ocean and northeastern Indian Ocean, where, it is believed, the earth's crust is shortened by consumption of descending plates. These are the same belts in which deep-focus earthquakes descend landward along the Benioff zones. The volcanoes scattered across southern Asia and north of the Mediterranean Sea, such as the biblical Ararat (16,700 feet [5,100 metres]) and Etna (10,800 feet [3,300 metres]) and Vesuvius (4,260 feet [1,300 metres]), are along geologically more complex belts of compression.

A second site of volcanoes is along rift zones in the spreading crust. Those of Iceland and of the Canary Islands lie along the North Atlantic midocean rift; Iceland also has fault-bounded blocks. In East Africa, Kilimanjaro (19,350 feet [5,900 metres]) in Tanzania is along such a rift zone with volcanic block mountains. Volcanoes like those in the mid-Pacific Hawaiian Islands and in the widely distributed oceanic seamounts are not related to the main plate margins, which coincide with the zones mentioned above.

Older mountain belts. Although some of the younger mountain chains of the earth are along continental plate margins, older ones have little apparent correlation with present global plates (Figure 1). It would appear that some, such as the Appalachian-Caledonian Belt, were continuous at some former time and were severed by the opening and spreading of the North Atlantic Ocean Basin through continental drift (*q.v.*). They may have had relationships to ancient global plates in a manner analogous to the relationship of younger mountains and modern plates. The contemporary view is that the crust beneath all present oceans is quite young, not as old as 200,000,000 years.

TECTONIC MOUNTAIN BELTS

The tectonic mountain chains of the earth have such varying compositions and structures that only a few generalizations can be applied to many of the belts. Some of their distinguishing characteristics are used to recognize and locate the roots of ancient mountain chains, now eroded to low level, for the belts are of many ages (Figure 1). At sufficient depth, all parts of continents contain rocks that have compositions and structures resulting from orogenesis (mountain building).

Fold and fault structures. The discrete mountain ranges on the periphery of the tectonic mountain system are formed by the erosion of folded sedimentary rocks. The folds generally face away from the centre of the system; that is, a plane bisecting the folds dips (inclines) toward the interior of the system. In the Appalachians of eastern United States and Quebec and in the Rocky Mountains in Colorado and Alberta, for example, they face toward the continental interior. The folds are broken by faults where strata have become steeply inclined. Low-angle faults frequently separate the folded rocks from an underlying, relatively undeformed basement (literally, bottom rocks) and its rigid cover. The Jura Mountains in the Alpine region contain folds that have moved over salt-bearing strata, and the Cumberland Mountains of eastern Kentucky and Tennessee have folded strata that moved westward on easily deformed and sheared shales.

In many mountain systems, areas of exotic (not common, in terms of local rock types) strata lie in thrust sheets (planes of movement along which some strata are thrust up and over other beds) on the margins of the chains. They are called allochthons (from without or elsewhere) because they were transported from other areas and their lithology (rock type) contrasts with that of rocks of the same age in the autochthon (the local mass or region) below the underlying thrust faults. In New York and western New England and in western and northern Newfoundland, the basement and its cover of Lower Paleozoic strata was buried under sheets that moved westward with a sliding motion from rising welts to the east. On the northern flank of the Alpine System in Austria and Switzerland and on the south flank of the Himalayas in India and Nepal, the folds are most complex. Some have been forced into nearly horizontal attitudes and then thrust along fault planes far from the core of the range. Masses that have been moved in this manner and have then become isolated by erosion are called klippen. Many of the thrust sheets are believed to be gravity slides (the movement was, in part, downslope) generated from rising mountains in the internal parts of the mountain systems.

Age of structures and multiple orogenies

The folds may be of one or of several ages. Thus, the deformation of the Appalachian Mountains from Alabama to Pennsylvania was an event of the Late Paleozoic Variscan orogeny. Similar folds in western New England and Quebec were formed in the Acadian (Shickshockian) orogeny of Middle Devonian time, as well as in an earlier mid-Ordovician phase of the Taconian orogeny. Often folds representing stages of deformation of divergent trends may exist within the strata in a single range.

Structures formed through the erosion of folded and faulted sedimentary rocks on the borders of certain mountain systems have been called the externides, in contrast to the internides, the central part of such mountain belts. The latter region is characterized by the presence of abundant volcanic rocks in the stratigraphic successions (sedimentary layers), severe deformation and metamorphism, migmatization—the alteration of rocks to crystalline texture—and invasion by plutonic rocks. Although these generalizations apply to some mountain systems, they are inadequately descriptive of others.

Rock types of the mountain belts. The oldest rocks within the internides generally are deformed sedimentary and volcanic rocks that delineate the former geosynclines. When they are characterized by volcanic rocks, such geosynclinal belts are called eugeosynclinal. The volcanic rocks within the belts had many sources. There are ophiolites and other submarine pillow lavas that formed on deep sea floors, as well as extrusive lavas and agglomerates (composed of fragments and particles of volcanic rock) resembling those in volcanoes that form

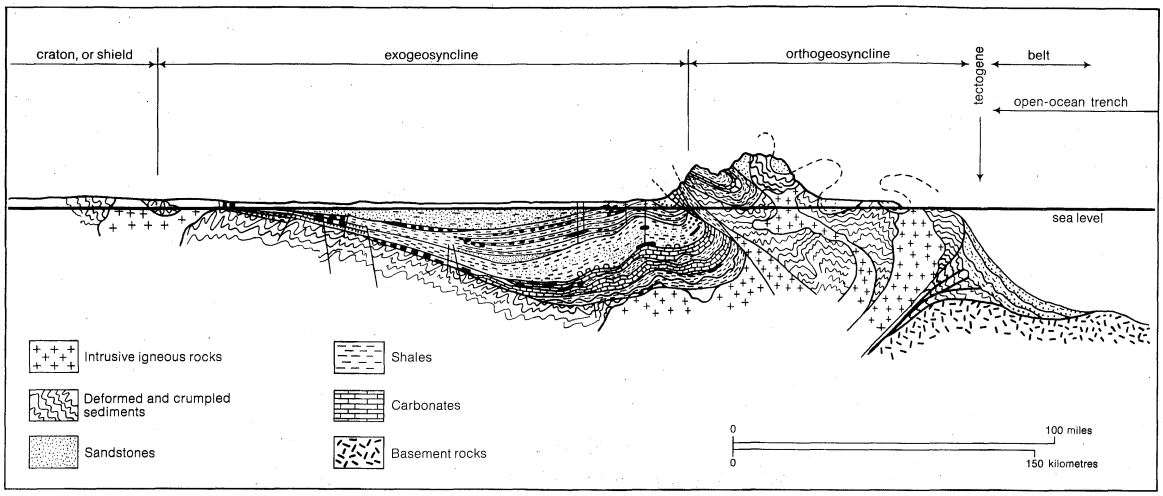

Figure 2: Idealized section across Indonesian–Japanese arc.

modern island arcs. Elsewhere, the belts contain gneisses (a metamorphic rock of banded structure) that show great alteration and deformation, and intrusive igneous rocks. Some belts are stratigraphically overlain by rock successions that have been less deformed. Such tracts represent multiple phases of orogeny within the long and complex history of the belt. They were land areas produced by deformation among the deeply subsided troughs, volcanic islands that comprise the eugeosynclinal belts. A few eugeosynclinal belts contain melanges, a chaotic assemblage of rocks, Shales, graywackes, and volcanic rocks, with interbedded mudstone and boulders of sedimentary and volcanic rocks, occur in lenses (layers that tend to converge) and bands.

Plutonic intrusions

The central parts of the mountain systems are the principal sites of the intrusion of plutonic igneous rocks. Some of these have been intruded within the belt in early phases of orogeny. Not only are they overlain by sedimentary and volcanic rocks that were deformed in later phases but they formed the surface of the uplifted land areas that were eroded to yield igneous rock debris in the succeeding sedimentary deposits. The plutonic rocks were partly emplaced while deformation was progressing and some of them thus bear the structural effect of the deformational stresses. Some so thoroughly assimilate the host, or country, rock as to form migmatites (rocks formed by the mixing of magmatic fluids with pre-existing rock). The later intrusions are relatively more massive and discordant. In many mountain systems, the batholiths (large intrusive bodies of rock) and smaller stocks are exposed in tracts of thousands of square kilometres. Batholiths are generally thought to be intrusions of very great volume that spread downward in the earth's crust. An alternative interpretation is that they are the products of solidification of magma (the liquid melt from which igneous rocks crystallize) that rose rather near to the surface because its density was less than that of the surrounding crust.

THEORIES OF OROGENESIS

Geosynclinal hypothesis. In 1858 it was observed that the thickness of the folded Paleozoic rocks in the Appalachian Mountains of the eastern United States is much greater than that of equivalent undisturbed rocks in the Mississippi Valley. Such belts of relatively thick sediments deposited as the site of deposition subsided were first called geosynclinal in 1873. From these observations came the doctrine that geosynclinal belts become mountain ranges. The American concept was based on the Appalachians; the geosynclines of North America were thought to be separated from permanent ocean basins by borderlands of ancient crystalline rocks. The European analogue was thought to be in the Alpine System, which had quite different characters.

Early in this century, there appeared an interpretation of mountain ranges in which deformation was considered to be bilaterally symmetrical, with overfolds and thrusts spreading out on both sides of an inner metamorphic and intruded zone as the original geosyncline was compressed. More elaborate models with multiple troughs and rises were later developed by structural geologists. Though each of these may have served to explain the principal features of a specific region, the specific analogies are doubtfully applicable to other ranges and systems. Many mountain systems have only a single direction of overfold and are not explainable in terms of these models.

Eugeosynclines and the tectogene

In the late 1930s the main geosynclinal belt of the Appalachians was interpreted as lying in the position of the supposed borderland belt, to the east of the present Appalachian Mountains, where the Appalachian Geosyncline had been first postulated. Rock sequences in the North American continental border region suggested the presence of deeply subsiding troughs with pillow lava flows, associated with volcanic rocks that might have formed in ancient volcanic island chains. Other sections suggested the former presence of tectonic lands, namely land areas that had been raised within the belt. Such belts in which volcanism had been prevalent were called eugeosynclinal and were said to be truly geosynclinal in the sense that they were the principal mobile belts in crustal tectonics.

The consistent presence of ultramafic (rocks consisting almost entirely of iron-magnesium silicate minerals) serpentinized bands was observed within such eugeosynclinal belts as well as in island arcs. At the time, they were associated with the concept of a tectogene, posited as a downward buckling or invagination of relatively light, thin crust descending deeply into the more dense earth mantle, as below oceanic trenches. The hypothetical tectogene was used to account for the surprisingly low gravity near such troughs; the doctrine of isostasy would require belts at very great depths to contain dense rocks of high gravity.

It was believed that this emplacement occurred at the beginning of deformation in each tectogene trough system. Serpentinized ultrabasic rocks (rich in iron and magnesium) were emplaced very early in the orogenic history and they evidently intruded rocks at shallow depths, because they are found within rocks interpreted as being parts of thrust sheets that originated from gravity slides along the borders of orogenic belts. A classic case is that of the ultrabasic rocks of the Bay of Islands, western Newfoundland, which are in masses transported in Middle Ordovician time.

Miogeosynclines and the craton

Eugeosynclinal volcanic belts contrast with linear, nonvolcanic belts that are termed miogeosynclinal; the latter are nearer the stable shield, the craton. The typical miogeosynclinal belt was thought to have thousands of feet of sediments, principally sandstones and carbonate rocks,

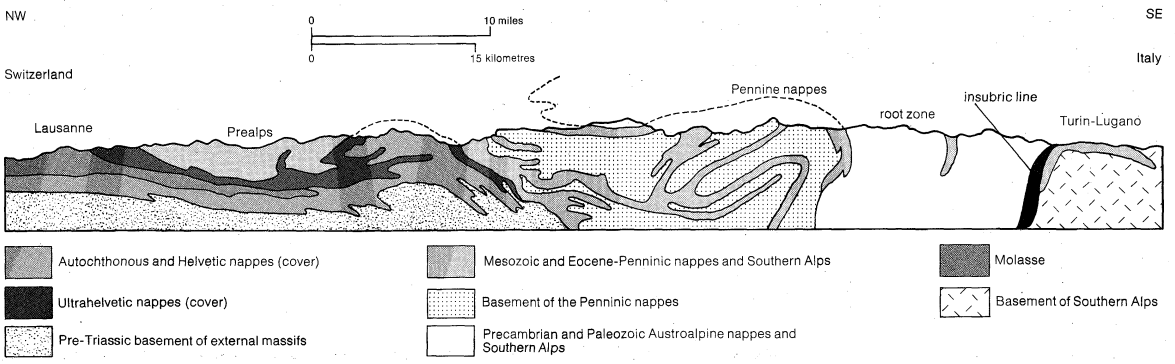

Figure 3: Generalized structure section through the Alps.
From J. Cadisch, *Geologie der Schweizer Alpen*

laid in a belt of differentially warped continental crust 400 kilometres (250 miles) wide. The folded Appalachians in the geosyncline as originally defined, were formed in a miogeosynclinal belt, extending into an ancient depression that subsided within the continent or craton as it received sediment eroded from the rising mountains within the eugeosynclinal belt. At the time that the eugeosynclinal belts were first recognized, it was assumed that ocean basins such as the Atlantic were earth features that had persisted from the very early history of the earth, and that the eugeosynclinal belts developed along the oceanic margins.

Thus, the conventional view in the early years of the 20th century in America, at least, was the geosynclines were independent of ocean basins (*q.v.*) and were intracontinental belts separated from oceans by borderlands. It was next recognized that instead of continent-like borderlands, volcanic-bearing eugeosynclinal belts had existed. The severe metamorphism and intrusion of these belts had led to the erroneous assumption that they had been long-lived continents of ancient rocks. In other continents, particularly in Europe where the Alps had been well studied, there had been suggestions that such volcanic geosynclinal belts might be oceanic, but there was no available way of substantiating such views. The so-called Steinmann Trinity of ophiolites, radiolarian cherts (siliceous rocks formed from the remains of marine organisms), and serpentine was clearly suggestive of oceanic depths, however.

Around 1950 the doctrine of the permanence of ocean basins prevailed. The accretion theory of continental growth was developed (see CONTINENTS, DEVELOPMENT OF) after knowledge of ages of intrusion had been gained by absolute age dating. The continents were thought to expand as orogenesis consolidated the rocks at the margins of ocean basins. This convention was challenged by the discovery that the oceans are geologically quite young. The possibility that other oceans of the past have been severed and destroyed also has been suggested as an alternative doctrine.

Sea-floor spreading and plate tectonics

About 1960 it became apparent that the earth is divisible into large blocks that separate at rifts within oceanic ridges and their offshoots, with which, together, they form the world rift system. Oceans broaden as ocean floors and contiguous continents spread from the midocean trenches. Reversals of magnetism in oceanic cores, when dated by paleontologic and radiometric methods, have been found to replicate quite closely the magnetic anomaly bands that roughly parallel the oceanic ridges. The greater age of ocean floor at distances farther away from the midocean ridges was subsequently proved by the dating of deep sea cores. Basically, the ocean floor at the sites of midocean ridges is relatively recent material, a few thousands of years old, whereas rocks as old as Cretaceous (65,000,000 to 136,000,000 years) in age occur farther away, toward the oceanic margins. Seismic observations show that zones marginal to oceanic trenches descend beneath adjoining continents where deep-focus earthquakes occur to depths of 700 kilometres. By 1968 the concept of global tectonics postulated oceanic crustal plates spreading apart at midocean ridges as in the Atlantic, and descending below continental margins as on the west of South America or below other oceanic plates of midocean volcanic arcs, as in the Pacific arcs. Although such ideas had been expressed many years earlier, their demonstration had depended on advances in geophysical and oceanographic techniques. These developments bear on the understanding of the origin of mountain systems.

The doctrine of the permanence of ocean basins was superseded by the knowledge that oceans are dynamic and ephemeral. The concepts of the relative youth of ocean basins and of the mobility of crustal plates have provided means by which the varied characters of mountain systems can be explained. Mountain building is related to the processes that both produce and destroy crustal plates. Recent volcanic island arcs and mountain belts, for example, exhibit strong correlation with belts of high seismicity as if to suggest that both are dependent on larger earth movements. Deep-focus earthquakes occur along the subduction zones where crustal plates descend. The relations of some recent mountain systems to present crustal structures is thus apparent. Analogies with rocks and structures in other belts lead to the conclusion that they formed along and within similar crustal plates in patterns that have been superseded, for oceans have been formed by spreading and have been destroyed by loss of margins as well as by compression. Mountain ranges have such great diversity that generalizations must be made with great caution. The causes of many of the changes through time are now speculative, but observations confirm the ephemeral nature of many of the larger earth features.

DEVELOPMENT OF MOUNTAIN SYSTEMS

Geosynclinal belts. Mountain systems generally have relatively greater thicknesses of stratified rocks than do the adjoining plains. The sediments are principally of marine origin and represent deposition in a belt that subsided deeply as deposition progressed. Such belts are geosynclinal. These principal mobile belts of the earth, the orthogeosynclinal belts, are separated into eugeosynclinal (truly) and miogeosynclinal (lesser), the former distinguished by its volcanism. Eugeosynclinal belts are made up of several elements in varying proportions: (1) basic lavas such as pillowed basalt, ophiolite, radiolarian chert, and graywackes (*q.v.*) deposited on the sea floor; (2) great thicknesses of intermediate lava (not as rich in iron and magnesium as basic or ultrabasic lavas) and fragmental volcanic rocks; and (3) sedimentary, volcanic, and plutonic rocks that are metamorphosed to varying degrees. Eugeosynclinal belts were subjected to plutonic intrusions and severe metamorphism and alteration of the rocks (forming migmatites) in recurring phases or pulses of orogenesis. The Paleozoic and Mesozoic rock successions of the Pacific coast of North America are prototypes of this sequence. The several elements of the eugeosynclinal belts, as previously stated, may have contrasting significance in terms of global tectonics. Though eugeosynclinal belts characterize the central cores of mountain systems, they are notably narrow or even absent in some of the major systems.

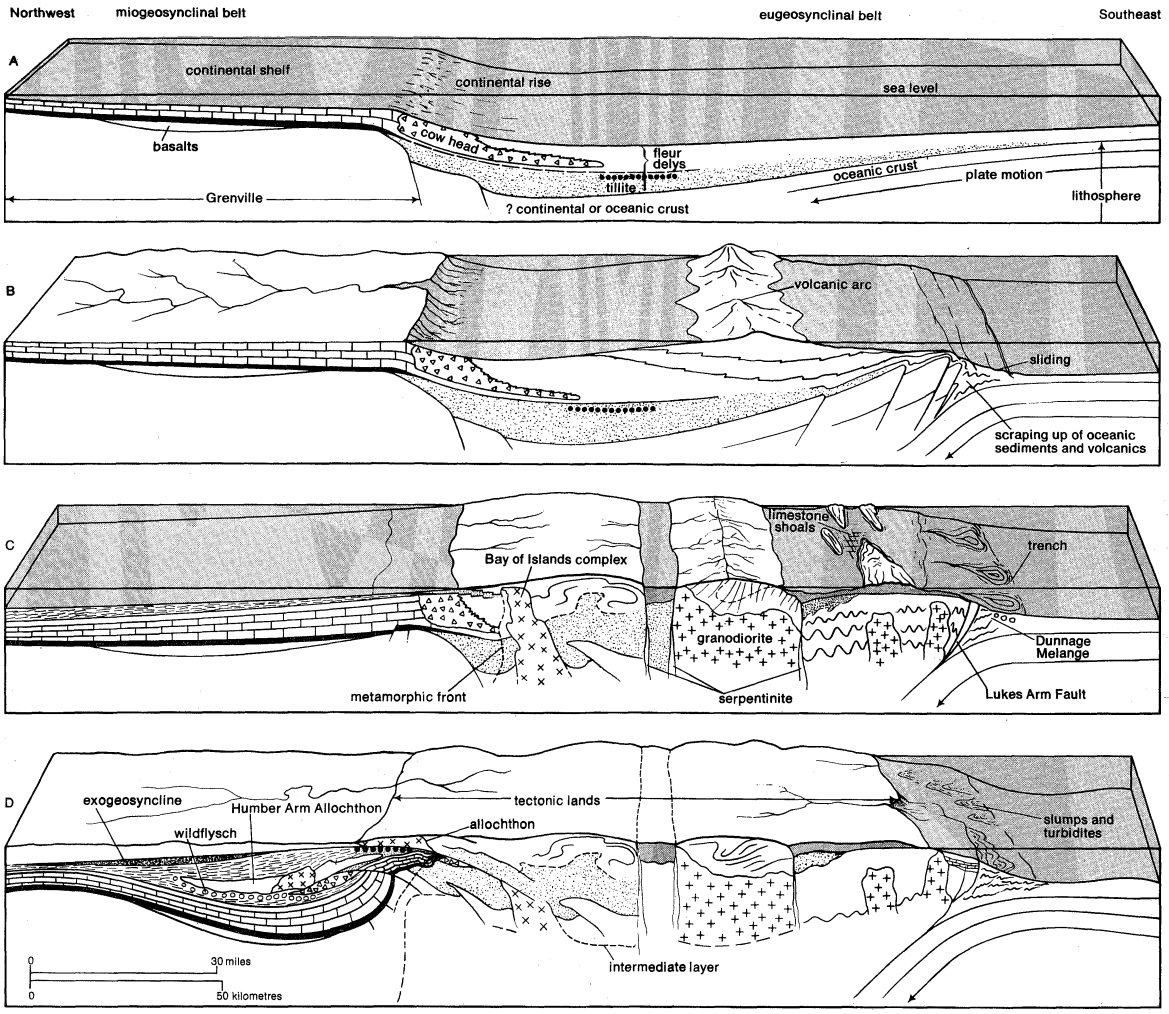

Figure 4: Four stages in the evolution of the continental margin of North America in Newfoundland during Ordovician time (initial stage is at top).

Flysch and other eugeosynclinal deposits

Sedimentary rocks (*q.v.*) associated with the lavas and fragmental volcanic rocks in eugeosynclinal belts are quite varied, reflecting not only the differing sites of deposition but the variety of source rocks accessible to erosion. Some eugeosynclinal belts have alternating coarse- and fine-grained poorly sorted sediments; these are termed flysch deposits to connote transportation by turbidity currents (water–sediment mixtures that are a variety of density currents [*q.v.*]) and rapid deposition. They formed from the erosion of rocks of tectonic islands within the belt or from volcanoes and islands of volcanic rocks and were transported into deeper water. Some eugeosynclinal belts have areas within them that are quite lacking in volcanic rocks, and are not restricted to the eugeosynclinal belts. Wherever deposition was very slow because of distance from source areas and subsidence was great, deep-water-laid "condensed" sections of consolidated clays and siliceous rocks (*q.v.*) such as radiolarian cherts are found. When the source was well-sorted sands on stable adjoining continental platforms and the sediments were carried by submarine currents and sand flow into deep water, the dominant rock is orthoquartzite (a nearly pure quartz sandstone), despite the fact that this rock is typical of miogeosynclinal deposits. Although flysch is a common constituent of eugeosynclinal belts, it is neither invariably present nor limited to them. The type of sediment depends on the exigencies of source and transport.

The lavas, often pillowed, are in associations with thick sequences of varied sedimentary rocks; this suggests that they have flowed into seas in great volcanic troughs. In other places, thousands of metres of lavas, agglomerates, and tuffs are interbedded with marine fossils of shallow water habitat. Such piles of volcanic rocks are laterally limited; they grade into nonvolcanic marine sediments. As they are distributed in belts and are partially subaerial, they may represent island archipelagoes, or arcs, in the ancient seas.

Melanges and chaotic deposits

Occasionally there are melanges, mudstones with some very large boulders, and chaotic mixtures of mud and rocks. Such deposits generally are produced by blocks and masses of sediment that slump from unstable depositional sites into a deep trough. In northern Italy and western Newfoundland, melanges are within gravity slides that have been carried from the margins of the central mountain core regions out onto the externides. Other melanges—*e.g.*, in the Franciscan terrane of late Mesozoic age in California and Oregon, the Lower Paleozoic Dunnage melange of northeastern Newfoundland, and the exotic bouldery mudstones of the Tertiary "root zones" of the northern Alps and the Indus Suture of the Himalayas—seem indigenous to the central regions. Among the rocks in the Franciscan Melange are glaucophane schists (metamorphic rocks deformed under the high-pressure, low-temperature conditions that prevail deep in the crust). There are bands of such schists in two metamorphic belts on Honshu Island, Japan. These frequently have ultramafic intrusions and often are serpentinized.

Subsidence and deformation of deposits

The rocks have been so deformed and altered by later disturbances that it is rarely possible to reconstruct details of the basin of deposition. Abrupt changes in thickness have led to the conclusion that some were not simple troughs but subsided differentially across submarine rifts.

The occasional melanges and the presence of ultramafic rocks and glaucophane schists suggest that these may have been in belts where oceanic floor slid below other plates along subduction zones, like ocean trenches. Perhaps the volcanic piles were in adjacent island arcs where the ocean's floor is consumed as it descends. Or they may have risen and flowed out along rifts in the ocean floor. Eugeosynclinal belts had a complex initial submarine topography.

Bands in the subsiding belt were deformed and raised while remaining areas lay at great depths. As a result areas of older rocks with structures that were formed at crustal depth were raised, eroded, and covered by younger sediments that indicate the occurrence of a smaller number of deformational events. In places the older metamorphosed sedimentary and volcanic rocks were intruded by plutonic rocks, raised, and bounded by faults (rift blocks) yielding coarse sediment that spread into adjoining subsiding troughs. The raising of mountainous lands within the margin of the eugeosynclinal belts had several effects. The poorly consolidated sediments, that had been laid in the geosyncline before it was compressed and rose, slid off the mountainous elevations into the adjoining depressions as thrust sheets or gravity slides, carrying with them the ultramafic rocks that had invaded the trough to shallow crustal depth shortly before it rose. These mobilized rock masses form the allochthons that are widespread in the externides of mountain systems, overlying miogeosynclinal prisms or with their fronts lying buried within.

The miogeosynclinal belts are typically very broad bands on the margins of the continental shields or cratons (stable continental interiors). Quartz sandstones and carbonate rocks are deposited on basement that subsided more rapidly than the craton, thus accommodating greater sediment thickness. They are exemplified by the Paleozoic sequences in the Nevada–Utah region of the western United States. This belt was deposited on a crust that, as the variable thickness demonstrates, was differentially deformed into swells and swales, domes and basins. These miogeosynclinal marginal deposits are quite distinctive and should not be confused with the nonvolcanic, oceanward-subsiding wedges of marine sediment along continental margins. Some of the principal mountain systems of the world, such as the highest ranges in the Himalayas, are of rocks deformed and raised from these nonvolcanic belts.

At times when mountains rose within the eugeosynclinal and miogeosynclinal belts, thick wedges or lenses of clastic (sandstones and shales, principally) sedimentary rocks were spread into the miogeosynclinal belts and cratonal margins as exogeosynclinal (outside or beyond the principal geosynclines) belts or foredeeps. The sediments in the Appalachian Mountains and Allegheny Plateau of Pennsylvania are in such a belt and were the site of the original geosynclinal concept. In some places linear troughs formed within the craton, and associated cratonal uplifts produced coarse sediment that was carried by streams into these zones of deposition, termed zeugogeosynclines. The Rocky Mountains of Colorado and New Mexico were formed by the folding and elevation of the rock within such a region; the typical zeugogeosyncline and a succeeding exogeosynclinal belt are both present and are intracratonic.

Another type of geosyncline is the rift trough or taphrogeosyncline, which is of more limited extent and is essentially postorogenic. Deposits formed in subsiding, tilted blocks received additional sediment eroded from adjacent rising blocks. The taphrogeosyncline is exemplified by the Triassic (190,000,000 to 225,000,000 years ago) basins of the Atlantic coast of North America. The rising margins became block mountains, examples of which are the Sierras and other Basin Ranges. Thus, there is no one simple pattern of structure or mode of origin applicable to all the mountains of the earth.

That the internal parts of the geosynclinal belts underwent a succession of orogenic phases is shown by the multiple ages derived by radiometric analyses of their intrusions and the unconformities that interrupt the stratigraphic successions. In time, the belt undergoes a final paroxysm and metamorphism, and plutonic intrusions serve to consolidate the belt into continental crust.

Through their life, eugeosynclinal belts are subject to lateral as well as vertical stresses. The two flanks are at least partially brought into closer proximity by folding and faulting, as well as by less obvious internal shearing and recrystallization. Workers have recently examined the possibility that the belt was once oceanic and that some of its loss of breadth was caused by the descent of crustal plates within it, perhaps along the melange zones that are present in many of the mountain systems. Estimates of crustal shortening are few and are based on varied assumptions and methods of judgment. The British Caledonides lie between the Moine Thrust of Northwest Scotland and a structural line passing northeastward from South Wales. The Caledonides are separated by the Highland Boundary Fault into a northern band (the "orthotectonic belt"), 125 miles (200 kilometres) wide, which exhibits very great deformation and metamorphism of several phases; and a remaining 240-mile-broad (384-kilometre-broad) belt (the "paratectonic belt") of less intense deformation. It has been estimated that internal deformation of the rocks in this latter zone alone has reduced its breadth from an original width of 600 miles (960 kilometres). The fact that the northern zone is the more severely deformed suggests that the original breadth of the Caledonian eugeosynclinal belt may well have exceeded 1,000 miles (1,600 kilometres), some three times the present width.

Some of the greatest ranges contain but little record of volcanic geosynclinal belts. The highest Himalayas are made of thick sequences of sedimentary rocks, folded and faulted, well to the south of a melange (south of Tibet) that contains the rock types associated with descending oceanic plates. The Indian Peninsula, the northern margin of ancient Gondwana, seems to have pressed in a northerly direction against Eurasia so as to consume any ocean floor that separated them. Similarly, in the Alps, where the Steinmann Trinity of representative oceanic rock was defined, the area of such rocks is limited along the Alpine root zone, and is interpreted as a subduction zone passing below the continental plate to the north. The basement below the associations of ophiolite, chert, and serpentine in the Alps does not seem to be oceanic, however, because it consists of gneissic rocks and granitic intrusions.

Subsequent diastrophism. With the consolidation of the geosynclinal belt by mountain building, it becomes part of the continental crust. Further uplifting and deformation then occur. The Caledonian and Acadian belts in northwestern Europe and northeastern North America were not only deformed by folding and intrusion but they were raised to mountainous elevation in the Devonian Period (*q.v.*), 345,000,000 to 395,000,000 years ago. The attendant erosion produced thousands of feet of a stream-laid sandstone: sediments were deposited in exogeosynclines on their northwestern margin and in intermontane basins. Fracture systems trending along the mountain systems developed. Subsequently, normal, high-angle faults to the north bounded Carboniferous sediments in the Atlantic Provinces of Canada; the faulting was partially contemporaneous with deposition.

Devonian and Triassic events

Similar linear fractures continued to develop. The Newark Group of Triassic rocks extending from Nova Scotia to Georgia contains three or four miles of stream- and lake-laid sediments, as well as hundreds of feet of lava flows. Down-faulted troughs, or taphrogeosynclines, received the detritus from raised fault–scarp mountains. The fault systems have been attributed to tensional fractures formed with epeirogenic (broad, regional upwarping) movements, unwarping the mountain belt after its consolidation. The same region has several sets of transcurrent faults, a fault type in which the rocks on one side moved laterally relative to the other. The fault systems are severed at the Newfoundland continental shelf as a result of sea-floor spreading (*q.v.*) of the Labrador Strait and Atlantic Ocean in later Mesozoic and Cenozoic time.

Basin and Range and Pacific coast events

The faulted block mountains of the Basin and Range Province in the western United States have a very complex and quite different origin. They lie within a region that underwent a succession of mountain-making events from the late Devonian (Antlerian orogeny), through the middle and Late Mesozoic Nevadan and Laramide orogenies, into the Tertiary, climaxed by Late Mesozoic plutonism that consolidated the belt to continental crust. The block mountain structures may not relate to any one of these events but to the spreading of the subcrust along the trend of the East Pacific Rise, a midocean ridge that passes beneath the continent in the Gulf of California and off western Oregon. The transcurrent San Andreas Fault in California has moved right laterally—that is, the west side moved northward relative to the east—from the Mesozoic Era (*q.v.*) onward, for as much as 400 kilometres (250 miles) according to some authorities. Though this fault also lies within an orogenic region, the movement, at least that movement of later date, may be at the junction of two crustal plates. There are similar faults within the Pacific Border northward to Alaska, and so the distribution may be related to the ocean margin. In any case, the block mountains are elevations within a larger system that has rocks that were deformed and intruded long before the events that produced the block ranges.

The elevation of the Sierra Nevada, a block mountain range to the west of the Basin and Range Province, was a Late Tertiary event, following the reduction of the region to low elevation in Early Tertiary time, but the internal structures are much older. The Alps and Himalayas, on the other hand, are younger mountains, formed in belts that were still troughs receiving marine sediments in Early Tertiary time. Indeed, the present elevation of many of the earth's principal mountains is a response to events in Tertiary and even Pleistocene times.

Causes of folding. The conventional explanation of this foreshortening of parts of the earth's crust was that the continents and oceans were essentially permanent, and therefore if the earth's diameter decreased through time, perhaps because of cooling or compaction, then the crust would shorten and contract, causing the folding of crustal rocks.

Another possible explanation is that the core of a mountain range rises vertically with steel faults along the margin of the rising area that spreads toward the surface. The sedimentary rocks of the crust would then move laterally on low-angle or nearly horizontal fault planes, the extended thrust sheets becoming folded in the process. Thus, the gravity slides would acquire their structures during their descent from the rising source of their origin. Such a process does not require crustal contraction, but it would permit permanence of continents and oceans.

A third possible method by which the production of folded mountains has been explained is related to early theories of continental drift (*q.v.*). In this view, the rise and deformation of mountain ranges are attributed to the pressing of the front of a continental block against the ocean. The physical problems of the process deterred consideration of drift as a plausible theory. It is not clear why the stronger continental block should be deformed by the opposition of an oceanic crust weak enough to permit drift into it. And even though the approach might explain mountains on the front of the moving block, it does not explain similar mountain systems, such as the Appalachians of North America, on the other side of the continents. Yet, studies of remanent magnetism of rocks on different continents do seem to show relative movement among them.

Finally, a fourth explanation posits oceans formed by spreading away from a linear belt—*i.e.*, the world rift system. This produces drift of a different kind. The movement is attributed to convection below the crust which moves mantle rocks away from the rift zones and the consumption of oceanic crust by subduction along other bands in ocean trenches. Though plate tectonics seem to account for some of the features of the principal orogenic belts, other ranges seem remote from plate margins, so that the folding of their rocks appears to be due to some other compressive force.

BIBLIOGRAPHY. The following books are suggested as sources of supplementary information: P.B. KING, *The Evolution of North America* (1959), a fine summary of the history of the North American mountain regions; R.A. PHINNEY (ed.), *The History of the Earth's Crust* (1968), papers on recent advances in plate tectonics, though very little directly on mountain building; P.C. BADGLEY, *Structural and Tectonic Principles* (1965), chapters on mountain-building processes, but written before sea-floor spreading and subduction were understood; M. KAY (ed.), *North Atlantic: Geology and Continental Drift* (1969), many papers on the nature and history of the Appalachian-Caledonian belt; A. GANSSER, *Geology of the Himalayas* (1964), an excellent description of this mountain range; J. RODGERS, *The Tectonics of the Appalachians* (1970) and M. KAY, *North American Geosynclines* (1951), discussions of the nature and distribution of geosynclines; P. CHADWICK, "Mountain Building Hypotheses," in S.K. RUNCORN (ed.), *Continental Drift* (1962). Classic works on the Alps are: E.B. BAILEY, *Tectonic Essays, Mainly Alpine* (1935); L.W. COLLET, *The Structure of the Alps* (1927); and J. CADISCH, *Geologie der Schweizer Alpen*, 2nd ed. (1953). F. FUCHS, *Zum Bau des Himalaya* (1967), a monograph comparable to that of Gansser complements and adds to the discussion of this range. Excellent papers concerning plate tectonics and subduction zones are: W. HAMILTON, "Mesozoic California and the Underflow of Pacific Mantle," *Bull. Geol. Soc. Am.*, 80:2409–2430 (1969); J.F. DEWEY and J.M. BIRD, "Mountain Belts and the New Global Tectonics," *J. Geophys. Res.*, 75:2625–2647 (1970); and W.R. DICKINSON, "Plate Tectonic Models of Geosynclines," *Earth and Planetary Sci. Letters*, 10:165–174 (1970).

Mountaineering

Mountaineering has not always been a sport. Throughout history, as man attempted to use and control the physical elements of the earth, mountains became symbols of his aspirations and ambitions. Because their peaks seemed close to the heavens, certain mountains—Olympus, Etna, Sinai, and Ararat, for example—had early significance for much of mankind as the mythological homes or sacred precincts of the gods. In Japan, Fujiyama is sacred to thousands of pilgrims who climb its slopes every summer, and in the Himalayas certain summits are still considered holy. Thus in May 1955 two two-man English parties stopped just short of the summit of Kānchenjunga, leaving the actual summit untrodden at the request of the Sikkimese government because it was considered sacred to the gods of Sikkim.

Early attempts to ascend peaks were inspired by other than sporting motives: to build altars or to see if spirits or dragons actually haunted once forbidden heights; to get an overview of one's own or a neighbouring country or of unexplored land; or to make meteorological, geological, or other scientific observations. Mountains presented barriers to progress, but over many centuries, the passes among them were gradually opened as routes for military expansion, exploration, communications, and trade. It is a far reach in time, however, from Moses' ascent of Mt. Sinai to the breaching of the Alps with a herd of elephants as a road to the conquest of northern Europe in the 3rd century BC, to the first recorded climbing of Mexico's Mt. Popocatepetl in 1595 by soldiers of Cortés, and a long way again to man's conquest of Mt. Everest. Centuries apart, these way stations symbolize aspects of man's approach to the mountains.

Mountaineering as a sport emerged fewer than 150 years ago, when English, French, and German climbers, together with their Swiss guides, began seriously to penetrate and ascend the mid-European Alps in the mid-19th century.

Mountain climbers must rely upon their own powers of physical endurance and judgment. Nature provides the only competition, demanding of the participant a combination of skill and self-reliance and giving him freedom from man-made rules and regulations. Mountaineering is perhaps the most intensely and purely participant of sports. Climbing mountains embodies the thrills produced by testing one's courage, resourcefulness, cunning, strength, ability, and stamina to the utmost in a situation

Selected List of the World's Highest Mountains

name	location	height		year first climbed
		feet	metres

*Highest in the world. †For some 30 years before 1832 thought to be the highest. ‡First major peak first ascended by an all-woman team (Japanese). §Highest peak in the U.S.S.R. ‖Highest peak in Western Hemisphere. ¶First major peak first ascended by a woman. ♀Highest peak in North America. ♂Probably the world's highest active volcano. □Highest peak in Africa. ◇First ascent in modern times. ▲Highest peak in western Europe. +Highest island mountain in the world. ⊕Highest peak in New Zealand.

of inherent risk. Mountaineering, however, to a greater degree than other sports, is a group activity, with each member both supporting and supported by the group's achievement at every stage.

Although mountaineering has a growing number of adherents, it does not attract anywhere near the millions that engage in such other outdoor participant sports as hunting, fishing, and skiing, for example; 500,000 active mountaineers in the world at one time is a generous estimate. But, while other sports are more popular, mountaineering is equally international in flavour—in part because of the distribution of the world's great peaks—if not in numbers of participants.

A selected list of the world's highest mountains giving their locations, heights, and years first climbed appears in the table above. See also MOUNTAIN RANGES AND MOUNTAIN BELTS.

HISTORY

During the 18th century more and more natural philosophers—the scientists of their day—made field trips into the Alps of Europe. They studied the complex structure of those mountains, conducted botanical investigations, and made meteorological observations; the area around Chamonix, France, became a special attraction to these investigators because of the great glaciers on the Mont Blanc chain. There mountaineering in a contemporary sporting sense was born when a young Genevese scientist, Horace-Bénédict de Saussure, on a first visit to Chamonix in 1760, viewed Mont Blanc (at 15,771 feet [4,807 metres] the tallest peak in Europe outside the Caucasus) and determined he would climb it or be responsible for its being climbed. He offered prize money for the first ascent of Mont Blanc, but it was not till 1786, more than 25 years later, that his money was claimed by a Chamonix doctor, Michel-Gabriel Paccard, and his porter, Jacques Balmat. A year later de Saussure himself climbed Mont Blanc, carrying the customary scientific instruments that presumably justified the enterprise. After 1850, groups of British climbers with Swiss, Italian, or French guides, scaled one after another of the high peaks of Switzerland. A landmark climb in the growth of the sport was the spectacular first ascent of the Matterhorn (14,692 ft [4,478 m]) on July 14, 1865. An English artist, Edward Whymper, who had gone to the Alps only to sketch, became one of the outstanding mountaineers of the 19th century and was the guiding spirit of this climb during which a French guide and three others of the party lost their lives on the descent.

First ascent of Mont Blanc

In the mid-19th century the Swiss developed a coterie of guides whose leadership helped make mountaineering a distinguished sport as they led the way to peak after peak throughout central Europe. That one guide lost his life on the ill-fated Matterhorn climb was symbolic of both the successes and risks of the burgeoning sport. An Italian guide, who was Whymper's chief competitor for the first Matterhorn ascent and who climbed it successfully from Italy three days later, in afteryears lost his life descending the mountain in a storm, first, however, bringing his party to safety.

Development of Swiss guide system

Since mountaineering consists of three elements, hiking in lower regions, the technical ability to climb steep rock, and comparable ability on snow and ice, elements of the sport have been frequently pursued for their own sake. A.F. Mummery, a brilliant British mountaineer of the late 19th century, who disappeared on Nānga Parbat (26,660 ft [8,126 m]) on one of the early Himalayan expeditions, was the true forerunner of rock climbing as a sport in its own true right.

By 1870 all of the principal Alpine summits had been scaled and climbers began to seek new and more difficult routes on peaks that had already been ascended; and, as

the few remaining minor peaks of the Alps were overcome, by the end of the 19th century climbers turned their attention to the Andes of South America, the North American Rockies, the Caucasus, Africa's peaks, and finally the Himalayan vastness. Aconcagua (22,834 ft [6,960 m]), the highest peak of the Andes, was first climbed in 1897, and the Grand Teton (13,747 ft [4,190 m]) in North America's Rocky Mountains was ascended in 1898. The Italian duke of the Abruzzi in 1897 made the first ascent of Mt. St. Elias (18,008 ft [5,489 m]), which stands athwart the international boundary of Alaska and Canada, and in 1906 successfully climbed Margherita in the Ruwenzori Group (16,763 ft [5,109 m]) in East Africa. In 1913 an American, Hudson Stuck, ascended Mt. McKinley (20,320 ft [6,194 m]) in Alaska, the highest peak in North America. The way was opening for greater conquests, but it would be midcentury before the final bastion, Mt. Everest, was ascended.

20th-century achievements. As the 20th century wore on, the truly international character of mountaineering began to reveal itself. Increasingly Austrians, Chinese, English, French, Germans, Indians, Italians, Japanese, and Russians turned their attention to opportunities inherent in the largest mountaineering landmass of the planet, the Himalayas. After World War I the British made Everest their particular goal. Meanwhile, climbers from other countries were making spectacularly successful climbs of other great Himalayan peaks. A Russian team climbed Stalin Peak (24,590 ft [7,495 m]), now renamed Communism Peak, in 1933; a German party succeeded on Siniolchu (22,600 ft [6,888 m]) in 1936; and the English climbed Nanda Devi (25,646 ft [7,817 m]) the same year. *The Alpine Journal* of London, a reliable chronicler of ascents, lists no peaks ascended for the first time between 1940–47, a reflection, of course, of the imperatives of World War II. The first "first" to be achieved after the war was that of Satopanth (23,213 ft [7,075 m]) in 1947 by René Dittert and his French climbing party.

At mid-20th century came the successful ascent by the French of Annapūrna I (26,504 ft [8,078 m]) in June 1950; Nānga Parbat (26,660 ft [8,126 m]) by the Germans and Austrians in 1953; K2 (28,251 ft [8,611 m]) by the Italians in 1954; Kānchenjunga (28,208 ft [8,598 m]) by the British in 1955; and Lhotse (27,923 ft [8,511 m]) by the Swiss in 1956. Beyond all of these, however, the success of the British on Mt. Everest (29,028 ft [8,848 m]) when a New Zealand beekeeper, Edmund Hillary, and the Sherpa guide, Tenzing Norgay, stood on the top of the world on May 29, 1953, was a culminating moment. This expedition, led by Col. John Hunt, was the eighth team in 30 years to attempt Everest, and there had also been three reconnaissance expeditions.

Everest, K2, and others

K2 was climbed by two members of an Italian party in July 1954. An Austrian party reached the summit of Cho Oyu (26,750 ft [8,153 m]), which was only slightly lower than Dhaulāgiri, in 1954. The summit party included Pasang Dawa Lama, who had proceeded in three days from an altitude of only 13,000 ft (3,962 m) to the summit (26,750 ft [8,153 m]).

In May 1955, a French party succeeded in getting all of its members plus a Sherpa guide to the summit of Makālu (27,824 ft [8,481 m]), a neighbour of Everest. Also in May 1955, as mentioned above, Kānchenjunga, at 28,208 ft (8,598 m) often considered one of the world's most difficult mountaineering problems, was climbed by an English expedition led by Charles Evans, who had been deputy leader of the successful first climb of Everest, the party stopping just short of the sacred summit at the request of the Sikkimese government. In May 1956 two separate Japanese parties climbed Manāslu (26,760 ft [8,156 m]) in Nepal, the world's ninth highest mountain. Mt. Everest's history did not end with the British ascent in 1953. In 1956 the Swiss placed two parties on its summit, while another Swiss team climbed neighbouring Lhotse (27,923 ft [8,511 m]), the world's fourth highest peak. In 1963 a U.S. team, led by Norman Dyhrenfurth, not only sent two parties from the South Col (high pass) of Everest to the summit but also sent a two-man team to the summit by the formidable West Ridge. Dhaulāgiri (26,810 ft [8,172 m]) was the last of the world's ten highest mountains to be climbed, in 1960, by a six-man Swiss team. The 1953 Nānga Parbat climb was unique in that the last attempt from high camp was a solo climb by Hermann Buhl, a member of a friction-ridden German–Austrian expedition. Because he reached the top late in the day, he was forced to bivouac in the open all night a short distance below the summit and next day was fortunate to regain high camp. The international aspects of mountaineering revealed by the various nationalities that had overcome the world's ten highest mountains was further reflected by the requests filed to climb in Nepal in the early 1970s. Permits requested for parties, seven of them for Everest, included 18 Japanese (one all-woman), 3 British, 2-each Australian and Italian, and 1-each Dutch, Korean, Argentinian, West German, and international.

Seeking new challenges. In the 1960s mountaineering underwent several transformations. As in the golden age of the Alps, once peaks were climbed, the emphasis moved to a search for more and more difficult routes. At the end of the decade, for instance, an international expedition began training for the assault in 1971 of the southwest face of Mt. Everest formerly regarded as unassailable. Climbers from Austria, Canada, France, Germany, Great Britain, India, Italy, Nepal, Norway, the Soviet Union, Switzerland, and the United States, including two women, participated in this enormous enterprise under the leadership of Dyhrenfurth and Col. James O.M. Roberts.

Women mountaineers

The inclusion of women in major expeditions such as this one, and all-women climbing parties, had become increasingly common. An all-woman Japanese climbing team scaled Annapūrna III (24,858 ft [7,577 m]) in 1970 and an all-woman U.S. group climbed Mt. McKinley in the same year.

Just as the most difficult routes in high mountains were increasingly undertaken, so were so-called impossible rock faces scaled through the use of artificial aids and advanced climbing techniques. Smooth faces of granite were overcome in climbs lasting days or even weeks at a time—for example, the 27-day conquest in 1970 of the sheer 3,000-ft (914 m) southeast face of the granite monolith El Capitan in the North American Sierra Nevadas by U.S. climbers.

The risk factor

With these greater skills in mountaineering and the ability to achieve seemingly impossible ascents, the risk factor in mountaineering, despite improved equipment and safety precautions, seemed to lead to more casualties. In the later 1960s the loss of leading climbers assumed depressing proportions. While dangers are many and always present for the inexperienced in the mountains, those dangers associated with bad weather, falling rock, avalanches, ice falls, crevasses, projecting shelves of snow (cornices), took a tragic toll of experienced mountaineers. Although the good climber knows how to identify dangerous conditions, those moments in the mountains for which he cannot plan or prepare sometimes prove to be fatal.

THE SPORT

For most climbers the pleasures of mountaineering are not inherent in the abused word conquest, but rather in the physical and spiritual satisfactions brought about through personal effort and contact with natural grandeur, success and failure, and ever-increasing proficiency. While all mountaineers might like to be a Hillary or Tenzing, and while there is a great difference between a massive party assembled to assault a Himalayan fortress peak and the lesser challenges of weekend cliff, summer trail, or local summit, the joys and challenges of the sport can be shared in any location.

Essential requirements

The nature of mountaineering is such that the elements of danger must always be respected. Nonetheless, the sport is not risky to those who have learned it properly and climb under appropriate conditions. The essential requirements are technical skill, judgment, and leadership ability. More men have died on low hills than on high climbs. The ability and willingness to recognize conditions that are adverse and to make the difficult decision to turn back from the climb when the odds creep up to that

point at which they are against the climbing party must be part of the leader's ability.

Hiking. Hiking has become a widely accepted and respected sport in itself and, as the first and essential element of mountaineering, must be regarded as fundamental. The ability to walk an uphill or downhill trail, rugged or smooth, kilometre after kilometre, is excellent training for the mountaineer and the best indication of his willingness to persist. Hiking is, indeed, the essential element of all climbing, for in the end mountains are climbed by placing one foot before another over and over again. The most arduous hours are those on the lower trails climbing slowly, steadily, but hour after hour, or before dawn on the tedious glacier trek. A climber who in his training has not recognized this disciplined necessity will deprive himself of many successes and pleasures on the heights.

Organization. The basic organization of the sport is the mountaineering, rock-climbing, or hiking club. Every nation with mountaineers has its own clubs, among which the Alpine Club in Great Britain, founded 1857, is perhaps the most venerable. The largest numbers of clubs are in the Alpine countries, in the British Isles including Scotland and Ireland, and in North America. Representative clubs in other areas include those in Spain and Poland, in Argentina, in India and Japan, in New Zealand, and in South Africa. Mountaineering and related clubs serve the purpose of fellowship but have the further intention of promoting responsible leadership, inculcating good practice on the mountains and encouraging members toward increased enjoyment of the hills. Most of the clubs publish annual or periodical reports, journals, or bulletins. Frequently, major mountaineering clubs participate financially in the sponsorship of major expeditions. While most clubs tend to have national or regional names, there is little chauvinism in the sport. This characteristic has been best reflected in the increasing number of international expeditions that has been noted.

Principles. While it is necessary for the complete mountaineer to be competent in all three phases of the sport—hiking, rock climbing, and snow and ice technique—each is quite different. There are wide variations within these categories, and even the most accomplished mountaineers will have varying degrees of competence in each. The good climber will strike that balance that is consonant with his own physical and mental capabilities and approach.

Rock climbing. Rock climbing, like hiking, is a widely practiced sport in its own right. The essentials of this aspect of mountaineering are often learned on local cliffs, where the teamwork of mountaineering, the use of the rope, and the coordinated prerequisites of control and rhythm are mastered. The rope, piton (a metal spike, with an eye or ring in one end, that can be driven into a crack in rock or ice), and carabiner (or snap link, a metal loop or ring that can be snapped into a piton and through which the rope may be passed) are used primarily as safety factors. An exception occurs in tension climbing in which the leader is supported by a judiciously placed series of pitons and carabiners through which the rope is passed. He is then supported on the rope by his fellow climbers as he slowly moves upward to place another piton and repeat the process. Pitons are used with discretion rather than in abundance. When pounded firmly into a crack, they will normally be secure. Various shapes of pitons have been designed to deal with various types of cracks or fissures in the rocks. Pitons are rarely used as handholds or footholds.

Aids and tension climbing

For the majority of rock climbers hands and feet alone are the essential, with the feet doing most of the labour. The layman's notion that one must be extraordinarily strong in arms and shoulders is true only for such situations as negotiation of serious overhangs. By and large, hands are used for balance, feet for support. Hands and arms are not used for dragging the climber up the cliff.

Balance is essential and the body weight is kept as directly over the feet as possible, the climber remaining as upright as the rock will permit. An erect stance enables the climber to use that fifth element of climbing, his eyes. Careful observation as one moves up a cliff will save many vain scrambles for foothold. Three points of contact with the rock are kept, either two hands and a foot or two feet and a hand. Jumping for holds is extremely dangerous because it allows no safety factor. Rhythmic climbing may be slow or fast according to the difficulty of the pitch. Rhythm is not easily mastered and when achieved becomes the mark of the truly fine climber.

The harder the climb, the more the hands are used for support. They are used differently in different situations. In a chimney, a pipelike, nearly cylindrical vertical shaft, they press on opposite sides in opposition to each other. In a crack, they can be used by the balling of a fist to jam in. On slabs, the pressure of the palms of the hand on smooth rock may provide the necessary friction for the hold.

Rope handling. It is always essential that a line of retreat be provided. To climb up beyond the ability to climb down is dangerous. Climbing down steep rock is usually harder than going up because of the difficulty in seeing holds from above and the normal reluctance of a climber to reach down and work his hands low enough as he descends. The quick way down is via the doubled rope in the technique called rappelling. The rope, one end being firmly held or secured, is wrapped around the body in such a way that it can be fed out by one hand slowly or quickly as desired to lower the body gradually down the face of the rock.

Climbing down and rappelling

Rope handling is a fine art, equally essential on snow, ice, and rock. Sufficient rope for the pitch to be climbed and of sufficient length for rappelling is needed. As a lifeline the rope receives the greatest care and respect. A good rope handler is a valued person on the climb. The art of placing pitons and carabiners and stringing the rope to best advantage for safety and economy of effort in ascending or descending, and of keeping it free of cracks where it might jam and places where it might get caught on rock outcrops or shrubbery, or be stepped on by an unwary climber is not learned easily and comes primarily through experience.

Snow and ice. Not least of the hazards of climbing a mountain are the constantly changing conditions of the high reaches where snow and ice are found. A good mountaineer will always want to increase his knowledge about snow conditions. He will wish to know what the sun will do to the snow in a given situation by the time the party is descending the mountain on its way back; he will wish to appraise when crampons (sets of spikes that can be strapped on boot soles for walking on ice) will make the ascent safer or quicker; he will become acquainted with the danger of a possible avalanche. In couloirs (steep-sided gullies) in which there is avalanche potential from above, it is necessary to move as quickly and expeditiously as possible. This condition may be the only one in mountaineering in which speed takes preference over almost every other criterion.

Crevasses on a glacier are found primarily where the glacier bends over and starts down a steeper slope or where the glacier turns a corner. Because glaciers more often than not are snow covered, it is necessary to learn how to detect crevasses simply by observing the surface of the snow. The gaping crack that occurs where the snow, instead of adhering to the lower reaches of the mountain, separates from it and fills part of the glacier field below is called a bergschrund. Bergschrunds increase the difficulty of mountaineering, particularly if snow bridges across them cannot be found.

Crevasses, icefalls, snow cornices

Icefalls on a glacier are a particular danger and have led to some of the mountains' greatest tragedies. Also hazardous are cornices of snow that resemble crests of waves and are formed by the wind on ridges. From the windward side it is hard to determine that they are there. They must be avoided because they can break off precipitously under the weight of a climber. It is necessary to cut across the top of a steep slope rather than to walk within the fracture zone of cornices. It is equally unwise to walk under a cornice if the route can be avoided.

The use of the ice-ax is extremely important as an adjunct to high mountaineering. Consisting of a pick and an adze opposed at one end of a shaft and a spike at the

Snow and ice aids

other, it is used for cutting steps in ice, probing crevasses, direct aid on steep slopes, balance as necessary, and for securing the rope (belaying). Crampons to preclude slipping are useful on steep slopes of snow and ice and in steps that have been cut. By biting into the surface they make progress possible where boots alone would not do. On many slopes crampons also render unnecessary the cutting of steps. On extremely difficult snow and ice, ice pitons and carabiners are used. The pitons when driven in are allowed to freeze in place.

In climbing long snow slopes, a tedious task, it is necessary to strike a slow and rhythmic pace that can be sustained for a long time. It is desirable, too, to make a start on the mountain early in the day when the snow is in hard condition. As in all phases of mountaineering, judgment is important when engaging in snow and ice climbing. The length of the climb, nature of the weather, heat of the sun, and potential avalanche danger must all be considered, as well as the condition of the party in experience, technical skill, acclimatization, and fatigue.

Winter climbing

Snow and ice climbing are often practiced during the winter. Conditions on small mountains can be as severe then as on high mountains in the summer. Low temperatures always present formidable liabilities. While winter mountaineering is limited as a sport, it is growing both as a training procedure and for its own particular pleasure. Such difficult north faces as those of the Eiger and the Matterhorn are now climbed in winter, but only by highly skilled parties after intensive preparations and with proper equipment.

The dangers of mountaineering are sometimes exaggerated in the public mind. Climbers who are well trained, and have good judgment, are usually able to climb for many years. The dangers of the mountain are pitfalls principally for those who are somewhere they should not be, who are improperly equipped, or who do not comprehend the dangers of the mountains or the physical condition required to cope with them. As more and more people enter the sport, however, and more and more difficult and challenging ascents are attempted, the potential of hazards increases—whether they be due to avalanche or rockfall, inexperience or carelessness, timidity or foolhardiness. As when the sport began, mountains still must be approached with understanding and respect.

Mountain Ranges and Mountain Belts

A mountain is a tract of land rising considerably above the surrounding surface. Mountains are usually found connected in chains or ranges. A relatively flat area elevated above the level of its surroundings is called a plateau. Mountain belts are elongated groups of mountain ranges and plateaus, broken by valleys and basins. The larger mountain belts of the world are aligned in two great systems, one circling the Pacific Ocean (Circum-Pacific Mountain System), the other spanning an east-trending zone from the Mediterranean Sea to Indonesia (Tethyan or Mediterranean–Himalayan Mountain System). Subsidiary mountain belts are those unrelated to both systems; usually they are less elevated and of smaller surface extent; they occur on all continents.

Mountain formation

Mountains may form by the accumulation of volcanic rocks on the earth's surface or by uplift of part of the earth's surface by tectonic (deformational) forces. Most of the great mountain belts have been formed by the compression and uplift of mobile (unstable) zones of marine sediments after contraction to one-half of their original width or less. During contraction the rocks were deformed, warped, folded, and broken into blocks (faulted). Mountain building therefore comprises two partly related processes: compression and contraction of a mobile zone of the earth's crust is called orogeny, whereas broader uplift that is not accompanied by considerable shortening is called epeirogeny. Both are caused by tectonic or deformational forces originating in the interior of the earth. Many of the major mountain belts are the sites of ongoing tectonic activity, as evidenced by earthquakes and volcanism. Most seismic and volcanic zones of the world are therefore related to mountain belts.

Mountain building is an important process in the evolution of continents. The continents formed from intersecting and overlapping mobile zones that were transformed to mountains during several periods of the geological past. Their deeply eroded roots constitute the foundation, or basement, of the continental platforms. Stratified sedimentary rocks generally form only a thin cover on top of this basement.

The existing mountains formed during the Alpine orogeny, which lasted from the Cretaceous Period (65,000,000 to 136,000,000 years ago) to the Holocene Epoch (the last 10,000 years). Their actual topography is determined by uplift that occurred in most mountains during the Pliocene and Pleistocene epochs—that is, during the last 7,000,000 years. Earlier periods of mountain building occurred during the Paleozoic Era, earlier than 225,000,000 years ago (Hercynian and Caledonian orogenies) and in Precambrian time, earlier than 570,000,000 years ago (Pan-African, Grenville, Hudsonian, and Kenorian orogenies).

Total uplift during a particular orogeny can be as great as 30 kilometres (19 miles) in parts of the major mountain belts; in general, it is between one and five kilometres. Rates of uplift are on the order of a few millimetres per year, but mountain building can be continuous for long periods of time—hence the attainment of overall great heights.

This article treats the several types of mountains that occur in nature and the major mountain systems. For further information on the origin and development of mountains, see the companion article MOUNTAIN-BUILDING PROCESSES, and see also ROCK DEFORMATION. An overview of mountain building during geological time is presented in EARTH, GEOLOGICAL HISTORY OF.

TYPES OF MOUNTAINS

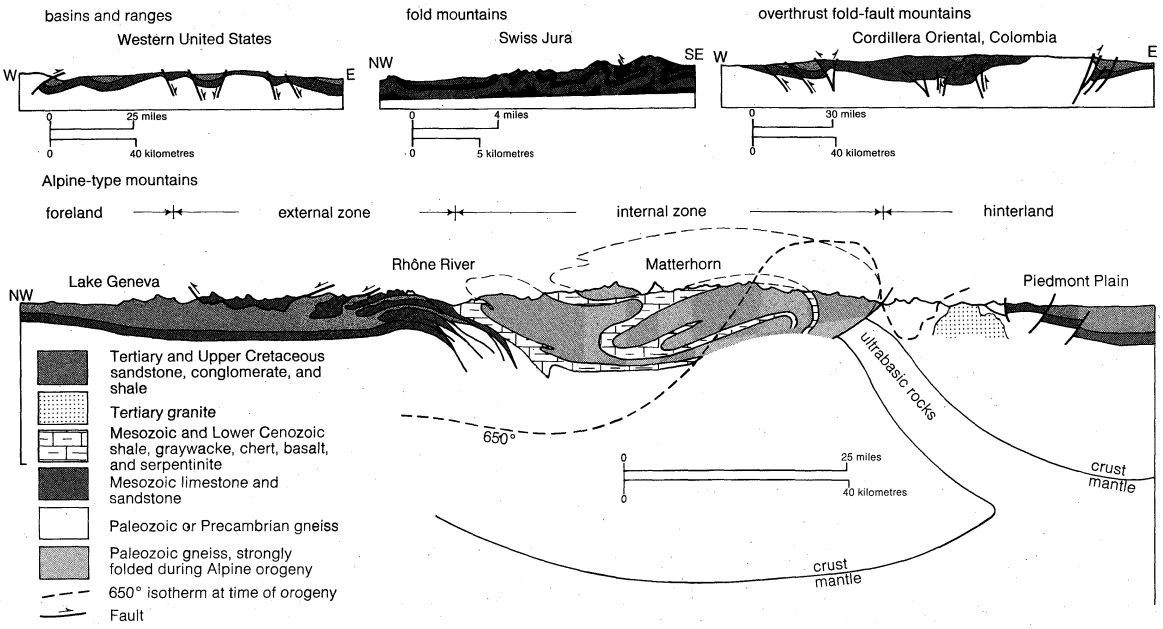
Dome mountains. Dome mountains form by fractureless upwarping or updoming of the land. Their topography is characterized by a relatively flat dissected surface sloping gradually toward the surrounding lowlands. The Black Hills of South Dakota are a typical example.

Block mountains. Block mountains are parts of the crust that have been raised along linear fracture zones in the form of huge blocks. Mountains produced in this way have rectilinear borders and rise abruptly from the adjoining lowlands. The Laurentian Uplands provide a good example.

Effects of block faulting

In many areas block faulting has affected granitic basement (foundation) overlain by a thin cover of stratified sedimentary rocks. Basement and cover have very different mechanical properties and respond differently to tectonic forces; the former will break into blocks that are uplifted, downthrust, or tilted, whereas the weaker sedimentary rocks will become crumpled and folded. This particular type of block mountain is called Germanotype, or Saxonic, after the classical example in central Europe.

Basins and ranges form when irregularly shaped fault blocks are uplifted as the surrounding terrain subsides. The uplifted blocks are eroded by running water and the debris derived from them is transported into the surrounding basins, where it accumulates. Continuing uplift of the ranges leads to upwarping and folding of the sediments of the basin fill at the margin of the ranges. The basins and ranges of Wyoming and Colorado formed in this way.



Representative geologic cross sections of basic mountain types (see text).

Mountains bordering rifts. Rifts are long, linear depressions, 35–350 kilometres (20–200 miles) wide and 300 to several thousand kilometres long, set in a broadly upwarped terrain; they are bounded by faults at both sides. Mountain ranges border the rift valleys and exhibit steep, commonly dissected fault scarps. They slope gradually away from the rifts. The upper Rhine Valley (Rhine Graben) and the Red Sea are rifts, and both are bordered by mountains to the east and west (see further RIFT VALLEYS).

Fold mountains. Fold mountains form by lateral compression and contemporaneous or subsequent uplift in a particular zone. Generally, they are underlain by a relatively thin cover of stratified sedimentary rocks that rests on top of a basement of granite or gneiss. The relatively weak rocks of the cover and the massive rocks of the basement react in different ways during the compression.

Simple and complex folding

Simple-fold mountains form where the rocks of the sedimentary cover have been folded by sliding laterally over the basement, like a carpet lying on a floor. Such mountains exhibit straight, parallel valleys and ridges; the valleys are carved out of soft rocks, whereas hard rocks remain as ridges. The Swiss Jura is a classical fold mountain of this type.

Fold-fault mountains of the overthrust type are more complex and form where compressive forces act upon basement and cover. The rigid basement rocks break into fault wedges along fractures, and the relatively mobile cover is folded into narrow systems of parallel folds. The Cordillera Oriental (Eastern Cordillera) of Colombia is a typical fold-fault belt.

Volcanic mountains. Volcanic mountains are built of overlapping lava flows and layers of tuff (consolidated volcanic dust). Steep volcanic cones (as in Japan) are built by outpouring from a central vent. Their conical shape may be modified by explosion or by collapse of a circular kettle, called caldera (for example, Krakatoa, Indonesia). Broad-shield volcanoes (Mauna Loa, Hawaii) form when less viscous lava flows from a central vent, and volcanic plateaus develop where large volumes of lava erupt from fissures (see further VOLCANOES).

Island arcs. Chains of volcanic islands that are arcuate in plan view are the most conspicuous physiographic element of the western Pacific Ocean. Their convex sides face the open ocean, from which they are separated by a deep oceanic trench. A platform or outer chain of islands rises along an abrupt fault scarp from the trench. The main chain of volcanic cones is located at the concave inner side of the arc. A small ocean basin separates the concave side of the arc from the continent behind.

Island arcs (*q.v.*) are the site of very intense tectonic activity. They constitute the earth's most important earthquake zones, and they are the sites of more than one-half of all active volcanoes. The sources of the seismic activity, or deep-focus earthquakes, are aligned in a plane that dips 30° to 50° from the oceanic trench beneath the arc. Overthrust faulting occurs at the inner wall of the trench, and the crust of the ocean is carried downward along the seismic plane, which is called a subduction zone.

Alpine-type mountains. Alpine-type mountains, such as the Alps or the North American Cordillera, are complex asymmetric belts of folded and faulted rocks. The belts rise abruptly from an adjacent foreland and are subdivided into two zones: an external zone adjoins the foreland, and an internal zone lies away from it.

Zones of Alpine mountains

The external zone is underlain by unmetamorphosed stratified rocks that have been folded or overthrust to form huge nappes (overturned folds). The internal zone is composed mainly of metamorphosed rocks, such as schists and gneisses, that have been deformed; complex overthrusts and great overturned folds are characteristic. These rock structures originated in an intensely deformed zone that is called a root zone. Material has been carried into deeper levels of the earth in the root zone, and it is thought to be analogous to the subduction zone of island arcs.

The metamorphism of rocks, granite intrusions, and volcanic activity that are indicated by Alpine belts also suggest analogies to island arcs: high-pressure metamorphism at low temperatures can occur only at places where cold material is carried into deep crustal levels—that is, in subduction zones.

Alpine-type mountains arose from mobile belts of oceanic or marine sediments called geosynclines. These are subdivided in two zones: a miogeosyncline, adjoining a continental platform, and a eugeosyncline, farther removed from a continent. Well-sorted sandstones and reef limestones, representative of deposits in shallow seas, accumulate in a miogeosyncline, whereas rocks of the eugeosyncline represent more variable conditions. Thick piles of shales, siltstones, and impure sandstones (graywackes) typically are present, and deepwater cherts and thick sequences of volcanic rocks also characterize the eugeosyncline. These volcanic rocks form large submarine-shield volcanoes and, in part, volcanic islands; they represent a rock association similar to the rocks that presently accumulate around island arcs. Generally speaking, the external zone of Alpine belts is composed of miogeosynclinal rocks, and the internal zone is composed of eugeosynclinal rocks. The belts immediately surrounding the Pacific Ocean are an exception because their external zone formed from eugeosynclinal rocks.

Alpine-type belts evolved in two settings: one at the boundary between a continent and an ocean (Circum-Pacific System) and the other between two continental masses (platforms), as in the Tethyan System. In the first case, folding occurs where the oceanic crust is pushed below the former continental margin. In the latter, folding is due to contraction of a former ocean and to "collision" between its bordering continents.

Alpine physiography

The physiography of Alpine belts is essentially determined by the most recent tectonic activity and structures. The main valleys generally follow late orogenic fault zones and warps, and differential erosion (resulting from differential rock resistance) shapes the mountain lands of the external zone. Systems of parallel valleys and ridges form from parallel anticlines and synclines or from parallel nappe zones, as in the Rocky Mountains of Alberta and Montana. Complex nappe structures give rise to complex drainage patterns that reflect the rock structures. The metamorphic rocks of the internal zone show little difference in resistivity to erosion; their physiography bears little relation to fold structure. Drainage patterns are rectilinear, following small faults, warps, or joint systems. Sharp ridges rise from the valleys and are crowned by steep peaks where several ridges meet.

Residual mountains. Residual mountains are remnants of any mountain types that have been greatly worn down by erosion. Landscapes of residual mountains are either produced by differential erosion or are exhumed ancient landscapes.

Differential erosion carves valleys in areas underlain by soft rocks, whereas hard rocks remain as ridges. Landscape forms consequently depend on the tectonic structures. In the southern Appalachians, for example, differential erosion has produced a valley-and-ridge province that mirrors an older fold structure. Rectilinear valleys of the Laurentian Uplands follow a fault-and-joint pattern of Precambrian age.

In other cases, old landscapes have been buried beneath soft sedimentary rocks. Uplift and subsequent removal of the soft cover exhumes the ancient land surface. This happened in the St. Francois Mountains of the Missouri Ozarks, where Precambrian hills were stripped of their sedimentary cover in Tertiary time (7,000,000 to 65,000,000 years ago).

Overview of mountain types

Alpine-type mountains and fold mountains are produced by compression and contemporaneous or subsequent uplift. Dome mountains and block mountains form by vertical movement, eventually accompanied by slight extension or separation of the crust.

Alpine-type mountains and rifts are at the opposite poles of this scale. Alpine-type mountains originated at continental margins during an orogeny, and island arcs are the oceanic counterpart of Alpine belts. Rifts, on the other hand, are zones within the continent that suffered slight extension. Very strong extension of a continent is not possible because the continental crust will split and its fragments will drift apart. This happened in the Red Sea Rift, where strong crustal extension has led to the separation of the African and Arabian platforms. The rift systems, therefore, are the continental counterparts of the midocean ridges, where extension is very strong.

Fold mountains and block-faulted terrains are transitional in type. Both form on continental platforms under the influence of either Alpine-type mountain building or rifting in adjacent areas. Fold mountains develop where segments of the continent have yielded to compressive forces transmitted from adjoining Alpine belts. Block-faulted terrains are either related to Alpine orogeny or to rifting in their vicinity.

WORLD MOUNTAIN SYSTEMS

Circum-Pacific System. The Circum-Pacific Mountain System consists of three segments that exhibit dissimilar geology and physiography. These are (1) the North American Cordillera and the mountain belts of eastern Siberia, (2) the South American Cordillera, and (3) the west Pacific island arcs.

The North American Cordillera is approximately 600–900 kilometres (370 to 560 miles) wide and narrows to 300 kilometres (190 miles) in southern California and southern Mexico. Its present form is dominated by two severely deformed Alpine belts of late Mesozoic and Cenozoic age (the Mesozoic Era ended and the Cenozoic Era began about 65,000,000 years ago) that make up the higher ranges in the east and west; they are separated by a less severely deformed intermontane zone of plateaus, basins, and lower ranges. The eastern belt is composed of several arcuate mountain chains facing the North American Platform (Brooks Range, Mackenzie and Franklin mountains, Rocky Mountains of Alberta and Montana, cordilleras of Mexico), separated by deep recesses. The western belt is curvilinear in plan and comprises the coastal ranges from Alaska to California. This subdivision of the cordillera is poorly defined in the southwestern United States, and the Pacific belt is absent from southern Mexico and Guatemala. Parts of the cordilleran system in the southwestern United States have been destroyed by Tertiary faulting in Nevada and Utah.

North American Cordillera

Intense folding took place in Middle and Late Paleozoic time (about 225,000,000 to 400,000,000 years ago), particularly in the central part of the cordillera. In the Late Paleozoic and Early Mesozoic, the cordillera consisted of several discontinuous ridges, some of which were crowned by volcanoes. Volcanic rocks and sandstones accumulated in the intervening troughs. In the Late Triassic and Early Jurassic (about 190,000,000 years ago), the rocks of the intermontane zone were slightly warped and faulted, whereas intense folding and metamorphism began in the core zones of both Alpine belts. Granites intruded the core zones and the intermontane zone. At the same time, a marginal trough formed east of the cordillera and received the clastic (fragmental sediments) debris produced by the erosion of the rising mountains. Folding was essentially concluded by Middle Tertiary time (about 30,000,000 years ago).

Fault basins broke up the mountain land in Late Cretaceous and Tertiary time and basins were filled with gravels and sands. Volcanic rocks erupted in the core zone of the Pacific belt and in the intermontane zone; they now cover parts of Oregon, Washington, and Mexico. They are surmounted by Pliocene to Recent volcanic cones (formed during the last 7,000,000 years, approximately) in the Coast Ranges of Washington and Oregon and in central Mexico. Intense earthquake activity is related to strike-slip faulting (essentially a lateral movement along a fault) in California and Alaska, where the coastal zone has drifted several hundreds of kilometres northward since Tertiary time. The elevations of the cordilleran system are largely determined by Late Cenozoic faulting, uplift, and upwarping, and subsequent erosion.

Mountain belts of eastern Siberia and Central America

The East Siberian belts are comparable to the North American Cordillera. They also consist of two Alpine belts separated by an intermontane zone. The continental belt comprises the mountains of Verkhoyansk, trending from the Arctic Ocean to the Sea of Okhotsk, whereas the Pacific or more oceanward belt comprises the ranges from Anadyr to Kamchatka. Both are separated by the Kolyma Massif.

The mountains of Central America and the Antillean Island Arc connect the cordilleras of North and South America. Both are underlain by Mesozoic and Cenozoic graywackes, cherts, and voluminous volcanic rocks that were folded during Tertiary time (2,500,000 to 65,000,000 years ago). Cones of active volcanoes are set upon the mountains of Guatemala, El Salvador, Honduras, and Costa Rica and form many of the islands in the eastern Antilles.

The mountain belts of the Andes bound South America on the west. The system consists of one mountain chain, the High Cordillera, in southern and central Chile; it widens in Peru and Bolivia, where it is built of two chains—the Eastern and Western Cordilleras (known as Cordillera Oriental and Occidental in South America)—separated by a high plateau (Altiplano). It narrows again in Ecuador. In Colombia and Venezuela it branches to form the Western, Central, and Eastern Cordilleras. A narrow coastal plain or a chain of lower mountains (coastal cordillera) accompanies the Andes to the west. A narrow

shelf and the Peru–Chile trench form the boundary between the Andes and the Pacific Ocean Basin.

Only the Western Cordillera of Colombia, part of the Eastern Cordillera in Venezuela, and the southernmost High Cordillera of Chile can be described as Alpine-type belts. The remainder of the Andes form fold-fault mountains. The Alpine belts consist of thick shales, graywackes, cherts, and volcanic rocks of Triassic, Jurassic, and Early Cretaceous age (130,000,000 to 225,000,000 years ago). These rocks were strongly folded and were metamorphosed in certain areas during the later Cretaceous and Tertiary. The remainder of the cordillera has a basement of Paleozoic and Precambrian metamorphic rocks. The basement has been covered by very thick andesites (volcanic rocks with more silica than basalts) and interbedded sedimentary rocks in a narrow belt following the Western Cordillera of Ecuador, Peru, and northern Chile during Jurassic and Cretaceous time. Elsewhere, Late Paleozoic and Mesozoic rocks were laid down in continental basins. Only for short periods, and in limited areas, did the sea cover the eastern parts of the Andes during the Mesozoic.

The rocks of the Andes were warped, faulted, and overthrust during the Late Cretaceous and Tertiary. Intense folding is limited to parts of the Western and Eastern cordilleras. At the same time, fault basins were filled with thick conglomerates and sandstones derived from the rising mountain chains. Huge granite massifs intruded the western parts of the Andes during the Mesozoic and Cenozoic.

Large parts of the western Andes were covered by thick sheets of rhyolitic volcanic rocks during the Late Tertiary. Innumerable andesite cones, many of which are still active, crown the Western Cordillera. Destructive earthquake activity is related to underthrusting of the crust of the Pacific Ocean below the Andes and to normal faulting in the mountain belt.

Island arcs of the western Pacific Ocean

Two sets of island arcs frame the western Pacific Ocean. The outer arc system, located at the boundary of the main oceanic basin, comprises the Aleutian, Kuril-Kamchatka, and Bonin-Mariana arcs, the Bismarck Archipelago and Solomon Islands, the Tonga-Kermadec arc, and New Zealand. The inner system consists of the Sakhalin-Japan-Ryukyu arc and the Philippine arc, and it joins the Tethyan Mountain System through the island arc of Indonesia. Both systems meet in triple junctions located in central Kamchatka, central Japan, and western New Guinea.

The smaller islands of the outer arcs are composed of Late Tertiary volcanic rocks. The part of the outer arcs from New Guinea to New Zealand and the inner-island arcs are Alpine-type belts underlain by Paleozoic and Mesozoic graywackes, cherts, shales, and very voluminous volcanic rocks that were folded during several orogenies between Triassic and Recent times. They were intruded by huge granite massifs during the Mesozoic and Cenozoic. The rocks have been metamorphosed in large zones of the arcs.

Andesitic cones of latest Tertiary and Recent age are set upon the inner parts of the island arcs. Many of them are still active. Intense seismic activity is caused by underthrusting of the crust of the ocean below the arcs, by normal faulting in the arcs (particularly in Japan), and by strike-slip faulting (particularly in New Zealand).

The Tethyan System. The Tethyan Mountain System separates the continental platforms of Eurasia from Africa and India. In the west it consists of two continuous Alpine-type belts separated by an intermontane zone. Both belts are composed of arcuate mountain ranges 1,000–2,000 kilometres (600–1,200 miles) long and separated by deep recesses; they face away from the intermontane zone. The northern belt is represented by the Betic Cordillera, the Alps, Carpathians, Balkan Mountains, Caucasus, and the Elburz ranges; the southern belt comprises the Tell Atlas, the Apennines, the mountain lands of Greece and Yugoslavia, the Taurus and Zagros, and the mountains of Oman and Baluchistan. The Hungarian basin, Rhodope Mountains (eastern Greece, southern Bulgaria), northern Turkey, and the plateaus of Iran and Afghanistan belong to the intermontane zone. From Afghanistan to Indonesia only one south-facing chain of Alpine belts is known (the Himalayas, the mountains of western Burma, and the Indonesian island arc); somewhat older ranges, whose relations to the Tethyan System are poorly known, exist in southeast China and Indochina, however. Several belts of fold-fault mountains are set in the foreland of the Tethyan System: the Pyrenees, Cantabrian, Iberian, and Catalonian mountains in Spain, the High Atlas in northwest Africa, and the Jura Mountains of Switzerland and France.

Early Mesozoic limestones resting on a metamorphosed basement of Paleozoic age form the framework of the external zones of the Alpine belts (that is, the northern half of the northern belt and the southern half of the southern belt) and the foreland fold belts. The internal zones of the belts are mainly made of Mesozoic shales and graywackes; an ophiolite association—radiolarian chert, submarine basalt, and serpentinite (composed of magnesium silicate minerals)—is a characteristic component. The intermontane zone consists of Mesozoic limestones, shales, and, in certain areas, volcanic rocks overlying a Paleozoic basement. These rocks were folded and overthrust during late Mesozoic and Cenozoic time.

Formation of the Tethyan System

The Tethyan Mountain System rose from a wide sea named the Tethys. The Tethys System began to form in the Carboniferous and Permian time (around 280,000,000 years ago) and reached its greatest width during the Early Mesozoic (200,000,000 years ago). The limestones of the external zones of the Alpine belts were deposited in shallow water close to the continents farther north and south. The deepwater shales and the ophiolites of the internal zones accumulated in two continuous zones of deep water. The intermontane zone again represents sediments of shallow water. Folding began in the intermontane zone and in the most internal parts of the Alpine belts during the Late Cretaceous (about 70,000,000 years ago).

Cordilleras began to rise in the internal parts of the Alpine belts during the Cretaceous. The clastic debris produced by their erosion accumulated in deep basins along the mountain front. The larger parts of the mountain belts were folded and uplifted in successive steps during the Tertiary Period (2,500,000 to 65,000,000 years ago). Simultaneously, the remaining marine basins became shallower. At the close of orogeny in the Late Tertiary, sands and gravels, derived from the uplifted mountain belts, accumulated in shallow seas and in flood plains bordering the rising mountains to the north and south. The rocks were metamorphosed in the internal zones of the Alpine belts and in parts of the intermontane zone during mountain building. Relatively small granite massifs intruded these zones, and some andesitic volcanic eruptions occurred.

During the Pliocene and Pleistocene (the last 7,000,000 years, approximately) the mountain ranges were uplifted and erosion produced their present landscapes. Earthquake activity is related to the underthrusting of the foreland below the Alpine ranges in the Himalayan-Indonesian segment of the mountain system, whereas it is related to strike-slip faulting (lateral movements) in Iran, Turkey, and Greece. Volcanic activity is strong in Indonesia and moderate in other areas.

Subsidiary mountain ranges. Parts of the platform areas of North and South America, Africa, India, and Australia form broadly upwarped domes. The regional upwarps commonly culminate one or a few hundred kilometres from the coast. They slope gently toward basins in the centre of the large continents (Amazon Basin, Congo Basin, Mississippi Basin). A narrow coastal strip is either sharply downwarped or downfaulted. Impressive mountainous areas with Alpine scenery developed where rivers dissected a greatly upwarped terrain located close to the shore of the ocean (for example, Serra da Matiqueira, Brazil; Cape Mountains, South Africa). The regional domes are parts of Precambrian Shield areas (ancient stable platforms) or parts of Alpine-type belts of Paleozoic age. These regions were eroded during the Early Mesozoic and subsequently were upwarped. The last ma-

jor period of uplift occurred in the Pliocene and Pleistocene (the last 7,000,000 years, approximately).

Basin and range areas of the United States and Asia

The Basin and Range Province of the southwestern United States is characterized by uplifted fault blocks separated by broad, flat basins. The Basin and Range Province cuts across parts of the North American Platform and the Cordillera. In the Platform area (Wyoming and Colorado), the ranges consist of metamorphic rocks of Precambrian age and Paleozoic limestones and quartzites that are undisturbed, except for the faulting and folding that produced the ranges. The ranges of the Cordilleran Province (Utah and Nevada) are underlain by Paleozoic rocks that had been folded and overthrust during Alpine-type mountain building prior to range faulting. Upfaulting of the ranges and subsidence of the basins began in the latest Cretaceous (about 70,000,000 years ago) and continued in successive pulses through much of the Tertiary. The sands and gravels produced by erosion of the ranges were deposited in the basins. After Middle Miocene time (about 15,000,000 years ago) the whole province was uplifted, and faulting continued at some range boundaries.

Basins and ranges and fold-fault belts make up much of central Siberia, Mongolia, Sinkiang, Tibet, and China. Some of the highest mountain ranges of the world are located in this region, among them the Pamir, Kunlun, Tien Shan, and Altai mountains. The ranges are separated by basins, the largest of which are the basins of Sinkiang, the Gobi desert, and the Huang Ho.

In northcentral Siberia (Zubaykalye or Transbaikalia) the higher ranges are underlain by a basement of metamorphic rocks of Precambrian age. In Tibet, Mongolia, Sinkiang, and the adjoining parts of the Soviet Union, the basement consists of Early Paleozoic belts of the Alpine type. The basement was eroded and covered by sedimentary rocks during Late Paleozoic and Early Mesozoic time (around 225,000,000 years ago). Great uplift of the ranges began in the Jurassic, and rocks were intensely folded in some zones. Basins subsided and were filled with sand and gravel derived from the rising ranges. Renewed uplift, gentle bending of sediments, and subsidence of basins continued during the Cretaceous and Tertiary. The main mountain-building period occurred during the later Pliocene and the Pleistocene. Mountain building continues in parts of the region, as indicated by seismic activity, as in the Pamir region, in Tibet, and in Sinkiang.

The block-faulted uplifts of western Europe (Spanish Meseta, Massif Central in France, German *Mittelgebirge*, and the mountains of Bohemia) are underlain by Precambrian and Paleozoic rocks that were folded and partially metamorphosed during Late Paleozoic time (around 200,000,000 years ago). The terrain was eroded during the Permian and then uplifted in successive steps during the Mesozoic and Cenozoic. Pliocene uplift shaped the present ranges.

Rift systems must also be mentioned within the context of subsidiary mountain ranges. The largest rift system in the world consists of the Red Sea Rift and its continuations to the north (Jordan Valley) and the south (East African rifts in Ethiopia, Kenya, Tanzania, and Malawi). Smaller rifts exist in central Europe (Upper Rhine rift) and Central Asia (Lake Baikal rift). Most of the rifts formed during the Early Tertiary (about 60,000,000 years ago). They are still tectonically active and therefore show considerable seismic activity. The Red Sea Rift is continuous with the oceanic-rift system of the Carlsberg Ridge in the Indian Ocean.

BIBLIOGRAPHY. The literature on mountain ranges and belts is both voluminous and diverse. Overviews are presented in the books by L.C. KING, *Morphology of the Earth* (1962); and L.V. DESITTER, *Structural Geology* (1956), among others. Other works, such as that by J. CADISCH, *Geologie der Schweizer Alpen*, 2nd ed. (1953), cover specific mountain belts or parts of mountain systems, but the interested reader should consult articles in a variety of periodicals, notably: *Geologische Rundschau*, the *Bulletin of the Geological Society of America*, the *Journal of Geophysical Research*, and publications of the Geological Survey of Canada, the U.S., the U.S.S.R., and other countries.

(E.Di.)

Mozambique

Mozambique (officially Portugal's Província de Moçambique), also known as Portuguese East Africa, is located on the southeastern coast of Africa between latitudes 10° 27′ and 26°52′ south. Its elongated territory of 303,073 square miles (784,961 square kilometres)—it is the second largest of Portugal's African possessions—has an Indian Ocean coastline of more than 1,700 miles (2,730 kilometres). Mozambique is bounded on the north by Tanzania, on the west by Malawi, Zambia, Rhodesia, and the Transvaal Province of South Africa, and on the south by Swaziland and by the Natal Province of South Africa. To the east lies the Mozambique Channel, which separates the African mainland from the island of Madagascar. (For details on associated physical features see articles on EAST AFRICAN LAKES; EAST AFRICAN MOUNTAINS; MOZAMBIQUE CHANNEL; and ZAMBEZI RIVER. For historical aspects see SOUTHERN AFRICA, HISTORY OF.)

Mozambique's spatial morphology is complex; in the south, it is only 55 miles (88 kilometres) wide; in the middle, about 200 miles (320 kilometres); and in the north, nearly 500 miles (800 kilometres). A wedge of its territory also extends westward along the Zambezi River, between Zambia and Rhodesia. Malawi, in turn, penetrates deeply into northern Mozambique.

Mozambique's pronounced territorial elongation has political, economic, and social significance. Its northern sectors lie adjacent to militantly nationalist black African states, while the south borders white-controlled South Africa.

With over 8,200,000 inhabitants, Mozambique is Portugal's most populous overseas domain. Although officially an overseas province of Portugal, Mozambique remains in effect a colonial dependency of Lisbon. The constitutional amendment of 1952, whereby the territory's colonial status was revised into a provincial one, served to shield it for a time from the scrutiny of United Nations committees concerned with colonial dependencies until, in 1960, the United Nations General Assembly proclaimed it to be a non-self-governing territory. Mozambique has not, however, been exempted from the political and military pressures of African nationalism. Throughout the late 1960s and into the early 1970s, the territory has faced attacks by Tanzania-based nationalist forces that, aided by local allies, have wrested a large part of the north from Portuguese control. While Portugal has maintained substantial armed forces in the field to combat the onslaught in the north, efforts have intensified to accelerate the pace of development elsewhere, to reduce the susceptibility of the territory to nationalist influence, and to link the country more closely to Portugal.

THE LANDSCAPE

Mozambique occupies southern Africa's largest coastal plain; nearly half of the total area lies below 750 feet (229 metres). This coastal lowland is widest in the south, where it covers virtually the entire width of the territory, but northward it becomes narrower. In central and northern Mozambique an interior plateau develops whose elevations range from 500 to 2,000 feet (152 to 610 metres). Toward the western boundaries with Malawi, Zambia, and Rhodesia, this plateau rises still higher, and mountainous terrain occurs. Highest elevations along the Zambia–Malawi border range from 5,741 feet (1,750 metres) in the extreme north, near Lake Malawi in Niassa District, to 7,241 feet (2,207 metres) in the northwest, near the intersection of the Zambia–Malawi boundary in Tete District.

The lengthy coastline is marked by several distinct features. In the extreme south lies the Bay of Lourenço Marques, also known as Delagoa Bay, protected from the Indian Ocean by a sandy spit. Delagoa Bay is the best natural harbour on the East African coast, and on its shore the capital of the territory, Lourenço Marques, has grown. Northward, from Delagoa Bay to the delta of the Zambezi River, the coast is sandy and swampy, with mangroves and offshore bars. North of the Zambezi Delta, however, sandy stretches of coast are interrupted by rocky cliffs and headlands as well as islands, many of

which are of coral formation. In addition to the Zambezi, some 50 other rivers reach the coast of Mozambique, including the Limpopo, the Save, the Búzi, the Lúrio, and the Messalo. In the far north the Rovuma River forms the boundary between Mozambique and Tanzania.

The Zambezi: a physiographic frontier

The pivotal geographical feature of Mozambique, in the interior as well as on the coast, is the Zambezi River (*q.v.*). Almost all the higher and more rugged terrain lies to the north of the river, while to the south the gently undulating coastal lowland prevails. Apart from the higher elevations near the Rhodesian Plateau, there is only one marked feature of positive relief to be located south of the Zambezi: the Serra de Gorongoza in Sofala District. This steep-sided granite massif, an inselberg (prominent residual mountain), reaches 6,112 feet (1,863 metres), but it is only some 12 miles (19 kilometres) wide. Elsewhere, southern Mozambique presents a gently rolling, rather featureless landscape, with an occasional group of low hills, broken by the wide alluvial valleys of the rivers. North of the Zambezi River, the undulating plateau has a landscape of the savanna type, with latosolic soils (red residual soils, leached of silica, and containing iron and aluminum hydroxides). Toward the interior, some spectacular mountains rise above the plateau surface. Lake Malawi (Nyasa) lies in the southern part of the East African Rift Valley, whose fault structures are thought to extend at least to the mouth of the Zambezi.

Mozambique's topography generally declines in elevation from west to east, so that, from the Rovuma River in the north to the Limpopo in the south, streams have an eastward orientation. The low gradients on the coastal plain, especially in the south, nevertheless render some of the stream courses irregular. The higher parts of the territory are sustained by the crystalline rocks of the ancient African basement complex or shield. In the Zambezi Basin and on the coastal plain, dipping toward the Mozambique Channel, lie more recent sedimentary rocks deposited during the Triassic Period (about 260,000,000 to 200,000,000 years ago). Still more recent sediments, of Late Cretaceous (about 100,000,000 to 70,000,000 years old) and Eocene (about 60,000,000 to 40,000,000 years old) age, lie in the eastern parts of the coastal plain. A notable feature is the rhyolite-sustained Lebombo Range, which coincides with the political boundary between Mozambique and Swaziland and also extends northward along the Transvaal border. The Lebombo may be the eastern flank of the Swaziland Rift Valley, an echelon continuation of the East African Rift Valley.

With the exception of northern Mozambique east of Lake Malawi, Mozambique's major rivers rise to the west of the territory, on the African high veld. The headwaters of the Limpopo lie on the margins of the Kalahari Desert: the Save River rises on the Rhodesian Great Dyke, and the Zambezi rises in the Angola–Zambia borderland. Since the interior plateaus receive moderate rainfall at best, with marked seasonal variation, water levels alter considerably. The largest drainage basin is that of the Zambezi River, which, with its Shire tributary (the outlet of Lake Malawi), drains most of the centrally situated districts of Tete, Manica e Sofala, and Zambézia.

Good soils are the exception rather than the rule in Mozambique. The soils of the plateau areas, derived from underlying granites, gneisses, and schists, are ferralitic (leached and iron–aluminum rich) and are generally rather infertile. In the dry interior to the north of the Limpopo Valley, sandy, ferruginous (iron-bearing) soils prevail, whose high permeability increases the area's dryness. Along the coastal plain there are waterlogged and organic soils, with some poorly developed alluvials. In the alluvial lowlands of several of the river basins, and in the *machongas* (humus-rich, moist patches of lowland between the coastal plain's dunes) lie Mozambique's most productive soils.

CLIMATE

As Mozambique lies on the tropical East African coast, apparently in the path of the southeast trade winds, and as the warm Mozambique Current flows southward offshore, one would expect a rainy, moist climate to prevail. This would seem the more likely as the mountains of the interior cause air currents to rise, thus increasing the probability of rain. Much of Mozambique is, however, subhumid, and drought is frequent in many areas. Lourenço Marques, for example, receives a mere 30 inches (7,595 millimetres) of rain in an average year; Inhambane, 36; Beira, 10; António Enes, 42; and Tete, 23. With the prevailing tropical temperatures (Lourenço Marques has an annual average of 73° F [23° C], while Quelimane's warmest month averages 82.5° F [28° C] and its coolest month 69° F [21° C]), much of this rainfall is lost by evaporation or by plant transpiration. Only north central and northwestern Mozambique generally maintain a favourable moisture balance.

Rainfall

Several reasons for Mozambique's comparatively low rainfall have been suggested. The configuration of the coastline may be such that the moisture-bringing trades blow parallel to most of it, rather than approaching it at an angle. Madagascar, across the Mozambique Channel, may interfere with the westward-moving trades and reduce their moisture content. The air layer that reaches the coast may be thin and therefore capable of generating little rain. Mozambique may also be under the influence of a permanent South African anticyclone, or high pressure area, repelling air masses moving in from the Indian Ocean.

Mozambique is tropical savanna country extending south beyond the Tropic of Capricorn. It is, nevertheless, its altitude rather than its latitude that moderates temperatures. Although Lourenço Marques lies nearly 1,000 miles south of Porto Amélia, its annual average temperature is only slightly lower, and its annual range only slightly greater. Chillier nights and cooler winter months are recorded in the higher zones along the Rhodesian and Zambian borders. There is a distinct rainy season, which is also the high-sun period, from October (or November) until March. The dry season usually lasts from April into September and sometimes longer. Annual precipitation figures show that Mozambique north of the Zambezi is a region of greater moisture and lesser drought incidence (although the Zambezi Basin around Tete is itself moisture deficient) but that the south suffers from drought and low rainfall, except along the littoral and against the Rhodesian Plateau slopes.

VEGETATION AND ANIMAL LIFE

Mozambique's vegetation is mostly tropical forest and savanna, with many barkcloth trees. Along the coast, especially between 17° and 20° south, the coconut palm is common. The coconut plantation at Quelimane, with 50,000 acres (202 square kilometres) and 4,000,000 palms, is often identified as the largest in the world. Several other types of palm, including the date palm, also occur. Along the upper reaches of the major rivers, notably the Zambezi and the Limpopo, the mopane tree prevails on the savanna, where the baobab tree is also a characteristic feature. Areas of mangrove exist along the coast, especially in the vicinity of the Zambezi Delta. Bamboo and spear grass occur abundantly along the river banks and in the marshy areas. Patches of forest, which include stands of ironwood and ebony, are generally found on better drained slopes amid savanna country. In the narrow ravines tree growth is dense, including the large Senegal khaya, used for timber.

Despite excessive hunting and the virtual extermination of game in some areas by professional hunters and poachers, Mozambique still remains rich in animal life. Lions are still numerous, and the leopard is often seen on the granite hills of the plateau slopes and in the denser bush. The cheetah, spotted hyena, jackal, serval (a long-legged wildcat), civet cat, mongoose, and wild dog occur in several areas, notably in the Moçambique and Manica e Sofala districts. Some animals also roam into the country from South Africa's Kruger National Park, which lies to the southwest. The elephant is common, as is the black rhinoceros; the white rhinoceros occurs, although more rarely. Many of the lower courses of Mozambique's rivers are inhabited by the hippopotamus. Among the herd

animals, the buffalo is especially numerous, and herds of zebra are often seen. Giraffes and wart hogs are also to be found. There are many antelopes. The scaly anteater is ubiquitous, and there are many species of rodents. Several kinds of monkeys and lemuroids exist, although the anthropoids are absent.

Snakes are common, especially the python, cobra, puff adder, and viper. Crocodiles abound in the rivers, and there are many lizards, chameleons, and several species of tortoises. In addition to scorpions and centipedes, insects are prolific. There are swarms of mosquitoes, locusts, tsetse flies, hippo flies, cockroaches, phylloxera (plant lice), termites, soldier ants, and flying ants.

Mozambique's bird life is varied. Flamingoes inhabit the northeast, especially Moçambique District, and species of cranes, storks, herons, pelicans, and ibises occur. The eagle, buzzard, and crow are omnipresent, as is the vulture. Guinea fowl, partridge, bustard, quail, wild goose, teal, and other kinds of duck are all found in large numbers.

TRADITIONAL REGIONS

As already mentioned, the Zambezi River forms a significant dividing line between northern and southern Mozambique. South of the river are the territory's major cities, Lourenço Marques and Beira. Southern Mozambique is adjacent to the Transvaal Province of South Africa and to Rhodesia, and its ports have long functioned as ports of entry and exit for South African and Rhodesian goods. African labourers by the tens of thousands have gone to work in the mines and on the fields of these neighbouring countries, and the Portuguese administration has benefitted from the resulting income derived both from labour agreements and from individual taxes. In southern Mozambique, also, are the chief sites of the agricultural settlements by means of which the administration seeks to accelerate development and to consolidate control through the encouragement of European immigration. The transport system is also more developed in the south.

Development in the south

Southern Mozambique is, moreover, relatively remote from the African nationalist threat in the north. Whereas southern Mozambique contains the majority of the approximately 100,000 Europeans who live in the territory, northern Mozambique contains some of its most densely peopled African districts. The northern districts of Zambézia and Moçambique together are inhabited by nearly 3,500,000 people—over 40 percent of the total population of the entire territory. With its larger black population, its remoteness from the capital, Lourenço Marques, its rudimentary transport system, and its lengthy boundary with Tanzania, northern Mozambique is vulnerable to attack and has consequently become the main theatre of the struggle Portugal is waging against black nationalism in Africa. While this fact is of immediate import, there are also other factors that distinguish the north from the south—the lack of economic opportunity inland, where Malawi and Zambia generate far less employment or trade than South Africa and Rhodesia, the scarcity of alternatives to subsistence agriculture, the imprint of Islām on some of the African peoples, and the generally stronger resistance to change.

HUMAN SETTLEMENT

The vast majority of Mozambique's African peoples live in dispersed homesteads, small hamlets, or villages. Although various types of dwellings are built, most African houses are cylindrical, with a conical thatched roof and with walls of wattle and daub. In the hamlets and villages, a cluster of these houses surrounds either a cattle corral or, occasionally, a central meeting ground dominated by a large tree. Surrounding each settlement are the fields worked communally by its inhabitants. Maize (corn) is the staple for most of the territory, although yields per acre are low and the annual production highly variable. Famine remains a local threat.

Much of rural Mozambique is thinly populated bush country, but pressure on the land occurs in the coastal areas of Moçambique and Zambézia districts and in southern Inhambane and Gaza as well as in the Lourenço Marques District. Because of a legacy of past slave raiding, endemic sleeping sickness, and low soil fertility, Niassa District in the north remains the emptiest area of the province. In the more fertile areas, Africans have combined some cash cropping, especially of cotton and rice, with their cultivation of staples.

Considerable population agglomerations have occurred in the hinterlands of the coastal towns, both as a result of greater soil fertility and as a result of the drawing power of such towns or cities as Lourenço Marques, João Belo, Inhambane, Beira, Quelimane, António Enes, and Moçambique. In these areas the rural homestead or hamlet pattern begins to vanish as truck farming appears and as the modernizing influence of the town alters the nature of settlements. Vegetable plots, some tobacco fields (mainly in the north), fields of rice and maize, and some sugar and citrus plantations occur. The European plantations and the fields devoted to cash cropping are almost everywhere interspersed with areas of African settlement or of bush country where little has changed.

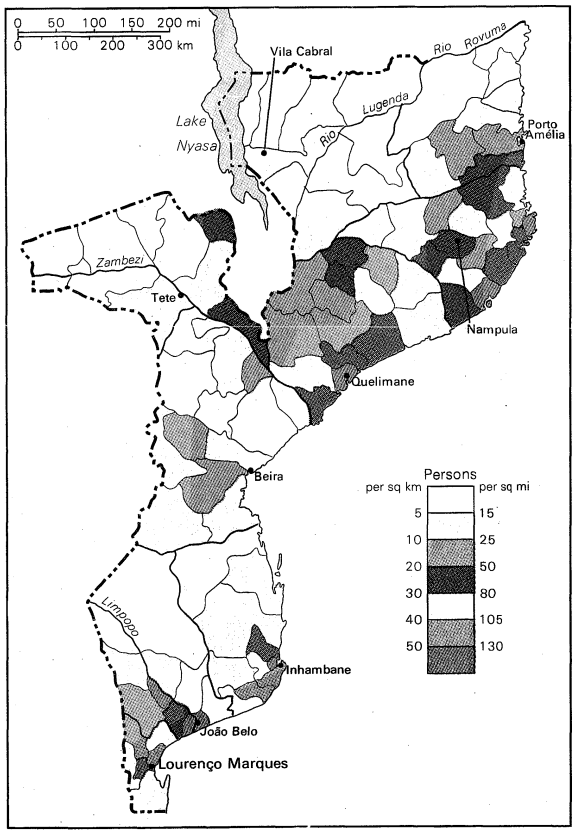
Lourenço Marques and Beira, both with metropolitan area populations exceeding 150,000, are modern, clean, and attractive cities. They are well planned, with wide avenues and ample shade trees. A meticulous attention to detail, as demonstrated by some inlaid sidewalks and by well-kept and terraced public gardens, suggests an administrative intention to provide a cultural focus for the territory. Large apartment houses and elaborate public buildings dominate the urban landscape. In the suburban areas there are villas and smaller homes in the characteristic Portuguese style. Both Lourenço Marques and Beira are somewhat compact; around the periphery of these cities, however, unplanned African shantytowns have grown up.

PEOPLE AND POPULATION

The African majority

The overwhelming majority (97 percent) of Mozambique's population of over 8,200,000 is black African. Most of the Africans belong to the Central Bantu group. Two major historical events that shaped the peopling of Mozambique—the great Bantu migration from the north and west and the northward migratory movement that followed the rise of the Zulu Empire in Natal to the south—created two subdivisions of the Central Bantu group in the territory. Again the Zambezi is a crucial dividing line: north of the river the people trace their lines of descent on the matrilinear principle, while patrilinear peoples prevail in the south.

The two main groupings thus identified can be further subdivided on an ethnolinguistic basis. The African peoples south of the Zambezi are related to those in Rhodesia. Approximately from the latitude of Beira southward are the Thonga, while to the north live the Shona (or Mashona). The Thonga and Shona are primarily farmers, although such groups as the Shangana (a subgroup of the Thonga) own sizable cattle herds in Gaza District. In the Zambezi Valley and northward two clusters are also recognizable. In the east are the Makua (Macua) and Makonde peoples, who both form part of the Yao tribal grouping, and who occupy most of the land between Malawi and the coast. The Makonde, who have a history of opposition to Portuguese rule and are currently involved in the war against the Portuguese in the north, are also settled in Tanzania, on the north bank of the Rovuma River. To the west live the Maravi as well as other Yao peoples, all of whom have tribal affiliations across the frontier. These Yao live in the northern corner adjacent to Lake Nyasa, as well as in Tanzania, while the Maravi occupy the Zambezi corridor north of the river, adjacent to Zambia and Malawi.



Population density of Mozambique

The former status of *assimilados* (*i.e.*, assimilated, or living as a European) has been replaced by universal full citizenship, but the non-African minority still constitutes the territory's elite. An extrapolation from the 1960 census suggests that there are now more than 150,000 Europeans in Mozambique, not counting the 60,000 armed forces that were in the territory in 1969. The European minority that controls most of the country, and which is almost entirely Portuguese, is concentrated in the urban centres and in the most productive agricultural zones. There are also an estimated 40,000 mestizos (persons of mixed ancestry). The largest cities contain Chinese, Goan, and Pakistani quarters, and these minorities play a leading role in trade and commerce. The Chinese community in Beira has long maintained its own primary school; in Lourenço Marques many shopkeepers, especially in the "Old Town" of the city, are Indian or Chinese. In the mid-1960s, membership in the territory's various economic associations numbered 4,000, out of which about 1,000 were non-Europeans, most of whom were Indians and Chinese. There are also some South Africans and Rhodesians, most of whom are officials or engaged in trade.

Mozambique's language pattern is as complex as its population is varied. African peoples speak several distinct Bantu languages, most of which are mutually unintelligible. The closest any African language comes to serving as a lingua franca is Swahili, which is spoken in the towns and villages along the coast, especially north of the Zambezi. Portuguese is the official language, but the literacy rate is estimated at only 6 percent. One result of the labour migration to the South African and Rhodesian mines has been to foster English among the African workers. A substantial number of the Portuguese population also speak English.

A similar variation occurs in religious affiliations. In the north, Islāmic traditions are superimposed on essentially animist African societies. In the south, Christianity has made deeper inroads, primarily in the form of Roman Catholicism. The position of the church has been defined by the Portuguese concordat and missionary agreement of 1940, which created a missionary see at Lourenço Marques, to which two dioceses at Beira and Nampula are suffragan. There is also some Protestant missionary activity. The religious diversity of Mozambique finds expression in the architecture of Lourenço Marques, which includes a Catholic cathedral and several Catholic churches, an Anglican cathedral, a Methodist church, a synagogue, a mosque, and a Chinese temple.

DEMOGRAPHY

The 1960 census reported a population of 6,600,000, of whom 6,460,000 were identified as "tribalized Africans," 148,000 as "civilized" (including the European and other non-African minorities), and between 4,000 and 5,000 as "westernized Africans." Reliable birth and mortality rates have never been available, and growth-rate estimates average 2.0 percent (births, 43 per 1,000; deaths, 23 per 1,000). Officially, infant mortality is reported as being between 90 and 100 per 1,000, but some observers state that there are areas where it may be near 50 percent. Emigration and immigration data are similarly unavailable. Further complexities have arisen as a result of the political conflict. More than 10,000 Makonde have reportedly fled to Tanzania in the past few years, and many Lomwe—a subgroup of the Yao people, mentioned earlier—have migrated into Malawi. Approximately 40 percent of all Thonga males at one time or another work in the mines of South Africa or Rhodesia, and an unknown percentage of them remain there. Some Shona, on the other hand, have crossed the border from either South Africa or Rhodesia to settle in southern Mozambique.

White immigration

White immigration has grown steadily over the past half century, but in the 1950s and 1960s the rate increased greatly. In 1930 there were only some 17,000 whites in Mozambique; in 1940, about 27,000; and in 1950, 48,000. In the 1950s the European population nearly doubled, and the 1970 estimate is about 150,000—excluding the armed forces. White immigration has been stimulated by increasing economic development, and by governmental policy, which has encouraged Portuguese to emigrate to Mozambique or Angola. While the majority of Portuguese emigrants settle in Angola, Mozambique has nevertheless received a share (25,344 in 1967). In the valleys of some of the territory's rivers, such as the Limpopo

and the Revuè, settlement schemes have been laid out, and farming families from Portugal are being encouraged to settle by offers of land and loans. In the basin of the Zambezi River, the Cabora Bassa Hydroelectric Project was under construction in the early 1970s. Although primarily aimed at the generation of cheap power, the Cabora Bassa Project will also serve to expand the irrigated acreage of land in the Zambezi Basin and will thus stimulate farm settlement on a large scale. Flood control and irrigation over a 3,000,000-acre (12,141-square-kilometre) area are foreseen.

Mozambique, Area and Population

	area*		population	
	sq mi	sq km	1960 census	1970 census
Districts (*distritos*)				
Cabo Delgado	30,260	78,374	549,000	567,000
Gaza	31,866	82,534	682,000	753,000
Inhambane	26,436	68,470	583,000	747,000
Lourenço Marques	6,480	16,783	437,000	799,000
Manica e Sofala	50,137	129,854	780,000	1,085,000
Moçambique	30,218	78,265	1,452,000	1,735,000
Niassa	46,384	120,135	281,000	297,000
Tete	38,886	100,714	471,000	492,000
Zambézia	39,722	102,880	1,369,000	1,757,000
Total Mozambique	300,389	778,009	6,604,000	8,234,000†

*Areas for the districts and the total are land areas. The total area for Mozambique is 303,073 sq mi (784,961 sq km). † Figures do not add to total given because of rounding.
Source: Official government figures.

Population distribution is characterized by (1) a concentration along the coast, except along the Zambezi Valley; (2) strong rural agglomeration, especially in Moçambique and Zambézia districts and in the south; and (3) very low densities in the areas of the upper Limpopo-Save, upper Zambezi, and upper Rovuma-Lugenda rivers. African and non-African population distributions should, however, be viewed separately. More than 90 percent of the Africans live in the rural areas, in the traditional manner, but between 75 and 80 percent of the Europeans live in the cities and towns. The Indian and Chinese minorities are almost completely urbanized.

Reliable demographic statistics being scarce, it is difficult to discern trends. The rate of European immigration may nevertheless be expected to continue to increase. Large areas in the north being out of Portuguese control, no accurate population count can be expected in this region for some time. Mozambique is known to have inadequate medical facilities (except in the towns), and the increase of less than 800,000, or 12.5 per thousand, in the African population between 1950 and 1960 may be attributable to a moderately high birth rate and high death rates. Some authorities feel that the birth rate remains moderate because of the absence of many male migrant labourers in South Africa and Rhodesia and because of a high infant mortality rate.

THE NATIONAL ECONOMY

Mozambique is not a rich territory. The great majority of the people are engaged in subsistence agriculture. No known mineral deposits are comparable to those of South Africa, Rhodesia, Zambia, or Zaire. Mozambique's assets are its soils, labour, and location. Its income comes chiefly from agriculture and transport.

The balance of trade normally shows a large deficit, which is partially made up by income from transportation. In 1968, for example, the value of exports totalled $100,000,000, and of imports $151,000,000. A large part of the $51,000,000 deficit was made up by earnings deriving from the transit trade link connecting South Africa and Rhodesia with Lourenço Marques and Beira. The remaining deficit, nevertheless, still totalled $11,200,000.

Portugal and South Africa are Mozambique's chief trading partners. Portugal buys about 40 percent of the territory's exports and supplies more than one-third of its imports, and South Africa's share in both directions averages 12 percent annually. India and the United Kingdom are also major partners; India buys much of Mozambique's cashew harvest. Cotton, sugar, and other agricultural products constitute the main volume of exports, while various kinds of machinery and textiles account for most of the import value.

RESOURCES

Mozambique's mineral resources may not yet be fully known, for recent discoveries reported include gold in Manica e Sofala, iron ore in Moçambique District and near Tete, and manganese near the South African border. Other hypothetical reserves include oil along the margin of the coastal plain. Hitherto, however, mining in Mozambique, despite an interesting history, has produced few results. As recently as the late 1960s the only substantial mining operation was the working of the coal deposit near Tete in the Zambezi Valley, used by the Mozambique and Rhodesian railroads. With the advent of the Cabora Bassa Project and with the recent discovery of iron ore, the possibility of an economic transformation of the area is mooted. Other minerals that have been mined include tantalite (Mozambique reportedly possesses the largest deposit of this rare mineral in the world) at Murrua in the north, gold in Bragança, iron in Namapa (where a Japanese firm is investing in its exploitation), and manganese and asbestos in Catuane in the southwest corner of the territory. In addition, beryl, graphite, ilmenite, mica, and bismuth have been extracted—all in small quantities—as well as natural gas near Maamba, northwest of Lourenço Marques. Despite reports of new discoveries (that of uranium was announced in 1970), the contribution of the territory's mineral resources to the economy nevertheless remains small.

Mineral prospects

Mozambique's biological resources have been put to various uses. Natural products, such as copra and cashew nuts, are collected by the Africans, and the cashew-nut industry has assumed large proportions following the construction of a processing plant at Vila de João Belo. Mozambique exports a small amount of timber, mainly from logging areas in Manica e Sofala District. More than half the exports are in sawn timber, used for railroad ties for South Africa. The varied fauna of the territory draws many hunters and visitors to Parque Nacional da Gorongosa. Thousands of South African tourists visit the coasts of Mozambique each year.

The electric power resources of Mozambique will be much increased by the completion of the Cabora Bassa Project. In the late 1960s the only hydroelectric project operating in Mozambique was that on the Revuè River, which generates power for an area that includes Beira, as well as Umtali in Rhodesia. The installation was recently enlarged, and an additional project was begun on the Maputo River in the extreme south of the territory. Meanwhile, Mozambique is also served by some 688 thermal power plants, most of which are small in scale; those at Lourenço Marques have a 53,000 kilowatt capacity.

SOURCES OF NATIONAL INCOME

The agricultural sector contributes the bulk of the exports by value. Cashew nuts and cotton each now account for about one-fifth of all export income. Sugar and related products account for about 10 percent, and vegetable oils, tea, sisal, and copra for smaller percentages. Timber exports, mainly from Manica e Sofala District, account for about 3 percent of annual export revenues. Mahogany, ebony, and sandalwood are the most important timbers produced. The nascent fishing industry catches fish for the home market.

Although the beginnings of a mining economy exist in Mozambique, the mining sector is still small. Petroleum products in the late 1960s accounted for about 11 percent of annual income, and coal for less than 1 percent. Iron is expected to increase in importance when development plans for the Nampa deposit are completed and exploitation begins.

The processing of primary products is the main industrial activity. Most industrial establishments are engaged in the pre-export treatment of cotton, sugar, tobacco, cashews, and other agricultural products or in the manu-

facture of products for the local market, such as footwear, foodstuffs, cement, fertilizers, beverages, and textiles. There has always been a shortage of capital, and the close proximity of South Africa and Rhodesia discourages industrial development in Mozambique.

As already mentioned, it is from the transit trade that Mozambique reaps major benefits. The junction of Lourenço Marques, which is connected by rail to Johannesburg and the Witwatersrand, as well as to Swaziland, is to serve as an outport for South African trade, and the prospect is for increasing revenues from this source. The Mozambique Convention between Portugal and South Africa stipulates that 40 percent of the southern Transvaal's transit traffic must go through Lourenço Marques. Beira has similarly earned revenue as the chief outlet for Rhodesia and Malawi and, to a lesser extent, for Zambia and even Katanga. Since 1955 the Pafuri Line has linked Lourenço Marques with the Rhodesian rail system.

Despite warfare in the north, efforts are being pursued to connect the port of Nacala in the Moçambique District with the Malawi system, thus establishing another outlet through Mozambique for a landlocked country. In the late 1960s the income derived from the transport operations of the ports and railroads was approximately $50,000,000 to $60,000,000, or over one-third of the value of all exports combined.

The African labour force

The African labour force is another source of revenue. For a century Africans have been volunteering for work in the South African mines; in 1897 the first of a series of formal agreements between the Portuguese administration and a South African government regulating migrant labour from Mozambique was signed. Apart from taxation on the earned income, withheld and paid directly to Lourenço Marques, South Africa pays the Portuguese administration a fee for every labourer who legally enters South Africa for contract work. In addition, passport and registration fees must be paid by the worker. Earlier in this century revenue obtained from migrant workers was larger, as a forced-labour system within Mozambique induced many Africans either to volunteer for work in South Africa or to enter South Africa illegally. Today conditions are different, and income from migrant labour has declined to about 2 percent of the annual total.

Tourism represents an expanding source of revenue for Mozambique, although in the late 1960s the credit derived from the industry was still below $5,000,000 annually.

MANAGEMENT OF THE ECONOMY

The economy tends to be centralized, so that private enterprise is somewhat restricted. With minor exceptions, all surface transport and communications systems are under state ownership, as are the municipal services. Mineral development has been left to private enterprise, except in large operations, where joint government–private sponsorship prevails. Manufacturing, banking, general commerce, and finance are open to private entrepreneurship. In agriculture the situation is complex. The government supports land-settlement projects and also plays a shareholder's role in farming cooperatives. There are also many privately owned farms and plantations.

The tax structure is complicated and cumbersome. Eight taxes are levied: (1) a tax paid by all government servants; (2) a personal income tax; (3) an industrial tax on corporate profits; (4) an urban building tax, drawn from rental incomes; (5) a tax on concessions granted by the government for exploitation of land, livestock, minerals, forests, or fish resources; (6) an excess profits tax; (7) a real estate transfer tax; and (8) an extraordinary tax, instituted in 1963 to raise revenue for defense.

Mozambique has participated in successive Portuguese National Development Plans (Plan de Fomento), of which the first was introduced in 1953, and the second in 1959. The agricultural settlement schemes form part of the third plan. While there has been an expectation that the Cabora Bassa project will signal a period of development, accompanied by a liberalization of economic policy—the 1965 Foreign Investment Law is seen as an augury of this—a shadow has been cast upon these hopes by conflict in the north. A number of the new developments—the extended northern railroad extension, the Namapa iron fields, and the Cabora Bassa Project itself —are near areas where Portuguese control is tenuous.

TRANSPORTATION

Transport networks are insufficiently developed, having been constructed more to serve the transit trade than the territory's own needs. Although it is possible to travel by rail from Lourenço Marques to Johannesburg and from Beira to Salisbury, there is no direct rail link between Mozambique's two major cities nor even a good road connecting them. Roads as well as railroads centre on three distinct foci: on Lourenço Marques in the south, Beira in the central region, and Moçambique in the north.

Roads. In recent development plans, the much-neglected road system of Mozambique received much attention, but in 1970 the territory, over 300,000 square miles (780,000 square kilometres) in extent, still had only about 1,100 miles (1,800 kilometres) of surfaced roads and well under 25,000 miles (40,000 kilometres) of roads of all descriptions, including mere tracks. Among the surfaced or graded gravel roads are the route from Lourenço Marques to Ressano Garcia at the Transvaal border, together with some side roads; the road from Beira to Umtali in Rhodesia, and a connecting route that leaves it at Vila Pery and runs to Tete on the Zambezi; and a stretch of road along the far north coast. The road from Lourenço Marques to Inhambane is being continued to connect with the Beira–Umtali highway. When completed it will provide the first all-weather, north–south link to the south of the Zambezi. Enormous areas of Mozambique remain virtually without roads.

Railways. Mozambique's transit function is emphasized by the disconnected pattern of its railroads. There are about 2,300 miles (3,700 kilometres) of rail in three systems. The Lourenço Marques system, owned by the Mozambique government, serves the Witwatersrand and Johannesburg; it also extends into Swaziland, from where it transports iron ore. In addition, feeder lines serve local areas in the Incomáti, Maputo, and Limpopo valleys. The Pafúri (Malvérnia) Line carries nearly half of the output of the copper fields of central Africa to the port of Lourenço Marques. The Beira system, whose main arterial line is state owned but which has two privately run feeders, serves Rhodesia, Malawi, Zambia, and Zaire. The system is V-shaped, with the western artery serving the Rhodesian interior and the northern lines serving Tete and Malawi. The Mozambique system begins at the port of Nacala and extends to Vila Cabral and the highlands near Lake Nyasa. It is the longest of the domestic lines. A connecting line is being constructed to link it with the Malawi system.

Ports. In a continent in which natural harbours are scarce, Mozambique is well endowed. Delagoa Bay, on the shores of which the port-capital of Lourenço Marques has developed, has a reputation as one of the best natural harbours in the world. Lourenço Marques can berth 16 oceangoing vessels in addition to smaller coastal steamers and oil tankers, for which special facilities exist. Several deep channels cross the bay to the open sea but dredging is necessary. Beira, a river port 15 miles (22 kilometres) from the open sea, is less favoured. The harbour is shallow, sand and silt accumulations necessitate constant dredging, and there is a troublesome bar across the mouth of the Púnguè River. Despite these disadvantages, Beira has a capacity nearly half that of Lourenço Marques. In addition to these two ports, there are several deepwater harbours along the coast. Nacala is the principal port of the north—the old Moçambique harbour is virtually abandoned—and is the eastern terminal for the Mozambique railroad system. Quelimane, located on the Cuacua, a Zambezi Delta distributary, is connected by a short railroad to the Mocuba agricultural area. Other smaller ports include Mocímboa da Praia, Porto Amélia, Memba, António Enes, Moma, Pebane, Macuze, Chinde, Mambone, and Inhambane.

Air transport. Lourenço Marques and Beira both have major international airports and are served by foreign

carriers as well as by the Mozambique airline, DETA (Direcção e Exploração dos Transportes Aéreas [Direction and Exploitation of Air Transport]). In addition, some 16 airports serve the smaller towns, and there are several dozen airfields and landing strips in the more isolated parts of the territory. Regular services are provided to the larger airports by DETA and to the international airports by Portuguese and South African carriers. The airport at Nampula in the north is an international terminal and is also being used for military purposes.

ADMINISTRATION

By the constitutional amendment of 1952, which proclaimed Mozambique to be an overseas province, the territory became an integral part of the Portuguese state. The Central Government in Lisbon, through the Overseas Ministry (which is headed by a Cabinet member), supervises the affairs of the territory. The Minister for Overseas Provinces is advised by an Overseas Council, consisting of persons representing metropolitan and overseas interests. In the Portuguese National Assembly, Mozambique holds seven of 130 seats.

The administrative structure

The province is administered by a governor general, who is appointed through the Overseas Ministry; although he has administrative powers in Mozambique, he may be overruled by Lisbon. His residence is in Lourenço Marques, where he is assisted in his executive work by an advisory group, the 18-member Economic and Social Council. This council is composed of representatives chosen by various interest groups in the province, representing business, labour, cultural organizations, and the civil service, as well as of a number of appointees. In his legislative functions the governor general consults a 29-member Legislative Council, which includes appointed as well as elected members. Some of the elected representatives are chosen by the general vote of eligible voters in the province. Although prospects of a legitimate opposition coming into existence have improved, there is no legal opposition party in Mozambique. The only political party is the National Union (*União Nacional*).

Administratively, Mozambique is divided into nine districts, or *distritos*, each with a local governor and an advisory board. These districts are further subdivided into smaller units; those enclosing urban places are called councils (*concelhos*) and those composed of rural areas are circumscriptions (*circunscrições*). African chiefs are paid by the government.

The political process is thus that prevailing in the corporate state. All executive officials in the territory, down to the level of the presidents of the urban councils, are appointed, not elected. The nominated members for the Social and Legislative councils must be acceptable to the administration. A rejected nominee may nevertheless present himself for election.

With the abolition of an official distinction between "indigenous" and "assimilated" (or "civilized") African residents of Mozambique, the composition of the voters' rolls is changing. Even should black voters come to outnumber white, however, control would remain in the hands of the central administration. Two challenges to the status quo have, nevertheless, come into existence. One is represented by the Associação do Naturais de Moçambique (Association of the Native-Born of Mozambique), an association of Mozambique-born businessmen, civil servants, labour people, and others. This organization has at times opposed all influences of metropolitan Portugal in Mozambican affairs and has taken on the characteristics of a political dissent group. Some of its members favour an independent Mozambique within the framework of a greater Portuguese community. The second challenge is represented by the two major African nationalist parties—both based in Dar Es Salaam, Tanzania—whose partisans are combating Portuguese authority in the north. One is FRELIMO (Frente de Libertação de Moçambique, "Mozambique Liberation Front"), and the other is COREMO (Comité Revolutionário de Moçambique, "Revolutionary Committee of Mozambique").

Justice. Portuguese law is applicable in Mozambique, but with some modifications. The Portuguese criminal code applies in all respects, but the civil code is appropriate to all persons who choose to be governed by it, rather than by the customary laws of traditional African society. Where conflict occurs, written law prevails. Some outlawed practices include witchcraft and sorcery as well as mutilation of the body. There are ordinary, special, municipal, and labour courts. The court of final appeal is the Metropolitan High Court in Lisbon.

Armed forces. All males are eligible for the armed forces, and military service is compulsory. Service, which begins at the age of 21, is normally of two years' duration. Since 1967, however, military service has also been open to women; the age of eligibility begins at 18, and the period of active duty is of four years' duration. For metropolitan Portuguese, two of the four years' service must be in Africa. The 1970 estimates suggest that some 45,000 troops were in the field in Mozambique.

SOCIAL SERVICES

Social services in Mozambique are poor. The latest available official figures in the early 1970s indicated that in a country of 8,000,000 people there were fewer than 1,200 teachers and fewer than 20,000 students at the second level of education (*i.e.*, ages 15 to 19). At the first level, including the initial years of schooling, attendance in 1964 was 358,378, but the attrition rate in the second and third year is about 90 percent. Portuguese reports for 1970 indicated 496,381 students were at the primary level, most of them in the special African schools. There is a university in Lourenço Marques.

Health and welfare

Health and welfare services are similarly rudimentary. The high infant mortality rate has already been mentioned. In the early 1970s there were less than 500 doctors in Mozambique, or about one doctor for every 16,500 persons, with a ratio of just over 1.5 hospital beds per 1,000 people.

The growth of shantytowns on the outskirts of the cities and towns has presented a challenge that has so far not been met, since funds for rehabilitation are not available.

The Portuguese secret police, PIDE (Polícia Internacional e de Defesa do Estado, or International Police for the Defense of the State), became operative in Mozambique for the first time in the late 1950s; since then it has questioned or detained suspected sympathizers of the African insurgency movements.

LIVING CONDITIONS

The cost of living in Mozambique is higher than in Portugal. Until the early 1960s, a dual system of wages existed that favoured the whites; Africans were paid much less for the same work and were not permitted to belong to workers' associations. Wages are low by South African standards, and many skilled and semiskilled white workers depart for South African jobs. Taxes are also high for the wage earner—a tax of 40 percent is levied on a salary of $3,000 (U.S.).

Health conditions favour the white man rather than the African; the inadequate doctor and hospital services are concentrated in the towns, and the rural areas have little medical service. A small number of medical personnel, sustained by the state or by the church, were active in some rural areas. The incidence of bilharzia—a disease communicated by water—has increased because of new irrigation projects; over 1,000,000 people were treated in outpatient clinics in 1967. Smallpox vaccination is compulsory, and it is estimated that 80 percent of the population have been vaccinated. Malaria, sleeping sickness, yaws, and diarrheal infections (the last probably the chief cause of the high infant mortality) all afflict the population, especially the African majority.

The average white resident has a better life than his African counterpart. Until the early 1960s, policies of forced labour, compulsory cropping, corporal punishment, and wage discrimination were in effect, resulting in international criticism of the Portuguese administration. While the decade of the 1960s saw the termination or revision of many of these policies, it was nevertheless too late to stave off some of the consequences. Reform in

Mozambique did away with the *shibalo* labour system; the word *shibalo* is derived from the Swahili word *shiba*, meaning serf. Under this system an African male between the ages of 18 and 55 who could not prove that he was leading a productive existence could be put to work for the state at a negligible wage. It also eliminated the *assimilados* system, whereby a few Africans who could qualify could achieve "assimilated" citizenship status. The effects of such systems, however, take time to disappear. Yet while Mozambique has always maintained a social stratification based on class, and to a considerable extent on religion, discrimination because of skin colour has always been less noticeable than elsewhere in Southern Africa. While some critics have maintained that the degree of integration achieved represents a facade behind which general racial discrimination prevails, patterns of racial mixing are observable in the public facilities of Lourenço Marques and Beira. The Portuguese no longer can afford to maintain a dual system of assimilation and subjugation. They now seek the acquiescence, if not the loyalty, of the African peoples of the territory.

CULTURAL LIFE AND INSTITUTIONS

Portuguese administrators have always taken a fierce pride in Portugal's cultural heritage and have consistently sought to inculcate Portuguese traditions.

To a considerable extent the cultural effort has taken root. Mozambique has developed a tradition that is a mixture of Portuguese and local culture. This blend is expressed in the architecture of Lourenço Marques, in the writings and poetry of black as well as white authors, in painting and sculpture, and in music. There is considerable interest in and encouragement of African traditional arts.

The major daily newspaper is Lourenço Marques' *Notícias*, which is state controlled and subject to censorship. The Radio Clube de Moçambique serves Mozambique, as well as broadcasting in English and Afrikaans to South Africa and Rhodesia.

CONCLUSION

In Mozambique, Portugal is seeking to free itself from the liabilities of an earlier colonial period in which laxity went largely unpunished and oppression provoked neither criticism nor retaliation. In a decade of adjustment and far-reaching reform, the Portuguese have sought both to redress past errors and to maintain their position. Thus, while a full-scale war is being fought in the north, the Portuguese administration is nevertheless planning to promote future development—an intention symbolized by the Cabora Bassa Project, which is due to be completed in the late 1970s. In the meantime the cost of the war in the north is heavy. Together with the wars in Angola and Portuguese Guinea, it accounted for 40 percent of Portugal's 1970 budget. Economists have calculated that Portugal can sustain the conflict indefinitely, but, on the other hand, the African armed opposition is obtaining more manpower and material, as well as more support from abroad. An increase in hostilities is anticipated, for while the African nationalists intend to prevent the construction of Cabora Bassa, the South African government, for its part, has shown a growing interest in the struggle.

Portuguese officials have repeatedly expressed the hope that Mozambique may in time emerge as an autonomous state on the Brazilian model, forming part of a greater *luso*-tropical world. For this hope to be realized, the most evident requirement is time—time to repair past mistakes and time to generate new development. The question to be answered is whether sufficient time will be available.

Mozart, Wolfgang Amadeus

Regarded by many as the greatest musical genius of all times, Wolfgang Amadeus Mozart was one of the world's three or four leading operatic composers and one of the central figures of the Viennese classical school.

Mozart, unfinished oil portrait by Joseph Lange, 1789. In the Internationale Stiftung Mozarteum, Salzburg, Austria.

Early life and works. Mozart was born in Salzburg, Austria, on January 27, 1756. His parents were Leopold Mozart, composer and vice Kapellmeister to the Archbishop of Salzburg, and his wife, Anna Maria, *née* Pertl, daughter of an official from St. Gilgen. Of their seven children, only two survived: a daughter, Maria Anna (known as Nannerl), born on July 30, 1751, and Wolfgang, who was christened Joannes Chrysostomus Wolfgangus Theophilus (in German, Gottlieb, in Latin, Amadeus; later, Mozart himself generally signed his letters and compositions either "W.A. Mozart" or "Wolfgang Amadé Mozart"). Both children soon evinced profound musical talent and were taught the science of music by Leopold, who, apart from being a well-known violinist and composer, was the author of a celebrated theoretical treatise, *Versuch einer gründlichen Violinschule*, which was published at Augsburg the year of Wolfgang's birth and which went through numerous editions in various languages until long after its author's death. One of the best, and certainly one of the most authentic, descriptions of Wolfgang's childhood occurs in a letter from Leopold to Wolfgang of February 16, 1778.

> As a child and a boy you were serious rather than childish and when you sat at the clavier or were otherwise intent on music, no one dared to have the slightest jest with you. Why, even your expression was so solemn that, observing the early efflorescence of your talent and your ever grave and thoughtful little face, many discerning people of different countries sadly doubted whether your life would be a long one.

At the age of five, Wolfgang was beginning to compose minuets and other pieces—a sufficient number of them have been preserved to show us his immediate grasp of musical forms—and he soon became proficient both on the harpsichord and on the violin. By the end of the 1770s he was gradually to abandon any public performances on the violin and concentrate on the pianoforte, becoming one of its foremost virtuosos.

Leopold considered that his children's talents might be better displayed and put to more profitable use than in provincial Salzburg, and he therefore began a series of journeys throughout Europe in which Nannerl and Wolfgang played separately and together.

The early tours. The first tours, made in 1762, may be summarized as follows: Munich in January and February (for the Elector); Vienna from September 18, 1762 (where Wolfgang had an unprecedented success at the imperial court); Pressburg; Vienna; Salzburg, where they returned on January 5, 1763.

The first grand European tour lasted from June 9, 1763, to November 30, 1766, and included the principal towns of southern Germany, the Rhineland, Brussels, and Paris (for the first winter, 1763–64, where Wolfgang published his first compositions, four violin sonatas, K. 6–9 in Köchel's catalog of 626 items), followed by a year and a half in London. There, Johann Christian Bach, youngest son of Johann Sebastian, became a friend of the family, and in London Mozart wrote his first symphonies (K. 16, 19) under the influence of J.C. Bach and his colleague Karl Friedrich Abel; the J.C. Bach influence was a vital one, lasting for many years. The Mozarts spent the winter of 1765–66 in Holland and then returned to Austria via Brussels, Paris, Geneva, Berne, and Munich.

First published works

The family left Salzburg for a second trip to Vienna on September 11, 1767, and returned on January 5, 1769. In Vienna, Wolfgang composed his first German operetta, *Bastien und Bastienne*, K. 50, and his first Italian opera, *La finta semplice*, K. 51, on a libretto by Marco Coltellini, who also provided books for Christoph Willibald von Gluck and Franz Joseph Haydn. Although the Italian opera was ordered by the Emperor, intrigues prevented its being produced; this is the beginning of a sorry tale of such resistance, not only to Mozart but also to Haydn, whose opera *La vera constanza* (composed 1776, produced 1779), commissioned by the court opera, was withdrawn by the composer in the face of strong opposition from the Italian party, led (more or less openly) by the composer Antonio Salieri. For the consecration of the Waisenhäus (Orphanage) Church on December 7, 1768, Wolfgang composed a new mass (recently identified as K. 139, in C minor) and other works, which he conducted before the Emperor and the court. Upon his return to Salzburg, the benevolent Archbishop Sigismund von Schrattenbach, always a friend and patron of the Mozart family, had the rejected *La finta semplice* performed in the archiepiscopal palace and made Wolfgang his *Konzertmeister* (without salary, since Wolfgang was hardly ever in Salzburg).

The Italian tours. The first Italian tour, which lasted from December 13, 1769, to March 28, 1771, included Rovereto, Verona, Milan, Parma, Bologna, Florence, Rome, and Naples. On their return, Leopold and Wolfgang spent three months in Bologna, where Wolfgang studied counterpoint with Padre Martini, and more than an equal period at Milan, where he executed a commission for a new opera, *Mitridate, rè di Ponto*, K. 87, which was first produced at the Teatro Reggio Ducal on December 26, 1770, with a large orchestra (14 first and 14 second violins; in all about 60 players) and repeated 20 times with enormous success. In March 1771 they were at Padua, where Wolfgang was asked to write a new oratorio, *La Betulia liberata*, K. 118, "which he can do at his leisure."

On the second Italian journey, which lasted from August 13 to December 15, 1771, Wolfgang went to Milan to compose and produce a dramatic serenata, *Ascanio in Alba*, K. 111, commissioned by the empress Maria Theresa for the marriage of her son, Archduke Ferdinand, to Princess Maria Beatrice d'Este of Modena. He composed the whole score in four weeks, and it was performed with great success on October 17, 1771, to the extent that Leopold had to write that "Wolfgang's serenata has killed Hasse's opera," which had been performed the day before —and that despite the colossal reputation of *il sassone* ("The Saxon"), as Johann Adolf Hasse was called in Italy.

On his third Italian journey, from October 24, 1772, to March 13, 1773, Mozart returned to Milan to execute the new commission for the Teatro Reggio Ducal, *Lucio Silla*, K. 135, an opera seria, first performed on December 26, 1772. Two weeks later Leopold could write, "Thank God, the opera is an extraordinary success, and every day the theatre is surprisingly full"; the opera ran for about 20 performances. *Lucio Silla* is a significant milestone in Mozart's stylistic development; it is full of felicitous details and the orchestration is particularly full and rich. Meanwhile, Archbishop Schrattenbach had died, to be succeeded by Hieronymus, Count Colloredo, bishop of Gurk, with whom the Mozarts never had the same friendly relations that they had enjoyed with his predecessor. For the new archbishop's installation on April 29, 1772, Mozart composed the festival opera *Il sogno di Scipione*, K. 126. While at Milan, he wrote the famous motet *Exsultate, jubilate*, K. 165, for the celebrated castrato Rauzzini, one of the singers in *Lucio Silla*.

Vienna, Salzburg, and Munich. The Mozarts visited Vienna again from July 14 to September 26, 1773. Father and son hoped to secure an appointment for the latter at the imperial court—to no avail. But in Vienna, Mozart came under the profound influence of Haydn's music, whose style—in common with that of many Austrian composers of the early 1770s (*e.g.*, Florian Leopold Gassmann, Carlos Ordoñez, J.B. Vanhal)—had undergone a radical change. From lighthearted rococo music, the new Haydn style now swerved abruptly to the *Sturm und Drang* ("storm and stress"), the title of a literary movement in Germany, derived from a characteristic play of that title by a German playwright, Friedrich Maximilian von Klinger. The Austrian musical "revolution" preceded that in German literature by some years, and the *Sturm und Drang* style began with Haydn as early as *c.* 1767–68.

Early quartets and symphonies

Mozart composed six string quartets (K. 168–173) under the shadow of Haydn's Opus 20 quartets of 1772; and Mozart's stormy *Symphony in G Minor*, K. 183, is a typical and excellently composed product of the restless Viennese symphonic style of this period—even the use of four, rather than two, horns is characteristic (see Vanhal's *Sinfonia in G Minor* and Haydn's *Symphony No. 39 in G Minor*, for two obvious precursors in the field). For the rest of 1773 and almost all of 1774, the family remained at Salzburg, Wolfgang diligently composing. Perhaps his best known compositions of this interlude are the *Bassoon Concerto in B Flat Major*, K. 191, and four symphonies (K. 199–202), of which the A major, K. 201, is the most popular.

Leopold and Wolfgang went to Munich from December 6, 1774, to March 8, 1775, where Wolfgang carried out a commission for an opera buffa, *La finta giardiniera*, K. 196. The day after its performance in January 1775, at the Residenz-Theater, Wolfgang writes: "Thank God! My opera was performed yesterday, the 13th, for the first time, and was such a success that it is impossible for me to describe the applause . . . the whole theatre was . . . packed." If Mozart hoped to enter the Elector's service, nothing came of the plan, and he returned to Salzburg, where he remained for the rest of 1775, the whole of 1776, and three-quarters of 1777. A very large quantity of music was composed, including the opera *Il rè pastore*, K. 208, an attractive and sophisticated piece on a rather over-used libretto by Pietro Metastasio; several masses, in which Wolfgang attempted to create a popular, "folklike" mass—of these the brilliant *Mass in C Major* (*Credo Mass*), K. 257, is particularly successful; the five famous violin concerti (K. 207, 211, 216, 218, 219); various serenades and divertimenti, foremost among them the enchanting *Serenata notturna*, K. 239, for strings and kettledrums, and the grand and lengthy *Serenade in D Major* (*Haffner Serenade*), K. 250, out of which

Mozart later created a symphony (adding kettledrums and making some other alterations), which has, curiously, escaped attention and has not even a Köchel number. Mozart also wrote several works for the pianoforte, an instrument that was gradually assuming great importance in his artistic world (six sonatas for Baron Dürnitz, K. 279–284; the *Triple Concerto*, K. 242; two concerti, K. 238, 246; etc.). Mozart's relations with the archbishop Colloredo became increasingly strained, and sometime in August 1777 (the document is undated) the composer applied for discharge from his duties. On August 28 the Archbishop dictated his reply, that "father and son have permission to seek their fortune elsewhere, according to the Gospel"; however, the final break between Mozart and the Archbishop did not occur until 1781.

Paris, Salzburg, and Munich. In September 1777 Mozart and his mother left Leopold behind and started on a long journey through Germany to Paris, where Wolfgang hoped to find some permanent appointment. They went to Munich, then to Mannheim, where Mozart fell in love with Aloysia, second daughter of the prompter and copyist Fridolin Weber. Aloysia had an exceptionally well trained coloratura soprano voice, and Mozart entertained the idea of going with her to Italy, but his father sternly forbade it. In Paris Mozart did not really gain any foothold, and on July 3, 1778, his mother died. He slowly returned home, arriving at Salzburg in the middle of January 1779. When on his return journey he stayed with the Webers, who had meanwhile moved to Munich, Aloysia scarcely seemed to recognize him. ("Today," writes Mozart on December 29, 1778, "I can only weep . . .").

Works of early maturity

Of the various compositions written on this trip, the best known are the six violin sonatas (K. 301–306), to which should be added a seventh (K. 296), some piano sonatas (including the famous A minor, K. 310), the music to *Les Petits riens* (a ballet by Jean-Georges Noverre, written in Paris), and three symphonic works for Joseph Legros of the Concert Spirituel, of which only one—the *Symphony No. 31 in D Major* (*Paris Symphony*), K. 297—has survived in its authentic and original state. Meanwhile, various court musicians had died at Salzburg, and Mozart applied in January 1779 for the position of court organist, formerly held by Anton Cajetan Adlgasser. His request was granted. The whole of 1779 and most of 1780 were spent in Salzburg, where Mozart's music enters its first period of consistent greatness. This new maturity, with dark-hued undertones that were to assume an ever-increasing importance in his style, is found in everything Mozart composed—the series of church music (particularly the two great C major masses, the *Coronation Mass*, K. 317, and the solemn and grandiose *Missa solemnis* in C major, K. 337); the dramatic and extremely modern music to *Thamos, König in Ägypten*, K. 345, which brought him into contact with Emanuel Schikaneder, whose touring company (the Böhm-Schikaneder Troupe) was then visiting Salzburg; two symphonies, of which the *Symphony No. 34 in C Major*, K. 338, is outstanding among Austrian symphonies at that time; the celebrated *Sinfonia concertante in E Flat Major for Violin, Viola and Orchestra*, K. 364; and his greatest and most profound orchestra serenade, the *Serenade in D Major* (*Post Horn Serenade*), K. 320, which Mozart later shortened and adapted into a symphony like that fashioned from the *Haffner Serenade*.

While in Salzburg Mozart, through friends at Munich, received a commission to compose a new opera seria, *Idomeneo*, K. 366 (and the ballet music K. 367). He went to Munich early in November 1780, and on January 29, 1781, the new opera was most enthusiastically received; the Archbishop being in Vienna at that time, Leopold and Nannerl came to Munich to witness Wolfgang's new triumph. For *Idomeneo* was the first stage work that revealed Mozart at the summit of his powers, and, although it is cast in the antiquated form of an opera seria, the music is so profound, so brilliantly composed, and so astonishingly orchestrated, that it retains its dramatic impact, despite the stereotyped libretto by the Salzburg court chaplain Abbate Varesco. Of other compositions written in Munich, the *Kyrie in D Minor*, K. 341, and the exquisite *Serenade in B Flat Major*, K. 361, for 13 wind instruments are outstanding—the latter showing an entirely new and original treatment of the wind band as a whole and the clarinet family (including basset horn) in particular. Mozart always preserved a special affection and aptitude for the clarinet, whose beauty had been scarcely realized by his precursors (Haydn, for example, had hardly used it since a few wind-band works of *c.* 1760).

Early in March 1781 the Archbishop summoned Mozart to Vienna, where he arrived on March 16. Mozart enjoyed the patronage of many members of the Viennese aristocracy, including Countess Thun and Count Cobenzl, and the Archbishop enjoyed the reflected glory of his young composer; but Colloredo did not allow him to play in houses other than his own and forced him to eat with the servants. The already strained relations between the two soon came to a head, and in a shameful scene the Prince-Archbishop of Salzburg addressed Mozart in the language of the street (using the third person singular reserved for low-grade servants), and Mozart resigned. Shortly afterward, not having received his official dismissal, Mozart brought it in person, only to be subjected to more street language from the Archbishop's high steward, Count Karl Arco, who earned for himself a dubious immortality by actually kicking Mozart out "on his behind" (Mozart's own words).

Later life and works. Mozart was now entirely on his own, the first composer after George Frideric Handel who risked an existence without some official patronage. After years of waiting, the emperor Joseph II finally engaged him on December 7, 1787, as chamber composer at 800 gulden annually (Gluck, his predecessor, had received 2,000 gulden). At the beginning of 1781, however, Mozart's prospects—despite Leopold's dismayed reactions from Salzburg—seemed favourable. Apart from his success at various concerts, at which the Emperor also applauded, Mozart soon received a commission to write a German opera for the National Singspiel, founded by the Emperor in 1778. This work, *Die Entführung aus dem Serail* (*The Abduction from the Seraglio*), on a libretto by Gottlieb Stephanie, the younger, after Christoph Friedrich Bretzner, was produced with great success on July 16, 1782, though a strong cabal had already aligned itself against Mozart. Meanwhile, he had moved in with the Webers, who had come to Vienna from Munich, and he fell in love with the third daughter, Constanze. Despite Leopold's strenuous protests, Mozart married Constanze at St. Stephen's Cathedral on August 4, 1782. There has been a great deal of criticism about Constanze—that she was fickle, a bad manager of finances, and so on—but they were very fond of each other, and Mozart wrote her affectionate letters all his life. The considered opinion of the great 19th-century Austrian scholar C.F. Pohl was that "she was a good and loving wife, accommodated herself in everything to her husband's disposition, and restrained him from many heedless actions."

Marriage to Constanze

Mozart soon came to hold his own subscription concerts, either at the Burgtheater or the Mehlgrube, which consisted of a full orchestra, with one or more vocal soloists, and Mozart himself playing his own concerti for piano and improvising on that instrument; his improvisations were much admired. It was for these concerts that Mozart wrote most of his great piano concerti, from K. 413 to K. 595. Mozart was not only a great pianist but was profoundly interested in the mechanical aspects and construction of the piano, to the development and perfection of which he contributed a great deal. Some of his improvisations may, perhaps, be gathered from such work as the *Fantasy in C Minor*, K. 475. Mozart had a pedal constructed for his piano, which he used when improvising and possibly also in realizing the basso continuo parts of his concerti.

Despite an intense activity as a pianist, Mozart's finances were never very secure. He perhaps reached the apex of his worldly gains shortly before he composed *Figaro*, and was living in comfortable quarters at the Domgasse behind St. Stephen's. Gradually, from 1785 to 1791, his

financial situation became more and more catastrophic, and he was forced to borrow ever-increasing sums from his friends, and particularly his Masonic brothers—Mozart was an ardent Freemason and a member of the Lodge "Zur gekrönten Hoffnung." It was from his fellow Mason, the banker Michael Puchberg, that Mozart borrowed most freely. The ever-present threat of these debts hung over Mozart's existence until his death.

Wolfgang and Constanze visited Leopold and Nannerl in Salzburg in August, September, and October of 1783; the visit was not a success, and Constanze was not much liked by the Salzburg Mozarts. Mozart performed the "Kyrie" and "Gloria" of his great (unfinished) *Mass in C Minor*, K. 427, in St Peter's in August 1783; although a torso, the mass is a noble work, showing Mozart's renewed study of Bach and Handel at the Sunday concerts of Baron Gottfried van Swieten, director of the National Library in Vienna, who was later to be closely connected with Haydn and to become a patron of the young Beethoven.

The great symphonies

Mozart had little time in the last ten years of his life to compose symphonies, but those he did manage to write are all masterpieces: the *Haffner*, K. 385, reduced from another serenade for that Salzburg family; the *Linz*, K. 425, composed on the way back from Salzburg to Vienna in October and November 1783; the *Prague*, K. 504, written for the Bohemian capital; and the last three (E flat major, G minor, and *Jupiter* in C major of 1788, K. 543, 550, 551). The last four, in particular, carry the art of the 18th-century symphony far beyond anything hitherto achieved except in a few of Haydn's works.

Leopold returned the visit to his son and daughter-in-law, from February 11 to April 25, 1785, and was witness to his son's material and artistic successes. Mozart was in the process of completing the six string quartets dedicated to Haydn (K. 387, 421, 428, 458, 464, 465), and when the last three were played to Haydn in Mozart's flat, Haydn said to Leopold: "Before God and as an honest man I tell you that your son is the greatest composer known to me either in person or by name." The string quartets also show Mozart to have mastered the form in a way far superior to anyone except Haydn; the ensuing works, particularly K. 499 in D major, but even the more superficial "Prussian" quartets for Berlin, show his complete grasp of this central form of chamber music. His quartets, indeed, are perhaps only surpassed in quality by the string quintets (of which two, C major and G minor, K. 515 and 516, are the most popular, though a lesser known one in D major, K. 593, is equally fine).

Late operatic works

The great operas that were composed after *Die Entführung* in these last ten years are as follows: *Le nozze di Figaro* (*The Marriage of Figaro*), K. 492, the first of three masterpieces written on librettos by Lorenzo da Ponte, first performed with enormous success on May 1, 1786, at the Burgtheater in Vienna and later repeated, with even more approbation, at Prague; *Don Giovanni*, K. 527, again on a libretto by da Ponte, first played at the National Theatre, Prague, on October 29, 1787, with sensational success (but when repeated at Vienna the next year, it was a failure although a few—among them Haydn—violently defended it); *Così fan tutte*, K. 588, the last da Ponte opera, produced at the Vienna Burgtheater on January 26, 1790, was not entirely successful, partly due to the fact that the emperor Joseph II died on February 20, throwing Vienna into some confusion; but *Così* was perhaps too richly scored, too cynical, too erotic, and too overpoweringly intense for the easygoing Viennese, who were amused by *Figaro* but less enchanted by its political undertones; *La clemenza di Tito*, K. 621, an opera seria on a libretto by Metastasio, was commissioned by the Estates of Bohemia for the coronation of the new emperor Leopold II at Prague in 1791; it was given there on September 6, but was badly sabotaged by the court in general and the Empress in particular, who referred to it as a *porcheria tedesca* ("German muck"). *Die Zauberflöte* (*The Magic Flute;* libretto by Emanuel Schikaneder), K. 620, was written for the little Theater auf der Wieden and made Schikaneder wealthy and famous. The first performance took place on September 30, 1791, and, while the initial reception was rather cool, audiences soon took to its fairy-tale "machine comedy" world, with its strong Masonic elements, the whole made immortal by Mozart's fantastic music. (Beethoven was to admire it particularly because, he said, in it Mozart wrote in every kind of form; it is certainly true that in *Die Zauberflöte* we find everything from north German *Choral-Vorspiel* to fugue, and from coloratura aria to *Volkslied*.)

In another attempt to save his failing finances, Mozart undertook an extensive concert tour, leaving Vienna on April 8, 1789, with his pupil and noble patron, Prince Karl Lichnowsky, who was later to be a firm supporter of Beethoven. Mozart went to Dresden, Leipzig (where he studied J.S. Bach's manuscripts), Berlin, and Prague, returning to Vienna on June 4, 1789; the financial results of the tour were negligible, as were those from his last concert tour to Frankfurt am Main, where the emperor Leopold II was crowned on October 9, 1790. His financial position was now catastrophic, for he was deeply in debt.

In the summer of 1791 a stranger commissioned the *Requiem Mass*, K. 626, from Mozart under rather mysterious circumstances; in fact the man behind it was Count Franz von Walsegg, an amateur musician who ordered works from professional composers and performed them under his own name. Mozart was not able to complete the *Requiem*, but from oral instructions and sketches (some have come to light as late as 1960), his pupil Franz Xavier Süssmayr was able to finish the work and present it to Walsegg.

Mozart's death

Mozart became seriously ill in the late autumn of 1791, and his rapid decline and death soon led people to whisper that he had been poisoned. But in the mid-20th century the medical research of Carl Bär showed that Mozart's heart had been strained by his youthful attacks of rheumatic fever and that his final attack of that same fever in December 1791, plus excessive bloodletting, contributed to the failure of his heart. He died in Vienna on December 5, 1791, and the next day he was buried, unattended by anyone except the gravedigger, at St. Mark's cemetery. Constanze was left, brokenhearted and in a state of nervous collapse, with huge debts. She later married the Danish diplomat Georg Nicolaus von Nissen and died in Salzburg in 1842.

Assessment. Because most of Mozart's major works were not printed until after his death—and some not until the middle and end of the 19th century—Mozart did not create a school. Although his operas were widely circulated all over Germany by 1795, it was many years before his work *in toto* was known to the average European musician; London in 1795, for instance, knew hardly anything of Mozart's music. During the Romantic age Mozart became the object of a veneration such as has hardly ever been accorded to any other musician except—later—Bach and Beethoven; and even today the sheer beauty, perfection, and profundity of his music continue to astonish and delight us. If Mozart wrote with staggering ability in every single form—including even dance music—perhaps his greatest single achievement is in the characterization of his operatic figures. They are not only subtle and very human, they are also capable of changing as the course of the drama unfolds. After Mozart perhaps only Giuseppe Verdi ever succeeded in creating such vital operatic personalities. Altogether it is possible that in Mozart the music of Western civilization reached an apex of perfection to which future ages will look back, just as, for centuries, men regarded with nostalgia the products of ancient Greece at the summit of its achievements.

MAJOR WORKS

The Köchel catalog forms the basic list of the works of Mozart. The compositions of Mozart are almost always identified by the letter K. (or, in German, KV, for *Köchelverzeichnis*, "catalog-register") followed by an Arabic numeral, which indicates the chronological order in which the work was composed.

Ludwig Ritter von Köchel is best remembered for the monumental *Chronologisch-thematisches Verzeichnis*, a thematic catalog that lists in chronological order of composition all the works of Mozart. Mozart did not always date

his compositions; as a result, there was a great deal of confusion as to the order and period of his works. It was to the task of bringing order out of chaos that Köchel set himself. Köchel had, however, a base upon which to build. Mozart himself had compiled a list of his works from February 1784. This list, plus an imperfect catalog by Aloys Fuchs (1837), and a publication based on Mozart's autograph scores by Johann Anton André (1828) were available to Köchel. Köchel classified the hundreds of unnumbered Mozart compositions into 23 categories and, on the basis of stylistic development and Mozart's musical handwriting, assigned a date of composition to each work. Each composition was given a single number, whether it was a single minuet for piano (K. 1, composed in 1762), an entire opera (K. 492, *The Marriage of Figaro*, 1786), or a work of several sections, such as K. 626, the *Requiem Mass* (1791—the final entry in the catalog). Köchel also included as appendices lists of works lost, existing as fragments, or of doubtful authenticity.

The Köchel catalog was published by Breitkopf and Härtel in 1862 and appeared in six editions. The third and definitive revision of the catalog is Alfred Einstein's (1937); he assigned new numbers of more accurate chronology. This revision, in turn, was supplemented by its author, and in 1947 these supplements appeared as an appendix to the 1937 revision.

Theatre music

OPERAS: 16 operas, including *Idomeneo, rè di Creta*, K. 366, first performed 1781; *Die Entführung aus dem Serail*, K. 384, 1782; *Le nozze di Figaro*, K. 492, 1786; *Don Giovanni*, K. 527, 1787; *Così fan tutte*, K. 588, 1790; *Die Zauberflöte*, K. 620, 1791; *La Clemenza di Tito*, K. 621, 1791.

OTHER THEATRE WORKS: Music for three plays; one Latin comedy (intermezzo); two serenatas; one ballet.

Church music

MASSES: *Requiem Mass* in D minor, K. 626, completed 1791 by Süssmayr; eight masses, including K. 317 in C major (*Coronation*), 1779; ten *Missae Breves*.

OTHER CHURCH WORKS: Four litanies; seven offertories; two vespers; two antiphons; three *Regina coeli* settings; two German motets; two Latin motets, K. 165 (*Exsultate jubilate*), 1773, and K. 618 (*Ave, verum corpus*), 1791; psalms and kyries; Passion cantata; oratorio, K. 118 (*La Betulia liberata*), 1771.

Secular vocal music

57 solo arias with orchestra; 9 vocal trios and 5 duets with instrumental accompaniment; 36 German songs for solo voice and piano; 35 unaccompanied canons and one sacred madrigal.

Instrumental music

SYMPHONIES: 41 symphonies, including K. 297 in D major (*Paris*), 1778; K. 385 in D major (*Haffner*), 1782; K. 425 in C major (*Linz*), 1783; K. 504 in D (*Prague*), 1786; K. 551 in C major (*Jupiter*), 1788; fragments of 7 other symphonies and 9 *sinfonie* related to other works.

SINFONIE CONCERTANTI: K. 364 in E flat major (for violin, viola, and orchestra), 1779; K. App. 9 (297b) in E flat major (for oboe, clarinet, horn, and bassoon), 1778.

CONCERTI: (PIANO): 21 concerti for piano and orchestra, including K. 537 in D major (*Coronation*), 1788; arrangements, separate movements, and cadenzas; one concerto for three pianos; one for two pianos. (VIOLIN): five concerti for violin and orchestra, all 1775; K. 190 (*Concertone* for two violins), 1773; other movements for violin and orchestra. (OTHER INSTRUMENTS): one concerto for bassoon, K. 191, 1774; two for flute, 1778; four for horn, 1782–86; one for clarinet, K. 622, 1791.

OTHER INSTRUMENTAL WORKS: 23 divertimenti; 13 serenades, including K. 250 in D major (*Haffner*), 1776; K 375 in E flat major (for two oboes, two clarinets, two basset horns, four horns, two bassoons, and double bass or double bassoon), 1781; and K. 525 in G major (*Eine kleine Nachtmusik*), 1787; one notturno and 2 cassations; marches and dances. (FOR PIANO): 20 sonatas; 16 sets of variations; 14 minuets; *Forty-three Pieces;* 6 fantasies, 2 with fugues; 2 fugues; 3 rondos; a number of other separate movements; 2 sonatas and one fugue for two pianos. (FOR STRINGS): 6 quintets, including K. 515 in C major and K. 516 in G minor, both 1787; 25 quartets, 6 dedicated to Haydn (including K. 458 in B flat, *The Hunt*), 1784, and 3 dedicated to the King of Prussia, 1789–90; 2 string duets and 3 trios. (FOR STRINGS WITH ACCOMPANIMENT): 35 sonatas for violin and piano; 2 piano quartets; 8 piano trios, including K. 498 in E flat major (for clarinet, viola, and piano), 1786; 2 sets of variations for violin and piano. (FOR OTHER INSTRUMENTS): 3 flute quartets; one oboe quartet; one clarinet quintet in A major, K. 581, 1789; 2 other quintets; 5 divertimenti for two clarinets and bassoon; 12 duets for wind instruments; other works for wind; 3 pieces for mechanical organ and 2 for glass harmonica and wind instruments.

BIBLIOGRAPHY. The Mozart literature is so vast that a mere listing of the titles would require several hundred pages. The following, therefore, is a rigorous selection of what might be called the basic Mozart literature. The most complete Mozart bibliography in recent years will be found in the Mozart article contained in *Die Musik in Geschichte und Gegenwart*, vol. 9, col. 812–839 (1961). FRANK X. NIEMTSCHEK, *Leben des K.K. Kapellmeisters Wolfgang Gottlieb Mozart* (1798; Eng. trans., *The Life of Mozart*, 1956), is the first book-length biography using authentic documents and containing information given to the author by Mozart's widow, Constanze. It is not scientific and is fragmentary but contains much invaluable material. G.N. VON NISSEN, *Biographie W.A. Mozarts* (1828), a large-scale biography written by Constanze Mozart's second husband, is essential to all Mozart scholars. O. JAHN, *W.A. Mozart*, 4 vol. (1856–59; Eng. trans., *Life of Mozart*, 3 vol., 1960), is the first scholarly attempt at a full-scale Mozart biography; it is in many respects superseded but contains important material. G. NOTTEBOHM, *Mozartiana* (1880), contains much material then new and reproduces a number of documents of which the original sources have since disappeared. H. ABERT, *W.A. Mozart* (1923; new ed. rev. by Abert's daughter, A.A. ABERT, 2 vol., 1956), is the great standard work of the 20th century that no Mozart lover or scholar can be without; apart from dealing with Mozart's music brilliantly, Abert also provides the first serious examination of the Italian operas by Mozart's precursors and contemporaries. A. EINSTEIN, *Mozart* (1945; Eng. trans., 2nd ed., 1956), is the sophisticated and intelligent result of many years' research for the 3rd edition of the Köchel catalog. R.M. HAAS, *Wolfgang Amadeus Mozart*, 2nd ed. (1950), is a brilliant study of particular perception concerning the music itself. The *Mozart-Jahrbuch* (1950–) is the yearly journal of Mozart studies in which the world's leading Mozart scholars offer their new discoveries. *Acta Mozartiana* (1954–) is a smaller publication but contains valuable material. O.E. DEUTSCH, *Mozart: Die Dokumente seines Lebens* (1961; Eng. trans., *Mozart: A Documented Biography*, 2nd ed., 1966), contains all the known contemporary documents about Mozart and is essential for any serious study of the composer. The same author's *Mozart und seine Welt in zeitgenössischen Bildern* (1961) is the finest iconographical study of Mozart and the world in which he lived. H.C. ROBBINS LANDON and D. MITCHELL (eds.), *The Mozart Companion*, 2nd ed. (1965), is a collection of essays on Mozart's music by a group of specialists, C. BAR, *Mozart—Krankheit, Tod, Bergräbnis* (1966), is a doctor's serious and penetrating analysis of Mozart's death, in which the theory that he was poisoned is disproved.

(H.C.R.L.)

Muʿāwiyah I

Muʿāwiyah ibn Abī Sufyān, a leader of early Islām, founded the Umayyad dynasty, which ruled the empire of the Caliphate from AD 661 to 750; he stands out as one of the few caliphs who is depicted both in Muslim historiography and in modern scholarship as a decisive force in Islāmic history. Undoubtedly one reason for the prominence assigned to him is that he was a controversial figure. Pious scholars of the dominant Sunnī sect of Islām together with writers of the minority, dissenting Shīʿah, have always heaped opprobrium on Muʿāwiyah: the Sunnīs because of his deviations from the pattern of leadership set by the Prophet Muḥammad and the "rightly guided" caliphs; the Shīʿah because he had usurped the caliphate from ʿAlī ibn Abī Ṭālib. Although Muʿāwiyah has been and still is condemned for his sins from these two quarters, he has also been the subject of lavish praise in Arabic literature as the ideal ruler. In other words, unlike most of the other caliphs, Muʿāwiyah looms large in Islāmic history because he has consistently aroused partisanship at different extremes. But beneath the biassed portraits given in traditional Muslim historiography, there is a person whose actual accomplishments were of great magnitude quite apart from partisan value judgments and interpretations. These accomplishments lay primarily in political and military administration, through which Muʿāwiyah was able to rebuild a Muslim state that had fallen into anarchy and to renew the Arab–Muslim military offensive against unbelievers.

Early years. It is ironic that a man who was to become political–religious head of Islām was born (*c.* 602) into a clan (ʿAbd Shams) that rejected Muḥammad, the Prophet, in his home city, Mecca, and continued to oppose him on the battlefield after he had emigrated to Medina. Muʿāwiyah did not become a Muslim until Muḥammad had conquered Mecca and had reconciled his former enemies by gifts. Possibly as a part of Muḥammad's policy of conciliation, Muʿāwiyah was made a scribe in his service. But Muʿāwiyah's contributions to Islāmic history are wholly associated with his career in Syria, which began shortly after the death of the Prophet, when he, along with his brother Yazīd, served in the tribal armies sent from Arabia against the Byzantine forces in Syria. Upon the death of Yazīd in 640, Muʿāwiyah was appointed governor of Damascus by the caliph ʿUmar and gradually gained mastery over other areas of Syria. By 647 Muʿāwiyah had built a Syrian tribal army strong enough to repel a Byzantine attack and in subsequent years to take the offensive against the Byzantines that resulted in the capture of Cyprus (649) and Rhodes (654) and a devastating defeat of the Byzantine navy off the coast of Lycia in Anatolia (655). At the same time, Muʿāwiyah periodically dispatched land expeditions into Anatolia. All these campaigns, however, came to a halt with the accession of ʿAlī to the caliphate, when a new and decisive phase of Muʿāwiyah's career began.

As kinsman of the slain caliph ʿUthmān, Muʿāwiyah bore the duty of revenge. Because ʿAlī neglected to apprehend and punish the murderers, Muʿāwiyah regarded him as an accomplice to the murder and refused to acknowledge his caliphate. Thereupon ʿAlī marched to the Euphrates border of Syria and engaged Muʿāwiyah's troops at the famous battle of Ṣiffīn (657). Muʿāwiyah's guile turned near defeat into a truce. Resorting to a trick that played upon the religious sensibilities of ʿAlī's forces, he persuaded the enemy to enter into negotiations that ultimately cast doubt on the legitimacy of ʿAlī's caliphate and alienated a sizable number of his supporters. When these former supporters—the Khārijites—rose in rebellion against ʿAlī, Muʿāwiyah took advantage of ʿAlī's difficulties in Iraq to send a force to seize control of Egypt. Thus, when ʿAlī was assassinated in 661, Muʿāwiyah held both Syria and Egypt and, as commander of the largest force in the Muslim Empire, had the strongest claim to the caliphate. ʿAlī's son Ḥasan was persuaded to remove himself from public life in exchange for a subsidy, which Muʿāwiyah provided.

The battle of Ṣiffīn

Caliphate (661–680). During his twenty-year governorship of Syria and during the war against ʿAlī, Muʿāwiyah had succeeded in recruiting and training a large Arab tribal army, which was remarkably loyal to him. It was therefore natural that he should base his caliphate in Syria, with Damascus as the new capital of Islām. But if Muʿāwiyah's chief support came from the tribes of Syria, the tribes of other areas posed the chief threat to his reign. It is not surprising then that early Umayyad government followed certain tribal principles as a means of retaining and winning the loyalty of the Arabs. The clearest examples of such a policy are provided by Muʿāwiyah's adoption of two tribal institutions: the council of notables—the *shūrā*—convoked by the caliph for consultation and the delegations—the *wufūd*—sent by tribes to keep the caliph informed of their interest. Within this context, Muʿāwiyah ruled as a traditional Arab chieftain. Although he may not have consciously encouraged renewed warfare against non-Muslim territory as a means of directing Bedouin aggressive tendencies into channels that would aggrandize Islām and stabilize his own power, there is no doubt that warfare served these purposes during his reign; and in this respect it is significant that Muʿāwiyah used the Syrian army only for domestic defense and for campaigns against the Byzantines, who threatened the borders of Syria. During the civil war, Muʿāwiyah had purchased a truce with the Byzantines in order to free his army for the struggle against ʿAlī. Soon after his accession to the caliphate, however, he curtailed the payment of tribute and sent expeditions against the Byzantines on an almost yearly basis. These campaigns served both to fulfill Muʿāwiyah's obligation to conduct holy war (*jihād*) against unbelievers and to keep his Syrian troops in fighting trim. Otherwise, the war against Byzantium was inconclusive. Even though two expeditions reached the vicinity of Constantinople, the Arabs never succeeded in permanently occupying territory in Asia Minor beyond the Taurus Mountains. Troops stationed in other parts of Muʿāwiyah's empire were sent on campaigns into remote areas. In North Africa, raids were conducted as far west as Tlemcen in present-day Algeria. More permanent, however, was the conquest of Tripolitana and Ifrīqīyah, which was consolidated by the foundation in 670 of the garrison city of Qairawan, soon to become the base for further expansion later in the Umayyad period. At the same time, a vigorous campaign was being conducted in the east by which Muslim borders were extended to the Oxus River, and Khorāsān was established as an Umayyad province.

Administrative developments

It had become apparent during the reigns of the first caliphs that tribal tradition and the practice of Muḥammad in Medina were inadequate resources for administering a vast empire. To solve this problem, Muʿāwiyah resorted to a solution that lay at hand in Syria—that is, the imitation of administrative procedures that had evolved during centuries of Roman and Byzantine rule. Although the process by which the borrowing took place is not clear, it is clear that Muʿāwiyah initiated certain practices that were apparently inspired by the previous tradition. Basically, he aimed at increased organization and centralization of the caliphal government in order to exert control over steadily expanding territories. This he achieved by the establishment of bureaus—*dīwāns*—in Damascus to conduct the affairs of government efficiently. Early Arabic sources credit two *dīwāns* in particular to Muʿāwiyah: the *dīwān al-khatam*, or chancellery, and the *barīd*, or postal service, both of which were obviously intended to improve communications within the empire. Prominent positions within the nascent bureaucracy were held by Christians, some of whom belonged to families that had served in Byzantine governments. The employment of Christians was a part of a broader policy of religious tolerance, necessitated by the presence of large Christian populations in the conquered provinces, especially in Syria itself.

Such administrative innovations coupled with the observance of tribal traditions caused historians of a later period to deny Muʿāwiyah the religious title of caliph and to characterize him as a king (*malik*) instead. As a symbol of the increasingly secular nature of the caliphate, derived in part from a non-Islāmic tradition, the title is apt for Muʿāwiyah and for most of the Umayyads. It is particularly appropriate for the most startling of all of Muʿāwiyah's innovations, the one by which he secured the allegiance of the tribes for the caliphate of his son Yazīd and thereby established the practice of hereditary rule in Islām. As an alternative to the various unreliable precedents for selecting a caliph, this measure was certainly consonant with Muʿāwiyah's policy and achievement as caliph, which, in summary, consisted of invigorating the theocratic origins of Islāmic governance with borrowings from other traditions better adapted to the demands of tribesmen and the needs of an empire. Muʿāwiyah died in Damascus in 680.

BIBLIOGRAPHY. The only detailed study of Muʿāwiyah in a Western language is HENRI LAMMENS, "Études sur le règne du Calife Omaiyade Moʿāwia I," *Mélanges de la Faculté Orientale de l'Université St. Joseph de Beyrouth*, 1:3–108 (1906), and 2:1–172 (1907). This work is summarized in Lammens' article, "Muʿāwiya," in the *Encyclopaedia of Islam*, 1st ed., vol. 3 (1936).

(D.P.L.)

Muḥammad

The founder of the religion of Islām and of the Arab Empire, Muḥammad initiated religious, social, and cultural developments of monumental significance in the history of mankind. The full form of his name is Abū al-Qāsim Muḥammad ibn ʿAbd Allāh ibn ʿAbd al-Muṭṭalib ibn Hāshim.

LIFE AND DEEDS

Early life. Born in Mecca *c.* 570 after the death of his father, ʿAbd Allāh, Muḥammad was at first under the care of his paternal grandfather, ʿAbd al-Muṭṭalib. Because the climate of Mecca was considered to be unhealthful, he was given as an infant to a wet nurse from a nomadic tribe and spent some time in the desert. At six he lost his mother, Āminah of the clan of Zuhra, and at eight his grandfather. Though his grandfather had been head of the prestigious Hāshem (Hāshim) clan and was prominent in Mecca politics, he was probably not the leading man in Mecca, as some sources suggest. Muḥammad came under the care of the new head of the clan, his uncle Abū Ṭālib, and is reputed to have accompanied him on trading journeys to Syria. About 595, on such a journey, he was in charge of the merchandise of a rich woman, Khadījah of the clan of Asad, and so impressed her that she offered marriage. She is said to have been about 40, but she bore Muḥammad at least two sons, who died young, and four daughters, of whom the best known was Fāṭimah, the wife of Muḥammad's cousin ʿAlī, who is regarded as Muḥammad's divinely ordained successor by the Shīʿah branch of Islām. Until after Khadījah's death in 619, Muḥammad took no other wife. The marriage was a turning point in Muḥammad's life. By Arab custom, minors did not inherit, and therefore Muḥammad had no share in the property of his father or grandfather; but by his marriage he obtained sufficient capital to engage in mercantile activity on a scale commensurate with his abilities.

Prophetic call and early religious activity. Muḥammad appears to have been of a reflective turn of mind and is said to have adopted the habit of occasionally spending nights in a hill cave near Mecca. The poverty and misfortunes of his early life doubtless made him aware of tensions in Meccan society. Mecca, inhabited by the tribe of Quraysh (Koreish), to which the Hāshim clan belonged, was a mercantile centre formed around a sanctuary, the Kaʿbah (Kaaba), which assured the safety of those who came to buy and sell at the fairs. In the later 6th century there was extensive trade by camel caravan between Yemen and Syria (Gaza and Damascus), bringing goods from India and Ethiopia to the Mediterranean; and the great merchants of Mecca had obtained monopoly control of this trade. Mecca was thus prosperous, but most of the wealth was in a few hands. Tribal solidarity was breaking up; merchants pursued individual interests and disregarded their traditional duties to the unfortunate. About 610, as he reflected on such matters, Muḥammad had a vision of a majestic being (later identified with the angel Gabriel) and heard a voice saying to him, "You are the Messenger of God." This marked the beginning of his career as messenger (or apostle) of God (*rasūl Allāh*), or Prophet (*nabī*). From this time, at frequent intervals until his death, he received "revelations"—that is, verbal messages that he believed came directly from God. Sometimes these were kept in memory by Muḥammad and his followers, and sometimes they were written down. About 650 they were collected and written in the Qur'ān (or Koran, the sacred scriptures of Islām), in the form that has endured till today. Muslims believe the Qur'ān is written in the very words of God himself, and sound scholarship requires that Muḥammad be adjudged sincere in his view that the Qur'ān was not the product of his conscious mind.

Muḥammad's vision

Muḥammad is said to have been perturbed after the vision and first revelation but to have been reassured by his wife, Khadījah. In his later experiences of receiving messages there was normally no vision. Occasionally there were physical concomitants, such as perspiring on a cold day, and these gave rise to the suggestion, now agreed to be unwarranted, that he was an epileptic. Sometimes he heard a noise like a bell but apparently never a voice. The essence of such an experience was that he found a verbal message in his heart—that is, in his conscious mind. With the help of Khadījah's Christian cousin Waraqah, he came to interpret these messages as in general identical with those sent by God through other prophets or messengers to Jews, Christians, and others and to believe that by the first great vision and by the receipt of the messages he was commissioned to communicate them to his fellow citizens and other Arabs. The proclamation of the messages must have been accompanied by explanation and exposition in his own words.

Soon he gathered some sympathetic friends who accepted his claim to be a prophet and joined him in common worship or prayers. These culminated in an act of prostration in which they touched the ground with their foreheads in acknowledgment of God's majesty—still a cardinal act in Islāmic worship. In about 613 he began preaching publicly, and he and his followers spent their days together in the house of a young man named al-Arqam. It is probable that they sometimes worshipped together in the Kaʿbah.

Pagan religious milieu

The people of Mecca at the time nominally worshipped many gods, but few believed that man was dependent on supernatural powers. The merchants thought most things could be accomplished by wealth and by human planning. Some men regarded Allāh as a "high god" who stood above lesser deities. (Allāh, the Arabic word for God, is used by Christian Arabs as well as Muslims.) The earliest passages of the Qur'ān revealed to Muḥammad emphasize the goodness and power of God as seen in nature and in the prosperity of the Meccans and call on the latter to be grateful and to worship "the Lord of the Kaʿbah," who is thus identified with God. Gratitude is to be expressed in generosity with one's wealth and avoidance of niggardliness. As a sanction, men are warned that they will appear before God on the Last Day to be judged according to their deeds and assigned to heaven or hell.

By proclaiming this message publicly, Muḥammad gained followers—39, it is said—before he entered the house of al-Arqam. The names of 70 followers are known prior to the appearance of opposition to the new religion, and there were probably more. Most were young men under 30 when they joined Muḥammad. They included sons and brothers of the richest men in Mecca and thus were by no means plebeians, though they might be described as persons excluded from the most lucrative forms of commerce. A handful of Muḥammad's early followers are spoken of as "weak," which merely means that they were not of the tribe of Quraysh and so not effectively protected by any clan. The new religion was eventually called Islām—*i.e.*, "'submission [to God]"—and its adherents were called Muslims—*i.e.*, "those submitting [to God]"—though the Qur'ān speaks of them primarily as "the believers."

Opposition at Mecca. Although Muḥammad's preaching was basically religious, there was implicit in it a critique of the conduct and attitudes of the rich merchants of Mecca. Attempts were made to get him to soften his criticism by offering him a fuller share in trade and a marriage alliance with one of the wealthiest families, but he decisively rejected such offers. About 615 more active opposition appeared. Points in the message of the Qur'ān were questioned, such as the assertion that men would be resurrected before the Judgment. Commercial pressure was brought to bear on Muḥammad's supporters, and in some families there was mild persecution of junior members who followed him. It is sometimes suggested that the main reason for opposition was economic—namely, the merchants' fear that the new religion would destroy the recognition of the Kaʿbah as a sanctuary—but this is unlikely. Certainly attacks on idols appeared in the Qur'ān, and Islām began to be characterized by the insistence that "there is no deity but God" (Allāh), but no attack was made on the Kaʿbah, and the idols mentioned had their chief shrines elsewhere. A leader of the opposition arose in the person of Abū Jahl, a contemporary of Muḥammad, who probably felt that the latter, despite his claim to be "only a warner" (of Judgment to come), was building up for himself a position of authority that might one day make him politically supreme in Mecca, because Arabs deeply respected the kind of wisdom or knowledge that Muḥammad clearly had. In about 616 Abū Jahl organized a boycott of the clan of Hāshim by the chief

Commercial pressure, boycott, and persecution

clans of Mecca, allegedly because the clan continued to protect Muḥammad and did not curb his preaching; but, since few of the clan were Muslims, other questions may have been involved. After three years the boycott petered out, perhaps because some of the participants found they were harming their own economic interests.

Both Muḥammad's wife Khadījah and his uncle Abū Ṭālib died in about 619, and another uncle, Abū Lahab, succeeded as head of the clan of Hāshim. He was closer to the richest merchants, and at their instigation he withdrew the protection of the clan from Muḥammad. This meant that Muḥammad could easily be attacked and therefore could no longer propagate his religion in Mecca. He left for the neighbouring town of aṭ-Ṭā'if, but the inhabitants were insufficiently prepared to receive his message, and he failed to find the support he hoped for. Before returning to Mecca, he had to beg for the protection of the head of another clan; it was granted, but conditions were presumably attached. In 620 Muḥammad began negotiations with clans in Medina, leading to his emigration, or *hijrah*, there in 622.

It is difficult to assess the nature and extent of the persecution of the Muslims in Mecca. There was little physical violence, and that almost always within the family. Muḥammad suffered from minor annoyances, such as having filth deposited outside his door. The persecution is said to have led to the emigration of some of the Muslims to Ethiopia about 615, but they may have been seeking opportunities for trade or military support for Muḥammad. Some remained until 628, long after Muḥammad was established in Medina. Whether or not the persecution was unbearable, the Muslims were very bitter about it.

The emigration from Mecca to Medina. In the summer of 621, 12 men from Medina, visiting Mecca for the annual pilgrimage to the Ka'bah (then a pagan shrine), secretly professed themselves Muslims to Muḥammad and went back to make propaganda for him at Medina. At the pilgrimage in June 622 a representative party of 75 persons from Medina, including two women, not merely professed Islām but also took an oath to defend Muḥammad as they would their own kin. These are known as the two Pledges of al-'Aqaba. Muḥammad now encouraged his faithful Meccan followers to make their way to Medina in small groups, and about 70 emigrated thus. The Meccans are said to have plotted to kill Muḥammad before he could leave. With his chief lieutenant he slipped away unperceived, used unfrequented paths, and reached Medina safely on September 24, 622. This is the famous *hijrah* (Latin Hegira), which may be rendered "emigration," though the basic idea is the severing of kinship ties. It is the traditional starting point of Islāmic history. The Islāmic Era (AH or Anno Hegirae) begins on the first day of the Arabic year in which the *hijrah* took place; viz., July 16, 622, in the Western calendar.

Medina was different from Mecca. It was an oasis in which date palms flourished and cereals could be grown. Agriculture had been developed by several Jewish clans, who had settled among the original Arabs, and they still had the best lands. Later Arab immigrants belonging to the tribes of al-Aws and al-Khazraj, however, were in a stronger position. The effective units among the Arabs were eight or more clans, but nearly all of these had become involved in serious feuds. Much blood had been shed in a battle at about 618, and peace was not fully restored. In inviting Muḥammad to Medina, many of the Arabs there probably hoped that he would act as an arbiter among the opposing parties, and their contact with the Jews may have prepared them for a messianic religious leader, who would deliver them from oppression and establish a kingdom in which justice prevailed.

The Constitution of Medina

A document has been preserved known as the Constitution of Medina. In its present form it is a combination of at least two earlier documents and is probably later than 627, but its main provisions are almost certainly those originally agreed upon between Muḥammad and the Muslims of Medina. In form the document creates a confederation on traditional Arab lines among nine groups—eight Arab clans and the emigrants from Mecca. Muḥammad is given no special position of authority, except that the preamble speaks of the agreement as made between "Muḥammad the prophet" and the Muslims now resident in Medina, and it is stated that serious disputes are to be referred to him. The Jewish groups had refused to acknowledge Muḥammad as prophet and in the document appear in a secondary character as attached to various Arab clans. For at least five years, Muḥammad had no direct authority over members of other clans, but, in the closing years of his life, the prestige of his military successes gave him almost autocratic power. The revelations he received at Medina often contained legal rules for the community of Muslims, but they dealt with political questions only rarely.

The first five years at Medina. The first 18 months at Medina were spent in settling down. Muḥammad was given a piece of land and had a house built, which eventually held apartments grouped around a central courtyard for each of his wives. The Muslims often joined Muḥammad at prayers in his home, which, after his death, became the mosque of Medina. The emigrants (*muhājirūn*, the men from Mecca) were at first guests of brother Muslims in Medina, but Muḥammad cannot have contemplated this situation continuing indefinitely. A few emigrants carried on trade in the local market run by a Jewish clan. Others, with the approval of Muḥammad, set out in normal Arab fashion on razzias (*ghazawāt*, "raids") in the hope of intercepting Meccan caravans passing near Medina on their way to Syria. Muḥammad himself led three such razzias in 623. They all failed, probably because traitors betrayed the Muslim movements to the enemy. At last, in January 624, a small band of men was sent eastward with sealed orders telling them to proceed to Nakhlah, near Mecca, and attack a caravan from Yemen. This they did successfully, and in doing so they violated pagan ideas of sanctity—thereby making the Meccans aware of the seriousness of the threat from Muḥammad.

About the same time Muḥammad changed his general policy in important respects. One was his "break with the Jews"; instead of making concessions to the Jews in the hope of gaining recognition of his prophethood, he asserted the specifically Arabian character of the Islāmic religion. Hitherto the Muslims had faced Jerusalem in prayer, but a revelation now bade them face Mecca. Perhaps because of this change some Muslims of Medina were readier to support Muḥammad. In March 624 he was able to lead about 315 men on a razzia to attack a wealthy Meccan caravan returning from Syria. The caravan, led by Abū Sufyān, the head of the Umayyah clan, eluded the Muslims by devious routes and forced marches. Abū Jahl, the head of the Makhzūm clan, however, leading a supporting force of perhaps 800 men, wanted to teach Muḥammad a lesson and did not withdraw. On March 15, 624, near a place called Badr, the two forces found themselves in a situation, perhaps contrived by Muḥammad, from which neither could withdraw without disgrace. In the ensuing battle at least 45 Meccans were killed, including Abū Jahl and other leading men, and nearly 70 taken prisoner, while the Muslims lost 14 killed. To Muḥammad this appeared to be a divine vindication of his prophethood, and he and all the Muslims were greatly elated.

The Battle of Badr and its consequences

In the flush of victory some persons in Medina who had satirized Muḥammad in verse were assassinated, perhaps with his connivance. He also made a minor disturbance an excuse for expelling the Jewish clan, which ran the market. This weakened his most serious opponent there, the "hypocrite" (*munāfiq*), or nominal Muslim, 'Abd Allāh ibn Ubayy, whose allies these Jews were. The remaining waverers among the Arabs probably became Muslims about this time. Thus the victory of Badr greatly strengthened Muḥammad. At the same time he was using marriage relationships to bring greater cohesion to the emigrants. Of his daughters, Fāṭimah was married to 'Alī (later fourth caliph, or leader of the Islāmic community) and Umm Kulthūm to 'Uthmān (third caliph). He himself was already married to 'Ā'ishah, daughter of Abū Bakr (first caliph), and was now

espoused also to Ḥafṣah, daughter of ʿUmar (second caliph), whose previous husband was one of the Muslims killed at Badr.

In the same year Muḥammad led larger Muslim forces on razzias against hostile nomadic tribes and had some success. Presumably, he realized that the Meccans were bound to try to avenge their defeat. Indeed, Abū Sufyān was energetically mobilizing Meccan power. On March 21, 625, he entered the oasis of Medina with 3,000 men. One of the features of Medina was a large number of small forts that were impregnable to Arab weapons and tactics. Muḥammad would have preferred the Muslims to retire to these; but those whose cereal crops were being laid waste persuaded him to go out to fight. By a night march with 1,000 men, he reached the hill of Uḥud on the further side of the Meccan camp. On the morning of March 23 the Meccan infantry attacked and was repulsed with considerable loss. As the Muslims pursued, the Meccan cavalry launched a flank attack after the archers guarding the Muslim left had abandoned their position. The Muslims were thrown into confusion. Some made for a fort and were cut down, but Muḥammad and the bulk of his force managed to gain the lower slopes of Uḥud, where they were safe from the cavalry. The Meccans, because of their losses, were unable to press home their advantages and without delay set out for home, while Muḥammad the next day made a show of pursuing. The battle produced neither a clear victor nor loser. In Badr and Uḥud together, the Meccans had killed about as many men as they had lost; but they had boasted that they would make the Muslims pay several times over, and they had not shown the degree of superiority appropriate to their leading position in Arabia. Muḥammad, though he had lost above 70 men, realized that this was a military reverse, not a defeat; but the confidence of the Muslims and perhaps his own had been struck a serious blow. If the victory of Badr was a sign of God's support, did Uḥud indicate that he had abandoned the Muslims? Muḥammad's faith soon overcame any momentary doubts, and he was gradually able to restore the confidence of his followers.

The Battle of Uḥud

For two years after Uḥud, both sides prepared for a decisive encounter. In the razzias Muḥammad led or sanctioned, he seems to have aimed at extending his own alliances and at preventing others from joining the Meccans. In at least two cases a small party of Muslims was tricked or ambushed, and most of their lives were lost. And another Jewish clan was expelled from Medina. At length, in April 627 Abū Sufyān led a great confederacy of 10,000 men against Medina. On this occasion Muḥammad had ordered the crops to be harvested and a trench to be dug to defend the main part of the oasis from the Meccan cavalry. For a fortnight the confederates besieged the Muslims. Attempts to cross the trench failed, and fodder for the horses was scarce, while Muḥammad's agents among the attackers fomented potential dissensions. Then, after a night of wind and rain the great army melted away. The Meccans had exerted their utmost might and had failed to dislodge Muḥammad, whose position was now greatly strengthened.

The siege of Medina

For more than two years now there had been opposition to Muḥammad in Medina, chiefly from ʿAbd Allāh ibn Ubayy and other so-called hypocrites (*munāfiquin*) who had abandoned Muḥammad at Uḥud and who together had fostered disaffection. Shortly before the siege Muḥammad had a showdown with ʿAbd Allāh ibn Ubayy, who had joined in spreading slanders about Muḥammad's wife ʿĀ'ishah. This confrontation revealed that ʿAbd Allāh had little support in Medina, and he became reconciled to Muḥammad. After the siege of Medina, Muḥammad attacked the Jewish clan of Qurayẓah, which had probably been intriguing against him. When they surrendered, the men were all savagely executed and the women and children sold as slaves.

The winning of the Meccans. Muḥammad's farsightedness as a statesman is manifest in the policies he next adopted. He might have proceeded to crush the Meccans, and he indeed put economic pressure on them; but his main aim was to gain their willing adherence to Islām. He had already realized that, insofar as the Arabs became Muslims, it would be necessary to direct outward the energies expended on razzias against one another. There could be no question of Muslims raiding Muslims. It is noteworthy that his largest razzias, apart from the expeditions against the Meccans, were along the route to Syria followed by the Arab armies after his death (see ISLAM, HISTORY OF). He doubtless realized that the administrative skill of the Meccan merchants would be required for any expansion of his embryonic state.

In a dream Muḥammad saw himself performing the annual pilgrimage to Mecca, and in March 628 he set out to do so, driving sacrificial animals; but he was disappointed because no more than 1,600 men would accompany him. The Meccans were determined to prevent the Muslims from entering their town, so Muḥammad halted at al-Ḥudaybiyah, on the edge of the sacred territory of Mecca. After some critical days the Meccans made a treaty with Muḥammad. Hostilities were to cease, and the Muslims were to be allowed to make the pilgrimage to Mecca in 629. The orderly withdrawal showed how completely Muḥammad controlled his followers. Partly to reward this orderly conduct, Muḥammad two months later led the same force against the Jewish oasis of Khaybar, north of Medina. After a siege it submitted, but the Jews were allowed to remain on condition of sending half of the date harvest to Medina. Thus throughout 628 and 629 Muḥammad's power was growing, since success led more men to become Muslims, for the religious attraction of Islām was apparently supplemented by material motives.

The Treaty of al-Ḥudaybiyah

Meanwhile Mecca was in decline. Several leading men had emigrated to Medina and become Muslims. New leaders had taken over from Abū Sufyān but had accomplished little, although the treaty with Muḥammad had removed his pressure on their caravans. Shortly after the treaty, Muḥammad had married Umm Ḥabībah, a daughter of Abū Sufyān and a widow whose Muslim husband had died in Ethiopia. This led to an understanding with Abū Sufyān, who began to work for the peaceful surrender of Mecca. It was probably when he was in Mecca for the pilgrimage in March 629 that Muḥammad became reconciled with another uncle, al-ʿAbbās, and married his uncle's sister-in-law Maymūnah.

An attack by Meccan allies in about November 629 upon allies of Muḥammad led to the latter's denunciation of the treaty of al-Ḥudaybiyah. After secret preparations he marched on Mecca in January 630 with 10,000 men. Abū Sufyān and other leading Meccans went out to meet him and formally submitted, and Muḥammad promised a general amnesty. When he entered Mecca there was virtually no resistance. Two Muslims and 28 of the enemy were killed. A score of persons were specifically excluded from the amnesty, but some were later pardoned. Thus Muḥammad, who had left Mecca as a persecuted prophet, not merely entered it again in triumph but also gained the allegiance of most of the Meccans. Though he did not insist on their becoming Muslims, many soon did so.

The victorious entrance into Mecca

Muḥammad spent 15 to 20 days in Mecca settling various matters of administration. Idols were destroyed in the Kaʿbah and in some small shrines in the neighbourhood. To relieve the poorest among his followers, he demanded loans from some of the wealthy Meccans. When he marched east to meet a new threat, 2,000 Meccans went with him.

The closing years: the unification of Arabia. Ever since the *hijrah*, Muḥammad had been forming alliances with nomadic tribes. At first these were probably nonaggression pacts, but, when he was strong enough to offer protection, he made it a condition of alliance that the tribe should become Muslim. While in Mecca Muḥammad had word of a large concentration of hostile nomads, and he set out to confront them. A battle took place at Ḥunayn in which part of Muḥammad's army was put to flight, but he himself and some older Muslims stood firm. The enemy was finally routed, and their dependents and possessions were all captured. They were allowed to ransom wives and children, but their livestock was divided as booty.

Muḥammad was now militarily the strongest man in Arabia. Most tribes sent deputations to Medina seeking alliance. It is difficult to say how much of Arabia joined his alliance, for the inner politics of each tribe were complex, and in some cases the deputation might represent only a small section. Muḥammad benefitted from the defeat of the Persian Empire by the Byzantine (Christian) Empire (627–628), for, in the Yemen and in places on the Persian Gulf, minorities that had relied on Persian support against Byzantium now turned to Muḥammad instead.

March to the Syrian border. The greatest of all of Muḥammad's razzias occurred at the end of 630, when he took 30,000 men on a month's journey to the Syrian border. In this campaign he pioneered the invasion of Syria and made agreements that became models for treaty arrangements with captured peoples. Some of the tribes near Syria were Christian and adhered to the Byzantines; chiefly as a result of this, Muḥammad's earlier friendship for the Christians, notably those of Ethiopia, changed to hostility. Before his death, armed opposition to him appeared in one or two parts of Arabia, but the Islāmic state was strong enough to deal with this. Thus he left most of Arabia united and poised for expansion into Syria and Iraq.

Muḥammad personally led the pilgrimage to Mecca, in March 632, in a form according with Islāmic belief. But his health was poor. About the beginning of June, he ceased attending to business, and on June 8 he died. No arrangements had been made for the succession, but Abū Bakr had been nominated to lead the prayers, and a meeting of all the Muslims in Medina agreed that he should be caliph (*khalīfah*), or successor.

CHARACTER AND ACHIEVEMENTS

Few great men have been so maligned as Muḥammad. Christian scholars of medieval Europe painted him as an imposter, a lecher, and a man of blood. A corruption of his name, Mahound, even came to signify the devil. This picture of Muḥammad and his religion still retains some influence. The English author Thomas Carlyle in 1840 was the first notable European to insist publicly that Muḥammad must have been sincere, because it was ridiculous to suppose an impostor would have been the founder of a great religion. Even if Muslims have often idealized him, a mass of detail in the early sources shows that he was an honest and upright man who had gained the respect and loyalty of others who were likewise honest and upright men. His other alleged faults must be considered in the light of his time and environment. He was not condemned for them by his contemporaries, except where he abandoned practices connected with idolatry. In several respects he was a social reformer.

The background of Muḥammad's marital arrangements is the prevalence in Arabia of a matrilineal kinship system (in which descent, status, and inheritance are traced through the mother's side), which led to the neglect of paternity and permitted forms of polyandry (having many husbands at once) sometimes verging on promiscuity. In permitting a Muslim to have four wives, the Qur'ān did not restrict an unlimited polygamy but instituted a new system based on patrilineal kinship, to which many Arabs were apparently turning. A woman could have only one husband at a time, or, if divorced, she had to wait over three months before remarrying, so that there could be no doubt about the paternity of any child. Muḥammad himself left nine wives and a Christian concubine. For each of his marriages there was a political reason, the forming of closer links with the father or relatives of the woman. Some contemporaries were scandalized at Muḥammad's marriage to Zaynab, divorced wife of his "adopted son" Zayd ibn Ḥārithah. By pagan custom this was incestuous; but the relationship was fictitious, and Muḥammad was apparently attacking the pagan system of relationships. In this sphere, then, Muḥammad was not satisfying his lusts but acting as a reformer.

Muḥammad's connivance at assassinations and his approval of the execution of the men of a Jewish clan for treachery are matters that cannot be denied. This was the style of life of the times, and two or three unsuccessful attempts on Muḥammad's life are recorded. Internal security in Arabia still depended on the law of retaliation, a life for a life, but Muḥammad tried to mitigate this in practice by encouraging men to accept from fellow Muslims a blood penalty of 100 camels in place of a life, for the murder of a member of their family or clan.

Muḥammad was admired by his contemporaries for his courage, resoluteness, and impartiality, and for a firmness that was tempered by generosity. He won men's hearts by his personal charm; his pleasant smile is remarked on. He was gentle, especially with children. Though he was sometimes silent in thought, for the most part he was engaged in purposeful activity. He walked vigorously and spoke rapidly. He became for later Muslims an exemplar of virtuous character, and stories presented him as realizing the Islāmic ideal of human life.

Muḥammad's chief significance is as founder of a state and of a religion. In his lifetime he created a federation of Arab tribes, which, in less than 20 years after his death, defeated the Byzantine and Persian empires, occupied a vast territory from Libya to Persia, and then developed into the Arab, or Islāmic, Empire. This process was favoured by the social tensions in Mecca and Medina and by the exhaustion of the two older empires after a long war; but Arab energies would not have achieved what they did had it not been for Muḥammad's gifts in handling men and his farsightedness as a statesman.

He made the religion of Islām, which now has some 500,000,000 adherents of many different races, the basis of Arab unity. In 13 centuries Islām has produced great saints, and there has been a high level of religious devotion and moral performance among ordinary Muslims. Islāmic doctrine maintains that God is the founder of the religion, not Muḥammad, but the latter played an important part in fostering the nascent religion. His concern with ultimate questions, his mystical outlook, and his moral seriousness were important adjuncts to the preaching of the Qur'ānic message.

BIBLIOGRAPHY

Biographical works: W. MONTGOMERY WATT, *Muhammad at Mecca* (1953) and *Muhammad at Medina* (1956), the most recent full-scale treatment, summarized in *Muhammad: Prophet and Statesman* (1961), by the same author; FRANTS BUHL, *Das Leben Mohammeds* (1930), a German translation of a work published in Danish in 1903 that is still considered reliable; TOR ANDRAE, *Mohammed, sein Leben und Glaube* (1932; Eng. trans., *Mohammed: The Man and His Faith*, 1936), chiefly concerned with religious aspects; A. GUILLAUME, *The Life of Muhammad: A Translation of Isḥāq's Sīrat rasūl Allāh* (1955), the primary Arabic biography; NABIA ABBOTT, *Aishah: The Beloved of Mohammed* (1942), a scholarly work; JOHN BAGOT GLUBB, *The Life and Times of Muhammad* (1970), a popular account based on the author's familiarity with Arab life.

Primary sources: The Qur'ān, of course, contains basic contemporary materials on Muḥammad, but it is difficult to assess them without broader historical knowledge. The vast collections of Traditions (Ḥadīth), or anecdotes about Muḥammad's words and deeds, are historically disputable and, besides, seldom tell us anything significant about Muḥammad's career. The main sources of historical value are the early biographies (8th–9th century), especially the *Sīrah* of IBN ISHAQ, as edited by IBN HISHAM, and the *Maghāzi* ("Expeditions") of AL-WAQIDI, together with the supplementary materials recorded by his associate IBN SAʿD. The last item contains much material about the Companions (persons in contact with Muḥammad) and thus about the Prophet's relation to and work with them. Some contemporary documents are preserved in the early biographical works, the most important being the so-called "Constitution of Medina." The latter is in Guillaume's translation of Ibn Isḥāq cited above; other documents are in Watt's *Muhammad at Medina.*

Muḥammad ʿAlī Pasha

The founder of the dynasty that ruled Egypt from the beginning of the 19th century until the middle of the 20th century, Muḥammad ʿAlī helped to create the conditions that made possible the emergence of a modern national state in Egypt.

Muhammad ʿAlī Pasha, lithograph by an unknown artist.

He was born in 1769 in Kavala (Kaválla), a small Macedonian seaport on the coast of the Aegean Sea in what is now Greece; his ethnic background is unknown, though he was certainly a Muslim and an Ottoman subject. Since he later accompanied a small Albanian (Arnavut) contingent to Egypt, he may have been an Albanian. His father, Ibrahim Agha, the commander of a small provincial force maintained by the governor of Kavala, died when Muḥammad ʿAlī was a boy, and he was brought up by the governor. At 18 he was married to one of the governor's relatives, who became the mother of five of Muḥammad ʿAlī's 95 children. He became involved in the tobacco trade, an experience that may account for his later commercial interests.

In 1798, Egypt, at that time a semi-autonomous province of the Ottoman Empire, was occupied by a French force under Napoleon Bonaparte. Muḥammad ʿAlī went there as part of an Ottoman expeditionary force to oppose the French. With great political skill, he managed by 1805 to be named the *wālī*, the Ottoman sultan's viceroy in Egypt, with the rank of pasha.

Appointment as Egypt's viceroy

Nowhere in the Ottoman Empire was there greater opportunity for a total restructuring of society than in Egypt. The three-year French occupation (1798–1801) had disrupted the country's traditional political and economic structure. Continuing the task begun by the French, Muḥammad ʿAlī put an end to Egypt's traditional society. He eliminated the Mamlūks, the former ruling oligarchy; he expropriated the old landholding classes; he turned the religious class into pensioners of the government; he restricted the activities of the native merchant and artisan groups; he neutralized the Bedouins; and he crushed all movements of rebellion among the peasants. The task of rebuilding Egypt along modern lines now lay before him.

But, though Muḥammad ʿAlī had considerable native intelligence and great personal charm, he was a man of limited knowledge and of narrow horizons. He proved insensitive to the possibilities now open to him and governed generally according to Ottoman principles. No group within Egyptian society was capable of forcing fundamental changes upon him; elements that might have served as the instruments of change had been crushed at the outset of his regime. Neither was there an ideology capable of bringing together the ruler and the ruled in a great national effort. The nationalism that swept Europe in this period meant little to Muḥammad ʿAlī and nothing to Egyptians. Finally, Muḥammad ʿAlī had to devote much of his effort to resisting attempts by his Ottoman overlord to remove him from office. His policies were designed more to entrench himself and his family in Egypt as its hereditary rulers than to create a new society.

Reform of Egypt's administration and economy

To strengthen his position within Egypt and to increase his revenues, Muḥammad ʿAlī instituted sweeping changes. By 1815 most of Egypt's agricultural land had been converted into state land and profits from agriculture became available to the ruler. He improved Egypt's irrigation system, on which its agriculture depended; he introduced new crops, such as cotton, which promised high cash returns; he reorganized the administrative structure of the government to insure strict control of the economy. He also attempted to construct a modern industrial system to process Egypt's raw materials. Disbanding his mercenary army, he created a fleet and an army of Egyptians conscripted from the peasant class but commanded by Turks and others recruited from outside Egypt. To supply services for his armed forces, he created Western-style schools to train doctors, engineers, veterinarians, and other specialists. He also began sending educational missions to European countries for training in modern techniques.

His industrial experiments failed, largely because Egypt lacked sources of power, a native managerial class, and a trained working class. Even the agricultural sector declined ultimately because of administrative mismanagement, excessive taxation, military conscription of the peasantry, and his monopolization of trade. By the mid-1830s Muḥammad ʿAlī's policy of turning Egypt into a massive plantation for his own benefit had reached a point of diminishing returns. Furthermore, his financial requirements had greatly increased because of his military campaigns.

These campaigns fell into three categories. In the first half of his reign, he supported the Ottoman sultan in suppressing rebellion both in Arabia and in Greece, and also invaded the Nilotic Sudan in search of recruits for his army and gold for his treasury. Victorious in all three campaigns, until European intervention in Greece caused the destruction of his fleet at Navarino in 1827, Muḥammad ʿAlī felt that he was strong enough to challenge the sultan. His first war against the sultan (1831–33) gained him control of Syria as far north as Adana. In the second war (1838–41) the decisive defeat of Ottoman troops at the Battle of Nezib (June 24, 1839) and the desertion of the Ottoman fleet to Muḥammad ʿAlī led to intervention by the European powers. In July 1840 Great Britain, Russia, Austria, and Prussia agreed to end Egyptian rule in Syria, shattering Muḥammad ʿAlī's hopes for greater independence from the Ottoman Empire. In 1841 he and his family were granted the hereditary right to rule Egypt and the Sudan, but his power was still subjected to restraints, and the sultan's suzerain rights remained intact.

Attempts at expansion

The final years of Muḥammad ʿAlī's reign were uneventful. He retired from office in 1848 and died in Alexandria on August 2, 1849. Many of his reforms were abandoned after his death, having been too closely allied to his policies of self aggrandizement to survive the period of expansion. But Muḥammad ʿAlī cleared the path for the creation of an independent Egyptian state; that his successors failed to meet the challenge of the modern world may be traced in part to the inadequacies of his rule, but their failures remain largely their own.

BIBLIOGRAPHY. HENRY DODWELL, *The Founder of Modern Egypt* (1931, reprinted 1967), is the only work in English to survey the reign of Muḥammad ʿAlī in all its aspects. For a more critical view of the Pasha's achievements, see HELEN ANNE B. RIVLIN, *The Agricultural Policy of Muḥammad ʿAlī in Egypt* (1961), which also contains an extensive annotated bibliography.

Muḥammad ibn Tughluq

Muḥammad ibn Tughluq extended the Delhi sultanate, the principal Muslim kingdom in north India in the late Middle Ages, to its farthest reach, and then, after exercising hegemony over the greater part of the subcontinent, as a result of misguided administrative actions and unexampled severity toward his opponents, lost his authority in the south. At the end of his reign, the sultanate had begun to decline in power.

Muḥammad was born about 1290, the son of the sultan Ghiyās-ud-Dīn Tughluq. Very little is known of his childhood, but he apparently received a good education. He possessed an encyclopaedic knowledge of the Qur'ān, Muslim jurisprudence, astronomy, logic, philosophy, medicine, and rhetoric. In 1321–22 his father sent him

Early years of his reign

against the city of Warangal in the Deccan, in which campaign, after initial reverses, he subdued the rebellious Hindu rajas. From his accession to the throne in 1325 until his death in 1351, Muḥammad contended with 22 rebellions, pursuing his policies consistently though ruthlessly. Ziyā'-ud-Dīn Baranī, his close companion and counsellor for 17 years, often advised him to abdicate, but Muḥammad disdainfully rejected his advice.

As his reign began, he attempted, without much success, to enlist the services of the *'ulamā'*, the Muslim divines, and the Ṣūfīs, the ascetic mystics. Failing to win the *'ulamā'* over, he tried to curtail their powers, as some of his predecessors had, by placing them on an equal footing with other citizens. The Sultan wanted to use the Ṣūfīs' prestigious position to stabilize his authority as ruler. Yet they had always refused any association with government and would not accept any grants or offices except under duress. Muḥammad tried every measure, conciliatory or coercive, to yoke them to his political wagon. Although he humiliated them, he could not break their opposition and succeeded only in dispersing them from the towns of northern India.

In the four pages of his so-called autobiography, Muḥammad's only surviving literary work, he confesses that he had wavered from traditional orthodoxy to philosophic doubts and then found his way to a rational faith. To still his own doubts, as well as to counteract the opposition of the Muslim divines, he obtained from the caliph in Cairo a *manshūr* (patent of royalty) legitimizing his authority.

Move to the south

The transfer of the capital in 1327 to Deogir (now Daulatābād) was intended to consolidate the conquests in southern India by large-scale, in some cases forced, migration of the people of Delhi to Deogir. As an administrative measure it failed, but it had far-reaching cultural effects. The spread of the Urdu language in the Deccan may be traced to this extensive influx of Muslims. He introduced several reforms in the monetary system, and his coins, in design as well as in workmanship and purity of metal, excelled those of his predecessors. His introduction of token currency, coins of baser metal with the face value of silver coins, however, failed dismally. A projected Khorāsān expedition (1327–28) that never materialized was intended to secure more defensible frontiers in the west. The Karajil (Garhwal-Kumaon) expedition (1329–30), an attempt to adjust the boundary dispute with the northern hill states then dominated by China, ended in disaster, but was followed by an exchange of emissaries between China and Delhi. The conquest of Nagarkot in the foothills of the Himalayas in northwest India was based on Muḥammad's policy of establishing secure frontiers.

Between 1328–29 the Sultan increased the land tax in the Doab—the land between the Ganges and Jumna rivers—but the taxpayers resisted it, especially because a severe drought coincided. Muḥammad was the first ruler to introduce rotation of crops, establish state farms, and extend cultivation and improve artificial irrigation by establishing a department of agriculture. When famine broke out in northern India (1338–40), he moved his residence to Swargdawari to supervise famine relief measures himself.

Muḥammad's last expedition against the rebel Ṭaghī ended with his death at Sondaha in Sind in 1351. He died with a smile on his face and verses of his own composition on his lips. In the words of a contemporary, "the Sultan was rid of the people and the people of the Sultan."

Assessment

Sultan Muḥammad was among the most controversial and enigmatic figures of the 14th century. A dauntless soldier, he was tolerant in religion, and was normally humane and humble, but these traits were vitiated at times by cruelty sometimes approaching the inhuman. He lived in constant conflict between faith and action, faith in the correctness of his policies and in the means by which he sought to implement them. A born revolutionary, he desired to create a more equitable social order by making Islām a religion of service rather than a means of exploitation. This end, he believed, could be achieved only by a strong centralized authority based on justice and patronage of the poor, the learned, and the pious and on the suppression of rebellions mainly of the privileged classes in a tradition-ridden society.

All contemporary historians based their assessment of Muḥammad on his administrative measures, which were neither vicious nor visionary. They failed because of the harshness of the Sultan in executing them, the challenge they posed to the privileged classes, the general lethargy and conservatism of his subjects, and the expansion of the empire with which Muḥammad's administrative machinery could not cope.

BIBLIOGRAPHY. No official history of the reign of Muḥammad ibn Tughluq has come down to us. All contemporary authorities speak of the Sultan as an elegant writer. The only literary work that has survived is a fragment (four pages) of what is considered by some writers as a fragment of his autobiography and by others as part of a letter the Sultan wrote to the Caliph at Cairo. Works by three of his most important contemporaries are: ZIA-UD-DIN BARANI, *Tārikh-i-Fīruz Shāhī*, Persian text (1860–62; partly translated in *The History of India As Told by Its Own Historians*, ed. by JOHN DOWSON, vol. 3, 1871), which includes a full-length account of Muḥammad ibn Tughluq's reign; *'Isāmī, Futuhus-salatin*, ed. by A.S. USHA (1948), text in Persian, a versified history of the Sultan's reign; and IBN BATUTAH, *Travels in Asia and Africa, 1325–1354*, trans. by H.A.R. GIBB (1929). Two modern works are ISHWARI PRASAD, *History of Qaranah Turks* (1936); and MAHDI HUSAIN, *The Rise and Fall of Muḥammad ibn Tughluq* (1938).

(S.A.R.)

Muḥāsibī, al-

The eminent Muslim mystic (Ṣūfī) and theologian al-Muḥāsibī owes his reputation chiefly to his psychological refinement of pietistic devotion and to his role as a precursor of the doctrine of latter Muslim orthodoxy. His name means "he who examines his conscience."

Abū 'Abd Allāh al-Ḥārith ibn Asad al-Muḥāsibī al-'Anazī was born in Basra toward the end of the 8th century. There is little historical information about his life. His parents apparently left for Baghdad shortly after his birth, perhaps attracted by the many opportunities afforded by the newly founded capital. His father had acquired some wealth, but Muḥāsibī is said to have refused it because of doctrinal differences. He led a normal life, owned a beautiful house, and liked sumptuous clothes. This image of the ordinary bourgeois, however, is qualified by a trait that Muḥāsibī imported from Basra: the spirituality of otherworldliness propagated by the famous Ṣūfī theologian al-Ḥasan al-Baṣrī (died 728).

Critique of Muslim asceticism and people

Muslim asceticism had developed some specific features: nightly recitals of the Qur'ān (the Muslim sacred scriptures), restrictions concerning the kind and quantity of food one should eat, and a special attire consisting of woollen clothing. These habits had been adapted from the life-style of Christian monks. But whereas Christian monks used to live in seclusion, a Muslim ascetic felt obliged to remain an active member of his community. Thus, Muḥāsibī came to realize that in his urban society with its inevitable public exposure, the practice of outward asceticism was open to ambiguity: although it could serve to suppress the normal sins of passion, it could also become a deceptive vehicle for inner vices like hypocrisy and pride. As soon as outward piety becomes a part of a person's image, it can act as a screen for the hidden intentions of the ego. Man has to recognize that sinful actions are frequently defined not by their objective reality but by the subjective attitude of the sinner. Outside the realm of the commandments and prohibitions of the Qur'ān, nothing should be labelled good or bad without restriction. The most commendable attitude is scrupulosity, although even this can be ambiguous, because it might result in spiritual paralysis. Asceticism is valuable as something additional, an act of supererogation, but it must always be tempered by attention paid to the inner and outer duties toward God (*ar-rī 'āyah li-ḥūqūq Allāh*, the title of Muḥāsibī's main work). The proper instrument for this is reason, the importance of which Muḥāsibī stressed far beyond the normal practice of mystics,

who often tended to emphasize irrationality and spiritual intoxication. The method he proposed was *muḥāsabah*, the anticipation of the Last Judgment through constant self-examination. This seems to have been an impediment to real mystical experiences; the ruthlessness of this psychological technique buried every attempt at ecstatic exaltation under an enormous inferiority complex.

Muḥāsibī propagated his ideas in didactic conversations, which he would record immediately afterward; his books still preserve this dialogical structure. His influence on posterity was immense, especially through his pupil Junayd. During his lifetime, however, he was regarded with suspicion, and his last years were embittered by persecution. He had joined a group of theologians who, led by ʿAbd Allāh ibn Kullāb (died 855), criticized the doctrines of the rationalist Muʿtazilite school dominant at that time. The discussion was focussed on the problem of the essence of God and the nature of his attributes. The Muʿtazilites, in stressing the unity of God, tended to reduce the attributes to mere nominal aspects; Muḥāsibī, in order to preserve their individual value, accentuated much more their independent status. And whereas the Muʿtazilites held the attribute of God's speech to be created, realized in temporal revelations like that of the Qur'ān, Muḥāsibī believed that it was also uncreated if seen under the aspect of the eternal Word of God. He did not go so far as to support the popular belief that the Qur'ān, too, was uncreated; he avoided this shibboleth used in the inquisition initiated in favour of the Muʿtazilites by the caliph al-Ma'mūn in 833. This diplomatic attitude became precarious when, in 850–851, a later caliph, al-Mutawakkil, put an end to the pro-Muʿtazilite policy of his predecessors and, two years later, prohibited rationalist theology altogether. Muḥāsibī's theological position was now viewed as treasonous by the former victims of the inquisition, precisely because he had been closest to them in their dogmatic outlook, for they considered the use of any rational theological method as heresy, regardless of the doctrine it supported. He was consequently forced to give up his public teaching and appears to have emigrated to Kūfah. Later on he was allowed to return to Baghdad, perhaps at the price of abandoning his theological convictions. Yet the boycott persisted: when he died there in 857, only four people attended his funeral.

Theological disputes and persecution

BIBLIOGRAPHY. MARGARET SMITH, *An Early Mystic of Baghdad* (1935), a biography of Muḥāsibī and an analysis of his mystical ideas; JOSEF VAN ESS, "Ibn Kullāb und die Miḥna," *Oriens*, 18–19:92–142 (1965–66), an article about Muḥāsibī's importance for the theology of his time.

(J.v.E.)

Mukden

Mukden, the Manchu name of the city known in Chinese as Shen-yang, capital of Liaoning Province, is the fourth or fifth most populous city in China and the industrial centre and largest city of the Northeast (formerly known as Manchuria). It is located on the Hun Ho (*ho*, "river"), a left-bank tributary of the Liao Ho, on the eastern edge of the Lower Liao Basin in the southern part of the central Northeast (Manchurian) Plain, about 100 miles (160 kilometres) north-northeast of the Gulf of Liaotung and about 140 miles west of the Yalu River, which forms the boundary between China and North Korea. In the early 1970s more than 3,000,000 persons were estimated to occupy the official municipal district, which covered 1,200 square miles.

History. *Early history.* The Lower Liao Basin, from the time of the Han dynasty (206 BC–AD 220), has been known as the Chinese Pale, an area of Chinese settlement, settled chiefly by immigrants from what are now the provinces of Hopeh and Shantung. The rest of Manchuria, not open to extensive Chinese settlement until relatively recent times, was under the control of various nomadic and tribal peoples of whom the Manchus became the most important. The Pale was largely set off from the rest of Manchuria by a discontinuous wall known as the Willow Palisade; and Mukden, then known as Shen, was a frontier post along the edge of the wall.

The Chinese Pale

The strategic and focal significance of its position was recognized at an early age. By the 10th century, it had become a major frontier settlement in the so-called Tung-ching Circuit of the Khitan kingdom, which had expanded across southern Manchuria into Korea from the steppelands of Jehol and western Manchuria. Its dominant peoples, also known as the Khitan, founded the Liao dynasty, which had its base in southern Manchuria and, for most of the period between 947 and 1125, controlled part of North China as well. Southern Manchuria was conquered by the Chin, or Juchen, peoples by 1122–23 and a century later by the Mongols, who by about 1280 had completed their conquest of all China. It was under the Mongols that the name Shen-yang was first applied to Mukden. Less than a century later, by 1368, the Ming dynasty had displaced the Mongols and extended its control over what had been the Chinese Pale of southern Manchuria, including the city that later became known as Mukden.

In the early 17th century, Nurhachi, a tribal chieftain, organized and united the various Manchu tribes in the eastern Manchurian highlands and established military and political control over all of Manchuria. With a view to the conquest of China, Nurhachi moved his capital down to the city on the plain of the Liao. Mukden, a Manchu name, proved an admirable organizing base for the conquest of China. In 1644, when the Manchus supplanted the Mings on the Imperial throne, the capital was transferred to Peking, and Mukden became known as Sheng-ching (Flourishing Capital). It retained its prestige as the older capital of the reigning dynasty, however; the treasures of the royal house were deposited in its palaces, and the tombs of the earlier emperors, particularly the mausoleum of Ch'ing T'ai Tsung (died 1643) at Pei Ling (North Mausoleum), about four miles from the city, are among the most famous monuments of China. In 1658 the provincial government of Feng-t'ien was established, and the city also became known as Feng-t'ien (Honoured Heaven). For 250 years thereafter, it grew steadily, especially in the last half of the 19th century when Chinese immigration to Manchuria reached flood proportions.

Use of Mukden as a base for the Manchu conquest

Modern history. In the period of struggle between Russia and Japan for dominance in Manchuria after 1895, Mukden was inevitably one of the key positions. From that time, when the Russians gained rights to build railroads in Manchuria, Mukden was a Russian stronghold; during the Russo-Japanese War (1904–05) it was the scene of the Battle of Mukden, which lasted from February 19 to March 10, 1905, when the city finally fell to the Japanese. After the war the Japanese concession in Mukden was one of their chief bases for the exploitation of southern Manchuria, but it was also the seat of government of the Chinese "viceroy" of the three Manchurian provinces, Feng-t'ien (Liaoning), Kirin, and Heilungkiang.

During the civil war and warlord period after World War I, the Chinese warlord Chang Tso-lin, a protégé of the Japanese, governed the Manchurian provinces from Mukden and participated with other warlords in the struggle for control of the shadowy government in Peking. The last warlord to resist the advance of the Kuomintang armies against Peking in 1928, he was killed in his retreat with his defeated troops.

Three years later, on September 18, 1931, another explosion touched off the Mukden Incident. An alleged Chinese bomb went off on the railway track near Mukden and gave the signal for a surprise Japanese attack on the Chinese Nationalist garrison and arsenal in Mukden. After protracted fighting, the Chinese forces were driven out of Manchuria. On September 24 the first puppet organization was set up in Mukden with the Committee for Preservation of Local Peace and Order. But, after the establishment of Manchukuo, a puppet state created out of Manchuria and Jehol, the capital was moved to Ch'angch'un, which the Japanese renamed Hsinking (Hsinching; New Capital). Under the puppet state of Manchutikuo (a later version of Manchukuo), Mukden was given its old Chinese name of Feng-t'ien. It also was the headquarters of the South Manchurian Railway (known

The Mukden Incident

familiarly as the Mantetsu), which was the most powerful corporate body in the new state and a direct arm of Japanese colonial policy. Although Hsinking was the capital, Mukden, which had grown rapidly with industrialization, was in fact the principal Manchurian city.

The Soviet Union declared war on Japan in early August 1945 and soon took Mukden. Several months after the surrender of Japan on August 14, 1945, Mukden was occupied by Chinese Nationalist troops (in March 1946), some of whom were flown in by U.S. transport planes. But, while Mukden had been occupied by Soviet troops, it and other Manchurian cities were stripped of much of their industrial plant. Chinese Communist forces also controlled large areas of Manchuria. During the ensuing civil war (1946–49) Mukden, a Nationalist stronghold, fell to Communist armies under Lin Piao on October 30, 1948. The city then served as a major base for the subsequent Communist conquest of the entire Chinese mainland in the following year and a half.

Between 1949 and 1954 Mukden, again under the name Shen-yang, served as the capital of the Northeast Administrative Region, one of six great administrative regions into which China as a whole was then divided. Under the leadership of Kao Kang, a leading Communist, the Northeast developed dramatically as a semi-autonomous, comparatively modernized region of China. In 1954 the regions were abolished, and Kao Kang was purged. Mukden then became the capital of Liaoning Province, one of three into which the Northeast was then divided. In 1956 it was reduced from a municipality of provincial rank to one of subprovincial rank.

The contemporary city. *Strategic location.* The site of Mukden commands the lower portion of the central Manchurian Plain, the largest erosional (instead of depositional) lowland in China and probably the most fertile. Mukden controls the main north–south corridor, which extends from the Liao Ho Basin to the south and north across the continental divide near Ssu-p'ing, Kirin Province, to the basin of the Sungari River, a tributary of the Amur, which drains much of the northern region of the Northeast. The Liao Ho Basin opens onto the Gulf of Liaotung, the northern arm of the Gulf of Chihli, a branch of the Yellow Sea. The Gulf of Chihli is a shallow, partly enclosed sea, across which movement from North China, including the Shantung Peninsula, to the Liao lowland has long been undertaken by the Chinese people. In addition, the gulf has also served as a trade route. In fact, most of the population of the Manchurian Plain had its ancestral origins in the northern Chinese provinces of Hopeh and Shantung, which border the Gulf of Chihli. The Hun Ho Valley has long provided Mukden with another major route: eastward toward the Yalu River and North Korea; and to the southeast of Mukden another major routeway leads across the east Manchurian hills to the mouth of the Yalu and again North Korea.

Climate. The climate of the city is similar to that of Minneapolis, Minnesota, or of Moscow, but the summers are somewhat warmer. January mean temperature is 9° F (–13° C); July mean is about 75° F (about 24° C). The winters are long and hard, the summers short and hot. Annual precipitation averages just over 26 inches (660 millimetres), most of it concentrated in the summer months, although winter snowfall and snow cover are common.

City plan. Mukden lies on a level site at an altitude of about 185 feet (56 metres). Its structure reflects its diverse origins and complex history. The core of the city is the small old Chinese city, most of whose original 10-mile-long surrounding earthen wall has either been removed or is in a state of disrepair. Within the old city are the former Manchu Imperial Palace and its associated structures, modelled after the Forbidden City in Peking. North of the old city are the tombs of the Manchu emperors, as at Pei Ling. To the east is the former Chinese arsenal district. To the west lies the extensive Japanese-built city, laid out on an irregular rectangular grid pattern but with circles and diagonals reminiscent of other examples of Japanese Imperial urban design. Grand boulevards, shaded by trees and divided into separate routeways for fast and slow traffic, are typical of this area, which came into being after 1905 and which was greatly expanded after 1931. Here also are the main administrative buildings and facilities such as the main post office, the larger hospitals, and the greater number of theatres and libraries. Parks and recreational areas also are common. To the far west is the newest part of the metropolis, T'ieh-hsi-chu (West of the Railroad District), laid out in a regular grid pattern oriented to the northeast. It was constructed after 1935 as a workingman's residential area, as the industrial base of the city expanded, and has since become the most rapidly growing district. The official municipal district of Mukden covers about 1,200 square miles (3,100 square kilometres), about 60 percent of which is built-up area; the remainder is essentially rural in character. This overbounding means in effect that the city has no suburbs. But the expansion of the urbanized area within the district promises to convert almost all of these open lands into urban-land uses as the population and functions of the city expand.

Traditional neighbourhoods and regions

Transportation. Mukden was the railway hub for the southern area of the Northeast and remains, next to Peking, the leading railway centre of modern China. Railways lead northward to Ch'ang-ch'un and Harbin; southward to Dairen and Port Arthur (later merged to form the municipality of Lü-ta); southeastward to Tan-tung and the mouth of the Yalu; and southwestward to Chinchou, Shan-hai-kuan and the North China Plain, including Peking and Tientsin. Large railway marshalling yards were associated with manufacturing facilities for rolling stock. The South Manchurian Railway, administered from Mukden, was self-sufficient in the production of rolling stock and locomotives, which were manufactured in Dairen. A basic road network also was constructed to converge on the growing city. Mukden's railway station, with an associated bus terminal, lies on the margins of the Japanese-built part of the city. Bus services link the various parts of the metropolis. A large airport, constructed by the Japanese, is on the northern outskirts.

Demography. Mukden municipality (including the old city, the new city developed by the Japanese, the old arsenal district, and the T'ieh-hsi-chu) was believed to have a population of well over 3,000,000 in 1970, as compared with about 2,300,000 in 1953, a little under 2,000,000 in 1945, and about 421,000 in 1931. When its immediate hinterland—which includes several of the major industrial cities of China—is taken into account, the total population under the domination of Mukden approaches 10,000,000. This makes it comparable in size as well as function to such diverse metropolitan complexes as Chicago, Ōsaka, and Calcutta.

Economic life. During the period of Japanese hegemony in southern Manchuria, Mukden was developed as the effective regional capital of the Northeast and served as its chief industrial centre. Within a radius of about 50 miles three great industrial cities were developed: An-shan, 50 miles to the south-southwest; Pen-ch'i, 30 miles to the southeast; and Fu-shun, 20 miles to the east on the Hun Ho.

Since 1950 Mukden has continued as the hub of the heavy industrial complex of the southern region of China's Northeast, the greatest in China. It is estimated that about a fourth of all the machinery production and metal fabricating in China is done there. Rolling stock, machine tools, wire and cables, cement, electrical equipment, chemicals and chemical fertilizers, and pharmaceuticals are produced there. The complex also includes oil-seed-processing plants, flour mills, paper plants, soap and leather factories, textile mills, and glass factories. A small local steel plant produces finished metal for some of these industries, using local scrap and drawing pig iron from the mills at An-shan. The smelting of metals such as copper, zinc, lead, and manganese also is an important part of the industrial mix of the city. Coal to fuel its industries comes from Fu-shun and Fou-hsin.

Industrial products

For its industrial and domestic power needs, the city is tied into the southern electric power grid of the North-

east, which depends for its power sources on a great dam on the Sungari near Kirin (city) and on an even larger high dam at Shui-feng (Sup'ung) on the Yalu, the power of which is shared with North Korea. In addition, Mukden has a large, 600,000-kilowatt coal-fired generating plant, the first two units of which were opened in 1959.

The city obtains its water supply from a reservoir on the Hun Ho, a few miles upstream of Fu-shun.

Education and culture. Mukden has long functioned as the education and cultural centre of the Northeast. The city houses a major university, Liaoning University (formerly Feng-hang University), Northeastern China Technical University, Northeastern Engineering College, Northeastern Institute of Finance and Economics, and a medical college. In addition to theatres and libraries (the Liaoning Library has more than 1,300,000 volumes), it is the home of the Northeastern Institute of Fine Arts and the Northeastern Music Institute. It is also the site of the Northeast Museum and of the North Mausoleum and other Chinese historical monuments. One of China's regional television stations also is located in Mukden.

(N.S.G.)

Muller, Hermann Joseph

One of the founders of genetics and a Nobel laureate, Hermann Joseph Muller is chiefly remembered for his idea of the gene as the basis of life, his demonstration that X rays produce mutations, and his advocacy—as a means of directing human evolution—of free choice from sperm banks for artificial insemination. Muller's main conceptual contribution to biology is that evolution is implicit in the two properties unique to the genetic material: that of acting as template in its own replication and that of undergoing occasional changes ("mutations") transmissible to the replicas.

By courtesy of Indiana University, Bloomington

Muller.

Muller was born on December 21, 1890, in New York City. He attended Columbia University (1907–09) on a scholarship supplemented by part-time jobs.

Work at Columbia University

At Columbia his interest in genetics was fired first, as an undergraduate, by E.B. Wilson, the founder of the cellular approach to heredity, and later, in a postgraduate course, by T.H. Morgan, who had just introduced the fruit fly *Drosophila* as a tool in experimental genetics. The possibility—indeed, the necessity, in Muller's later view—of consciously guiding the evolution of man was the initial motive in Muller's scientific work and social attitudes. His early experience at Columbia convinced him that the first necessary prerequisite was a better understanding of the processes of heredity and variation.

A laboratory assistantship in zoology in 1912 allowed him to spend part of his time doing research on *Drosophila* at Columbia. He produced a series of papers, now classic, on the mechanism of crossing-over, obtaining his Ph.D. in 1916. The work of the *Drosophila* group, headed by Morgan, was summarized in 1915 in the book *The Mechanism of Mendelian Heredity*. This book is a cornerstone of classical genetics.

After three years at the Rice Institute, Houston, Texas, and an interlude at Columbia as instructor, Muller in 1920 became associate professor (later professor) in the department of zoology, University of Texas, Austin, where he remained until 1932.

The 12 years at Austin were scientifically the most productive in Muller's life. The study of the process of mutation led Muller to form a picture of the nature of genetic material and later to the experimental induction of mutations (the basis of his Nobel Prize in 1946). In 1931 he was elected to the U.S. National Academy of Sciences.

Despite Muller's progress, the pressure of work, his despair at social conditions during the Depression, the constraints on the free expression of his Socialist views in Texas, and domestic difficulties (his marriage of 1923 to the mathematician Jessie Marie Jacobs came to an end in 1932), all combined to produce a nervous breakdown. As a diversion, he spent one year at the Kaiser Wilhelm Institute in Berlin, where, in conjunction with a group of colleagues, he originated the biophysical attack on the nature of the gene. In September 1933 he moved to Leningrad at the invitation of N.I. Vavilov, head of the Institute of Genetics there. Shortly after, the Institute was transferred to Moscow, and Muller moved with it. For Muller, the opportunity of working in genetics in a Socialist society was a fulfillment of a long-held wish. The inspiration and help of Vavilov and a group of able, enthusiastic young collaborators provided a fertile environment for Muller's research.

Muller's work in the Soviet Union

Genetics in the Soviet Union at this time could have made great strides. But the false doctrines of the biologist T.D. Lysenko became politically powerful, bringing to an end the activities of all flourishing research groups. Soviet biology was consequently left unprepared for the next leap toward molecular biology.

Muller fought Lysenkoism whenever possible, but ultimately had to leave the U.S.S.R. He spent three years at the Institute of Animal Genetics in Edinburgh, returning to the United States in August 1940. The period in Edinburgh was very fruitful. He had a profound impact on genetics in Great Britain and helped to organize the VIIth International Congress of Genetics. At the Institute he met Dorothea Johanna Kantorowitz, a German refugee, who became his second wife in 1939.

On returning to the United States, Muller obtained temporary positions at Amherst College in Massachusetts (1941–45), and, finally, a professorship in zoology at Indiana University, Bloomington.

The award of the Nobel Prize to Muller in 1946 increased both his opportunity and his sense of obligation regarding social activity. At the onset of the atomic age he was foremost in promoting awareness of the dangers of radiation to future generations. He also became more actively involved in discussions on the evolutionary future of man in relation to the relaxed processes of selection operating in modern society. His concern for man's future and the positive action that he had advocated for many years are summarized in the clearest terms in his address ("What genetic course will man steer?") to the International Congress of Human Genetics in 1966. Muller died on April 5, 1967.

A never-ending curiosity, a great breadth and depth of imagination, and a deep humanity combined with uncanny experimental dexterity made Muller a commanding figure in the biology of the 20th century.

BIBLIOGRAPHY. G. PONTECORVO, "Hermann Joseph Muller 1890–1967," *Biogr. Mem. Fellows R. Soc.*, 14:349–389 (1968), contains the list of some manuscripts and the complete list of about 370 publications, and includes both detailed biographical data and an evaluation of Muller's work. Publications, manuscripts, and correspondence are deposited in the Lilly Library, Indiana University, Bloomington. *Studies in Genetics: The Selected Papers of H.J. Muller* (1962), contains a selection of papers, and of excerpts from papers, adequate for an appreciation of Muller's work and ideas. The selection was made by Muller himself.

(G.Po.)

Müller, Johannes Peter

Johannes Müller was one of the great natural philosophers of the 19th century. In German medicine and biology he marked the transition from naturalistic speculation to precise observation and physiological experimentation. In physiology, anatomy, and zoology he established new concepts and trained outstanding students who broadened the scope of medicine by introducing the techniques of natural science.

Müller, lithograph by Louisa Corbaux, after a drawing by S. Lawrence.

Müller was born in Koblenz on July 14, 1801, the son of a shoemaker. In 1819, he entered the University of Bonn, where the faculty of medicine was permeated with a naturalistic romanticism, which the young Müller eagerly espoused. His thesis *Über die Bewegungsgesetze der Tiere* (1822; "On the Laws of Movement of Animals") was written in the naturalistic manner. He continued his studies at the University of Berlin, where he came under the influence of the sober, precise anatomist Karl Rudolphi and thereby freed himself from naturalistic speculation.

In 1824 he was granted a lectureship in physiology and comparative anatomy at the University of Bonn. In his inaugural lecture, "Physiology, a science in need of a philosophical view of nature," he outlined his approach to science, maintaining that the physiologist must combine empirically established facts with philosophical thinking. Two years later he was appointed associate professor, and in 1830 he became a full professor.

In the meantime, his voluminous *Zur vergleichenden Physiologie des Gesichtssinnes* . . . (1826; "the Comparative Physiology of Visual Sense . . . ") brought Müller to the attention of scholars by its wealth of new material on human and animal vision; he included the results of analyses of human expressions and research on the compound eyes of insects and crustaceans. His most important achievement, however, was the discovery that each of the sense organs responds to different kinds of stimuli in its own particular way or, as Müller wrote, with its own specific energy. The phenomena of the external world are perceived, therefore, only by the changes they produce in sensory systems. His findings had an impact even on the theory of knowledge.

Significance of his early work in physiology

Müller's monograph "On Imaginary Apparitions" was also published in 1826. According to this theory the eye as a sensory system reacts not only to external optical stimuli but can also be excited by internal stimuli generated by the imagination. Thus, persons who report seeing religious visions, ghosts, or phantoms may actually be experiencing optical sensations and believe them to be of external origin, even though they do not in fact have an adequate external stimulus.

Because of his research Müller became the best known figure in the Bonn faculty of medicine. Maintaining an almost incredible level of output, he examined many problems in physiology, evolution, and comparative anatomy. He studied the passage of impulses from afferent nerves (going to the brain and spinal cord) to efferent nerves (going away from the same centres), further elucidating the concept of reflex action. By careful experiments on living frogs, he confirmed the law named after Charles Bell and François Magendie, according to which the anterior roots of the nerves originating from the spinal cord are motor and the posterior roots are sensory. He investigated the nervous system of lower animal species, the intricate structure of glands, and the process of secretion. When tracing the development of the genitalia, he discovered what is now known as the Müllerian duct, which forms the female internal sexual organs. He contributed to our knowledge of the composition of the blood and lymph, the process of coagulation, the structure of lymph hearts of frogs, the formation of images on the retina of the eye, and the propagation of sound in the middle ear.

Studies in physiology and pathology in Berlin

In 1833 Müller was called to Berlin to succeed Rudolphi. In his new post he again carefully explored many problems concerning animal function and structure. His early years in Berlin were devoted mainly to physiology. His *Handbuch der Physiologie des Menschen für Vorlesungen* (2 vol., 1834–40; Eng. trans., *Elements of Physiology*, 2 vol., 1837–42) was recognized throughout the world and established a beneficial interchange between physiology and hospital practice in Germany. It stimulated further basic research and became a starting point for the mechanistic concept of life processes, which was widely accepted in the second half of the 19th century.

Inspired by the vast Berlin anatomical collection, Müller became interested again in pathology. After the demonstration by his assistant, Theodor Schwann, that the cell was the basic unit of structure in the animal body, he concentrated on the cellular structure of tumours with the aid of a microscope. In 1838 his work *Über den feineren Bau und die Formen der krankhaften Geschwülste* (*On the Nature and Structural Characteristics of Cancer, and of Those Morbid Growths Which May Be Confounded With It*, 1840) began to establish pathological histology as an independent branch of science. Müller also distinguished himself as a teacher. His students included the renowned physiologist and physicist Hermann Helmholtz and the cellular pathologist Rudolf Virchow.

Later work in taxonomy and morphology

Beginning in 1840 Müller increasingly focussed his research on comparative anatomy and zoology, in so doing becoming one of the most respected scholars in these subjects. He was a master at collecting and classifying specimens; he devised an improved classification of fish, and, based on an ingenious analysis of vocal organs, did the same for singing birds. For several years he concentrated on the lowest forms of marine vertebrates, the Cyclostomata and Chondrichthyes. He painstakingly described the structures and complex development of members of various classes of the invertebrate phylum Echinodermata. His last research activities were concerned with the marine protozoans Radiolaria and Foraminifera.

In 1827, 1840, and 1848, Müller suffered periods of depression that rendered him incapable of working for months on end. They may perhaps be attributed—as his periods of explosive productivity—to a manic-depressive disposition. It may also be regarded as the cause of his death, on April 28, 1858, in Berlin. Some scholars have assumed that he died by his own hand.

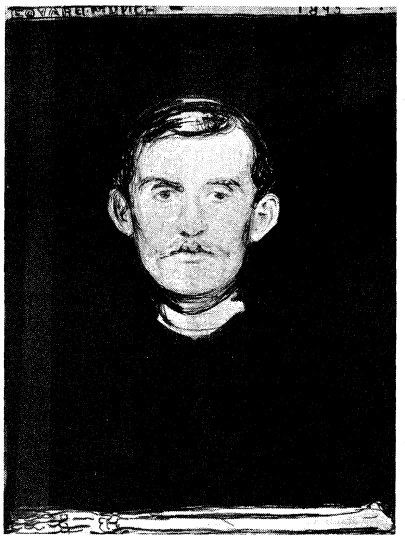
Munch, Edvard

Revolting against the stilted academicism of 19th-century naturalistic painting, the Scandinavian painter and printmaker Edvard Munch developed a highly personal art that was the forerunner of 20th-century Expressionism. When he was 26 he wrote, "I shall paint living people who breathe, feel, suffer, and love. The sacredness of this will be understood and people will take off their hats as though they were in church." The emotional power of these expressions of the human condition made him not only the greatest Norwegian artist but one of the most noted figures in the early development of modern art.

By courtesy of the Albertina, Vienna



Munch, self-portrait, lithograph, 1895. In the Albertina, Vienna. 45.7 × 32 cm.

Born on December 12, 1863, at Löten into a family prominent for its contribution to the political and cultural life of Norway, Munch was the second eldest of five children. His mother died of tuberculosis when he was five; ten years later his eldest sister died of the same disease, and another sister became mentally ill. Both his father and brother also died while Munch was a youth. The spectre of death and terminal illness that filled his childhood was to preoccupy him throughout his life, becoming one of the principal themes in his work. "The Sick Child" (1886; Nasjonalgalleriet, Oslo), "The Death Chamber" (1892; Munch-museet, Oslo), "By the Death Bed" (1895; Rasmus Meyers Collection, Bergen), and "The Dead Mother" (1899; Kunsthalle, Bremen, West Germany) are among the many paintings and prints that reflect his macabre childhood impressions.

The death theme in Munch's work

At an early age, Munch showed a flair for drawing but received little formal training. For a short time, he attended the School of Art and Handcraft in Christiania (Oslo). His student works were criticized by Christian Krohg (1852–1925), the important Norwegian naturalistic painter, who introduced Munch to French Impressionism. After his first trip to Paris in 1885, such pictures as "The Evening Hour" were executed in an Impressionistic manner. Subsequent exposure to contemporary French art effected a major change in his style, when (*c.* 1890) he was influenced by the Postimpressionist work of such French painters as Paul Gauguin and Henri de Toulouse-Lautrec, as well as by Art Nouveau design. The Impressionistic "Spring Day on Karl Johan Street" (1891; Gallery of Painting, Bergen) contrasted to the Expressionistic "Evening on Karl Johan Street" (1892; Rasmus Meyers Collection, Bergen) dramatically marks this stylistic transition.

The Christiania of Munch's youth was a provincial town, ruled by what he regarded as a narrow-minded and self-righteous gentility, whose cultural interests were limited and conventional. Munch early became associated with a Bohemian element involved with new ideas of social behaviour, morals, and art. The effect of this milieu was emancipating, and Munch's art became increasingly concerned with sex and social conditions.

Munch was to count among his friends many important literary personalities, including the Scandinavian playwrights Henrik Ibsen and August Strindberg, the Norwegian novelist Knut Hamsun, and the French Symbolist poet Stéphane Mallarmé. He had a particular affinity to the social realism of Ibsen's works and designed sets for productions of *Hedda Gabler* and *Ghosts*, as well as illustrating an edition of *The Pretenders*.

In 1892, Munch was invited to exhibit in Germany by the Verein Berliner Künstler (Union of Berlin Artists), a society of Berlin artists. The exhibit of 45 works opened on November 5 and closed a week later. The violent emotionalism and unconventional imagery of these works created a bitter controversy. The "Munch Affair" was hotly debated in the German press, developing into a struggle over the freedom of artistic expression. Munch's expressionism was soon accepted, however, and he became a European celebrity, living mainly in Berlin and Paris. In 1894, influenced by the revival of the graphic arts in Germany during the 1890s, he began to make prints. Using the mediums of etching, lithography, and woodcut, Munch was to become one of the most significant modern printmakers. Noted for its simplicity and directness, the imagery in his prints was characterized by the same ruthless subjectivity seen in his paintings.

Controversy in Berlin

The 16 years between Munch's first Berlin exhibition and a nervous breakdown in 1908 were the most important of his career. He drove himself with a frightening, neurotic compulsiveness. In a tortuous linear style, he expressed the misery and anxiety of human existence. "The Cry," perhaps Munch's most famous work, is a symbol of modern man's spiritual anguish. This work clearly points to the evocative violence of German Expressionist painting of the early 20th century and to the convulsive reality of another major modern symbol, Pablo Picasso's "Guernica" (1937; Museum of Modern Art, New York).

After 1910, Munch resided permanently in Norway. The self-consuming and introverted aspects of his earlier works, in which the individual is victimized by passion and the malevolence of nature, are replaced by the joy of life, and the abundance of nature and man's affinity with it. Direct contact with nature, always important to Munch, is expressed in numerous landscapes painted in a free, vigorous, and broad manner. The brighter and richer colour of these paintings is a further expression of his more positive frame of mind. During this period, his most monumental works were the murals he painted for the Aula, or festival hall, of Oslo University.

Abandoning printmaking, Munch spent his last years in solitude at his home near Oslo, where he continued to paint with unflagging energy until his death on January 23, 1944. Munch bequeathed his estate and all the paintings, prints, and drawings in his possession to the city of Oslo, which erected the Munch Museum in 1963.

MAJOR WORKS

PAINTINGS: "The Sick Child" (1886; Nasjonalgalleriet, Oslo); "The Evening Hour" (1888; Munch Museum, Oslo); "Inger Munch" (1892; Nasjonalgalleriet, Oslo); "Evening on Karl Johan Street" (1892; Rasmus Meyers Collection, Bergen); "The Cry" (1893; Nasjonalgalleriet, Oslo); "Vampire" (1893–94; Munch Museum, Oslo); "Ashes" (1894; Nasjonalgalleriet, Oslo); "Puberty" (1894; Nasjonalgalleriet, Oslo); "In Hell, Self-Portrait" (*c.* 1895; Munch Museum, Oslo); "Self-Portrait with a Cigarette" (1895; Nasjonalgalleriet, Oslo); "Jealousy" (1895?; Rasmus Meyers Collection, Bergen); "The Dance of Life" (1899–1900; Nasjonalgalleriet, Oslo); "The Red Vine" (1900; Munch Museum, Oslo); "White Night" (1901; Nasjonalgalleriet, Oslo); "Village Street" (1905; Munch Museum, Oslo); "Marat's Death" (1906; Munch Museum, Oslo); "The Bathers Triptych" (1907–13; Munch Museum, Oslo); murals for the Aula of Oslo University (1910–16); "Self-Portrait—Spanish Influenza" (1919; Nasjonalgalleriet, Oslo); "Model by the Armchair" (1929; Munch Museum, Oslo); "Between Clock and Bed, Self-Portrait" (1940; Munch Museum, Oslo).

BIBLIOGRAPHY. GUSTAV SCHIEFLER, *Edvard Munchs graphische Kunst* (1923), represents a nearly complete catalog of the artist's graphic opus; S. WILLOCH (ed.), *Edvard Munchs raderinger* (1950), a complete collection of repro-

ductions of the artist's etchings. Most of the biographical works on the artist and his works are written in German or Scandinavian languages. In English the following books give a representative introduction to the subject: ARVE MOEN, *Edvard Munch: Age and Milieu* (1956), *Edvard Munch: Women and Eros* (1957), *Edvard Munch: Nature and Animals* (1958), illustrated with practically all major works in colour and in black and white, with a bibliography of books also in German and Scandinavian languages; J.H. LANGAARD and REIDAR REVOLD, *Masterpieces from the Artist's own Collection* (1959); OTTO BENESCH, *Edvard Munch* (1960); PAL HOUGEN, *Edvard Munch and the Munch Museum* (1968); ROLF STENERSEN, *A Close up of a Genius* (1969); and WERNER TIMM, *The Graphic Art of Edvard Munch* (1969).

(A.S.M.)

Munich

Sometimes called "Germany's secret capital," Munich (German München) is, after Berlin and Hamburg, the third largest city in the German Federal Republic and the largest city of the *Land* (state) of Bayern (Bavaria). It is an exceptionally attractive city and is, indeed, considered by many to be one of the finest in Europe because of its wealth of Baroque, Rococo, and neoclassical architecture. Situated some 30 miles from the edge of the Alps, its unique character might perhaps be described as a combination of German practicality with Alpine romanticism, of urban thinking with a rural way of life. Although it is thoroughly modernized, it retains something of the genial sociability (*Gemütlichkeit*) of the old royal Bavaria. This, in a high-spirited form, is happily shown in the autumn of each year, when the people of Munich, particularly its 30,000 students, celebrate with beer, music, and traditional costumes their famous folk festival, the Oktoberfest.

Origin of name

History. Munich, or München (a word meaning the Home of the Monks) as it was originally called, traces its origin to the Benedictine monastery at Tegernsee, which was probably founded in AD 750. Henry the Lion, duke of Bavaria during the latter half of the 12th century, in 1157 granted the monks the right to establish a market where the road used for transporting salt from Salzburg met the Isar River. A bridge was built the following year, and the marketplace was fortified. From this small beginning, Munich thus grew and flourished, and Duke Henry may be regarded as its true founder.

Munich's subsequent history was influenced by two important factors: the increase in the flow of trade in Europe and the succession of Otto of Wittelsbach to the Bavarian duchy in 1180. For over 700 years the Wittelsbach family, whose home it became from 1255, was closely connected with the town's destiny. Three members, in particular, of this great German dynasty were pre-eminent.

In the early 14th century the emperor Louis IV, called the Bavarian, erected a second city wall and, after a disastrous fire in 1327, rebuilt and expanded the town to the size at which it remained up to the end of the 18th century.

Under the elector Maximilian I (1597–1651), a powerful and effective ruler who was also a patron of the arts, Munich increased in wealth and size and saw the flowering of its Renaissance architecture. The Thirty Years' War, however, brought suffering. It was occupied briefly by the Swedes under Gustavus Adolphus in 1632, and two years later a plague epidemic killed off one-third of its population of about 20,000.

The third Wittelsbach who left his mark on the town was Louis I, king of Bavaria from 1825 to 1848. It was he who planned and created modern Munich (see below) and whose architects established in their public buildings the style of Romantic Classicism, which still gives the city its characteristic aspect.

The 19th century was Munich's greatest period of growth and development. In the early part, when what had been a purely Roman Catholic town admitted Protestants to citizenship for the first time, the population was 40,000. In 1854 it became a "city" with 100,000 inhabitants, and by 1900 the population exceeded 500,000. In the second half of the century, Munich's cultural importance in Europe was particularly enhanced when Louis II, by his championing of the composer Richard Wagner, revived its fame as a city of music and the stage.

The rule of the Wittelsbach dynasty finally ended with the abdication of Louis III in November 1918, and in the immediate aftermath of World War I, Munich was the scene of severe revolutionary fighting, especially in the spring of 1919, when the Räterepublik—the Socialist Republic of Workers' and Soldiers' Councils—was proclaimed. More significantly, the city witnessed the political activity of Adolf Hitler in the 1920s. It was there that he joined the National Socialist (Nazi) Party and became its leader, held vast open-air meetings, and organized his first party army. The beer cellar where he held meetings that led to the *Putsch* ("rising") against the Bavarian authorities on November 8, 1923, can still be seen.

The Munich *Putsch*

In World War II, Munich suffered heavily from bomb raids, with 43 percent of its buildings destroyed, but most of the damage has been repaired.

The contemporary city. *Location and boundaries.* Munich is situated in Upper Bavaria, 1,700 feet above sea level, some 30 miles north of the edge of the Alps, and about 65 miles east-southeast of Augsburg. The city area covers 120 square miles (311 square kilometres), extending 13 miles from north to south and 16 miles from west to east. The Isar River flows through the middle of the town.

Architectural features. The old town, clustered around the ancient crossroads of the marketplace in the Marienplatz, has become more and more of a business centre and has lost much of its ancient character. Among the old buildings that still stand, though damaged in World War II, are three of the seven town gates—Karlstor, Sendlingertor, and Isartor, all dating from the 14th century—and medieval buildings such as the cathedral, the Frauenkirche (1468–88), whose massive cupola-capped towers are conspicuous landmarks, and the old town hall (1470–80), in the Marienplatz, with its beautiful wooden barrel vault. Nearby, the Peterskirche, Munich's oldest church (1169), which was completely destroyed in World War II, has been rebuilt almost in its original form. The former arsenal of the town at Jakobsplatz is now the municipal museum; among its treasures are the ten original Maruska (Morisken) dancers carved in wood in about 1480 by Erasmus Grasser for the town hall.

The Wittelsbach residences

The oldest of the Wittelsbach residences, the 15th-century Alte Hof, has to a great extent retained its medieval appearance. A later residence, the Neue Veste (New Fortress), lies between the Hofgarten and Max-Josef-Platz. The building dates from 1385, but the style of every period up to the 19th century was tried out on it with superb effect; it was destroyed in World War II but has been reconstructed. Of the Maxburg, built in 1590 by Duke William V, only one tower remains; a modern steel and concrete building now stands in its place. Other survivals from this period are the Münzhof, at one time the Duke's art gallery and stables (1563–67), and the Michaelkirche (1583–97), which is considered to be the most important Renaissance church in Germany and one of the most beautiful in central Europe.

The old town is predominantly Baroque and Rococo. Italian models inspired the late-17th-century Theatinerkirche, the early-18th-century Dreifaltigkeitkirche, and Bürgersaal. St. Michael at Berg am Laim, the Johann-Nepomuk-Kirche, and the Residenztheater (the court theatre) were completed between 1743 and 1753. The last named, a magnificent Rococo theatre, in the Neue Veste, designed by the French architect François de Cuvilliés, was largely destroyed in World War II, but much of its interior decoration had been evacuated and saved, and the theatre was reconstructed in its original form and reopened in 1958. Outside the town walls were built summer castles: Schleissheim and Nymphenburg, the latter with its hunting lodge the Amalienburg Pavilion, another Rococo masterpiece by Cuvilliés. The Bavarian landed gentry and court nobility built their houses around the court at the same time early in the 18th century. Of these the Preysing palais, the Palais Pocci, and the Palais Holnstein still remain.

Munich with the towers (from left to right) of Peterskirche, Frauenkirche, the town hall, and the Heiliggeistkirche, now the municipal museum.

Developments under King Louis I

Munich received the first great impetus to expand beyond the old town through the magnificent building and artistic development under King Louis I in the 19th century. Between the Siegestor (Victory Arch) and the Feldherrnhalle (Hall of Generals), he had the monumental Ludwigstrasse built and constructed there the state library, the Ludwigskirche, and the university. Other work commissioned by Louis I were the Königsplatz with the Glyptothek, which houses a collection of ancient and modern sculpture, the Propyläen, the Staatsgalerie, the Alte Pinakothek (containing one of the great European collections of paintings), the king's apartments, and the court banqueting hall. Louis' son Maximilian II (1848-64) built the Maximilianstrasse with the Maximilianeum, today the seat of the Bavarian Landtag (Diet).

The people. Munich's population in 1970 was approximately 1,300,000, 11 percent of whom were non-German. The metropolitan region, comprising an additional 140 communities, has about 1,800,000, inhabitants. The annual increase in population is 30,000, which is due not to an increase in the birthrate but to immigration. This trend may be explained by the attractions of a cultural centre near the Alps but especially by the changes in the economic structure of the German Federal Republic, which has made Munich an increasingly important centre of trade.

Economic life. Munich has in the past suffered economically because of its distance from seaports and from the Ruhr coal mines. But this situation improved when fuels other than coal came into more general use. There was a shift from heavy to light industry, to the manufacture, for example, of precision instruments and of optical and electrical appliances and to the production of foods, cosmetics, and clothing.

Munich beer

The brewing industry is traditional in Munich, with seven well-known breweries—Löwenbräu, Pschorr, Paulaner, Spaten, Hacker, Hofbräu, and Augustiner—producing about 88,000,000 gallons of beer a year. Also important are book publishing and printing and motion-picture production, mainly television, industrial, and educational films. Tourism and the hotel business, for long a profitable line, especially because of the number of trade fairs, exhibitions, and congresses taking place in Munich, were given particular prominence in the city's preparations for the 1972 Olympic Games.

Munich is a centre of great banking houses and, because of its geographical position, possesses one of the largest wholesale markets in Europe for fruit, vegetables, and animal produce.

Transportation. Munich is connected by rail to all the main towns of Germany and Austria, and three *Autobahnen* (expressways)—from Stuttgart, Nürnberg, and Salzburg—converge on the city. The airport at Riem on the eastern outskirts was, because of its limited capacity and nearness to the city, due to be replaced in the 1970s by a larger airport near Erding to the northeast. In the city, traffic congestion has become a serious problem, and to ameliorate the situation, an underground railway (subway) begun in 1968 was completed in 1971.

Government. Munich is administered by a lord mayor, two mayors, and some 40,000 civil servants. This organization is controlled by the city parliament of 60 citizens elected for six years. As capital of Bavaria the city is also the seat of the Bavarian government and parliament.

Education and cultural life. The university, called Ludwig-Maximilians-Universität, was moved from Landshut, on the Isar River, to Munich in 1826. In 1970 it had more than 23,000 students. Among other important educational establishments are the Technische Hochschule München (technical college), founded in 1868, and academies of art and music.

Munich has long been a centre for the arts. Music, especially opera, has flourished. In addition to the Bavarian State Opera Company and the Munich Philharmonic and other orchestras, there are the Bavarian State Dramatic Company and 20 private theatres. Important libraries include the Bavarian State Library, with more than 2,000,000 volumes, the University Library, and the library of the Deutsches Museums (a science library).

There are some outstanding museums and art galleries. In addition to the Glyptothek, the Staatsgalerie, and the Alte Pinakothek (see above), the Bavarian National Museum contains German art and applied art since the Middle Ages; the Residenzmuseum has paintings, sculpture,

furniture, and ceramics; and the Deutsches Museum on Museum Island in the Isar River is a huge and comprehensive museum of science, engineering, and technology. There is also a Modern Art Museum and numerous small art galleries.

The Englischer Garten

Recreation. Munich has many parks and gardens, of which the best known is the Englischer Garten, covering 600 acres near the Isar. This imitation of an English park was laid out in the late 18th century by the British-American scientist Sir Benjamin Thompson (Count von Rumford), who spent 11 years in the Bavarian civil service and was created a count of the Holy Roman Empire for his services.

BIBLIOGRAPHY. For a comprehensive survey, see LUDWIG HOLLWECK, *München: Staatsgeschichte in Jahresporträts* (1968); the same author's compilation, *Unser München* (1967), describes the city in the 20th century. The KREIS DER FREUNDE ALT-MUNCHENS, *München im Wandel der Jahrhunderte*, 2nd ed. (1958), provides good historical coverage. Important for an understanding of the 19th-century political and cultural history of Munich is RUPERT HACKER (ed.), *Ludwig II von Bayern in Augenzeugenberichten* (1966). LUDWIG SCHROTT, *Münchner Alltag in acht Jahrhunderten* (1969), is a good social history describing the daily lives of the city's inhabitants through eight centuries.

(F.Bu./Mi.Sc.)

Müntzer, Thomas

Thomas Müntzer, a leading radical reformer of the 16th-century Protestant Reformation, remains a figure of deep religious and social significance in modern European history. As an exponent of the supremacy of the inner light of the Holy Spirit as against the authority of Scriptures, Müntzer was said by Luther to have swallowed the Holy Spirit, "feathers and all" (the symbol of the Holy Spirit is the dove). Marxists in the 20th century view Müntzer as one of the first major figures in the struggle for a classless society.

By courtesy of the Herzog Anton Ulrich-Museum, Braunschweig

Müntzer, engraving by an unknown artist, 1525.

Early life and career

Thomas Müntzer (Münzer; Monczer; Latin Monetarius) was born sometime before 1490, the son of a burgher in Stolberg in the Harz Mountains. Of his childhood and youth very little is known. Traces of his family, who presumably had to leave Stolberg because of civil disturbances involving heretical ideas, are to be found in Aschersleben, Halberstadt, and Quedlinburg, where he may have attended the Latin school. His name appears in the 1506 register of Leipzig University, and in 1512 he attended the University of Frankfurt an der Oder, later earning the academic ranks of master of arts and bachelor of theology. As a linguistic specialist in Latin, Greek, and Hebrew and an accomplished scholar of ancient and humanistic literature—particularly the Old and New Testaments—he belonged to the most learned and intellectually significant group of his time. He was an assistant teacher in Halle (Saale) in 1513 and a clergyman as well as a teacher in Aschersleben in 1514 and 1515. In these capacities he represented the interests of the middle class in its striving for church reforms. He initiated secret alliances between various groups in order to achieve the reforms.

From 1516 to 1517 Müntzer worked as a prior at Frohse monastery at Aschersleben; in 1517–18 he taught at the Braunschweig Martineum (city secondary school) until, in 1518, he was attracted to Martin Luther and his ideas of reform. The designation Martinian was first applied to Müntzer in 1519 after he spoke out against the Franciscan monastic order, the Roman Catholic ecclesiastical hierarchy, and the veneration of the saints. He early showed himself to be an independent thinker. After occasional participation in debates between Luther and the German theologian Johann Eck (1486-1543), in Leipzig, he pursued intensive literary studies at the monastery of Beuditz at Weissenfels (1519–20). There he developed, especially under the influence of mysticism, his own view of the Reformation. From an action-hungry conspirator in local burgher plots he became a reformer who began to see the work inaugurated by Luther as a fundamental change in both ecclesiastical and secular life, and therefore as a revolution. He henceforth judged Luther's position by this criterion.

In Zwickau (1520–21), Müntzer prospered as a pastor in the socially tense condition that existed between the upper classes and early miners' guilds. In this work, he sided with the common people, who seemed to him to be the executors of the divine law and will on earth. More and more he found himself opposed to Catholic practices as well as to the reform concepts of the Lutherans. More and more he found himself holding to the sectarian view that true authority lay in the inner light given by God to his own, rather than in the Bible, a view taught by Nikolaus Storch, a leader of a radical reform group known as the "Zwickau prophets." Driven away from Zwickau, Müntzer sought on trips to Saaz (Žatec) and Prague (1521) to win to his viewpoint the Taborites, a Bohemian group that followed the teaching of Jan Hus, a 15th-century reformer. At Nordhausen (1522), Müntzer became fully aware of his opposition to Luther, where, in a struggle against Luther's supporters, his theological differences of opinion with them became more pronounced. For the first time it was the Lutherans who were to effect his expulsion from a city.

Although he began his religious revolt by following Luther's theological doctrines, Müntzer soon went his own way. Believing that teachings came from the spirit, he placed them in opposition to the Lutheran doctrines of justification (justification by faith alone) and of the authority of Scripture (Scripture as the exclusive source of divine truth). The revolutionary aspect of Müntzer's theology lay in his linking his concept of the inevitable conquest of the anti-Christian earthly government with the thesis that the common people themselves, as the instruments of God, would have to execute this change. He believed that the common people, because of their lack of property and their unspoiled ignorance, would disclose the will of God.

Müntzer arrived in Halle at the end of 1522, travelling by way of Weimar and Wittenberg. By his preaching in Glaucha, he won numerous disciples. Here he may also have met his later wife, the nun Ottilie von Gersen. From this union there were two children. Before Easter of 1523, Müntzer found employment as pastor of a Saxon community in Allstedt, near the Mansfeld mining area.

Important writings and radical reform activities

His most important religious, liturgical, and political writings originated here. They included *German Church Office, German-Protestant Mass, Protestation or Defense . . . Regarding the Beginning of the True Christian Faith and Baptism, Of Written Faith,* and *Precise Exposure of False Belief.* Here too, he drafted a speech, "Motivation for Defense," and delivered his "Princes' Sermon," in which he unsuccessfully tried to mold those princes of Saxony who were inclined toward Reformation principles into a league for resistance against what he called the

anti-Christian nobility and for the protection of his own preaching. Built upon the idea of "Christian unification" and also as a self-defense organization, the Allstedt alliance originated in 1524 and remained the centre of his doctrine until the fall of 1524, when he left Allstedt.

In Mühlhausen he organized the working classes into a group called the "Eternal Covenant of God" and lent a resolute character to the innerstate movement (based on the rule of the elect who are known by their inner experience of conversion) that had lasted since 1523. After another expulsion he went to Nürnberg, where his main political writings were published. He then went on to Hegau and Klettgau, the area where the Peasants' Revolt (an abortive revolt in 1524–25 against the nobles over rising taxes, deflation, and other grievances) was beginning, and stayed through the winter in Griessen. His experience with the rising insurrection impelled him to go back to Mühlhausen, which became the centre of the middle German revolt (after the overthrow of the governing council and the formation of what the insurgents called an "eternal council" in March 1525). Following Müntzer's dogmatic program, the common people triumphed in April–May 1525 over the religious and civil authorities. Cities and even some of the lesser nobility joined the alliance. Müntzer and his followers lent determination and consistency to the revolt. They were not, however, capable of overcoming the local and regional narrow-mindedness of the people. In the Battle of Frankenhausen, May 15, 1525, they were defeated by the superior strength of the princes.

Out of egoistical, material, and provincial motives, Müntzer dismissed resistance to his movement as a revolt against God. He believed that only if the common people were to realize the law of God within themselves, and place the interests of the group above those of the individual, would they be capable of demonstrating the will of God externally for the transformation of society. Müntzer's work was mainly concerned with the religious and ethical training of the peasants, but in expecting them to comprehend his concept of a future society without social and legal distinctions, he demanded too much. During the rebellion, Müntzer attempted to relate the battle of the peasants, tradesmen, and commoners about immediate concerns with that of the liberation of all Christendom and adapted himself to the everyday concerns of the various groups. The collapse of the revolt seemed to him to be the judgment of God on the as yet unpurified people, but not synonomous with the defeat of his idea of a new society. Müntzer was taken prisoner, tortured, and on May 27, at the princes' camp at Mühlhausen, was tried and executed.

Symbolism of Müntzer

After the bloody suppression of the Peasants' Revolt, Müntzer's program became a symbol for revolutionary movements, in which there would be a free people, which tolerated no governmental authority and itself wielded the sword. According to some scholars, especially Marxists, the revolutionary elements of Müntzer's thought were suppressed by those who opposed his views; and his character was hidden under a thick web of falsifications, fiction, and vulgarities, allowing only an apparition, the devil incarnate, to remain.

Even 100 years after his death, Müntzer's works appeared on the papal list of forbidden books. The Müntzer legend, which dates back to Luther, had preserved itself with great tenacity and could not be suppressed even by the 18th-century rationalistic Enlightenment. Not until the 19th century did Müntzer become an object of scholarly investigation. His personality and work were reinterpreted under the influence of the French Revolution, Hegelian concepts of history as a dialectic of opposing ideas, and democratic political movements of the mid-19th century, as well as the Marxist view of history. Marxist historical writing treats Müntzer as a starting point in the revolutionary tradition that led through the class struggles of the 19th and 20th centuries to Socialism, in which it sees Müntzer's basic concerns fulfilled. Efforts have been made in some Protestant historical writing to bring the heretic Müntzer back into the church. As an example, Mennonite historical writing has preserved an interpretation of Müntzer that is different from most Protestant and Roman Catholic views. Thus, the picture of Müntzer remains a matter of controversy, due to the markedly political relevance of Müntzer's ideas.

BIBLIOGRAPHY. *Schriften und Briefe von Thomas Müntzer* (1968), is the first critical complete edition that comprises all known written works by Müntzer. Critical text editions are *Politische Schriften* (1950), with commentary by CARL HINRICHS; and *Politische Schriften, Manifeste, Briefe 1524/25* (1970), with preface and commentary by MANFRED BENSING and BERND RUEDIGER. Müntzer's reformation concept and revolutionary action, discussed by M.M. SMIRIN in *Die Volksreformation des Thomas Münzer und der grosse Bauernkrieg*, 2nd ed. (1956; orig. pub. in Russian, 1947), strongly stimulated the Marxist Müntzer research. Luther's territorial reformation and Müntzer's people reformation are examined by ALFRED MEUSEL in *Thomas Müntzer und seine Zeit* (1952). MANFRED BENSING, *Thomas Müntzer und der Thüringer Aufstand 1525* (1966), deals with the zenith and the conclusion of the life of Thomas Müntzer in the German Peasants' War. ERNST BLOCH, *Thomas Müntzer als Theologe der Revolution* (1921, reprinted 1960); ANNEMARIE LOHMANN, *Zur geistigen Entwicklung Thomas Müntzers* (1931); CARL HINRICHS, *Luther und Müntzer, ihre Auseinandersetzung über Obrigkeit und Widerstandsrecht* (1952); and WALTER ELLIGER, *Thomas Müntzer* (1960), deal with Müntzer's ideological development. The presently known biographical knowledge and contemporary images of Müntzer are found in MANFRED BENSING, *Thomas Müntzer* (1965). MAX STEINMETZ, *Das Müntzerbild von Martin Luther bis Friedrich Engels* (1971), examines revolutionary Müntzer traditions as well as the falsification of the Müntzer image in the 16th to 19th centuries. All the above works are in German. Very little has been published on Müntzer in English. See, however, ERNEST GORDON RUPP, "Thomas Müntzer: Prophet of Radical Christianity," *Bulletin of the John Rylands Library*, 48:467–487 (1966); and "Thomas Müntzer, Hans Huth and the 'Gospel of All Creatures'," *ibid.*, 43:492–519 (1961); and ERIC W. GRITSCH, *Reformer Without a Church: The Life and Thought of Thomas Muentzer, 1488?–1525* (1967).

Muscle Contraction

Motion is often said to be a characteristic of all living things. The more closely various living organisms and cells are examined, the more evidence accumulates to support this idea. The most obvious and striking movements, such as walking and running by higher animals, are produced by the action of muscles—organs composed of contractile tissue—which make up a large part of the bodies of these animals. There are, however, many examples of nonmuscular movements of cells and of primitive organisms.

For a comparative discussion of the muscle systems of animals, see MUSCLE SYSTEMS. The muscle system of man and diseases of muscles are dealt with in MUSCLE SYSTEM, HUMAN; and MUSCLE DISEASES.

This article is divided into the following sections:

I. General features
  Primitive contractile systems
  Muscle in higher animals
II. The nature and properties of striated muscle
  Structure and organization
  The neuromuscular junction: nerve–muscle communication
  Mechanical properties
  Energy transformations
  Metabolic pathways producing ATP
  Molecular components
  Molecular mechanisms of contraction
III. The nature and properties of cardiac muscle
  Structure and organization
  Mechanical properties
  Metabolic pathways
IV. The nature and properties of smooth muscle
  Vertebrate smooth muscle
  Invertebrate smooth muscle

I. General features

In all types of primitive motility described below, there are at least two points of similarity to muscle contraction —the requirement for an energy-yielding reaction and the presence of contractile protein.

PRIMITIVE CONTRACTILE SYSTEM

Cilia and flagella. Motion can be caused by the action of cilia or flagella, microscopic hairlike structures that extend out of the cell surface.

Cilia occur in large numbers on cell surfaces and move in a coordinated way. The pattern of motion during the beat of an individual cilium is fairly simple. During the power stroke, the cilium is slightly curved and rigid as it pushes through the surrounding medium, an action somewhat like the arm stroke of a swimmer; the cilium then becomes limp and remains flexible, thus reducing friction as it goes through the recovery stroke and returns to its original position. Unicellular organisms such as the paramecium, a protozoan that lives in freshwater ponds and streams, propel themselves by the action of cilia. But there are ciliated cells within the vertebrate body as well. Their cilia cause fluid and mucus to flow along the surface of interior passages such as the lining of the respiratory tract.

Flagella (singular, flagellum) are structurally similar to cilia, except that they are longer (sometimes up to 50 times longer) than cilia and usually number only one or two per cell. The stroke pattern by which a flagellum causes motion is somewhat more complicated than that of a cilium. In a flagellated cell, waves propagated along the length of the flagellum cause a helical, or spinning, movement of the cell as it is propelled forward. Sperm cells of most higher organisms move by the action of flagella. Many types of unicellular algae and protozoans use flagella in swimming through the water in which they live.

Electron-microscopic examination of both a cilium and a flagellum shows that each contains a regular pattern of tubules extending along their length. Cross sections of cilia and flagella reveal an outer ring of nine pairs of tubules and a central pair of tubules. Each tubule is made up of filaments that consist of a string of globular subunits. Like the contraction of a muscle, the movement of a cilium or a flagellum requires energy, which is obtained from the breakdown of the chemical compound adenosine triphosphate (ATP). The action of these cellular extensions does not depend on some process that takes place inside the cells, since either of them, when separated from a cell, will beat as usual upon the addition of ATP to the surrounding medium.

Some types of bacteria have flagella that differ somewhat from the type described above. Their motion seems to depend completely on a cellular particle called the basal granule, to which the flagellum is attached. Such flagella do not move when detached from their cells and provided with ATP.

Movement on "false feet"

Amoeboid motion. Cells capable of amoeboid motion have flexible surfaces, or boundaries. Motion occurs as an extension of the cytoplasm, called a pseudopod ("false foot"), flows outward and deforms the cell surface, and is followed by the rest of the cell. Many pseudopods may be formed at the same time, and their action does not seem to be coordinated.

The cytoplasm, or cell fluid, inside amoeboid cells is in two forms. The inner part, called the endoplasm, is thin and watery. It flows forward inside the advancing pseudopod, and at the leading end it flows in a fountainhead pattern, changing into a stiffer outer gellike form called the cortical layer. The cortical layer flows to the base of the pseudopod, where it converges toward the centre and is transformed back into endoplasm. It seems likely that the force responsible for amoeboid motion is generated by either the endoplasm-to-gel transformation at the leading end of the pseudopod or by the gel-to-endoplasm transformation at the base.

Amoeboid motion is, of course, characteristic of the amoeba, a one-celled protozoan, but it is also found in other cells. Slime molds, for example, move by amoeboid motions, as do certain cells in higher animals (*e.g.*, embryonic cells, types of white blood cells). A chemical compound in slime molds is very similar to actin, one of the contractile proteins in the muscles of higher animals. (In muscle contraction, actin interacts with myosin, the other contractile protein, and at one stage they combine with each other.) Experimentally, the actin-like compound from slime molds can combine with the myosin from rabbit muscle, suggesting a similar contractile mechanism for both types of organisms.

Even in stationary cells there is always some turbulence or slow streaming of the cytoplasm. This motion, called cyclosis, is important for the transport of various chemicals within the cell. It is like amoeboid motion, except that it does not deform the boundary of the cells and does not result in cell movement.

MUSCLE IN HIGHER ANIMALS

In higher animals such as vertebrates, most movements are caused by skeletal, cardiac, and smooth muscles. The skeletal muscles, which have visible stripes, or striations, when viewed with the microscope, usually contract rapidly and are under the voluntary control of the animal. Cardiac muscle, which makes up the heart, is unique in being striated but not under voluntary control; it continues pumping automatically throughout life. Smooth muscle, which does not have microscopic striations, usually contracts quite slowly and often undergoes rhythmic pulsations. It comprises the muscles of the intestinal walls and other parts of the internal organs (viscera). The action of most smooth muscle in vertebrates is not under voluntary control.

More is known about the operation of muscle at the molecular level than about any other tissue. One factor that has contributed to this knowledge is the close relationship between the structure and function of muscle—the study of the structure of muscle has added enormously to understanding its operation.

The levels of muscle structure

The structure of muscle can be considered on many levels of size ranging from the whole muscle, which can be examined with the unaided eye, to the arrangement of individual molecules in the contractile proteins, some of which are in the nanometre (1 nm = 10^{-9}, or one-billionth, metre) size range and must be magnified hundreds of thousands of times to be visible.

II. The nature and properties of striated muscle

STRUCTURE AND ORGANIZATION

Whole muscle. Striated, or striped muscle constitutes a large fraction of the total body weight. The movement of the limbs depends on the contraction of striated muscles, and posture is maintained by them. Both ends of most striated muscles are attached to the skeleton and thus are often called skeletal muscles. They are attached to the bones by tendons, which have some elasticity provided by the proteins collagen and elastin, the major chemical components of tendons.

Each striated muscle has blood vessels and nerves associated with it. The vessels transport blood to and from the muscle, supplying oxygen and nutrients and removing carbon dioxide and other wastes. The signals that initiate contraction are sent from the central nervous system to the muscle via the motor nerves. Each muscle also has important sensory structures called stretch receptors, which monitor the state of the muscle and return the information to the central nervous system. Stretch receptors are sensitive to the velocity of the movement of the muscle and the change in length of the muscle. They complete a feedback system that allows the central nervous system to assess muscular movement and to adjust motor signals in light of the movement.

The muscle fibre. Living muscle is composed of many long, cylindrical-shaped fibres from 0.02 to 0.08 millimetre in diameter (Figure 1). In some muscles the fibres run the entire length of the muscle, up to several centimetres long. In others a tendon extends along each edge, and the fibres run diagonally across the muscle between the tendons. Considerable variation can be found among the different skeletal muscles, the actual arrangement of the fibres depending on the function of the muscle.

The fibres in living muscle appear transparent when viewed in an ordinary optical microscope. Special types of microscopes, however, reveal a high degree of organization within the living fibre, a series of alternately dark

The appearance of muscle fibres

and bright bands. Each band extends across the fibre perpendicular to the length of the fibre. This cross-banded pattern can also be seen in chemically prepared and stained sections of muscle. (The structures responsible for the banding pattern are dealt with in a later section; see below *The myofibril.*)

Microscopic examination of stained sections of fibres reveals many features in addition to the cross bands. Each fibre is surrounded by a rather complex, multilayered structure, the sarcolemma. The outermost layer is a fine network of fibrils, which, at the ends of the muscle, extend into the tendons and form the structural link with them. The next layer of the sarcolemma is a foundation, or basement, membrane. The innermost layer is a plasma membrane like the ones that surround most cells; in electron micrographs it shows the usual form of two dark lines with a light one between them. This three-layered plasma membrane, which consists of lipid (fat) and protein molecules, maintains the electrical potential that plays a major role in stimulating muscle contraction.

Sarcoplasm is the special name for the cytoplasm of a muscle fibre. It is a water solution containing adenosine triphosphate (ATP), compounds called phosphagens, and all the enzyme, reactant, intermediate, and product molecules involved in many reactions, including one of the sequences of reactions (glycolysis) that produce ATP. The major ions (charged components) present in the sarcoplasm are magnesium (Mg^{++}), potassium (K^{+}), and sodium (Na^{+}). During contraction an appreciable amount of calcium ion (Ca^{++}) is also present in the sarcoplasm. Large structural units are suspended in the sarcoplasm as well.

Unlike most other cells in the body, including smooth or cardiac muscle cells, each striated muscle cell, or fibre, contains many nuclei. This is the result of the fusion of singly nucleated cells that occurs during the embryological development of striated muscle. After fusion, the cells never again divide.

Another prominent feature of muscle fibre is the presence of cell components called mitochondria. They contain the enzymes involved in the Krebs cycle and oxidative phosphorylation, two series of chemical reactions that produce the ATP necessary to muscle contraction. These reactions produce large amounts of ATP at a low rate and can fulfill the energy requirements of continuously active muscle. Muscles that operate at a steady, low level of activity are reddish, as a result of cytochromes, molecules involved in oxidative phosphorylation, and myoglobin, an oxygen-carrying molecule in the sarcoplasm. Striated muscles that work in bursts of activity, however, have fewer mitochondria and depend more heavily on reactions that do not require oxygen to make ATP. Such muscle fibres contain fewer molecules of cytochromes or myoglobin and constitute white muscles.

Prominent subcellular features

Small darkly stained granules can be seen in the sarcoplasm of muscle prepared for viewing with the electron microscope. The granules are aggregates of glycogen, a storage form of carbohydrate. The breakdown of glycogen and the metabolism of the individual units of carbohydrate through glycolysis, the Krebs cycle, and oxidative phosphorylation are important sources of ATP.

The myofibril. Electron micrographs of very thin sections of muscle fibres reveal groups of filaments oriented with their axes parallel to the length of the fibre. Two sizes of filaments, thick ones and thin ones, are present. Each array of filaments, called a myofibril, is shaped like a cylindrical column. Along the length of each myofibril alternate sets of thick and thin filaments (Figure 1) overlap, or interdigitate, presenting alternate bands of dark regions (with thick filaments and overlapping thin ones) and light regions (with only thin filaments). Within a fibre all the myofibrils are in register, so that the regions of similar density lie next to each other, giving the fibre the characteristic striated appearance it shows in the phase-contrast microscope and in stained sections viewed with a light microscope.

Each myofibril is about one or two micrometres, or microns (μ; $\mu = 10^{-6}$ metre), in diameter and extends the entire length of the muscle fibre. The number of myofibrils per fibre is quite variable. At the end of the fibre the myofibrils are attached to the sarcolemma.

Forty to 80 nanometres usually separate adjacent myofibrils in a fibre. This space contains two distinct systems of membranes involved in different aspects of the activation of muscle contraction (Figure 2). One system is a

From *Journal of Cell Biology* (1965)

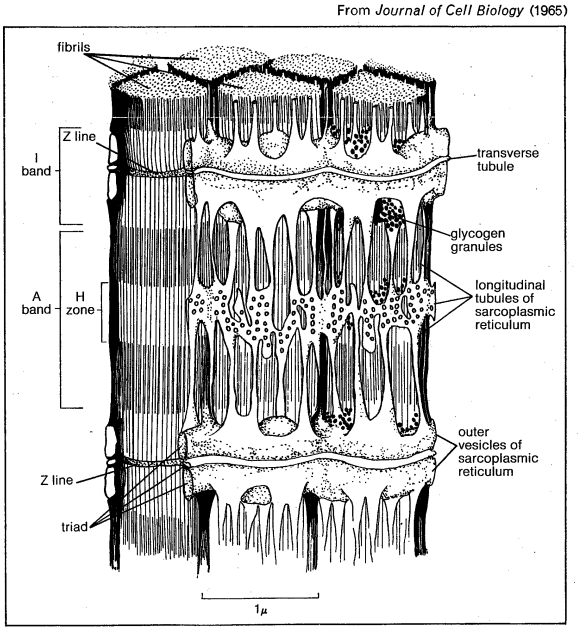

Figure 2: Ultrastructure of a group of myofibrils, showing the sarcoplasmic reticulum and transverse tubules, which constitute the two membrane systems within a muscle fibre.

series of channels that open through the sarcolemma to the extra-fibre space. These channels are called the transverse tubules because they run across the fibre; in other words, they lie on circular planes perpendicular to the fibre length. The transverse tubular system is a network

of interconnecting rings, each of which surrounds a myofibril. It provides an important communication pathway between the outside of the fibre and the myofibrils, some of which are located deep inside the fibre. The exact spatial relationship of the tubules to the filaments in the myofibril depends on the species of animal.

Transverse tubules and the sarcoplasmic reticulum

The other membrane system that surrounds the myofibril is the sarcoplasmic reticulum, a series of closed sac-like membranes. Each myofibril has a cufflike layer of sarcoplasmic reticulum surrounding it and extending between the transverse tubules. Near the transverse tubule, relatively simple enlarged sacs called terminal cisternae form from the sarcoplasmic reticulum. The walls of the transverse tubule and the terminal cisternae (singular cisterna) lie close together but with no direct physical continuity between them. In most vertebrates, each transverse tubule has two cisternae closely associated with it, forming a three-element complex called a triad. In fish and crustaceans, however, only one cisterna is associated with each transverse tubule, thus forming a dyad. The parts of the sarcoplasmic reticulum farther away from the transverse tubule are called longitudinal tubules; these narrow channels run parallel to the length of the myofibril. The sarcoplasmic reticulum controls the level of calcium ions in the sarcoplasm. The terminal cisternae apparently are the sites from which the calcium ions are released when the muscle is stimulated, and the longitudinal tubules are the sites at which calcium ions are bound again and effectively removed from the sarcoplasm.

The myofilament. As mentioned earlier, the myofibril is a column-like array of filaments. Figure 2 is a diagram of a longitudinal section through a myofibril. In the centre of the I band—the light band, of low density—there is a prominent dense line called the Z line. The area between two Z lines, a sarcomere, can be considered to be the primary structural and functional unit directly responsible for muscle contraction. The myofibril can thus be thought of as a stack of sarcomeres.

The A band, which contains thick filaments partly overlapped with thin filaments, appears dark. At very high magnification, small bridgelike structures can be seen on the thick filaments extending toward the thin filaments in the overlap region (Figure 1). They are called cross bridges and are believed to be responsible for the movement and force developed during contraction. In the middle of the A band, where only thick filaments are present, is a region called the H zone; it looks somewhat lighter than the overlap region of the A band. Also in the A band is a narrow, lightly stained region that contains bare thick filaments without cross bridges and is called the pseudo-H zone. In the centre of the A band is a narrow, darkly stained region called the M band, in which occur fine bridges between the thick filaments. The bridges differ from the cross bridges between the thick and thin filaments and are in fact composed of an entirely different protein.

Cross bridges to the thin filaments

If cross sections of the myofibril at different levels of the sarcomere are examined in the electron microscope, the filaments can be seen end-on, and the three-dimensional nature of the lattice of filaments can be appreciated (Figure 3). The I band contains only thin filaments, with a diameter of six to eight nanometres. In the A band, in the overlap region, the thin filaments appear with thick ones (diameter of 12 nanometres) in an extremely regular pattern, or lattice. In vertebrates, the thick filaments are arranged in a hexagonal lattice, and the thin ones are located at the trigonal positions of the lattice; in other words, a thin filament is located in the centre of each triangular-shaped area formed by considering three thick filaments to be the corners of a triangle. Sections through the H zone contain only thick filaments arranged in the same hexagonal pattern they form in the overlap region. In the M band, the hexagonal array of thick filaments can be seen with M bridges running between them.

The thick filaments are composed of about 200 molecules of the protein myosin. Myosin has two outstanding roles—a structural one, as the building block for the thick filament; and an enzymatic one, as the catalyst of the breakdown of ATP during contraction. The individual myosin molecule has a molecular weight (based on the weight of a hydrogen atom as 1) of about 500,000; it contains two major protein chains and a few small ones, the entire molecule being about 160 nanometres in length and asymmetrically shaped. The rodlike tail region, about 120 nanometres long, consists of two chains of protein wound together to form a helix (coil). At the other end of the molecule, the two protein chains form two globular headlike regions which have the ability to combine with the protein actin (see below *Molecular components*).

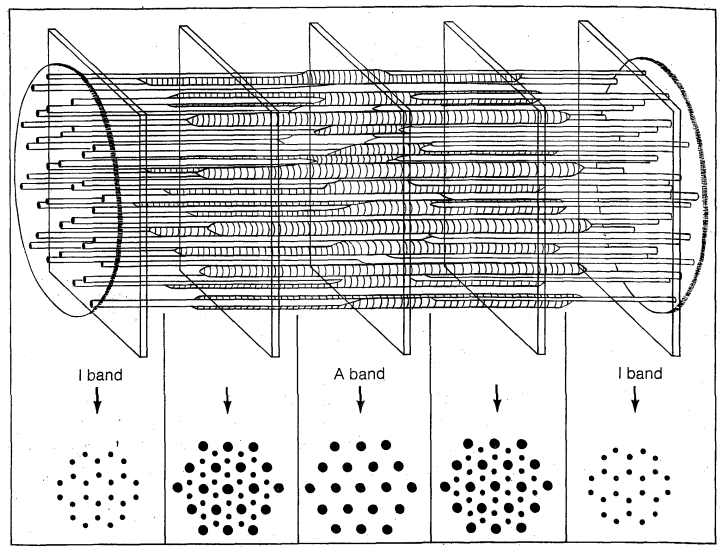

Figure 3: Muscle fibril, showing perspective model of the sarcomere.

From H.E. Huxley, *The Contraction of Muscle* (Copyright © 1958); Scientific American, Inc., all rights reserved

In the centre of the thick filament the molecules are assembled in a tail-to-tail fashion. Along the rest of the filament they are arranged head to tail. The tail parts of the molecules form the core of the filament; the head portions project out from the filament. This kind of arrangement explains, on a molecular basis, the appearance of the thick filaments in the A band of sectioned muscle. The cross bridges are actually the globular head regions of myosin molecules extending outward from the filament, and the smooth pseudo-H zone is the region of tail-to-tail aggregation, in which there are only tails and no heads.

Molecular arrangement in thick filaments

During contraction the thin filaments move into the A band, and the overlap of the thick and the thin filaments increases. The direction of movement at the ends of a thick filament is different. If a longitudinal section of the sarcomere is considered, the thin filaments on the left side of the A band would move to the right into the A band, and the filaments on the right of the A band would move to the left into the A band. The basis for the directionality of the motion partly results from the structural polarity of the thick filament itself, since, at opposite ends of the filament, the myosin molecules themselves are oriented in opposite directions.

The precise three-dimensional arrangement of the cross bridges projecting from the thick filament cannot be seen easily in electron micrographs but can be determined from X-ray diffraction study of living muscle (Figure 4). Two bridges project from opposite sides of the filament every 14.3 nanometres along the length of the filament. Each successive set of bridges is located at a position rotated 120° farther around the filament. The pattern of six bridges—three sets of two bridges—repeats itself every 42.9 nanometres along the thick filament.

Proteins of the thin filaments

The thin filaments contain three different proteins—actin, tropomyosin, and troponin. The actin in the thin filaments is in the form of beadlike units in two long strands, twisted around each other to form a helix. Each of the beadlike units is about 5.5 nanometres in diameter and consists of a single molecule of actin. There are 13 of these units in each complete turn of one strand around

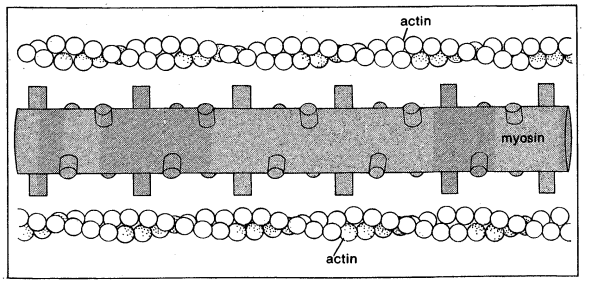

Figure 4: Arrangement of the cross bridges projecting from the thick filaments and the globular units of actin in the thin filaments of a muscle fibril.
From *Hospital Practice* (June 1970)

the helix. The double-stranded structure repeats itself every 36.5 nanometres along the thin filament. Actin is believed to be directly involved in the process of contraction since the cross bridges can become attached to it. Although it is not apparent from the shape of the actin units, these molecules are polarized.

Tropomyosin, a rod-shaped molecule about 40 nanometres long, with a molecular weight of about 70,000 combines with actin and is believed to lie in the groove between the two strands of actin in the thin filament. Troponin, a globular protein, with a molecular weight of about 50,000, does not combine directly with actin but, instead, forms a complex with tropomyosin, which attaches to filaments of actin. Tropomyosin lies along the entire length of the thin filament, and a troponin molecule is located every 40 nanometres along the filament. Troponin and tropomyosin are both involved in the regulation of contraction and relaxation of muscles.

The thin filaments do not simply run through the Z line; they begin on one side of the Z line just opposite the space between two thin filaments located on the opposite side of the Z line. The exact structure of the Z line has not yet been completely established, but it is thought that four filaments extend from the end of each thin filament to four different thin filaments on the other side of the Z line. This type of arrangement would give the Z line a three-dimensional structure resembling a series of pyramid-like units.

The fine M bridges are composed of a protein that has not yet been fully characterized, but it has been determined that it is not myosin, actin, tropomyosin, or troponin. The M bridges run between sites on the thick filaments at which myosin molecules are joined tail to tail. It may be that the M bridges keep the filaments in register during contraction.

THE NEUROMUSCULAR JUNCTION: NERVE–MUSCLE COMMUNICATION

Nervous control of muscle action

Nature of the communication. The activity of the nervous system is largely responsible for the control of muscle action. In vertebrates, nerve impulses travel along the surface of the motor nerve cells as waves of electrical changes, or depolarization and subsequent repolarization, and cause the contraction of the voluntary muscles.

Each nerve cell and muscle fibre is surrounded by its own membrane, but between the membrane of the nerve ending and the membrane of the muscle fibre is a gap filled with a solution of ions in water. When the electric signal reaches the nerve ending, it must cross the gap in order to stimulate the muscle. It does so by chemical rather than electrical transmission. Synapse is the general name for the site of this type of chemical communication between separate, electrically excitable cells; the special name for the synapse between nerve and muscle is the neuromuscular junction.

Anatomy of the junction. The vertebrate muscle fibres that contract in response to a single motor nerve impulse are striated fibres called "twitch" fibres. Each fibre has one nerve ending associated with it, forming one neuromuscular junction per muscle fibre (Figure 5B). Near the neuromuscular junction, the motor nerve branches and loses its fatlike, myelin covering but is partly surrounded by Schwann cells, which elsewhere cover the neuron and produce myelin. The nerve terminal—the end of the nerve cell—lies close to a specialized region of muscle fibre called the end plate. The muscle membrane at the end plate is arranged in a folded pattern: one long fold runs parallel to the long axis of the muscle fibre. The nerve terminal lies in this fold. A set of small folds, junctional folds, in the muscle membrane run perpendicular to the long one (Figure 5B). Within the gap that lies between the nerve membrane and the folded muscle membrane (Figure 5C) lies the basement membrane, which does not connect the two types of cells. In the nerve terminal are mitochondria, which produce the ATP used in the energy conversions of the cell, and structures that are more directly involved in the transmission process: vesicles, or bubble-like structures, about 50 nanometres in diameter, which congregate opposite the junctional folds in the muscle membrane. The vesicles contain a certain amount, or quantum, of acetylcholine, the chemical transmitter substance in vertebrate motor nerves.

The nerve terminal and the end plate

The transmission process. The function of the neuromuscular junction is to transfer the information from the nerve to the muscle so that muscle contraction results. This transfer is accomplished in several steps. The nerve impulse arrives at the nerve terminal and accelerates the secretion of the transmitter substance, acetylcholine, from the nerve endings into the space next to the junctional folds. (It has been suggested that transmitter release occurs as a large number of vesicles come in contact with activated areas of the nerve membrane; each vesicle joins with the membrane and empties its contents into the gap.)

Once released, the acetylcholine molecules flow across the gap to the junctional folds in the muscle membrane, where they act on special receptor sites in the end-plate membrane and produce an end-plate potential. The permeability of the membrane to certain small ions is increased, and depolarization, or decrease in the electrical potential, across the end-plate membrane results. After acetylcholine has acted on the receptor sites, it is destroyed by the action of acetylcholine esterase, an enzyme located in the muscle end-plate region. This is a very important process, because it turns off the nerve-to-muscle signal and allows the muscle to relax. Choline, which is a product of the breakdown of acetylcholine, can be reabsorbed by the nerve ending and used to make more of the active transmitter.

Meanwhile, the end-plate potential gets weaker and fades out as it travels over the end-plate region; *i.e.*, it is nonregenerative. (An analogy would be the spreading and weakening waves that appear on a pond surface after a pebble is thrown into it.) This nonregenerative end-

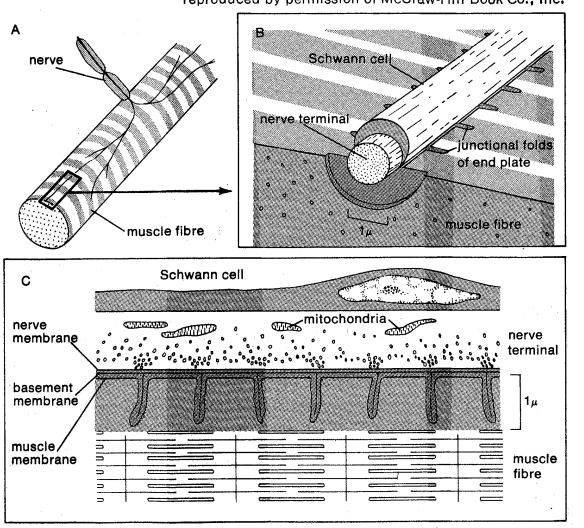

Figure 5: (A) Motor nerve ending and muscle fibre. (B) Enlarged section of small rectangle in (A), showing end plate and nerve terminal. (C) Longitudinal section through the neuromuscular junction.

plate response, however, initiates a different type of potential change across the sarcolemma, the membrane covering the rest of the muscle fibre. This electrical impulse, or action potential, travels over the entire surface of the muscle fibre and leads to contraction.

The action potential

The muscle action potential differs from the end-plate potential in two important ways. First, unlike the end-plate potential, the action potential is self-regenerating, which means that the wave of depolarization does not fade out but is maintained at the same magnitude as it travels along the muscle fibre. Second, the magnitude of the action potential, or degree of depolarization of the sarcolemma, is the same regardless of the strength of the nerve stimulus as long as it is above a certain minimum, or threshold, value. This is often referred to as the "all-or-none" character of the action potential. The special aspects of the end-plate potential and the action potential described above depend on the special properties of the flow of ions across membranes and are typical of twitch muscle fibres.

In other types of muscle, the events that follow nerve stimulation are somewhat different. Slow, or tonic, muscle fibres in some frog muscles, for example, require several stimulations to produce contraction; a single nerve stimulus is not sufficient. These muscle fibres do not have a mechanism for producing self-regenerating action potentials and do not show all-or-none behaviour. Tonic fibres, however, have many neuromuscular junctions distributed along the fibre surface, and the depolarizations produced at these junctions accumulate as they travel along the fibre surface. Thus the size of the depolarization of the muscle can have a variety of values depending on the strength of the nerve stimulation.

In the motor nerve and voluntary muscles, both fast and slow, of vertebrates, the nerve stimulus results in muscle contraction. Neuromuscular transmission, however, can communicate other messages in other systems. One example is the special nerves and muscles in the legs of crustaceans; nerve impulses cause the muscles to relax rather than contract. The nerve fibres in such a case are called inhibitory fibres; they work along with excitatory fibres, which cause contraction, and the two types coordinating the movements of the crab's legs.

Neuromuscular transmission also varies according to the type of transmitter substance. As mentioned above, acetylcholine is the transmitter in the well-studied vertebrate motor nerve–voluntary muscle system. Some of the autonomic nerves—those taking part in involuntary functions and responses of the body—are likewise mediated by the release of acetylcholine. Such autonomic nerves are called cholinergic nerves on the basis of their transmitter substance. Some examples of the muscular responses initiated by these nerves are: dilation of blood vessels in the skin, contraction of the walls of the digestive tract, and constriction of the pupils of the eye. Other autonomic nerves, however, act by releasing epinephrine (adrenaline) and norepinephrine; they are called adrenergic nerves. The actions induced by these nerves generally oppose those induced by cholinergic nerves: constriction of the blood vessels in the skin, relaxation of the smooth muscles of the digestive tract, and dilation of pupils. The transmitter substances have not yet been identified in some nerve–muscle systems, for example in the asynchronous flight muscles of insects and the inhibitory nerve fibres of crustaceans.

Cholinergic and adrenergic nerves

MECHANICAL PROPERTIES

The physical aspects. Vertebrates are able to move about and to exert and bear forces because of the contraction of the striated, or skeletal muscles, which constitute a large part of the body. These activities usually involve several structures operating in different ways. The skeleton with the muscles attached to it operates as a lever system. When a muscle shortens, it moves the joints that it spans. In addition, in coordinated movement usually several muscles contract in different ways. As some muscles shorten, others develop a force while at a fixed length, and still others may be lengthened by an external force even as they contract.

The force that a muscle develops is a "pulling" force, never a "pushing" force. The direction of movement, however, is determined by the size of the load exerted on the muscle. If the load is small enough, the muscle can shorten and produce a pulling motion (an isotonic condition). If the load is just equal to the maximum force the muscle can develop, the muscle will remain stationary (an isometric condition). An even larger load will stretch the muscle; the substantial force it exerts could be described as a pulling force that does not succeed in producing a pulling motion.

Factors modifying contraction

The size and the rate of the mechanical responses to stimulation, whether by a nerve in the body or by direct electrical shocks of an isolated muscle, depend on the muscle and the temperature. In a frog sartorius muscle (of the leg) at 0° C (32° F), the action potential reaches its peak of depolarization about 1.5 milliseconds (0.0015 second) after the stimulus. The first seven milliseconds after the stimulus is the latent period, during which time the tension in the muscle does not change. Until about 11.5 milliseconds the tension falls slightly, a response called latency relaxation. From 11.5 to 15 milliseconds, the tension again builds up to its initial starting level. From then on, the progress of tension development depends on the load on the muscle.

The very early tension changes require much more rapid and sensitive measuring and recording instruments than are necessary for studying other aspects of the contraction process. The latent period is the amount of time needed for the electrical signal, which appears as an action potential at the surface membrane, to be translated and travel to the contractile apparatus within the muscle fibres. The explanation for latency relaxation, however, is not so clear. It may be related to a change in shape of the sarcoplasmic reticulum. This structure makes up about 15 percent of the fibre volume and releases a large amount of calcium ions at about the time latency relaxation occurs. This ion flow may alter the shape of the reticulum and thus temporarily decrease the tension in the fibre as a whole.

Twitch and tetanus responses. Skeletal muscles respond to a single electric shock of sufficient magnitude by rapid, intense contractions called phasic contractions. If the ends of a frog sartorius muscle (at 0° C) are fixed to prevent shortening, the tension increases for about 200 milliseconds and then begins to decrease, at first rather rapidly and then more slowly. More happens during this mechanical response to a single stimulation, called a twitch, than the tension record suggests (Figure 6).

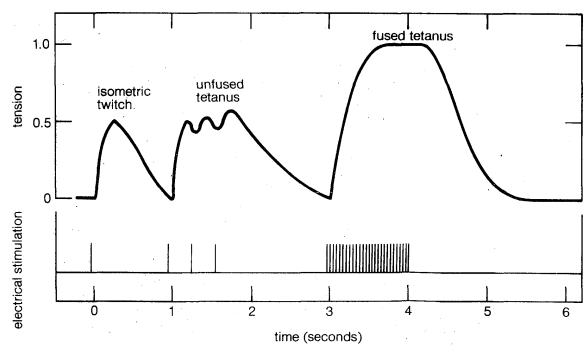

Figure 6: The effect of the rate of stimulation on the development of force in a frog muscle (at 0° C).

The mechanical response to repeated stimulation depends on the rate of the stimulation. Muscle, like other excitable tissues, has a period following its action potential during which the membrane will not respond to stimulation regardless of the strength. This absolute refractory period in the frog sartorius at 0° C lasts about ten milliseconds after stimulation. Therefore, a second pulse coming within that time span will not elicit any response. If, however, the pulses are 300 milliseconds apart, the muscle will be relaxing when the second pulse is given, and the tension will appear in waves in phase with the stimulation, causing an unfused tetanus. It is possible to stimu-

Absolute refractory period

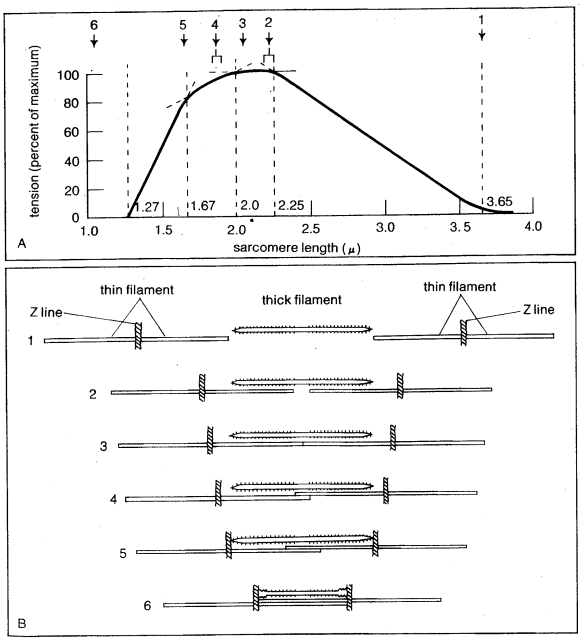

Figure 7: (A) The amount of force developed during an isometric tetanus of a single muscle fibre at various sarcomere lengths. (B) Relative positions of the thick and thin filaments at various sarcomere lengths.
From *Journal of Physiology* (1966)

late the muscle at a frequency between these extremes so that the tension developed by the muscle remains constant. This latter type of contraction is called a fused tetanus, and the rate of stimulation that produces it is called the fusion frequency. The exact rate depends upon the particular muscle and the temperature.

Usually, the maximum tetanus tension is from 1.2 to 1.8 times greater than the maximum tension during a twitch. This sizable difference has a rather subtle origin and points out the complexity of contraction even under isometric conditions. Within the muscle many elastic structures, connected in series with the contractile elements, are stretched during contraction. The attachment of the muscle fibres to the tendons at the end of the muscle, the attachment of the thin filaments to the Z lines, and even the actin–myosin cross bridge links probably contribute to this elastic component. In the frog sartorius muscle, the elasticity of the series elastic elements represents only a small percentage of the resting length of the muscle. Full maximum tension is not apparent at the end of the muscle until the contractile elements have shortened enough to stretch the elastic elements—somewhat like taking up the slack in rope before a pull on one end can be felt at the other end. In a twitch, the activity of the muscle is so brief that the contractile elements cannot extend the elastic elements completely before relaxation begins; as a result, the tension at the ends of the muscle does not reach the maximum possible level. During a tetanus, on the other hand, the activity of the contractile elements is maintained, and they can eventually shorten enough to extend fully the series elastic elements. When this has been accomplished, the maximum tension is apparent at the ends of the muscle.

Effects of series elasticity

Length–tension relationship. The force developed by a muscle, whether it is contracting or resting, is strongly dependent on the length of the muscle (Figure 7). Resting skeletal muscle does not exert any force at lengths less than the normal length of the resting muscle in the body (l_o). When resting skeletal muscle is extended somewhat beyond l_o, however, a passive force begins to assert itself. The exact length at which this passive force occurs depends on the particular muscle. This force is characterized as passive because it is developed in noncontracting or inactive muscles by the elastic elements of the muscle.

Skeletal muscles do not develop any force when they are stimulated at lengths of less than about 50 percent l_o. The amount of force developed, however, increases during isometric contractions at lengths from 50 to 100 percent of l_o. Once beyond l_o, the passive force becomes a factor. Thus, for contracting muscle at lengths greater than l_o, the total force has two components, a passive one, resulting from elasticity, and an active one, resulting from contraction. For isometric contractions at successively greater lengths beyond l_o, the active force developed during contraction decreases; at about 150 percent l_o, the muscle fails to develop any active force.

The structural basis for the dependence of the magnitude of active force on the length of skeletal muscle has been established in experiments with single fibres rather than whole muscles. With this more exact technique, details of the relationship between active force and sarcomere length have been found, and the active force has been correlated with the relative position of thick and thin filaments during contraction at each sarcomere length. It was determined that tension increases as the sarcomere length shortens from 3.65 to 2.25μ (Figure 7A, 1 and 2) because more sites for actin-myosin cross-bridge interaction become available as the overlap of the thick and thin filaments increases (7B, 1 and 2). The force is constant from sarcomere length 2.25 to 2.00 μ (7A, 2 and 3) as the thin filaments move over the bare region devoid of cross bridges in the centre of the thick filaments (7B, 2 and 3). As the sarcomeres shorten further, from 2.00 to 1.67 μ (7A, 3 to 5), the thin filaments overlap each other, preventing effective interaction with myosin in the thick filaments (7B, 3 and 5) and consequently diminishing the force. Finally, from sarcomere length 1.67 to 1.27 μ (7A, 5 to 6) the thick filaments run up against the Z lines (7B, 6) and internal resistance causes an even greater diminution of the force.

Contractions involving large movement. When a muscle shortens and lifts a constant load as it is stimulated, it is contracting under isotonic conditions (Figure 8). The

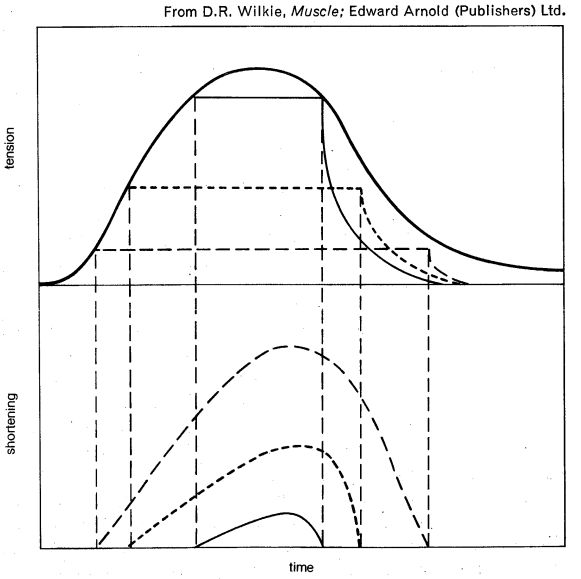

Figure 8: Force development (tension) and change in muscle length during an isotonic contraction (see text).

size of the load determines the magnitude of the time delay between the beginning of stimulation and the beginning of shortening. After stimulation starts, the force increases, just as in an isometric contraction, and, when the force is equal to the load, the muscle begins to shorten and lifts the load. The heavier the load, the longer it takes for the muscle to develop the required force and hence the delay before shortening begins. When the activity of both the muscle and the force in it begin to decline, the load stretches the muscle back to its initial length. The tension in the muscle is equal to the load during the shortening and the lengthening of the muscle, except during brief periods of acceleration as the muscle begins to move. Only after the muscle is back at its initial length does the tension begin to diminish. The size of the load also determines the velocity of shortening, and this relationship be-

Effects of the load on muscle contraction

tween load and velocity also applies to cardiac and smooth muscle. It can be mathematically described by Hill's equation:

$$V = \frac{(P_o - P)b}{P + a},$$

in which V is the velocity of shortening; P_o is the maximum force developed under isometric conditions; P is the force developed at a particular muscle length; and b and a are physical constants. A graphic interpretation of these values results in a rectilinear hyperbola called the force–velocity curve (Figure 9). From this curve can be determined both the velocity of shortening when the load is known and the force developed to overcome the load when the velocity is known.

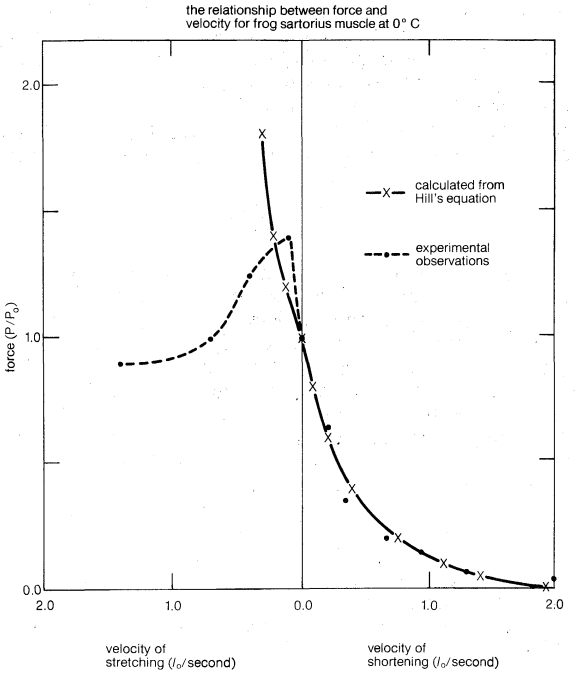

Figure 9: The force-velocity curve: relationship of the velocity of movement to the amount of force developed during tetanic stimulation (see text).

ENERGY TRANSFORMATIONS

When a chemical reaction occurs, energy is absorbed or released. In a contracting muscle, chemical reactions release energy that appears either as mechanical work or as heat. The first law of thermodynamics, or the law of conservation of energy, states that the heat and work produced must equal the energy released by the chemical reactions. The muscles that shorten and do external work liberate more energy as heat and work than do those that contract under isometric conditions and do not shorten or do external work. In light of the law of conservation of energy, this finding means that the amount of chemical reaction that takes place during contraction depends on the type of contraction performed by the muscle. In other words, the flow of energy is subject to regulation.

The practical work of muscles

The muscle's ability to do work is of great practical importance, since it enables animals to move their limbs and perform other actions. The efficiency of the process of muscle contraction depends on the fate of the free energy released in chemical reactions—*i.e.*, whether it is converted primarily into work or degraded into heat. Although the production of heat can detract from the efficiency of working muscle, energy that appears as heat is not always wasted. In warm-blooded animals, for example, the heat released by muscles maintains a constant body temperature regardless of the environmental temperature. When an animal shivers in the cold, a large amount of heat is generated in the muscles. The muscles alternately contract and relax, releasing energy chiefly as heat.

The energy-yielding reaction. Muscles use the free energy released by chemical reactions by coupling the chemical reaction to physical changes in the contractile proteins. The exact molecular details of this fundamental coupling process are not yet completely known. Of the reactions that have been identified, the splitting of adenosine triphosphate (ATP) is the energy-yielding reaction nearest to the contractile event. Water participates in this reaction in which ATP is broken down to adenosine diphosphate (ADP) and phosphate (P_i); the reaction that occurs in the muscle, during which chemical free energy is converted into work, can be written as follows:

$$\text{ATP} + H_2O + \text{contractile elements} \rightarrow \text{ADP} + P_i + \text{contractile elements} + \text{work} + \text{heat}.$$

This equation emphasizes the obligatory role of the contractile elements and the coupled nature of the reaction that produces work.

ATP is involved in the contraction of muscles in many types of animals. In some the ATP reaction can also be coupled to systems that convert the free energy from the ATP reaction into other kinds of energy. Some fishes, for example, convert it into electricity, and fireflies convert it into light. Within an animal, the net formation or breakdown of ATP is coupled to a large number of chemical reactions.

The ATP-building reaction. In a resting vertebrate muscle, the available supply of ATP can sustain maximal muscle work for less than one second. The muscle, therefore, must continuously replenish its ATP store, and this is done in many different ways. One mechanism for the formation of ATP operates so rapidly that for a long time scientists were unable to detect any change in the amount of ATP in the muscle as a result of contraction. This immediate rebuilding of ATP is accomplished by the reactions of compounds called phosphagens. All of them contain phosphorus in a chemical unit called a phosphoryl group, which they transfer to ADP to produce ATP. Whereas different phosphagens occur in various animals, all of them contain two common chemical units—a guanidino group and a phosphoryl group.

Phosphagens

The reaction for the rebuilding of the ATP that is utilized during contraction in vertebrate muscle can be written as follows:

$$\text{ADP} + \text{PCr} \rightarrow \text{ATP} + \text{Cr}.$$

The phosphagen, phosphorylcreatine (PCr), gives rise to creatine (Cr) upon the formation of ATP. This reaction is catalyzed by the enzyme ADP: creatine phosphoryl transferase.

Resting skeletal muscle has about ten times more phosphagen compound than ATP. During rapid and intense contraction, the phosphagen can be utilized to rebuild ATP rapidly and maintain its level in the muscle only so long as the phosphagen lasts, which in a maximally working human muscle is just a few seconds. The phosphagen level is replenished after contraction by a reversal of the reaction given previously. In this reaction, ATP is utilized to form phosphagen (PCr) from creatine (Cr); ADP is also formed.

$$\text{ATP} + \text{Cr} \rightarrow \text{ADP} + \text{PCr}$$

This occurs at the same time that ATP is produced by various reactions that are described in a later section.

As mentioned earlier, changes in the ATP level during contraction are difficult to measure. Such changes can be observed, however, when the muscle is treated with the chemical 2,4-dinitro-fluorobenzene (DNFB), which inhibits the enzyme ADP:creatine phosphoryl transferase. In DNFB-treated muscles, the ATP level decreases during contraction; the ADP and phosphate (P_i) levels increase, and phosphorylcreatine and creatine levels remain constant. The mechanical properties of DNFB-treated muscle during maximal contraction are the same as those of untreated muscles, except that DNFB-treated muscle runs out of ATP sooner and therefore contracts for a shorter time.

The amount of phosphagen is higher in skeletal muscle than it is in cardiac or smooth muscle. This correlates

with the type of activity of the muscles. Skeletal muscle operates in bursts of activity, whereas cardiac and smooth muscle contract in a regular pattern. Skeletal muscle needs an immediate supply of a large amount of ATP, which is provided by the phosphagen reaction; cardiac and smooth muscle, which use ATP at a lower rate, rely on slower reactions to fill their energy requirements.

METABOLIC PATHWAYS PRODUCING ATP

ATP from the sugar glucose or a derivative

In skeletal muscle most of the ATP is produced in metabolic pathways involving reactions of the sugar glucose or some other carbohydrate derived from glucose. During contraction, for example, glucose is made available for these reactions by the breakdown of glycogen, the storage form of carbohydrate in animal cells. During the recovery period following relaxation, the glycogen supply is replenished by synthesizing glycogen from glucose brought to the muscle in the blood.

The glycolytic pathway. In all but the most brief, intense contractions—during which phosphagen is utilized to form ATP—additional ATP is supplied by a set of chemical reactions called the glycolytic pathway, or the Embden-Meyerhof-Parnas pathway. These reactions are especially important when the muscle is doing work at a high rate. The enzymes that catalyze these reactions are located in the sarcoplasm, as is glucose, the major starting material. The glycolytic pathway can be summarized as follows: reactions of glucose to lactate are coupled to formation of ATP from ADP and phosphate.

$$\underset{\text{glucose}}{C_6H_{12}O_6} + 2\ \text{ADP} + 2\ P_i \rightarrow \underset{\text{lactate}}{2C_3H_6O_3} + 2\ \text{ATP} + 2H_2O$$

As already indicated, ATP is broken down in the contractile reaction to form ADP and P_i, which can then be recycled into the pathway. The lactate, a waste product, diffuses out of the muscle and is transported by the blood to the liver. The removal of lactate from the muscle is slower than its production; if the muscle contracts for an extended period, the accumulation of lactate in the muscle causes fatigue and ultimately muscle cramps.

Most of the lactate taken to the liver is converted to glucose, from which glycogen is formed in a series of reactions that require ATP to provide more ATP. About one-sixth of the lactate is oxidized to carbon dioxide and water through metabolic pathways such as the Krebs cycle and oxidative phosphorylation. Because these reactions require oxygen after the exercise is done, a so-called oxygen debt accumulates during brief intense exercise. Animals breathe hard after intense exercise to supply the oxygen needed for the reconversion of lactate.

The relative speed of glycolysis

The glycolytic pathway can operate up to 1,000 times faster in a contracting muscle than it does in a resting muscle. Two regulatory mechanisms play roles in the increase in the rates of these reactions. First, reacting compounds (reactants) accumulate; for example, more glucose is available because glycogen breakdown increases during contraction, and ADP and P_i accumulate. The second type of regulation depends on the activity of the enzyme phosphofructokinase, which catalyzes one of the early steps in glycolysis. This enzyme can unite with, or bind, either ATP or AMP. When ATP is bound, the activity of the enzyme is low; that is the reaction it catalyzes proceeds slowly. When AMP is bound, however, the enzyme has a high activity. During contraction the ATP level drops and that of ADP increases; ADP, in turn, produces AMP as well as ATP, in a reaction catalyzed by the enzyme adenylate kinase, or myokinase. The AMP then can bind with the phosphofructokinase, thereby accelerating glycolysis and the production of ATP. The formation of ATP in the myokinase reaction enables the muscle to use the energy in the ADP formed during contraction.

The oxidative pathways. A large amount of ATP is produced by the complete oxidation of carbon-containing compounds (*e.g.*, glucose) to carbon dioxide and water in reactions of the Krebs cycle and oxidative phosphorylation. These reactions take place inside the membrane-bound components of cells called mitochondria. Carbohydrate can enter the oxidative pathways at a branch point in the glycolytic pathway. At the branch point, two kinds of reaction can occur: pyruvate, a three-carbon compound, can either react to form lactate or lose a carbon dioxide molecule to form a two-carbon unit, which then enters the Krebs cycle. If the muscle is working hard and using ATP rapidly, lactate is formed. If it is working slowly, a larger fraction of the carbon enters the oxidative pathways.

During reactions of the Krebs cycle, carbon dioxide and hydrogen atoms are removed from the compounds that enter the cycle. The carbon dioxide diffuses out of the muscle and is carried by the blood to the lungs, where it is exhaled. The electrons from the hydrogen atoms are passed through an electron-transport chain consisting of the series of reactions involving cytochrome molecules. These events occur in the mitochondria, in which ADP is also combining with phosphate (P_i) to form ATP. In the last step of this reaction sequence, the hydrogen atoms combine with oxygen to form water. The net reaction for each glucose molecule that enters the glycolytic pathway and proceeds through the Krebs cycle and oxidative phosphorylation is summarized below.

$$\underset{\text{glucose}}{C_6H_{12}O_6} + 6\ O_2 + 38\ \text{ADP} + 38\ P_i \rightarrow 6\ CO_2 + 38\ \text{ATP} + 44\ H_2O$$

Efficiency of oxidative pathways

Although the oxidative pathways result in the formation of more ATP from each glucose molecule than does the glycolytic pathway, the complete process is much slower than glycolysis. The rate of ATP production by the oxidative pathways is limited by the rate at which starting materials can be delivered to the mitochondria. The slowest steps are those involving the passage of the carbon-containing compounds from the sarcoplasm into the mitochondria and the delivery of oxygen, which ultimately comes from the air that is breathed. In red blood cells oxygen is combined with hemoglobin, a protein containing four identical subunits, during its transfer from the lungs to the muscles. Muscle contains myoglobin, which has a structure similar to a single subunit of hemoglobin. Myoglobin, which combines with and can store oxygen, is responsible for transporting much of the oxygen through the sarcoplasm to the mitochondria. Myoglobin is especially important in the heart and "red" muscles, which rely heavily on oxidative metabolism for the production of ATP.

During intense exercise of skeletal muscle, ATP is supplied almost entirely by carbohydrate metabolism. During rest or very light exercise, however, skeletal muscle depends largely on the oxidation of stored fats for the production of ATP. Two-carbon units and hydrogen atoms are removed from fats in a stepwise fashion. The two-carbon units enter the Krebs cycle, as do the identical units derived from carbohydrates, as the compound acetyl co-enzyme A. The hydrogen atoms from the breakdown of the fat and from the reactions of the Krebs cycle proceed through oxidative phosphorylation, and ATP is produced.

Heart muscle, which operates constantly but at a lower level of intensity than does skeletal muscle, also depends on oxidative reactions for ATP. Most of the two-carbon units, however, are derived from either fatty acids or ketones, components of fat, brought to the heart by the blood (see also METABOLISM for further detail on metabolic pathways).

MOLECULAR COMPONENTS

The myofilaments, which are the structural elements responsible for muscle contraction, are composed of several different proteins, constituting about 50 percent of the total protein in muscle. The other 50 percent consists of the proteins in the Z line and M band, the enzymes in the sarcoplasm and mitochondria, collagen, and the proteins in membrane structures. Of the myofilament proteins, myosin and actin are known to play a direct part in the contractile event. Troponin and tropomyosin, which are located in the thin filaments, regulate contraction by controlling the interaction of myosin and actin.

Myosin. Myosin makes up more than half of the myofilament protein and is the major component of the thick filaments in muscle. Each molecule of myosin has a mo-

lecular weight of about 500,000 and contains two long protein chains and two or three short chains. Each of the long chains has a molecular weight of 225,000 and contains an estimated 1,800 amino acids; they are, in fact, the longest protein chains that have yet been studied.

The myosin molecule can be split to produce two fragments, light meromyosin (LMM) and heavy meromyosin (HMM).

LMM and HMM fragments of myosin

The LMM portion, about 80 nanometres long, contains most of the tail region of the original myosin molecule. In it each of the two long chains of protein is in a helical conformation, and the two chains are wound around each other to form a so-called superhelix. The LMM portion forms the backbone of the thick filament in the muscle. The HMM portion, also about 80 nanometres long, consists of two globular head regions attached to a part of the superhelical tail region of the myosin molecule. It forms the cross bridges that protrude from the thick filaments in muscle and interact with the thin actin-containing filaments. HMM contains the enzymatic site that catalyzes the splitting of ATP.

There are some structural differences in myosins isolated from different muscles within the same animal and from muscles at different stages of development. Myosins from muscles in the fetus and the adult of the rabbit, for example, contain different amounts of unusual amino acids (*e.g.*, methylhistidine) and have different degrees of sensitivity to trypsin, an enzyme used to split the myosin molecule.

In addition to forming an important structural part of the thick filaments in muscle, myosin has enzymatic activity: it catalyzes the splitting of ATP in muscle. Of the known chemical reactions that occur during contraction, this one is most closely associated with the actual contractile event. Isolated myosin splits ATP, but its properties are modified by the presence of actin and other myofilament proteins in the muscle.

Several factors influence the enzymatic activity of myosin—*i.e.*, the rate at which the breakdown of ATP proceeds. The presence of other muscle proteins is one factor. The activity of myosin is also very strongly dependent on the amount of magnesium ion or calcium ion present.

Actin. Actin, which constitutes about 25 percent of the protein of myofilaments, is the major component of the thin filaments in muscle. An individual molecule of actin is a single protein chain coiled to form a roughly egg-shaped unit. Actin in this form, called globular actin or G-actin, has one calcium ion and one molecule of ATP bound to it. Under the proper conditions G-actin is transformed into the fibrous form, or F-actin, that exists in the thin filament in muscle. In F-actin the globular units are in two long strands twisted around each other. When the G-to-F transformation takes place, the ATP bound to G-actin breaks down, releasing inorganic phosphate (P_i) and leaving an ADP molecule bound to each actin unit. The transformation of G-actin to F-actin is a complex reaction in which specific sites on the molecules must interact during the transformation process.

Transformation of G-actin to F-actin

Actomyosin. Mixtures of isolated myosin and actin are used to study the relationship between the ATP breakdown reaction and the interaction of myosin and actin. The ATP reaction can be followed by measuring the change in the amount of a reactant, or product, present in the solution. The myosin–actin interaction also changes the physical properties of the mixture. If the concentration of ions in the solution is low, myosin molecules aggregate into filaments, and the solution is viscous. As myosin and actin interact, they squeeze out water and form a tight compact gel mass; the process is called superprecipitation.

Purified actin and myosin, in the presence of magnesium ions and ATP, superprecipitate and split ATP. If troponin and tropomyosin are also present, however, the actin and myosin do not interact, and ATP is not broken down. This inhibitory effect corresponds to the state of relaxation in the intact muscle. When calcium ions are added, they combine with troponin, inhibition is released, actin and myosin interact, and ATP is broken down. This corresponds to the state of contraction in intact muscle. The exact mechanism by which troponin, tropomyosin, and calcium ions regulate the myosin–actin interaction is not yet known. In the relaxed muscle, each thin filament contains one troponin and one tropomyosin molecule for every seven actin units.

A somewhat different scheme of regulation operates in the muscle of mollusks. As in vertebrate muscles, calcium ions act as the initiator of contraction. The difference is that the component that binds calcium ions in the mollusc muscle is associated with myosin rather than with the actin-containing thin filaments.

MOLECULAR MECHANISMS OF CONTRACTION

Excitation–contraction coupling. The nerve impulse that ultimately results in muscle contraction appears as an action potential at the sarcolemma, the membrane that surrounds the muscle fibre. This electrical signal is communicated to the myofilaments inside the fibre in the following way. When the action potential reaches the opening of the transverse tubules (channels that open through the sarcolemma to the space outside the fibre; see above *Structure and organization: The myofibril*) in the surface of the fibre, it travels down into the fibre along the tubular membranes, which are continuous with the surface membrane, to within a fraction of a micron of each functional contractile unit (Figure 2). In frog muscle the transverse tubules surround the myofibril at the level of each Z line, and in mammalian muscles they are located at the edge of the A bands and I bands. At the triads (the three-element complex consisting of one transverse tubule and two cisternae, which are enlarged saclike membranes) the transverse tubule walls are very close to the membranes of the terminal cisternae of the sarcoplasmic reticulum.

By some as yet unknown mechanism, the change in the electrical properties of the transverse tubule during an action potential causes the very rapid release by the terminal cisternae of relatively large amounts of calcium ion into the sarcoplasm. As the concentration of calcium ions increases in the sarcoplasm, they become bound to the troponin in the thin filaments. This releases (or removes) the troponin–tropomyosin-mediated inhibition of the myosin–actin interaction. As the stimulation of the muscle continues, the terminal cisternae continue to release calcium ions. At the same time, however, some of the calcium ions are being removed from the sarcoplasm by another portion of the sarcoplasmic reticulum, the longitudinal tubules. Once the calcium ions are inside the lumen (cavity) of the longitudinal tubules, many of them slowly diffuse back to the terminal cisternae. Some step in the process of removal of calcium ions from the sarcoplasm by the sarcoplasmic reticulum is an energy-requiring one. The breakdown of ATP is the chemical reaction that supplies the energy, and two calcium ions are apparently removed from the sarcoplasm for each ATP molecule that is split. The exact energy-requiring process is not yet known, but is likely to involve the transport of calcium ions through the membrane into the lumen of the sarcoplasmic reticulum.

The effect of calcium ions

The development of muscular force. Until the early 1950s, most theories to explain muscle contraction were based on the idea that a single structural element, which extended the entire length of the muscle, folded up or changed shape in some way, causing the muscle to shorten. In the early 1950s, however, it became clear that there were two types of filaments in muscle and that neither extended the entire length of the muscle. Furthermore, it was found that the overall length of the filaments did not change during contraction. Those findings ruled out most of the then existing theories about the mechanism of muscle contraction and provided the basis for the now widely accepted sliding-filament theory.

According to the sliding-filament theory, movement involves the two sets of filaments, thick ones and thin ones, which are arranged in an overlapping array in each sarcomere (see Figure 1). Shortening of the entire muscle occurs as the thin filaments on both sides of the A band slide further into the A band (see Figure 7B). As the sliding progresses, the areas of the sarcomere containing only one type of filament—that is, the I band and the H zone—decrease in size because more and more of the thin and

thick filaments overlap each other. On the other hand, the A band remains the same length because the thick filaments do not change in length except in extreme shortening. The distance from the Z line to the edge of the H zone also remains virtually the same length because it is determined by the length of the thin filaments.

Although the sliding-filament theory seems basically correct, it must be expanded to explain certain aspects of contraction: how the force that moves the filaments past each other is generated; how ATP takes part in the process of contraction. A major difference between the various expanded versions of the theory is that some depend on the operation of the cross bridges, while others do not.

Expanded cross-bridge theories

In the cross-bridge theories, the sliding of the filaments is thought to result from the interaction of the cross bridges with the thin filaments during contraction. Each time a bridge links to a thin filament and operates in a specific way (see below), it causes a small movement of the thin filament along the thick filament. Since muscles are able to shorten considerably, requiring sliding of the filaments through large distances, there must be repeated cycles of interaction between a given cross bridge and successive sites on the thin filament.

According to one theory, the cross bridge contains a flexible peptide (*i.e.*, a very short chain of amino acids) with a partly ionized molecule of ATP attached to it. When the bridge is not attached to the thin filament, the negatively charged ATP is repelled by another negative charge in the myosin molecule near the attachment of the peptide to the rest of the myosin molecule. This repulsion maintains the peptide in an extended form, which is partly a random coil and partly the fully extended form (β form). When the muscle is activated by calcium ions and the cross bridge attaches to actin in the thin filament, the charge on ATP is neutralized and repulsion ceases. As a result, the peptide takes on a much shorter folded form (α helix). The formation of hydrogen bonds in this form provides the energy necessary to pull the thin filaments farther into the A band. When the peptide has shortened, the ATP attached to it comes into contact with the myosin ATP-splitting enzyme (ATP-ase) located at the base of the peptide; ATP is split, breaking the link between the thick and thin filaments. The charge repulsion is restored when the ATP is reformed. The peptide is then re-extended into the partly β form and is ready to link with the next site on the thin filament.

In a different model of cross-bridge operation, the cross bridges attach to the thin filament and then tilt the angle of their attachments by an undescribed mechanism. This tilting of the cross bridges pushes the thin filament, producing a sliding motion. ATP is split at some unspecified stage during this process.

Non-cross-bridge mechanisms

In the non-cross-bridge mechanisms, the force responsible for the sliding of the filaments is attributed to electrical forces between the thick and thin filaments—not to the cross bridges or to any other physical link between the filaments. It has been proposed that both sets of filaments (thin and thick) are negatively charged during rest. Following the release of calcium ions, the thin filaments become positively charged and tend to slide into the array of the thick filaments.

III. The nature and properties of cardiac muscle

The heart is the pump that keeps blood circulating throughout the body and thereby transports nutrients, breakdown products, antibodies, hormones, and gases to and from the tissues. The heart consists mostly of muscle, the myocardial cells (collectively termed the myocardium), arranged in several ways that set it apart from other types of muscle. The outstanding characteristics of the action of the heart are its contractility, which is the basis for its pumping action, and the rhythmicity of the contraction.

STRUCTURE AND ORGANIZATION

Because the gross design of the heart as a pump depends on the type of respiratory and circulatory system of the animal, a variety of hearts occur in the animal kingdom. In all hearts, however, the pumping action results from the contraction of at least one chamber. The four chambers of the mammalian heart—the two atria and the two ventricles—are composed primarily of contractile tissue. The atria act chiefly as chambers for receiving the blood. The ventricles, with thicker walls, do most of the pumping.

The myocardial cells. The sheets, or bands, of muscle fibres (myocardial cells) of the ventricles are arranged in a complex pattern. Some encircle only the cavity of the left ventricle. Others surround both ventricles in a helical pattern. This arrangement is advantageous because, when the ventricular muscle contracts, the blood is virtually wrung, rather than pushed, out of the heart.

Intercalated disks

Myocardial cells are branched and form a netlike pattern, with occasional dense regions called intercalated disks at sites where two myocardial cells abut. Each disk shows two distinct regions. One region, which runs perpendicular to the long axis of the contractile filaments, occurs only at the level of the Z line in the sarcomere. The contractile filaments themselves never cross the disk region from one cell to another. The thin filaments branch at this region of the disk, producing a dense region that can be seen in the light microscope. At the intercalated disk the membranes of the two abutting cells are highly folded, providing a large area of contact between the cells and perhaps also adding to the mechanical strength of the tissue. The second region of the intercalated disk occurs at the point at which the membranes of two adjacent cells lie next to each other parallel to the contractile filaments. In this special area, called the nexus, the membranes of the two cells appear to fuse and form a tight junction. It is thought that the nexus areas present a much lower resistance to intercellular electrical communication than usually exists between separate cells. This property enables the heart to respond to stimulation as a single functional unit even though it is composed of many individual myocardial cells.

Other aspects of the fine structure of myocardial cells are similar to those of skeletal muscle cells. Cardiac muscle, however, does not have as extensive a system of sarcoplasmic reticulum as does skeletal muscle. Cardiac muscle seems to depend on the influx of calcium ions from either the extracellular space or some other area during contraction, to supplement the calcium ions released from the sarcoplasmic reticulum.

The pacemakers of the heart. In addition to the cells that look and act like typical muscle cells, the heart contains cells that have very few myofibrils. These cells constitute the pacemaking areas, which are primarily responsible for the rhythmic nature of the contraction and for conducting the activating signal through the heart.

Self-activation of the heart

The autorhythmicity, or self-activating character, of the heart clearly sets it apart from skeletal muscle. Each animal species has a characteristic heart rate determined by specialized cells that constitute the pacemaker of the heart.

In the normal human heart, a group of cells called the sino-atrial node, located on the inner wall of the right atrium, acts as the pacemaker. The node operates in conjunction with a special conduction system that spreads the excitation over the heart, coordinating the progress of its contraction. The system's components are the atrioventricular node and the Purkinje fibres. The atrioventricular node is located in the lower part of the right atrium, close to the septum between the right and left parts of the heart. From the atrioventricular node the network of Purkinje fibres proceeds to the ventricles and then branches out over the surface, penetrating the ventricular walls.

Although the atrioventricular node and the Purkinje fibres have the ability to act as pacemakers—initiating rhythmic contraction of the heart muscle—they do not do so normally. Some unknown mechanism permits the cells with the highest rate of pacemaker activity to dominate those with lower rates of activity. In humans the sino-atrial node, with its intrinsic rate of 70 to 80 excitations per minute, acts as the pacemaker under normal conditions. If it fails to operate for some reason, such as disease, the pacemaker role may be taken over by the

atrioventricular node, whose rate of excitation is 40 to 60 per minute, or the Purkinje fibres, whose rate is 15 to 40 excitations per minute.

MECHANICAL PROPERTIES

The initiation of systole

The contraction–relaxation cycle. The contraction of the heart, or systole, is initiated by the action of the pacemaker, whose cells have special membrane properties that cause them to generate electrical signals spontaneously. When the membrane potential reaches a certain level, an action potential is propagated and is communicated directly to the atrial cells adjacent to the sino-atrial node. The action potential spreads over the atria and activates the myocardial cells, causing them to contract and force blood into the ventricles.

The action potential is then transmitted from the atria to the ventricles via the atrioventricular node and Purkinje fibres. Since the node fibres are smaller than the atrial cells, the progress of the action potential slows at this point, delaying contraction of the ventricular muscle until the atria have emptied their contents into the ventricles. When the action potential has been transmitted through the atrioventricular node, it reaches the larger Purkinje fibres, through which conduction is faster than through the ventricular tissue itself. The Purkinje fibres branch out over the surface of the ventricles and into their thick walls. The widespread distribution of the Purkinje fibres, as well as their speed of conduction, causes the entire ventricular muscle mass to contract almost simultaneously. This contraction forcibly wrings the blood out of the right ventricle into the pulmonary artery toward the lungs and out of the left ventricle into the aorta toward the rest of the body.

The source of the action potential and the conduction pathways for it are especially suited to the function of the heart. The action potential itself has a special characteristic: long duration. It is 20 to 50 times longer than the action potential in skeletal muscle.

Just as in skeletal muscle, depolarization is followed by a time of decreased excitability. The first part of this time is the absolute refractory period, during which the membrane will not conduct an impulse regardless of the strength of the stimulus applied to it. Following this is the relative refractory period, during which the membrane will respond, but the stimulus must be much stronger than normal. In cardiac muscle, the refractory periods outlast the action potential and are almost as long as the contractile response. This ensures that the contractile elements have time to relax before the membrane has recovered its normal degree of excitability. An important consequence of the long refractory period is that cardiac muscle cannot be tetanized to produce constant tension, a safety factor for an organ that depends on the repetition of complete cycles of contraction and relaxation to operate as a pump.

Adaptability of the heart

Regulation of the heartbeat. The fact that the heart beats faster during and after hard work and during periods of excitement or fright exemplifies the remarkable ability of this organ to adapt to the changing demands placed on it by the body. One mechanism responsible for this adaptiveness operates in the heart itself and can be expressed as Starling's law of the heart: the quantity of blood that fills the ventricles during relaxation, or diastole, regulates the force of the subsequent contraction of the ventricles during systole. The more blood that enters the heart, the more vigorous the subsequent contraction. This kind of response helps avoid a backup of blood in the veins and tissues. A similar situation occurs in skeletal muscle.

The pacemaker cells are the sole source of the excitation of the heart and set the normal rate of rhythmic contraction and relaxation. The nerves that serve the heart do not keep the heart beating but act only to modify the rate of the heartbeat; they originate in the medulla oblongata, the basal part of the brain, and consist of two types: inhibitory (the vagus nerves) and stimulatory (sympathetic) nerves.

The vagus nerves innervate the atrial portions of the heart only. They act by releasing acetylcholine, which increases the electrical potential across the cell membranes, and thus slow down or, in extreme cases, stop transmission of impulses in the sino-atrial and atrioventricular nodes. If transmission is stopped, the Purkinje fibres, which are located in the ventricles and therefore are not under the influence of the vagus nerves, may begin to act as pacemaker cells. The sympathetic nerves, found in all parts of the heart, act by releasing norepinephrine. Stimulation of the nerves leading to the sino-atrial node increases the rate of electrical discharge of the node and thus speeds the heartbeat.

METABOLIC PATHWAYS

The myocardium converts chemical energy, derived from nutrients, into the mechanical energy that propels the blood through the body and a certain amount of heat. The molecule used by the contractile elements in the energy-conversion process is ATP (adenosine triphosphate).

One starting material for the production of ATP in the heart is glycogen, which is broken down into glucose units and then metabolized through the steps of the glycolytic pathway (see above *Energy transformations*); three molecules of ATP are formed for each glucose unit. Although the other product, pyruvate, can react to form the compound (acetyl co-enzyme A) that can enter the tricarboxylic acid, or Krebs, cycle, most acetyl co-enzyme A in the heart is formed from free fatty acids brought to the heart in the blood. In the Krebs cycle, the carbon atoms in acetyl co-enzyme A are oxidized to carbon dioxide; the hydrogen atoms formed take part in oxidative phosphorylation, and react with oxygen to form water. During this process three molecules of ATP are formed.

Conversion of glucose to ATP in the heart

Normally, the heart depends on the metabolic processes that take place in the presence of oxygen. If carbohydrate (as glucose) is the starting material, 38 molecules of ATP are produced for each glucose unit metabolized. If fats are the starting material, 12 molecules of ATP are produced for each two-carbon unit derived from free fatty acids. If the oxygen supply to the heart is limited, some ATP can be formed through the glycolytic pathway, by the metabolism of glucose to pyruvate and then to lactate. Under completely anaerobic conditions (no oxygen at all), however, the amount of ATP produced is inadequate to keep the heart functioning for very long.

IV. The nature and properties of smooth muscle

VERTEBRATE SMOOTH MUSCLE

The term smooth muscle derives from the uniform appearance of the cytoplasm of stained sections when examined under the low magnification of a light microscope. Although many cellular structures can be seen in the electron microscope, they are not nearly as striking as the internal organization of skeletal muscle cells.

Many organs of vertebrates contain smooth muscle: the stomach, intestines, bile ducts, bladder and urinary tracts, uterus, and blood vessels. Smooth muscle exhibits much variation and is often separated into two major groups—visceral and multi-unit. Visceral muscles operate as a syncytium (*i.e.*, as a single functional unit), and many of them also have pacemaker, or self-stimulating activity. A multi-unit smooth muscle is a group of cells, each of which is subject to nervous control and can act individually in the same manner as individual fibres in a skeletal muscle. Actually, there is probably a wide spectrum of smooth muscle types between these extremes.

Some of the details of the structure and operation of muscle in the intestine and in the vasa deferentia (singular vas deferens, a duct leading from the testes to the penis) are described in this section. These tissues contain muscles that embody the major characteristics of the two categories: intestine representing visceral smooth muscle and vas deferens representing multi-unit smooth muscle.

Visceral, or single-unit, muscle. *Structure and arrangement.* The individual smooth muscle cell of the intestine is often roughly spindle-shaped, wide in the middle and tapering to the ends; some are ribbon shaped or rod shaped. In the thickest middle section the diameter is usually five to ten microns (μ), ten to 20 times smaller

Size of smooth muscle cells

than skeletal muscle fibres. The length of a smooth muscle cell ranges between 50 and 500 μ. How closely packed the cells are depends on the tissue and is correlated with its operation. In syncytial-type muscles of the intestinal walls, the cells are often arranged in branched groups, or bundles, of a few hundred cells. Adjacent cells in a bundle are usually separated by 50 to 80 nanometres of basement membrane. The bundles of cells are separated from each other by layers of collagen fibrils and elastin. Blood vessels and nerves may also occur in the extracellular spaces.

Smooth muscle cells have an ellipsoidal nucleus in about the middle of the cell. Mitochondria, endoplasmic reticulum, and, in some cells, glycogen granules are present. Thin filaments have a diameter of 50 nanometres and contain the proteins actin, tropomyosin, and troponin, just as do the thin filaments of skeletal muscles. Recent studies have disclosed thick filaments as well (these apparently were destroyed by the preparation procedures used in earlier electron-microscopic studies).

Several features of the arrangement of the filaments within smooth muscle set it apart from other types of muscle. The thick filaments, surrounded by many thin ones, are not arranged in a regular array as they are in skeletal and cardiac muscle. Neither does smooth muscle contain Z lines; however, there are scattered dense regions that may represent a structure analogous to the Z line. In some cells, thin filaments converge at the dense regions; other thin filaments are attached to the cell membrane. Despite the relatively low degree of order in the arrangement of the filaments, the sliding-filament mechanism is thought to operate during contraction of smooth muscle.

Like cardiac muscle, some smooth muscle has regions of close contact between individual cells. The membranes of adjacent cells occasionally come into very close contact forming nexuses, areas of cell-to-cell communication that enable the muscle to function as a syncytium. There are also small bridges between cells and fingerlike projections at the ends of cells.

Contraction in the form of peristaltic waves

Nature of contraction. In most of the tubular organs, smooth-muscle contraction is in the form of peristaltic waves. A small area of the contraction partly encircles the tube and moves along it for only a short distance before fading.

Unlike other excitable tissues, such as nerve and skeletal muscle, the membrane potential is constantly drifting or fluctuating rather slowly. A burst of action potentials, however, accompanies contraction. These signals originate in many regions of the intestinal muscle that act as pacemakers. Specific pacemaker cells such as are found in the heart apparently do not occur; instead pacemaker activity continuously moves to different smooth muscle cells of the intestine.

In pacemaker regions the membrane slowly and spontaneously depolarizes. These slow potentials, or slow waves, are small and spread in a diffuse way. They do not directly cause contraction of the muscle; however, when the slow potential reaches the threshold value for the membrane, action potentials are propagated. These pass from cell to cell by way of the nexuses between cell membranes. In this way all the cells in a bundle (of perhaps a few hundred cells) get the signal to contract. There also seems to be some communication between the bundles. A wave of contraction (which may include thousands of cells) then progresses partly around the intestine and then along it for a distance of a few centimetres. Intestinal smooth muscle, therefore, operates as a syncytium. To varying degrees, many other vertebrate smooth muscles, especially in the digestive tract, operate in the same manner.

Variable excitability of intestinal muscle

The electrical, or membrane, excitability of intestinal muscle cells is quite variable. Both the level of the resting potential and magnitude of the threshold potential can change. The activity of the nerves supplying the muscle is one factor that influences membrane properties. The structural relationship of the nerves and muscles differs from that in skeletal muscles. In the taenia coli, a muscle forming a particular part of the large intestine, a bundle of small autonomic nerves surrounded by Schwann cells penetrates the muscle. Occasional portions of the nerves are bare (*i.e.*, not surrounded by Schwann cells), forming areas probably analogous to the synapse region of the motor nerves. Unlike motor nerves, however, these autonomic nerves end at sites about 100 nanometres away from the intestinal muscle, and there appear to be no receptive structures in the muscle membrane opposite the nerve ending.

Despite this lack of highly organized nerve–muscle junction, the nerves do influence membrane properties and intestinal-muscle action. Two types of nerves are involved: the sympathetic nerves, which inhibit contraction (an effect mimicked by the chemical epinephrine), and the parasympathetic nerves, which intensify contraction (an effect mimicked by acetylcholine). Other syncytial smooth muscles, such as the ureter, operate without neural influence; waves of contraction are coordinated by the muscle itself.

The mechanical state of the muscle is another factor that can influence its excitability. When intestinal muscle is stretched, the passive, or elastic, tension in it increases, and the resting potential becomes less negative; *i.e.*, it changes in the direction of depolarization, and the rate of discharge of action potentials increases. The mechanical properties of smooth muscle depend to some extent on the large amount of elastic material in the tissue, which probably contributes significantly to the regulation of contractile activity and to the overall operation of the tissue.

Multi-unit muscle. The other type of vertebrate smooth muscle is the non-syncytial, or multi-unit, muscle, as exemplified in the vas deferens. The vasa deferentia do not have pacemaker activity but depend entirely on the nerves for activation. The nerves lie in depressions in the muscle, a much closer spatial relationship between nerve and muscle than occurs in syncytial smooth muscles. Every muscle cell of a vas deferens has at least one nerve ending associated with it. The nerve endings contain two types of vesicles: granular vesicles, which contain compounds resembling adrenaline that probably act as transmitters, and agranular vesicles, which contain acetylcholine, the chemical transmitter in vertebrate skeletal muscle. When a single nerve impulse occurs, it results in a small change in the membrane potential of the muscle cell. This change, called a junctional potential, is probably caused by the direct influence of a transmitter substance on the muscle membrane. Junctional potentials resulting from a series of nerve impulses can accumulate, progressively depolarize the membrane, and attain the threshold, at which point action potentials are propagated. The transmitter apparently is not rapidly destroyed since it seems to diffuse to other cells in addition to the one closest to the nerve ending.

Vesicles in nerve endings

INVERTEBRATE SMOOTH MUSCLE

Catch muscle. One of the most interesting types of muscle, invertebrate "catch" muscle, contains the protein paramyosin. The muscles are present in clams, scallops, and oysters, animals with two shells. The paramyosin-containing fibres are in the adductor muscles that hold the shells closed, an action accomplished by maintaining tension against a springy ligament at the hinge point of the shells. When the adductor muscles relax, the ligament is released, and the shells open by spring action. The remarkable aspect of the adductor muscles is that they can remain contracted continuously for weeks. This type of contraction is called the "catch" state.

Structure and arrangement. The cells of the catch muscles are very long and contain two types of filaments. One type, similar to the thin filaments in striated skeletal muscle, contains the protein actin and has the same dimensions as a skeletal thin filament. The other kind of filament, however, is unique to catch muscles. It contains both paramyosin and myosin: the core of the filament is paramyosin and the covering is myosin. It ranges in diameter from 30 to 150 nanometres—about ten times greater than a thick, myosin-containing filament found in striated skeletal muscle or heart muscle. The paramyosin-contain-

ing filaments are about 30 nanometres long—about 20 times longer than the myosin-containing filaments in skeletal muscle.

Nature of contraction. Evidence suggests that contraction in catch muscles is based on actin–myosin interaction and a sliding-filament mechanism. Paramyosin may modify this interaction and confer the special properties of the catch state. It may also be responsible for the great mechanical strength of the filaments in these muscles.

The catch state resembles the tetanized state of skeletal muscle in that a constant amount of tension is maintained by the muscle. The relationship of the membrane activity to contraction in the two cases is, however, quite different. A skeletal muscle can be tetanized by stimulating it electrically so that action potentials are continuously propagated, and relaxation is impossible. If the rate of stimulation is too low, tetanus does not result, and the tension will rise and fall in phase with the membrane potential. In the catch state, on the other hand, bursts of action potentials appear intermittently, but the tension in the muscle is not synchronized with them.

Since catch muscle can remain contracted even when the membrane is quiescent, how is the contraction turned off? What induces relaxation? Experiments on muscles removed from animals suggest that certain nerves may cause relaxation from the catch state by releasing serotonin, a chemical found in muscle, which acts as an inhibitory transmitter substance.

Experimental stimulation of catch muscle

Mechanical properties. If an isolated catch muscle is stimulated with direct electrical current or by application of acetylcholine, the muscle goes into the catch state, a steady tonic contraction. The same kind of muscle can be made to contract and relax rapidly like a vertebrate skeletal muscle by stimulation with alternating electrical current. This twitchlike response is called a phasic contraction. The mechanical properties of the muscle are quite different in these two kinds of contractions. If a muscle is stretched while in the catch state, it resists the stretch with a much greater force than when it is stretched during a phasic contraction. In other words, the muscle has greater stiffness in tonic contraction than it has in phasic contraction. At any given moment in the catch state, there are apparently more cross-bridge links than in a phasic contraction.

Metabolic pathways. In catch muscles, as in the muscles of vertebrates, ATP is the molecule believed to be directly involved in the energy-transforming processes. During contraction ATP is broken down; it can be reconstituted rapidly by the transfer to ADP of a phosphoryl group from phosphorylarginine, a phosphagen compound. Although catch muscles break down an appreciable amount of ATP during the development of tension, the maintenance of contraction requires only a small amount of ATP breakdown. This is certainly an important factor underlying the ability of catch muscle to remain contracted for a long time without fatiguing.

Quick action muscle. The muscles that operate the wings of some insects contract very rapidly indeed and, weight for weight, can produce more work per second than any other type of muscle. These asynchronous flight muscles are found in insects (*e.g.*, bees, flies, and mosquitoes) that have great manoeuverability during flight. Insects such as butterflies have synchronous muscles, similar to those of other animals. One major difference between the two types of muscle is in the relationship of the nerve impulses to the contractions of the muscle. In synchronous muscle, contraction is produced in direct response to, or is synchronized with, the arrival of nerve impulses at the muscle. In asynchronous muscle, on the other hand, contraction and relaxation proceed at a rate much faster than that at which nerve impulses reach the muscle, more than 1,000 cycles per second in the flight muscles of gnats, for example.

Asynchronous flight muscles

The basis for the differences between these muscles is not completely known. Although asynchronous muscle has a highly organized internal structure similar to that of synchronous muscle, it lacks an extensive sarcoplasmic reticulum, and so the calcium released during activation of the muscle is not removed rapidly from the sarcoplasm. Asynchronous flight muscles thus remain activated during a series of contraction–relaxation cycles. Rapid shortening of the muscle causes an immediate loss of force. The subsequent stretching of the muscle is caused by the elastic properties of the thorax of the insect and results in the redevelopment of tension.

Another striking example of rapid movement is the jumping of an insect such as the flea. The muscle in this action is not a particularly rapid acting muscle; it contracts powerfully and stretches a tendon, thus bending the insect's leg. The quick relaxation of a complementary muscle allows the leg to extend extremely rapidly, using the elastic energy of the stretched tendon.

(R.E.Da./N.A.C.)

Muscle Diseases

Muscles are bodily tissues that by the contraction of their fibres perform mechanical functions such as those concerned with movement, sustaining weight, balancing, or with narrowing the bore of blood vessels. The voluntary muscles, also called the skeletal muscles, are the muscles of the arms, legs, trunk, neck, and face that are subject to conscious control. It is these muscles that are referred to in the term muscle diseases. Disorders affecting the involuntary muscles, the muscles not subject ordinarily to conscious control, such as those in the walls of blood vessels or of the intestines, are considered to be among the diseases or disorders of the bodily systems of which the muscles are a part—the digestive system, the respiratory system, or the cardiovascular system, for example. (The disorders and diseases of the third type of muscle, that of the heart, are also dealt with in discussions of cardiovascular diseases rather than of diseases of muscle.)

Causes of muscle disease

Voluntary muscles constitute a major part of the human body and are involved in a wide variety of disease states. Muscle disorders may stem from local disorders, such as injury, local disturbance of the blood circulation, local infection, or disuse, or from the general effects of serious systemic disease, including cancer, chronic infections, diseases involving the endocrine (ductless) glands and nutritional deficiencies. There are also primary diseases of muscle (*e.g.*, muscular dystrophy; see below *The muscular dystrophies*), which have been a field of major re-

search in recent years. Nerve and muscle operate as a functional unit, and disease of the motor neurons results in muscular atrophy (wasting) and paralysis. (Neurons are nerve cells; sensory neurons are stimulated by impulses from sensory organs, such as those in the skin or the nose; motor neurons transmit impulses to the muscles and glands, controlling their functioning.)

Dealt with in this article are the manifestations of muscle disease with a note on the abnormalities found in diseased muscle tissue. Included are brief discussions of some of the more important varieties of muscle disease, including some information on their causes, how they are identified, the type of treatment employed, and the outlook for recovery.

COMMON INDICATIONS

Muscular wasting (atrophy) and weakness are among the most common indications of muscular disease. Though the degree of weakness is not necessarily proportional to the amount of wasting, it usually is so if there is specific involvement of nerve or muscle.

Pain is ordinarily present in muscle disease due to defects in blood circulation or injury or involving inflammation of the muscle. It is rare, except as a result of abnormal posture or fatigue, in muscular dystrophy—a familial disease characterized by progressive wasting of the muscles. Cramps are associated with disease of the nerve cells, either motor or sensory; with biochemical disorders (*e.g.*, they may occur in hypercalcemia, a condition in which the blood level of calcium is abnormally high); when the muscle tissues are affected by some form of poisoning; and as a result of disease of the blood vessels. But cramps may also occur when untrained persons exercise, particularly when they are cold.

Enlargement of muscles—muscular hypertrophy—occurs naturally in athletes. Hypertrophy not associated with exercise occurs in two unusual forms of muscular dystrophy, known to doctors as myotonia congenita and hypertrophia musculorum vera. (The latter condition combines increased muscle size with strength; in myotonia congenita muscle cramping is an additional feature.) Pseudohypertrophy, muscular enlargement with weakness, occurs in other forms of muscular dystrophy, particularly the rapidly developing variety called the Duchenne type.

Another manifestation of muscular disease, persistent weakness that is made worse by exercise, is the primary characteristic of the disease myasthenia gravis.

Tetany, tetanus, and fasciculation

Tetany is the occurrence of intermittent spasms, or involuntary contractions, of muscles, particularly of the arms and legs and the larynx, or voice box; it results from low levels of calcium in the blood and from alkalosis, an increased alkalinity of the blood and tissues. Tetanus, a similar term, is a state of continued muscle spasm, particularly of the jaw muscles, caused by toxins produced by a particular bacillus, *Clostridium tetani*. Tetanus is also called lockjaw.

The twitching of muscle fibres controlled by a single motor nerve cell, a process called fasciculation, may occur in a normal person but may be an important indication that muscular atrophy is due to disease of motor nerve cells in the spinal cord. Fasciculation is seen most clearly in muscles close to the surface of the skin.

Intermittent claudication (*i.e.*, a temporary lameness accompanied by cramps and pain) results from insufficiency of blood supply to the legs. The pain and cramps, usually centred in the calves and caused by arteriosclerosis (hardening and thickening of the vessel walls) of the arteries of the legs, tend to occur after a period of walking and to disappear after a few minutes of rest.

Characteristic changes in diseased muscle tissue are evident when specimens of the tissue are examined under a microscope. In muscular dystrophy there is gross variation in fibre size, with splitting of fibres and presence of increased fat and connective tissue within the muscle. In atrophy due to nervous-system disease, groups of atrophied muscle fibres can be seen. In inflammatory disease, fibres that are injured or dead are present, and large numbers of the cells that ordinarily swarm to areas of inflammation can be seen.

TYPES OF MUSCLE DISEASE

Secondary effects of systemic disease. Mention has already been made of the effects produced on the muscles by diseases of the nervous system and of the blood vessels. Other conditions involving the muscles include a group of conditions of unknown cause in which nonbacterial inflammation of the muscles is a prominent feature; muscle disorders caused by endocrine and metabolic disease; disorders due to nutritional deficiencies or intoxication (poisoning); and those associated with cancer.

Inflammatory disease of unknown cause. A group of diseases, of which dermatomyositis and polymyositis are the most important members, has nonbacterial inflammation of the muscles as a prominent feature. Various suggestions have been made as to the origin of these diseases. They include virus infection and auto-immune disorders (allergic reaction to one's own tissues). Many types of polymyositis have been differentiated. At least two of the types affect women in disproportionate numbers, and one type is found in children. Another is associated with cancer. Rash and inflammation of the joints may be present. Treatment with hormones from the adrenal cortex (the outer substance of the adrenal gland) or with synthetic substances for these hormones is beneficial. Formerly acute polymyositis was generally fatal, from effects on the respiratory system, the heart, or the kidneys. Some affected persons now recover, although muscular weakness usually persists.

Nonbacterial inflammation

Endocrine and metabolic disorders. In thyrotoxicosis, a systemic disease caused by overactivity of the thyroid gland, muscular weakness and atrophy are frequently present and may be the first manifestations of the disease. The protrusion of the eyes that is often a feature of thyrotoxicosis is due to the collection of abnormal quantities of fluid in the soft tissues of the eye socket; among these tissues are the extraocular muscles, which control the movements of the eyes.

In myxedema, a conditon resulting from insufficient secretion by the thyroid gland, movements are often slow and the muscles weak and easily fatigued.

When the parathyroid glands are overactive for any reason, there may be substantial muscular weakness, occasionally with muscle cramps and pains. The same set of manifestations occurs when there are abnormally high levels of calcium in the blood for other reasons, which may include the existence of cancer.

Diseases of the pituitary and adrenal glands may cause muscular weakness and wasting. On the other hand, increased muscle bulk and strength may be found early in the course of acromegaly, a disease marked by enlargement of both bony and soft parts of the hands, feet, and face. Acromegaly results from oversecretion of the growth hormone by the anterior lobe of the pituitary. As the condition progresses, the increased muscular strength gives way to weakness.

Cushing's syndrome and Addison's disease

Cushing's syndrome involves weakness of the muscles, particularly of the shoulders, pelvis, and trunk. This condition, the effects of which include fattening of the face, neck, and trunk, impotence, hairiness in females, and high blood pressure, results from abnormally high secretion of adrenal hormones.

Generalized weakness and fatigability of the muscles are also symptoms of Addison's disease, in which reduced secretion of adrenal hormone results in reduced blood levels of sodium and chloride and raised potassium levels, conditions that are probably directly responsible for the effects on the muscles. Limpness and weakness of muscles may occur in any situation in which the blood levels of potassium are abnormally low, as in certain forms of kidney disease and periodic paralysis, a rare hereditary disease.

The carbohydrate glycogen is an important source of muscle energy, and muscle weakness is found in a rare but important group of hereditary diseases, the so-called glycogen-storage diseases, in which various enzyme defects prevent the release of energy by the normal break-

down of glycogen in muscles. As a result abnormal amounts of glycogen are stored in the muscles and other organs. The best known type clinically affecting muscles is McArdle's disease, in which the muscles are unable to degrade glycogen to lactic acid on exertion because of the absence of the enzyme phosphorylase. With a microscope, abnormal accumulations of glycogen can be seen distributed within muscle cells. Features of the condition include pain, stiffness, and weakness in the muscles on exertion. McArdle's disease usually begins in childhood. No specific treatment is available, and persons affected are usually required to restrict exertion to tolerable limits. The condition does not appear to become steadily worse, but there are threats to continuing activity and to life when the muscle protein myoglobin is excreted in the urine or when cardiac problems develop.

Symptoms similar to those of McArdle's disease occur when there is a deficiency of the enzyme phosphofructokinase.

Another glycogen-storage disease results from deficiency of acid maltase, an enzyme normally distributed widely in the body. In this disease both heart and voluntary muscle is affected, and death occurs within a year or so of birth as a rule.

Nutritional disorders and toxic conditions. In man, muscular weakness associated with deficiencies of specific nutrients usually derives from damage to the nervous system. Muscle disorder can derive from vitamin D deficiency. In cystic fibrosis of the pancreas, a disease in which abnormal spaces and accumulations of fibrous tissue are found in the pancreas and in which other abnormalities occur involving the lungs, the liver, and the exocrine glands (glands that have ducts), the muscle weakness that occurs is thought to be due to lack of vitamin E.

Cystic fibrosis of the pancreas

Muscle disorders can be caused by poisoning with any of a number of substances. There are two types of muscle disease in chronic alcoholics: an acute form is characterized by muscular pain, tenderness, and swelling, with excretion of the muscle protein myoglobin in severe cases; in a less acute form, weakness with little wasting develops over the course of a few weeks. Recovery occurs in both varieties if alcohol is not consumed. Carbon monoxide poisoning can cause damage and death of muscle tissue. Chloroquine, an antimalarial drug also used in the treatment of other diseases, may have a toxic effect upon muscle tissue, as may vincristine sulfate, a preparation employed in the treatment of malignant disease.

Malignant disease. The direct invasion of muscles by primary cancer is more common than the involvement of muscles by metastases (*i.e.*, secondary cancers that develop at a distance from the primary site). Muscle disorders are encountered that result from metabolic diseases associated with cancer. Characteristic weakness and other abnormalities of the shoulder and pelvic muscles and muscles of the trunk have been reported in persons with lung cancer. A linkage between dermatomyositis and cancer has been reported for many years. Indeed, the presence of certain types of muscle disorder, such as those mentioned of the shoulder and pelvic muscles, may be the first indication of cancer.

Aging. Muscle bulk and strength both diminish with the coming of old age, although the loss of strength does not equal that of size. Pathologic changes found in muscles of the aged include reduction in the number of fibres with irregular reduction in their bulk; appearance of pigment; and increase in fat cells and connective tissue.

Primary muscle diseases and disorders. *Myoglobinuria.* Myoglobinuria, the excretion of the muscle protein myoglobin in the urine, is a warning of the serious danger of kidney disease. It occurs as the result of crush injuries to the muscles or of death of muscle tissue because of interference with the blood supply. It also occurs from metabolic disease, polymyositis, and poisoning of the muscle tissues, as from eating contaminated fish. Myoglobinuria can also occur in young men after heavy exertion and in young children experiencing acute infections.

The muscular dystrophies. The muscular dystrophies are a group of hereditary disorders characterized by progressive muscular atrophy and weakness. In most varieties the muscles of the limb girdles—the pelvic and shoulder muscles—are involved.

In contrast to the several varieties of muscular dystrophy that are relatively benign, the Duchenne type, which commonly affects boys in early childhood, steadily grows worse and usually ends fatally in adolescence. The first symptoms include difficulty in walking, rising from the floor, or climbing stairs. Certain muscles, usually of the calves, buttocks, and thighs, become enlarged but weaker (a condition called pseudohypertrophy) in the early stages. Death is from heart failure or respiratory complications.

Duchenne type of muscular dystrophy

The myotonias are a subgroup of the muscular dystrophies. In dystrophia myotonica, a form of muscular dystrophy that affects both sexes, muscular weakness and wasting are accompanied by myotonia, the continuation of muscular contraction after the cessation of voluntary movement. After the eyelids have been firmly shut, for example, by a person affected by this disorder, he may be unable to reopen his eyes instantly. Other features of dystrophia myotonica include premature baldness, emaciation, atrophy of the sex glands, cataracts (opacity of the lenses of the eyes), abnormalities of the heart, diabetes, and mental changes. Disability can be evident in childhood but usually is first noticed in adolescence or early adulthood. The condition becomes progressively worse, although some affected persons survive into extreme old age.

Two other types of myotonia are myotonia congenita, or Thomsen's disease, and paramyotonia congenita. The former is a familial disorder causing widespread muscular hypertrophy and stiffness that is relieved by exercise and made worse by rest and by cold. It becomes evident in early life. The tendency toward a delay in relaxation of muscles after they have undergone a vigorous voluntary contraction tends to diminish in later years. Paramyotonia congenita is characterized by myotonia on exposure to cold and by attacks of generalized muscular weakness.

Although muscular dystrophy cannot be cured, remedial devices and measures, including physical therapy, if not carried to the point of fatigue, spinal supports, and splints for the limbs, may be useful. Prevention of obesity is considered important, especially in the Duchenne type of dystrophy, and infections are promptly eliminated. The identification of carriers of the trait and genetic counselling represent the best hope of reducing the incidence of this group of diseases.

Myasthenia gravis. Myasthenia gravis, which results from a failure in the transmission of nerve impulses to the muscles, is characterized by persistent muscular weakness and a tendency of muscles to be easily fatigued. Estimates of the prevalence of the disease range from one in 10,000 to one in 50,000. It is considerably more common in women than in men.

In milder cases weakness may be limited to a few muscles—for example, those that move the eyes or are concerned with swallowing and with speech; in severe cases fatigability and paralysis may be widespread.

The most active stage of the disease is during the first five years, during which there may be a threat to life; thereafter the risk to life is less, but there may be serious continuing disability. The diagnosis is made from the response of the muscular weakness to cholinergic drugs. These are drugs that liberate acetylcholine, a substance involved in the transmission of nerve impulses. The cholinergic drugs are also used in treatment of the disorder. Removal of the thymus is also resorted to, especially in young women.

Diagnosis and treatment of myasthenia gravis

Specific inflammatory diseases. Bacterial myositis, inflammation of muscle tissues as the result of infection with bacteria, is commonly localized and is the aftermath of injury. Staphylococcus organisms are usually responsible. General indications of infection, such as fever and increased numbers of white blood cells, are accompanied by local signs of inflammation such as reddening, swelling, and warmth. Abscess formation is rare, except in the tropics. In general, bacterial myositis responds to treatment with antibiotics and with minor surgery. Gas gan-

grene, myositis due to infection with *Clostridium welchii*, is a serious wound infection that poses special problems. Treatment involves combatting the infection, removal of dead tissue, and dealing with shock.

Viral myositis may also occur. The best example of this is Bornholm disease, also called epidemic myalgia, devil's grip, and epidemic pleurodynia, caused by the Coxsackie virus. Affected persons recover completely after a brief period of intense muscular pain and fever.

In addition to bacteria and viruses, the muscles may be invaded by animal organisms, including protozoa, the simplest animal forms, and helminths, or worms. Among the better known examples of worm infestation is trichinosis, infection with the roundworm *Trichinella spiralis* as a result of eating infested pork that has not been thoroughly cooked. Reproduction of the worm takes place in the intestines. Larvae migrate from the intestinal walls and bury themselves in muscle tissue. Fever, muscular pains, and sometimes weakness result from the invasion of the muscles. The clinical course of trichinosis is about two months; most affected persons recover, but death can result from invasion of the heart muscle.

Trichinosis

Effects of injury, exercise, and cold. Muscle can be damaged by direct injury, as by a blow, or from tearing of muscle fibres during heavy work or athletic events. Rupture of muscle fibres is accompanied by bleeding and swelling. Traumatic myositis ossificans may result, in which case there is proliferation of connective tissue in the damaged area of the muscle, followed by the appearance of cartilage and bone. The most familiar example is the development of bony tissue in the muscles on the inside of the thighs in horse riders. Crush injuries of muscle can lead to myoglobinuria and kidney damage. In Volkman's ischemic contracture, which occurs shortly after limb injuries, especially fractures in the region of the elbow joint, the fingers and wrist take on a persistently bent position.

The phenomenon of shin splints, known technically as the anterior tibial syndrome, is well known to athletes. In the early stages of training, the pretibial muscles at the front of the lower legs become swollen and painful. The anterior tibial syndrome is a more profound reaction in the same muscle groups after unusual exertion, especially in the untrained. The muscles are swollen, painful and weakened. In extreme cases permanent muscle damage may result, although local surgery may prevent this.

Muscle damage can follow exposure to cold—for example, when the legs are immersed in cold water for long periods ("immersion" or "trench" foot). The muscle changes are due to impaired circulation and also the direct effects of cold on nerves and muscles.

BIBLIOGRAPHY. A comprehensive modern review of the myopathies will be found in J.N. WALTON (ed.), *Disorders of Voluntary Muscle*, 2nd ed. (1969); this work also contains up-to-date chapters on the anatomy and physiology of muscle. Detailed information on all aspects of the myopathies is contained in R.D. ADAMS, D. DENNY-BROWN, and C.M. PEARSON, *Diseases of Muscle: A study in Pathology*, 2nd ed. (1962). For a comprehensive and authoritative review of the anatomy and physiology of muscle, see G.H. BOURNE (ed.), *The Structure and Function of Muscle*, 3 vol. (1960).

(R.A.He.)

Muscle System, Human

The human muscle system comprises the skeletal muscles —those muscles, sometimes called the striated muscles, that are under voluntary control and are concerned with movement, posture, and balance; the muscles, called smooth muscles, that are under involuntary control and are found in the walls of blood vessels and of such structures as the urinary bladder, the intestines, and the stomach; and the heart muscle, or myocardium. An extensive discussion of these various types of muscle is contained in the articles MUSCLE SYSTEMS and MUSCLE CONTRACTION. The present article is primarily concerned with those changes that occurred in man's muscular system as a result of the long evolutionary process that involved his assumption of an upright posture. Because of the interdependence of the skeletal muscle and bones, evolutionary changes in the latter are also touched upon.

Trend of human specialization. The human muscular system inherits the pattern of vertebrates in general and of mammals in particular. Its most distinctive features reflect varying degrees of success in adapting a quadrupedal type of musculature to the task of controlling an upright biped. Human civilization has been created by emancipated hands, liberated from supportive function by profound redesign of the musculoskeletal complex.

Man has added standing to sitting as a posture of composure. The muscular fatigue that prolonged standing entails has been mitigated by drastic changes in the skeleton. The hip joint and the knee joint have been stabilized in an extended position so that man can stand with hip, knee, and ankle axes in vertical array. This ability minimizes the effect of gravity on the limb segments. Modification of the ankle has allowed the heel to touch the ground and thus has increased the area of foot support. The trunk has been brought into erect position over the hip joints by the development of the lumbar curvature, the curvature in that part of the spine that extends from the level of the chest to that of the pelvis.

Skeletal changes

Even during active locomotion man's hands are free for other employment, since the lower limbs have assumed responsibility for transportation of the rest of the body, the head, arms, and trunk.

Muscles of the lower limb. In addition to the increase in amount of muscle in the lower limb that has brought the mass of each leg to one-sixth that of the body, there have been changes in the relative development of particular muscles. Antigravity muscles, such as the soleus of the calf, the vasti of the thigh, and the gluteus maximus of the buttock, have increased in size. Restriction of the base of support to two feet, as during the process of walking, and frequently to one, has magnified the problem of lateral stability. A tendency to fall sideways is avoided by a change in the arrangement of the ilium, the flat upper part of the hipbone, so that the gluteus medius and minimus muscles are attached to it at the side of the body rather than at the back. The gluteus maximus is enlarged for a different reason: so that it can stretch sufficiently in an oblique direction to decrease the rotation of the trunk and diminish its tendency to jackknife forward when the foot on the opposite side makes contact with the ground. Continued strong development of the adductors, the muscles on the inside of the thighs that bring the thighs toward the midline of the body, is caused by their bending and extending the legs.

The human ankle and foot have undergone drastic redesign. The toes have diminished in size and importance. With prehension (grasping) no longer a function of the first metatarsal (the bone directly in back of the big toe) and the peroneus longus muscle, the muscle remains important as a deterrent of splayed foot. The use of the ball of the foot as a major contact area during propulsion has augmented the importance of the muscles that produce inversion about the subtalar axis (*i.e.*, that lift the heel and lower the ball). Included in this group of muscles is the triceps surae, a calf muscle, the unnatural shortness of which can cause disability. The tibialis anterior, a muscle at the front of the lower leg, prevents the front part of the foot from slapping down after the heel has touched the ground and also lifts the toe when the foot is being swung forward during walking. The plantaris has lost its function of tensing the plantar fascia, a dense, fibrous membrane in the sole of the foot, and is noted in man for the pain that follows rupture of its long tendon.

Muscles of the upper limb. The upper limb of man has retained an overall generalized structure with its details adapted to upright existence. Among the primitive features that persist are the clavicle, or collarbone, that still functions as part of the shoulder; ability to twist one of the forearm bones, the radius, around the other, the ulna, so that the palm is turned forward or backward—a process called pronation-supination—and a full complement of five digits in the hand.

Surviving primitive features

In quadrupedal life the thorax, or chest, is suspended between the shoulder blades by a muscular hammock formed by the serratus anterior muscle. In upright sitting and standing, the shoulder girdle is suspended from the

trunk. The scapula, or shoulder blade, floats over the thoracic surface by reason of the arrangement of the fibres of the serratus anterior muscle and the support against gravity provided by the trapezius, rhomboideus and levator scapulae muscles. When the arms are required to push forward against an object at shoulder level, their action is reminiscent of quadrupedal support.

The change in the shape of the chest to emphasize breadth rather than depth altered the relation of muscles in the shoulder region, with increase in size of the latissimus dorsi muscle and the pectoralis major muscle. The human pectoralis minor muscle has forsaken its attachment to the humerus, the long bone of the upper arm, and presumably derives some stability from attaching to the coracoid process, a projection from the scapula, instead of gliding over it.

The retention of a full-fledged thumb by man distinguishes him from his relatives, who swing through the trees. The muscles that can place the thumb in apposition to the other digits are responsible for human grasp, a manoeuvre that precedes both constructive effort and intelligent inspection.

Muscles of the head and neck. The human head is still evolving. Use of the hands for feeding facilitated a reduction in the size of the jaw, and advances in food processing affect dental function and muscles of mastication. Development of coordinated binocular vision occasioned change in the position of the eye sockets and intricate correlation of the ocular muscles. Control of the apertures of the face by muscles derived from the hyoid arch (the second of the cartilaginous or bony arches that encircle the upper end of the digestive tract in more primitive organisms) has been expanded into the use of facial expression for communication. Increase in the size of the brain has contributed to the positioning of the occipital condyles (rounded projections on the occipital bone, at the base and back of the skull) so that the head balances on the vertebral column with minimum muscular effort.

Muscles of the trunk. The organs of the human trunk must function adequately with the trunk horizontal but must be prepared for maximum activity when it is upright. The weight of the abdominal viscera aids inhalation when the trunk is upright but becomes an expiratory force when the body rests on its back. The muscles of the abdominal wall act against gravity when they contract and force the abdominal viscera upward during upright exhalation. Concurrent changes have taken place in the diaphragm and the muscles between the ribs.

The abdominal pressure that acts on the thorax is even more effective at the pelvic outlet. Its muscular closure involves the perineal muscles (which include the sphincters that close the anus and the urethra), derivatives of the sphincter cloacae (the muscle closing the common passage for urine and feces in lower animals) and the muscles of the pelvic floor. The latter originate from the pelvis and insert on the tail. In man the tail has become vestigial, and the pelvic floor muscles have been renamed the levator ani and the coccygeus.

Muscular compression of the abdomen and thorax aids the vertebral column in supporting the body and providing a firm base for upper limb action. Anteroposterior (fore and aft) stability of the trunk is achieved by balancing the flexing action of gravity against back muscles that act to extend the spine. Lateral stability is enhanced by the augmented lever arms provided the spinal muscles by the broadening of the chest.

Muscle Systems

All animals must either move to find food or, if they are sedentary, have means of bringing food to themselves. Many invertebrates and all vertebrates depend upon contractile tissue called muscle to move themselves about. Muscles in turn are grouped into coordinated systems for greater efficiency.

General features

DEFINITIONS AND DISTINCTIONS

Irritability, the capacity to respond to stimulation, is a property of all living matter. Irritability in which a cell develops an internal tension that usually causes it, or some part of it, to shorten, bend, or otherwise change its shape is called biocontraction and is a widespread, possibly universal, phenomenon in all living cells. In all cases of biocontraction, chemical energy stored in the cell must be transformed into mechanical energy; but how this is done at the biochemical level and the nature of the cellular structures (organelles) involved are only beginning to be understood (see MUSCLE CONTRACTION).

Highly organized fibrillar or tubular elements occur in the cytoplasm of cells with well-developed contractile capability. The various kinds of muscle systems are only one category of specialized contractile system. Other, more widespread ones include the spindle, a temporary organelle that appears in the cytoplasm of a dividing cell (see CELL AND CELL DIVISION), and cilia and flagella that occur on many plant and animal cells. The rapid and dramatic responses of certain plants, such as the sensitive plant and the Venus's-flytrap, are only remotely analogous to the performance of animal muscle (see STEREOTYPED RESPONSE).

Muscle systems can be defined as biocontractile systems in which the cell, or part of it, is elongated and specialized so that it has the ability to develop tension along the axis of its elongation. Often the tension is manifested by a shortening of the cell against a constant force (isotonic contraction), but the ends of the cell may be attached to structures held firmly apart so that an increasing tension is developed without shortening (isometric contraction). The contractile organelles of the cell are minute threads called myofilaments, which extend parallel to the cell's long axis (Figure 1). These myofilaments are so small (50 Å [Ångstroms] to 100 Å) that they can be detected only with an electron microscope, but often they are grouped into larger fibrillar bundles called myonemes and myofibrils, which can be seen with a light microscope. Although the larger fibrillar elements are not always present in muscular systems, the myofilaments are. Myofilaments are composed of protein complexes, the most common one being actomyosin, although tropomyosin comprises the major part of the myofilaments in certain invertebrates.

SIGNIFICANCE OF MUSCLE TISSUE

The importance of muscle systems to animals has been indicated. Most invertebrates and all vertebrates depend upon muscle action to move about in search of food, mates, and a favourable environment. Larger animals with skeletons also depend upon muscle action to help maintain the proper relationships of skeletal elements needed to protect or to support the animal.

The action of muscles

Muscle action propels blood through animal circulatory systems, and in many species it also controls the diameter of peripheral vessels and hence the distribution of blood to the tissues. Muscle action also moves food into and along the digestive tract, water or air across respiratory surfaces, and discharges excretory and reproductive products. It may play the sole role in these processes, as in most vertebrates, or may be assisted by ciliary action, as in many invertebrates.

In addition to these widespread functions, a number of specialized activities are performed by muscles in certain species. Muscles attached to pigment-bearing cells (chromatophores) are responsible for the rapid colour changes of a squid or octopus; they surround certain glands and thus aid in the discharge of secretions; they move the hair of mammals, thereby playing a role in temperature regulation; they may move sense organs, or they may form an

integral part of sense organs, as do the ciliary muscles responsible for accommodation in the eyes of vertebrates and some mollusks.

Muscle contraction is accompanied by electrical phenomena and by heat production, and organisms in fact sometimes make use of these attributes of muscle activity. The electric organs of certain fishes are modified muscular tissue in which the electrical phenomena are accentuated. Body heat derives principally from muscle action. During the isotonic contraction of a typical muscle, only about 40 percent of the energy utilized is converted to work; the rest becomes heat (Figure 2A). In isometric contraction, in which no work other than stretching connective tissues within the muscle is done, most of the energy is released by heat. This heat is simply dissipated by most animals but in the higher vertebrates, particularly birds and mammals, it sustains the high level of metabolism characteristic of these warm-blooded animals. When body temperature falls too low, the rapid-fire involuntary muscle contraction and relaxation called shivering helps to produce heat and restore body temperature.

ARRANGEMENT AND GROSS FUNCTION OF MUSCLE TISSUE

The muscle fibre. Although a few invertebrates have simple muscle systems that involve the specialization of only part of a cell or a few isolated cells, most animals have muscle systems made up of groups of elongated, specialized cells. Each cell is referred to as a muscle fibre. The fibres are bound together by some connective tissues through which blood vessels and nerves pass. In vertebrate muscle, individual fibres have a protein-polysaccharide coating and a network of fine threads that transmit the force of muscle fibre contraction to surrounding tissues. This layer around individual fibres constitutes the endomysium. Groups of fibres may be surrounded by a connective tissue, the perimysium, and arrayed in bundles of various sizes. Finally, the entire muscle, often composed of many bundles, may be surrounded by another connective tissue layer known as the epimysium. Although a number of invertebrate muscles are similarly organized, many are very small and consist of only a few muscle fibres with little connective tissue between them. Collagen, a major component of the connective tissue of vertebrates, is absent in arthropods.

Functional kinds of muscle. Muscles are divided by physiologists into two broad groups: phasic and tonic. Phasic muscles are composed of fibres that are capable of rapid activation and relaxation. They are well adapted to bring about rapid movement of brief duration. The fibres of tonic muscles contract and relax more slowly; they induce slow and sustained movements or hold parts together for a long period of time. While it is often useful to think of muscles as phasic or tonic, it is difficult to characterize a muscle clearly as one or the other, for contraction and relaxation times of different muscles vary widely; furthermore, some muscles may contract phasically at one time and tonically at another.

Phasic and tonic muscles

A typical phasic muscle is usually attached to a skeletal element that can move when the muscle contracts and shortens. In arthropods the muscle fibres attach directly to the body covering, but in vertebrates attachment of muscle to a bone is by connective tissues. The muscle cells may be very close to the point of attachment, in which case the muscle is said to have a fleshy attachment; or the connective tissues may form cordlike tendons or broad, thin sheets known as aponeuroses that pass to the attachment. The end of a muscle attached to the movable element is said to be its insertion; the opposite end, attached to a fixed element, is its origin (Figure 2B). Insertion and origin are convenient descriptive terms, but it must be emphasized that the tension at either end is the same.

Physics of muscle. The skeletal elements to which muscles attach are often lever systems, and muscles exert a force on them that enables work to be done. Most of these lever systems are classified as third order levers (the fulcrum and weight being at extreme opposite ends) because the muscles attach close to the joints (fulcra), whereas the work is done at the farthest end of the lever arms (Figure 2B). Muscles work at a mechanical disadvantage because the length of the force arm (the perpendicular distance between the fulcrum and line of muscle action) is less than the length of the work arm (the perpendicular distance between fulcrum and point of application of the work). The compensatory advantages of this arrangement, however, are compactness of the body and speed of movement. A short contraction of a muscle near the fulcrum induces a quick and more extensive movement at the distal end of the lever. Shifts in the ratio between force and work arms can alter the power and speed relations of the system. A fast-moving animal, such as a horse, has long legs (long work arms) and muscles acting very close to the joints between legs and girdles (short force arms). In contrast, a burrowing animal, such as a mole, has short limbs and muscles that act farther away from the

fulcra; its limbs move more slowly but can develop relatively more power.

Arrangement of the fibres within a muscle is also related to the extent and power of muscle contraction. Seldom are muscle fibres as long as a muscle, but many muscles, such as the biceps in the human arm, are composed of relatively long fibres lying nearly parallel to each other (Figure 3A). Since muscle fibres can contract about one-

Pinnate muscle

third of their resting length, this arrangement is suitable to an extensive and quick movement. The deltoid muscle in the human shoulder is said to be pinnate: relatively short fibres attach diagonally onto a tendon that penetrates far into the muscle. A pinnate muscle contains many more and shorter fibres than a parallel muscle of equal mass. This arrangement clearly reduces the extent of muscle contraction but increases the force that it can exert. It must be recognized, however, that not all of the force is effective because the fibres pull at an angle to the direction of tendon pull so that some force is lost. Pinnate muscles also have the advantage of bulging less when the fibres shorten, for much of the shortening is taken up by a change in their angle of pull. Pinnate muscles often occur in places where much bulging would be disadvantageous. Many arthropod muscles, which lie inside a rigid exoskeleton, are pinnate.

Since muscles can only do work by contracting, antagonistic forces must restore the original state. A few muscles work against a nonmuscular force, and so their relaxation permits the opposite action. The phasic adductor muscle of a clam can quickly pull the two halves of the shell together against the force of an elastic spring ligament in the hinge; when the phasic adductor and other muscles relax, the shell opens. Usually, however, muscles are arranged into antagonistic groups so that one will pull in one direction and another in the opposite direction.

Tonic muscle

Fibres in a tonic muscle also may be attached to skeletal elements. In addition to the phasic adductor referred to above, many clams have a tonic adductor that can hold the two halves of the shell together for a long period of time. Usually, however, tonic muscle fibres are arranged in an interlacing mass, as in the foot of a snail, or form layers in the walls of blood vessels, intestines, bladders, and other hollow organs (Figure 3B). The fibres do not have strict origins and insertions; rather, they pull upon each other and surrounding soft tissues so that they change the shape and size of the organs of which they are a part. Often these muscle fibres work against the force of the contents of the organ. When fibres in the wall of a urinary bladder contract, the bladder evacuates its contents. The gradual refilling of the bladder stretches the fibres out again. In the gut, where peristaltic and churning movements are more complex, the muscle fibres are arranged in antagonistic layers. An inner, circular layer in the wall constricts the cavity (lumen) and increases the force on the gut contents. This action, in turn, causes the segment of the gut involved to lengthen, for the force developing on the gut contents can only be released in this direction. The circular layer is opposed by an outer longitudinal muscle layer that shortens the gut segment and widens the lumen.

Muscle contractile systems and contraction

SIMPLE CONTRACTILE SYSTEMS

Contraction in primitive multicellular animals is accomplished by very simple systems that involve either a part of a single cell or, at most, a few cells. Many sponges have simple contractile cells that originate in the epithelial, or surface, layer, among them the myocytes that form a sphincter around the opening through which water is discharged from the central cavity. The epitheliomuscle cells in the polyps of coelenterates constitute another example of a simple contractile system. The main part of each cell is cuboidal and performs a variety of functions, but the base of the cell forms elongated processes that contain contractile elements organized into several relatively large contractile threads called myonemes.

During the course of evolution, animals and their movements have become more complex, and simple contractile systems have been replaced by well-developed muscular tissue. Yet simple contractile systems persist in certain higher animals in which a few isolated contractile cells perform the needed function. Myoepithelial cells of epithelial origin are found in the sweat, mammary, and salivary glands of mammals. They usually are elongate, star-shaped cells 30 to 90 micrometres long and contain myofilaments. They lie directly under the secretory cells of the gland, especially around the terminal part of the gland and around the duct cells. Presumably, they aid in the discharge of glandular secretions.

Persistence of contractile systems in higher animals

COMPLEX CONTRACTILE TISSUES

Complex contractile systems occur in jellyfishes, which swim about and are more active than polyps, and in all groups of animals above coelenterates in the evolutionary scale. These systems take the form of well-developed muscle tissue; that is, integrated groups of elongated cells (muscle fibres) each of which contains a great many longitudinally arranged myofilaments in its cytoplasm.

Vertebrate muscle tissue, which was studied before invertebrate tissue, is classified as striated or smooth according to the presence or absence of cross striations in the fibres when they are viewed with a light microscope (Figure 4). When the spectrum of invertebrate muscle is

From C.A. Villee, W.F. Walker, and F.E. Smith, *General Zoology* (1963), W.B. Saunders Company

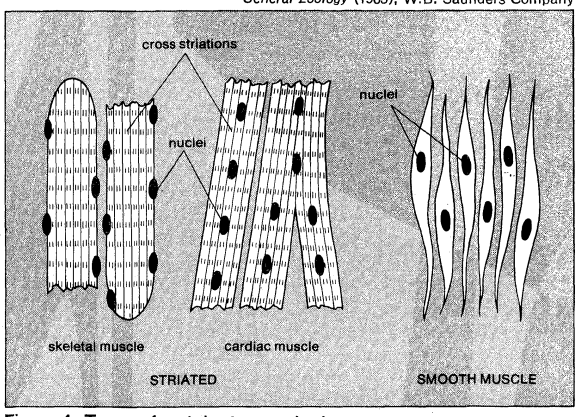

Figure 4: Types of vertebrate muscle tissue.

also included, it is clear that this classification is an oversimplification. "Striated" and "smooth" are simply broad morphological categories of convenience. Smooth muscle in particular shows a wide divergence of morphological and physiological attributes.

Striated muscle. In striated muscle the myofilaments are usually grouped into a number of larger myofibrils, the filaments aligned so that dark and light staining bands alternate along the length of each fibril. Since a cell contains many myofibrils and the dark and light bands of adjacent fibrils are usually lined up, the entire fibre has a cross-striated appearance (Figure 4). In general, striated muscle is present in both invertebrates and vertebrates in

which phasic contractions occur. Bands of striated muscle are found in the more rapid swimming jellyfishes, and striated muscle occurs sporadically in most of the higher invertebrate phyla. Nearly all of the musculature of arthropods is striated. Among vertebrates, striated muscles are found wherever rapid or continuous motion is usual; *e.g.*, in structures used in locomotion, breathing, and pumping blood. Muscle tissue in the heart wall of vertebrates differs somewhat from most striated muscle and is referred to as cardiac muscle. All other vertebrate striated muscles are known as skeletal muscles; they are closely associated with the skeleton or evolved from muscles that were. Invertebrate striated muscles that have been carefully studied resemble the skeletal muscles of vertebrates in their essential structure.

Types of striated muscle

Skeletal muscle is composed of exceedingly long, cylindrical fibres the ends of which are blunt and rounded. Their length ranges from about 1 millimetre to the length of the muscle itself. Most have a diameter ranging from 0.01 to 0.1 millimetre, although fibres in the flight muscle of some insects have diameters of up to 2 millimetres.

The fibres usually contain many elongated nuclei lying just beneath the outer plasma membrane, or sarcolemma. The cytoplasm of the fibre, called sarcoplasm, is largely filled with myofilaments grouped into myofibrils the banded segments of which are designated with letter names (*e.g.*, A, I, H, etc.). A staggered arrangement of thin actin myofilaments and thicker myosin ones forms the basis for the banded pattern. Contraction involves a sliding of these filaments past one another (see MUSCLE CONTRACTION).

In addition to the myofibrils, the sarcoplasm of striated and other types of muscle includes the components characteristic of most cells, although certain ones are reduced and others more obvious. As would be expected, cell organelles called mitochondria are numerous, for they contain the enzymes for oxidative metabolism and therefore play a vital role in energy release. They are particularly abundant in very active muscle and comprise up to 40 percent of muscle weight in the flight muscle of certain insects. Energy reserves in the form of glycogen granules are also abundant.

In most animals the needed oxygen is supplied by capillaries or vascular spaces that are close to the muscle fibres, but in insects oxygen is brought directly to the cells by tubules. Myoglobin, which can store oxygen, is abundant in red fibres, which in general contract and relax slower than white fibres that contain less myoglobin. A muscle may be predominantly one or the other. Certain of man's hip muscles, such as the gluteus maximus, which undergo sustained contraction in the maintenance of posture, are predominantly red muscle; whereas certain finger muscles, which contract less frequently and faster, are predominantly white muscle.

Red and white fibres

Cardiac muscle, the specialized striated muscle of the vertebrate heart, is organized into distinct, elongated, cellular units, each with its own nucleus located near the centre of the cell (Figure 4). The cells are united firmly with each other end for end by specialized junctions known as intercalated disks. Many of the cells branch and unite with other cells so that the whole heart musculature forms a network. Thick and thin myofilaments are interrelated with each other in the same way as in skeletal muscle, so that the banding pattern is identical. The myofilaments, however, are not organized into well-defined myofibrils but rather tend to form a continuous mass of parallel filaments broken up by deep furrows and clefts in which the other sarcoplasmic constituents are located. Cardiac muscle has more sarcoplasm than skeletal muscle; more mitochondria and glycogen are present, providing repeated contractions without an oxygen debt.

The ventricles of the vertebrate heart contain a network of conducting tracts that enable a wave of excitation to spread quickly to all parts. These tracts are composed of modified cardiac muscle known as Purkinje fibres, named for the pioneer experimental physiologist. Purkinje fibres are much larger than typical cardiac muscle cells, lacking intercalated disks, and having fewer myofilaments, which are grouped into myofibrils.

Classic smooth muscle. In all smooth or nonstriated muscle tissue, myofilaments are not arrayed in such a way as to give a cross-banded appearance. In general, smooth muscle is found both in invertebrates and vertebrates where tonic contraction occurs, but smooth muscle is also used by many invertebrates in certain types of phasic activity.

The type of smooth muscle found in the viscera of vertebrates, which was the first to be studied, may be referred to as classic smooth muscle. It is found in the walls of visceral organs, ducts, and blood vessels, in the iris and ciliary body of the eye, and attached to the hair follicles in the skin of mammals. A very similar type of smooth muscle is also found in many invertebrate groups. Occasionally, smooth muscle fibres are grouped into small muscles; but usually they are arranged into complex, interlacing networks, as in the feet of mollusks, or in distinct layers, as in the gut wall of vertebrates.

The cells of classic smooth muscle are spindle-shaped fibres, wide at the centre where the single nucleus is located and tapering to a point at each end (Figure 4). Although the fibres in the pharynx retractor of the garden slug can be as long as 20 millimetres, most classic smooth muscle fibres are much shorter than striated muscle fibres —on the order of 0.2 millimetre in the gut of vertebrates and as short as 0.01 to 0.02 millimetre in the walls of the blood vessels and in the muscles of many invertebrates. The fibres are staggered with respect to each other so that the thick part of one is adjacent to the thinner parts of another.

Spindle-shaped cells

Very thin, parallel myofilaments fill much of the cytoplasm. In invertebrate smooth muscle the filaments are not grouped into myofibrils, but myofibrils can be detected in vertebrate smooth muscle by using special fixing and staining methods. Smooth muscle in the pharynx retractor of the slug contains myofilaments of two sizes and in this respect resembles striated muscle. A similar situation has been reported in several other invertebrates, but most smooth muscle appears to have only very thin filaments with, in some cases, a few widely scattered thick filaments. While actomyosin has been extracted from smooth muscle filaments, actin and myosin have not been localized in any particular filament or part of a filament; their arrangement must be different from that in striated muscle.

Helical smooth muscle. Helical smooth muscle is a specialized type of smooth muscle in which the myofilaments are grouped into myofibrils that have a helical course through the peripheral part of the muscle fibre. This type of muscle is limited to certain invertebrate tissue, notably the body wall of annelid worms, appendages of some sea slugs, most musculature of cephalopods, the mobile arms of certain starfishes and sea lilies, and the heart of some mollusks. In most annelids the cells appear rather flat in cross section, but in other cases they are circular. Two sizes of myofilaments have been found in cephalopods. An actomyosin-like protein complex has been extracted, but it is not known whether the proteins are found in different filaments.

The significance of the helical arrangement of the myofibrils is uncertain. Theoretically, such a pattern should enable the muscle fibre to shorten to a greater extent than it could if its myofibrils were parallel, because a shortening of the myofibrils would also impart a steeper pitch to them. Organs having this type of muscle appear to be capable of quicker and more extensive contraction than organs with classic smooth muscle.

Paramyosin smooth muscle. Paramyosin smooth muscle is the most unusual and least understood of all types. It is limited to mollusks and has been studied most intensively in clams. The adductor muscle or muscles of a clam usually consists of two parts: a tonic part that holds the shell halves together against the tension of the springy hinge ligament and a less tonic, or phasic, part that closes an open shell. The tonic part is always paramyosin muscle, and the less tonic part is often paramyosin muscle, also.

The cytoplasm of paramyosin muscle contains long filaments with a relatively large diameter of 0.1 micrometre equal to that of small myofibrils. Each filament is com-

posed of many longitudinal, ribbon-shaped paramyosin elements tightly packed together. Paramyosin is composed largely of a unique, water insoluble tropomyosin complex. Actomyosin is present, but in small amounts. Paramyosin has an exceptional capacity to remain for long periods in the contracted state.

MUSCLE CONTRACTION

Muscle contraction is discussed in detail elsewhere (see MUSCLE CONTRACTION), but a summary of certain aspects is necessary to understand the differences encountered in the diverse muscle systems of animals. The membrane of a resting muscle fibre has a resting electrical potential that derives from the differential distribution of positive and negative ions upon its inner and outer surfaces (see also BIOELECTRICITY). Excitation involves an increase in the permeability of the membrane to certain ions so that they move quickly through the membrane and reduce the resting potential. A sufficient reduction leads to the initiation of the active state, by which is meant the totality of chemical events within the fibre that leads to the development of tension in the contractile elements. It is important to recognize that two different sets of phenomena are involved: (1) the excitation of the fibre membrane, which is measured by electrical changes, and (2) the development of the active state, which is measured by the mechanical tension.

Excitation and tension

In living systems, activation typically results from stretching, action of certain hormones, and, most importantly, nerve impulses. A single nerve impulse is often not enough to trigger a fibre contraction, but a rapid succession of two or more impulses may influence each other in such a way as to initiate the active state. The first impulse may cause changes that enable a second impulse that quickly follows it to have a greater effect (facilitation), and/or the effects of succeeding impulses may simply be added to those of earlier impulses if they arrive before the effects of the earlier ones have worn off (summation). Facilitation and summation can occur both in the electrical phenomena at the membrane and in the development of tension. Certain fibres contract maximally only if they are stimulated repeatedly and while the active state induced by earlier stimuli is still high so that mechanical facilitation and summation can occur. The active state and contraction eventually reach a plateau in which the fibre is in a state of maximum contraction known as tetanus. Since maximum tension develops gradually and on repetitive stimulation, this method of fibre activation is referred to as a "slow system."

All-or-none response

Other fibres do not respond at all until an action potential is generated, and then the response is maximal (all-or-none phenomenon). Since the active state quickly reaches its maximum without mechanical facilitation and summation, this type of fibre activation is described as the "twitch" or "fast system." The fibre membrane has a brief refractory period during which another action potential cannot be induced.

Muscle tissues differ greatly in their physiological properties and pattern of innervation. Most vertebrate striated muscle belongs to the fast system, for each fibre receives only a single neuron terminal; but there are cases, primarily among amphibians, in which fibres receive the multiterminal innervation characteristic of the slow system. In many invertebrates the same muscle fibre may receive terminals from neurons belonging to both the fast and slow systems (polyneuronal innervation).

Cardiac and classic smooth muscle resemble the fast system in being activated by nerve-induced action potentials, but each fibre does not receive a neuron terminal. Neurons terminate on only a few fibres in the pacemaker region of hearts, but terminals are more widespread in smooth muscle. Excitation spreads from active fibres to adjacent ones through areas of close membrane contact. Spread may be through typical muscle tissue, or it may be assisted, as in the vertebrate heart, by modified muscle tissue. Smooth muscle displays a gradation of tension development, but individual twitches cannot summate in cardiac muscle because the active state elicited by one stimulus has nearly decayed before the muscle can be reactivated (for further information on the heart muscles of invertebrates and vertebrates see MUSCLE CONTRACTION).

Invertebrate muscle systems

EVOLUTION OF INVERTEBRATE MUSCLE SYSTEMS

A bewildering array of structural and functional diversity is found in the contractile mechanisms of invertebrates, yet the main trends in the evolution of the muscular systems can be traced through major representative stages. Morphologically simple contractile mechanisms make their first appearance in single-celled organisms such as Protozoa. *Vorticella*, for example, has a contractile thread (myoneme) in its stalk that enables it to pull away quickly from irritating stimuli (Figure 5A). Other simple mechanisms are found in the sponges. Flattened pinacocytes, which cover much of the sponge surface, can round up slightly and compress the body if the skeleton is not too rigid.

Simple contractile devices

More highly organized contractile tissue is found in the coelenterates, such as jellyfish and sea anemones, in which many surface, or epithelial, cells are modified as epitheliomuscle cells and have elongated bases containing two or more myonemes (Figure 5B). The processes of the outer layer of cells parallel the longitudinal axis of the polyp, whereas those of the antagonistic inner layer lie tangential to this axis. In slow-moving polyps, such as *Hydra*, the processes resemble classic smooth muscle, but in some of the faster moving jellyfishes the processes form bands of striated muscle. Sea anemones have well-developed retractor muscles in the folds that divide the gastrovascular cavity. Other muscle processes mediate the movements of the tentacles and mouth.

Mesodermal muscle tissue, completely independent of epithelial cells, is first found in acoelomate (lacking body

Muscle layers

cavity) worms. Thin layers of elongate muscle fibres lie beneath the epidermis of the free-living flatworms and especially in those species that are too large to rely solely on cilia for locomotion. Often an outer circular layer of muscle is underlain by a diagonal layer and a still deeper longitudinal layer (Figure 5C). Other muscle fibres penetrate deeper tissue, and still others mediate the movements of the proboscis and copulatory organs. Most of the fibres are smooth, but ones with simple striation patterns are occasionally found. Muscles are particularly well developed in the parasitic flatworms, in which they form thick layers in the body wall, and are also associated with the hooks and suckers by which the organism attaches into the tissue of its host. The tail of the cercarian (tadpole-shaped) larva of flukes is the most intricate muscular locomotor organ found in this phylum. A circular layer of smooth muscle fibres lies beneath the cuticle, and a diagonal layer of striated fibres beneath the circular layer. The tissue is very rich in mitochondria, suggesting an efficient energy transfer system.

Pseudocoelomates have muscles in the body wall and muscles associated with certain bristles and with copulatory organs. A muscle layer also begins to become associated with the gut, which is nonmuscular in lower forms. Gut muscles are particularly well developed anteriorly in association with complex mouthparts and a sucking pharynx. Nematodes have only one layer of longitudinal muscle fibres in their body wall (Figure 5D). Fibres contracting alternately on opposite sides of the body produce the characteristic lashing movements of these worms. The nonstriated contractile fibrils of these cells are concentrated in the periphery of the cells beneath the epidermis. These cells are of a unique type in that nerve extensions do not go to them, rather the cells themselves have long cytoplasmic innervation extensions through the pseudocoel to one of four epidermal nerve tracts. Related animals called rotifers do not have a continuous subepidermal muscle layer but rather have discrete bands of fibres (Figure 5E). Contraction of circular bands increases pseudocoelomic fluid pressure and lengthens the body; contraction of longitudinal bands, which extend across one or more cuticular rings, shortens the body or retracts the head and foot. Subepidermal muscle bands are particularly well developed in the primitive creeping species in which one finds an amazing complexity of little muscles, each composed of only a few fibres, both smooth and striated.

Body wall and gut musculature

Higher invertebrates have a coelom (body cavity), except where it has been secondarily reduced, and muscular tissue is more clearly separable than in lower species into parts associated with the body wall and gut. Body wall musculature is particularly well developed. Most coelomates also have circulatory systems in which fluid is propelled by the muscular pulsation of blood vessels or by one or more "hearts." Pulsating blood vessels are rare in lower invertebrate groups.

On the basis of the fate of an embryonic opening called the blastopore, coelomates can be divided into two groups: deuterostomes, in which the blastopore becomes the anus; and protostomes, in which the blastopore becomes the mouth. Most invertebrate members of the deuterostomous evolutionary line are sessile or slow-moving animals in which the musculature is usually not very elaborate. Circular and longitudinal muscles are found in the body wall of echinoderms. Many extend between the calcareous plates and move the arms. These muscles are not well developed in a sluggish starfish, but they are important in the highly mobile arms of serpent stars. In the latter case the muscle is of the helical smooth type, but usually it is classical smooth muscle. Other muscles are associated with the small, nipping pedicellariae (small footlike organs) that keep the surface clean; with the spines of sea urchins; with the ampullae (pouches) and tube feet of the ambulacral system; and with the digestive tract. Sea urchins feed by scraping material from rocks with a device known as Aristotle's lantern, consisting of an intricate framework of 40 bony elements supporting a series of "teeth" and an equally complex array of small muscles.

Most protostomous invertebrates, which include the mollusks, annelids, and arthropods, are very active animals with complex muscle systems. Muscles associated with locomotion and with the skeleton are particularly interesting. In mollusks the body wall is responsible for locomotion; and parts of it, such as the foot or mantle, are very muscular. Snails move by slow rhythmic waves of the foot; bivalves thrust their foot into the substrate, the distal end swells as an anchor, and then the rest of the body is pulled toward the end of the foot. The complexity of foot action requires a complex network of interlacing muscle fibres and not simple layers. Muscle action is responsible for the rhythmic waves and for foot shortening, but the extension of a clam's foot is brought about largely by the swelling of erectile-like vascular tissue. In bivalves an elastic ligament in the hinge opens the shell, but the two halves can be quickly drawn together and held together for long periods of time by the action of one or more adductor muscles. The adductors must be capable of both phasic and tonic action, and an unusual type of muscle tissue is present. Most is paramyosin smooth muscle, and this appears to be responsible for both phasic and tonic action in some muscles. In other cases the phasic adductor, or phasic part of a single adductor, is a different type of tissue. The phasic adductor of the scallop, which swims by rapidly clamping its shells together, is striated muscle. Squids, the most active of mollusks, can dart quickly by the contraction of longitudinal and circular layers of muscle in their mantle. Their action alternately takes water into the mantle cavity and expels it as a jet through a funnel. These muscles are of the helical smooth type.

Complex muscle systems

Most annelid body wall muscles are also of the helical smooth type and have a ribbon shape. Earthworms make an extensive use of a hydraulic coelom in locomotion. Contraction of an outer layer of circular muscle fibres in the body wall compresses the coelomic fluid and extends the worm; contraction of a deeper longitudinal layer of fibres shortens the worm. Many marine worms creep and swim by lateral trunk undulations and finlike parapodial movements. Longitudinal muscle bands are particularly prominent in these worms, and parapodial muscles are complex. Striated muscles occur in part of the gut (the gizzard) in certain species.

Arthropods have an armoured body composed of many segments and jointed appendages. As in vertebrates, muscles act across each of the joints so that the muscles are very numerous. Individual muscles may consist of only a few fibres. Arthropod muscles, even gut muscles, are nearly always striated. There is little connective tissue between the fibres that attach directly to the epidermis or to the overlying exoskeleton. Often the attachment area and mechanical advantage of a muscle is increased by its insertion onto a lever-like inward extension of the exoskeleton known as an apodeme (Figure 6).

The basic arrangement of arthropod muscles can be seen in one of the legs. The base of the leg articulates with the body by a surface layer, or flexible cuticle, allowing a wide range of movements. Many muscles attach to this

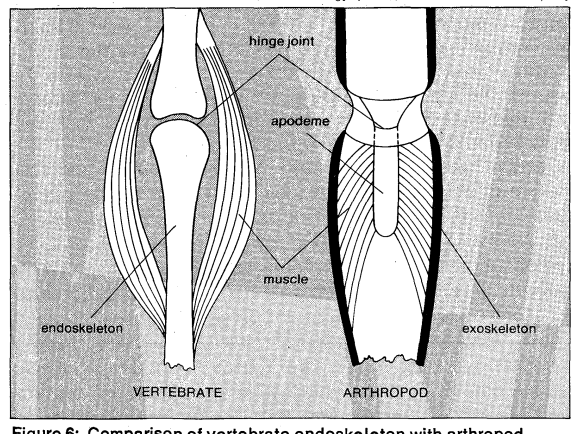

Figure 6: Comparison of vertebrate endoskeleton with arthropod exoskeleton, showing arrangement of muscles and skeleton at a joint.

part of the leg. More distal limb segments, however, are usually simple hinge joints capable of moving only in a single plane; they are operated by a single pair of antagonistic muscles. Muscles also attach directly upon the bases of the wings and move them up and down in those insects having slow wing movements (*e.g.*, butterflies, cockroaches, and dragonflies). The flight muscles of mosquitoes and other insects with very rapid wing movements attach onto parts of the thoracic skeleton and move the wings indirectly by rapidly altering the shape of the thorax.

FUNCTION AND REGULATION OF MUSCLE ACTION

To be of value to the organism, muscles must be capable of making a response appropriate to the changes in the internal and external environmental conditions. This capability, of course, requires that the action of different muscles be integrated so that they interact in an adaptive way. It also requires that single muscles be capable of giving varied responses with respect to speed of contraction and relaxation and the degree of tension development. Conditions may call for a quick contraction of short duration to escape a predator or to catch prey, or, for a slow sustained contraction to maintain posture; they may call for a weak contraction or for a very powerful one. Gradation of muscle action with respect to these variables may be a function of the muscle tissue itself, of the way it is stimulated, or of both.

Integration of muscle action

The contractile elements of sponges are independent effectors capable of responding directly to environmental stimuli. There is a great deal of self-regulation in such effector cells, for their action is appropriate to the nature and intensity of the stimulus. As animals and their responses become more complex during the course of evolution, regulation of muscle activity comes increasingly under the control of the nervous system. Some independent muscle activity is retained, however, in certain higher organisms. Coelenterate contractile tissue can give a local response to a local stimulus. Muscles in insect spiracles that control the passage of air in and out of the tracheal system are particularly sensitive to carbon dioxide and relax when the gas reaches certain levels; gut and heart muscles often have an inherent rhythm and are only partly under the control of the nervous system.

The first stage in the evolution of nervous control of muscle action is seen in the coelenterates. Neurosensory cells, some receptor cells, and a primitive nervous system are present. Impulses can travel from a point of stimulation in all directions and elicit a diffuse and general response. Certain locomotor and feeding activities, however, require an ordered sequence of specific and graded actions, so it is clear that some integration and regulation also occur. Most invertebrates above the coelenterate level have well-developed nervous systems that make possible a high degree of integration and control of muscle activity.

Coelenterate muscle. Despite the apparent simplicity of the neuromuscular apparatus of coelenterates, certain muscles of these animals are capable of making both slow and fast responses and responses of different tensions. Sometimes these differences involve a different pattern of innervation. Some polyps and jellyfishes have two nerve nets, one responsible for rapid and specific conduction and contraction and one for a slower and more general contraction. It is possible, however, in some cases that both types of responses result from a different pattern of stimulation through the same nerve net. A single stimulus does not induce a contraction in the muscle that retracts the mesentery (a tissue partition) of a sea anemone but causes a facilitation in the muscle, enabling a second stimulus following at a one-second interval to elicit a contraction. Succeeding stimuli at one-second intervals induce further contractions that rapidly summate to a maximum. In addition, stimulating the same muscle with stimuli of the same intensity but at a rate of one every three to five seconds induces a slower contraction the tension of which develops gradually over a period of minutes. A similar situation is found in the sphincter of the sea anemone. Although there is a fast and slow system physiologically in these muscles, there is no clear morphological evidence for the dual pattern of innervation usually found where there are both types of response. Some anemone muscles show only the slow pattern. In these cases the muscle fibres are supplied by relatively few neurons, and it is probable that the slowness of the response reflects some conduction of excitation from one muscle fibre to another. Muscles showing fast and slow responses are supplied by a much richer nerve net containing more neurons. It has been proposed that low frequency stimulation and the slow response involve some fibre-to-fibre conduction and a gradual recruitment of more contractile elements, whereas more rapid stimulation activates more fibres directly.

Stimulation via nerve nets

Arthropod postural muscles. Slow, fast, and intermediate rates of contraction are developed to a high degree in arthropod postural muscles. Limb muscles of decapod crustaceans, such as shrimps, lobsters, and crabs, have been studied most intensively. Only a few neurons need supply a muscle because the neurons branch extensively. One neuron may supply muscle fibres in several different muscles, and within a single muscle each neuron supplies many muscle fibres with multiterminal endings. A wide range of responses is possible because certain neurons have different effects and most muscle fibres are supplied by more than one type; *e.g.*, in muscle from the claw of the rock lobster (*Panulirus*) 38 percent of the fibres receive branches from a single excitatory neuron; 26 percent from two excitatory neurons; 29 percent from three excitatory neurons; and 4 percent from four different excitatory neurons.

In addition to receiving one or more excitatory neurons, each muscle fibre in crustacean muscle also receives one or two inhibitory neurons. Stimulation of these slows down, reduces, or may completely prevent muscle contraction.

Final responses in decapod limb muscles

The final response of a decapod limb muscle depends on the rate of stimulation of different types of neurons and the interactions between them. A continuum of contraction is possible from fast to slow, short to long, weak to strong. This sytem is a remarkable adaptation, enabling a few neurons and a relatively small number of muscles to give a range of responses comparable to that seen in the far larger systems of vertebrates.

Insect postural muscles have a pattern of innervation somewhat similar to that of crustaceans except for the absence of inhibitory neurons. The muscle fibres in the jumping muscles of the hindleg of a grasshopper are adapted to give a quick, maximal response to a single stimulus; but muscle fibres in many other muscles are supplied by a fast and a slow neuron, which may terminate in the same junctions. The number of neurons is low, and cases are known where only two neurons supply an entire muscle. As in crustaceans, fewer impulses are needed to activate the muscle through the fast system than through the slow, and tension development is more rapid. In some cases a third nerve fibre to the muscle fibres appears to increase the tension elicited by the stimulation of the other neurons.

Insect resonant flight and tymbal muscles. The indirect or resonant flight muscles of flies and of bees and wasps and the sound-producing, or tymbal, muscles of cicadas are of special interest because they contract at frequencies far greater than those in any other muscles. These muscles move the wings indirectly by distorting the body wall. High-speed frequencies can be determined by the sound pitch generated. The whine of a mosquito indicates a wing beat of over 600 per second, and tymbal membranes vibrate at maximum frequencies of nearly 7,000 cycles per second. Such frequencies far exceed the rate at which muscle contraction can be caused by nerve-induced action potentials. At best, several milliseconds are required for each action potential and its attendant refractory period. Moreover, rapid stimulation through nerves usually leads to a fusion of twitches into a tetanic contraction. Contraction of bumblebee flight muscles tetanize at a nerve impulse rate of only 40 per second. Clearly some other mechanism must be involved in the very high contraction rates of indirect flight and tymbal muscles.

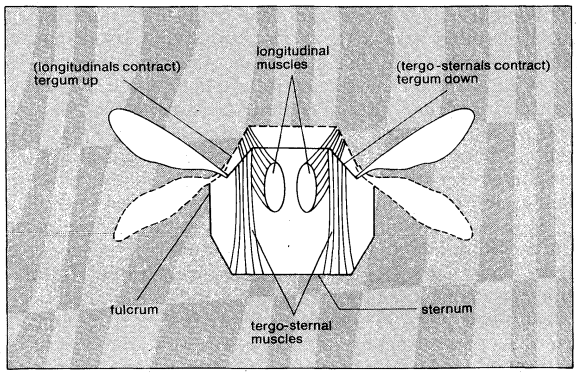

Figure 7: Muscles involved in insect flight (see text).
From C.A. Villee, W.F. Walker, and F.E. Smith, *General Zoology* (1963), W.B. Saunders Company

Mechanics of flight muscles

Mechanical factors play a very important role in the activity of these muscles. The major indirect flight muscles are a pair of vertical ones that extend between the dorsal plate (tergum) of the wing-bearing segment and the sternum (Figure 7). These muscles contract nearly isometrically because an increase in tension must develop in them before the tergum moves. When a certain tension is reached, the elastic tergum "buckles in" and pushes the wing base to which it is attached ventrally. Since the wing is hinged on a lateral section of the body wall (lateral pleural plate), a downward push on its base raises its distal end. The sudden buckling of the tergum releases the tension in the vertical muscles, permitting the tergum to snap back to its original position, lowering the wings and stretching the muscles as it does so. This stretching, rather than a nerve impulse, reactivates the muscle and elicits another contraction. Recovery is assisted by an antagonistic set of longitudinal muscles that attach onto elastic tergal processes extending inward at the anterior and posterior ends of this thoracic segment. These muscles act in a similar way; they are stretched out and activated by the contraction of the vertical muscles, and their contraction assists in bowing out the tergum and stretching the vertical muscles. In the tymbal organ, a tymbal muscle pulls a chitinous membrane inward beyond a point of stability. It snaps inward, releasing the tension in the muscle, and then snaps outward through its own elasticity and restretches the muscle.

Contractions induced by mechanical stretching of the muscle continue as long as the muscle remains in an active state and can follow each other quickly because the active state, unlike the action potential, has no refractory period. Nerve impulses and action potentials are not needed for every contraction but are only needed to maintain the contractile elements in an active state. There may be one action potential for every 20 wing beats, or, in insects having slow wing movements, one action potential for each wing beat.

Mollusk muscle. Separate fast and slow systems exist in the muscles of many other invertebrate groups, but the basis for the two systems is not well understood. Some of the complexities involved can be appreciated by considering the muscles of certain mollusks.

The fast system of the squid

Squids, which rely on rapid movements to catch food or to escape prey, have a fast system in their mantle muscles. These muscles are of the helical smooth type and are innervated by ten giant nerve axons. Their stimulation leads to a rapid and synchronous contraction of the mantle. A single stimulus through one of the axons elicits both a maximal electric response and twitch in the muscle fibre it supplies. There is no electrical or mechanical facilitation and summation, so that a more rapid rate of stimulation does not increase the tension, although it can lead to a brief tetanic contraction. In addition to this fast system mediated by the giant axons, smaller neurons supply mantle fibres and induce slow, graded contractions. One stimulus induces a small electrical difference at a junction of nerve and muscle and a contraction that facilitates subsequent stimuli that build upon it. A maximum tension is reached, however, at a stimulus rate of only a few per second; the degree of gradation, therefore, is not nearly as extensive as in arthropods. It is not clear whether the fast and slow systems work through the same or different muscle fibres. Inhibitory fibres have not been found in mantle muscles, but they have been demonstrated in the muscles of pigment cells of cephalopods.

Fast (phasic) and slow (tonic) systems are also present in the adductor muscle of bivalves, and here different muscle fibres, often with a different tissue structure, are sometimes involved. The phasic portion of the adductor may be striated as in the scallop, which swims by rapidly clamping its shells together. Fast, synchronized electric responses have been recorded from striated fibres of the scallop. The tonic portion of the adductor is paramyosin smooth muscle and is remarkable for its ability to remain contracted when only one stimulus every few seconds is delivered.

In other cases both phasic and tonic activity have been observed in the same paramyosin muscle. An example is the byssus retractor muscle of the mussel, which pulls on the byssus threads, which the animal secretes to cling to its substrate. Stimulation with alternating current leads to a brief phasic contraction, but stimulation with direct current leads to a sustained tonic contraction. Tonic contraction can be quickly terminated by stimulating inhibitory or relaxing nerves or by applying certain drugs.

The maintenance of tonic contraction for a long period has posed a particularly puzzling problem. In life, the byssus contractor can remain contracted for weeks and relaxes only when the animal changes its position. This prolonged contraction may reside in unusual elastic properties of the muscle.

Or it may be that paramyosin changes its state when tonically stimulated and that the increased viscosity characteristic of contraction can "set" and hold its changed state. Paramyosin muscle clearly has unusual elastic properties and relaxing capabilities, but a complete answer to its capacity for sustained contraction is not yet known.

The vertebrate muscular system

EMBRYONIC DEVELOPMENT AND DIVISIONS OF THE MUSCULAR SYSTEM

Except for the ectodermally derived muscles of the iris of the eye and the myoepithelial cell of certain superficial glands, vertebrate musculature originates from the middle layer, or mesoderm, of the embryo. In areas where muscle is destined to develop, mesodermal cells, many of which are at first loosely associated star-shaped cells from loose tissue termed mesenchyme, begin to elongate and myofibrils begin to appear within them. These early muscle-forming cells, known as myoblasts, differentiate into smooth, cardiac, and striated muscle fibres. There is evidence that multinucleate striated fibres derive from a fusion of myoblasts, but nuclear division without cytoplasmic division may also occur.

Mesodermal origin of somatic and visceral muscles

Several mesodermal regions can be recognized in an embryo, and these give rise in lower vertebrates such as fishes to the two major groups of muscles recognized in comparative studies: somatic and visceral muscles. The most dorsal mesodermal region lying along the back on either side of the developing neural tube gives rise to the somites. These take the form of a series of paired segments that extend from the region of the eye into the tail, with a gap in the series adjacent to the developing ear. Most of each somite develops into a block of premuscular tissue known as a myotome, and most of the myotomes extend laterally and ventrally beneath the skin toward the midventral line of the embryo.

Musculature derived from the somites is called somatic musculature. It lies in the body wall and appendages and is innervated by somatic motor neurons that travel in the dorsal roots of spinal nerves and in those cranial nerves believed to be serially homologous to the dorsal roots. All somatic musculature becomes striated, and most of it is associated with the skeleton. The mesodermal region just below the somites constitutes the kidney-forming mesoderm; most of it is destined to form urogenital structures. Lateral plate mesoderm lies ventral to the nephrogenic mesoderm. It is not segmented but is cleaved by the body

cavity, or coelom, into an outer, or somatic, layer and an inner, or splanchnic, layer. Although the somatic layer forms only the outer lining of the coelomic cavity in lower vertebrates, it contributes in higher vertebrates to the cells that give rise to the somatic musculature in the lateroventral part of the body wall and appendages. The splanchnic layer gives rise to the visceral muscles. These lie in the wall of the gut and derived organs, in blood vessels, and in the heart. Muscles in certain urogenital ducts, which come from nephrogenic mesoderm, are also considered to be visceral. Visceral musculature is innervated by visceral motor neurons that travel in specific cranial nerves and in the autonomic parts of spinal nerves.

The somatic musculature is often subdivided into axial musculature, along the axis of the body, and appendicular musculature, located more peripherally in the appendages.

Axial musculature

The most anterior axial musculature, derived primitively from the first three body segments, or somites, becomes associated with the developing eye and forms the extrinsic ocular muscles. Myotomes in the occipital region of the head and in the embryo's neck cannot extend directly ventrally because of the presence of gill pouches. They grow posteriorly and ventrally behind the gill pouches and then extend forward in the floor of the gill region to the lower jaw. In this way the ventral portions of these myotomes give rise to the hypobranchial musculature of the tongue and ventral surface of the neck. The rest of the axial musculature can be thought of as trunk musculature; most lies in the trunk, although some extends onto the dorsal surface of the neck and into the tail. Except in the most primitive fishes, the trunk myotomes separate during development into dorsal parts that give rise to the epaxial (above the axis) muscles of the back and underparts that give rise to the hypaxial (beneath the axis) muscles on the sides and ventral surface of the trunk.

Appendicular musculature

Appendicular muscles are defined as those somatic muscles that develop from mesenchyme within the embryonic limb buds. In fishes this premuscular mesenchyme separates from the myotomes very early during development, but in higher vertebrates some of it migrates into the limb buds from the somatic layer of the lateral plate mesoderm. As the appendicular skeleton develops, the premuscular tissue in a limb bud becomes separated into dorsal and ventral masses from which the individual muscles later differentiate. Consequently, dorsal (abductor and extensor) and ventral (adductor and flexor) limb muscles can be recognized. Most of them extend from the girdle into the limb or lie within the limb; but some grow from the limb base medially to the trunk—*e.g.*, latissimus dorsi. Such muscles should not be confused with muscles that start their development elsewhere and secondarily extend to the girdles; *e.g.*, certain trunk muscles and visceral muscles.

Most of the visceral musculature forms part of the wall of the digestive tract, blood vessels, and other hollow organs. Visceral musculature in the anterior part of the gut tube, however, becomes associated with the gill, or visceral, arches and constitutes a special subgroup known as branchiomeric musculature.

Branchiomeric musculature

Branchiomeric musculature becomes striated, but most of the remaining visceral musculature is smooth or, in the heart, cardiac. Only the branchiomeric musculature forms discrete enough entities to be of interest to gross and comparative anatomists. These muscles are grouped according to the visceral arch with which they are associated: mandibular muscles with the first arch, hyoid muscles with the second arch, and branchial muscles with the remaining arches.

Ancestral vertebrates evolved morphogenetic processes that led to the development of an adult musculature adapted to the animal's aquatic mode of life. The muscles that develop from the primordia referred to above are not complex, and most stay close to their sites of origin. As trunk muscles differentiate from the myotomes they remain segmented, for a segmented musculature is very effective in inducing the lateral body undulations used in swimming; the dorsal and ventral premuscular masses often differentiate into a single dorsal and ventral fin muscle, for fin movements are not complex; hyoid muscles remain attached to the hyoid arch, and so forth.

As vertebrates adapted to terrestrial life, fundamental changes occurred in methods of support, locomotion, feeding, and breathing. These changes were reflected in alterations in the musculature, but morphogenetic processes leading to these alterations evolved as modifications primarily in the later stages of an inherited pattern of development. The early embryonic muscle primordia of mammals, therefore, are very similar to those of fish; and myotomes, for example, are still segmented even though there will be little segmentation in the adult musculature. The alterations that occur in later development result chiefly from three processes. (1) Parts of adjacent muscle primordia may fuse to form continuous muscles extending over many body segments. The lateroventral parts of the myotomes in the abdominal region unite to form continuous sheets of muscle such as the external oblique. (2) A single muscle primordium may become subdivided. The dorsal and ventral premuscular masses in the appendages give rise to a great many appendicular muscles used for support and locomotion on land. (3) A muscle primordium, or muscles that develop from it, may migrate some distance from the site of origin. In an early mammalian embryo the developing heart lies far anteriorly in the future neck region, and the diaphragm begins to form directly posterior to it. Presmuscular tissue that enters the diaphragm is, therefore, derived from the posterior cervical myotomes. Only later in development do the heart and diaphragm migrate posteriorly.

Muscle homologies

These sorts of changes often make it difficult to recognize the group to which some muscles of adult higher vertebrates belong and to establish their homologies with the muscles of lower vertebrates. Relative position in the body, which is usually a good clue to homology, may be different. Fortunately, nerves enter the developing muscles early and tend to accompany the muscles during their later developmental movements. Innervation is conservative and is a good guide to muscle identity, but changes in innervation sometimes occur. Recourse must then be made to developmental studies to establish muscle homology.

EVOLUTION OF THE VERTEBRATE MUSCULAR SYSTEM

The major changes that have occurred in the muscles of vertebrates during their evolution from fishes to mammals can be most easily followed by discussing them according to the groups to which they belong.

Ocular muscles. All vertebrates with well-developed eyes have a group of strap-shaped extrinsic ocular muscles that insert onto the eyeball and move it. The basic pattern of the group is established in fishes, in which four rectus muscles originate from the posterior corner of the orbit and two oblique muscles from the anterior corner. All develop from the first three somites and hence are supplied by the cranial nerves of these somites.

Eye movements are similar in all vertebrates, and few evolutionary changes have occurred. Terrestrial vertebrates retain the six muscles found in fishes. Many species, especially those with relatively large eyeballs, have a retractor bulbi that ensheathes the optic nerve and helps to hold the eyeball in place. Tetrapods (the land vertebrates) have moveable eyelids that protect the eye. A levator palpebrae superioris raises the upper eyelid in mammals; and an orbicularis oculi, derived from the hyoid group of branchiomeric muscles, closes the eyelid.

Hypobranchial muscles. Fishes have a simple hypobranchial musculature consisting of several longitudinal muscles that extend from the pectoral girdle forward in the floor of the gill region to the bases of the branchial arches, hyoid arch, and lower jaw (Figure 8A). The coraco-mandibular and rectus cervicis, which attach, respectively, on the lower jaw and hyoid arch, open the jaw; the deeper coracobranchials attach onto the gill arches and help to expand the pharynx and gill pouches to suck in water for breathing. These muscles develop embryonically from the ventral parts of the occipital and anterior trunk myotomes.

Gills are lost in terrestrial vertebrates and with them the respiratory functions of these muscles. Manipulating food

Neal and H.W. Rank. Copyright © 1944 by McGraw-Hill Book Co. Used with permission of McGraw-Hill Book Company

in the mouth and swallowing it, however, becomes more difficult because there is not a steady flow of water through the mouth and pharynx. Terrestrial vertebrates evolved a muscular tongue that plays an important role in food manipulation and swallowing. Mammals have a lingualis muscle within the tongue and others that extend into the tongue from the chin (genioglossus), hyoid (hyoglossus), and skull base (styloglossus). All have evolved from the anterior part of the hypobranchial musculature. Swallowing also entails a forward and backward movement of the hyoid bone and larynx, which is accomplished by longitudinal muscles derived from both the anterior and posterior parts of the hypobranchial musculature. Their names indicate their attachments: geniohyoid (chin hyoid); sternohyoid (sternum hyoid); omohyoid (pectoral girdle hyoid); sternothyroid (sternum thyroid [the thyroid is a laryngeal cartilage]); and thyrohyoid (thyroid hyoid).

Trunk muscles. Trunk and tail muscles constitute the bulk of the musculature of a fish. They consist of a series of segmented myomeres derived from the embryonic myotomes. Except in cyclostomes, such as the hagfishes and lampreys, the myomeres are divided by a longitudinal and horizontal sheet of connective tissue into dorsal epaxial and ventral hypaxial portions (Figure 8A). The epaxial segments extend from the back of the skull nearly to the end of the tail; the hypaxial ones do not extend farther anteriorly than the pectoral girdle. Waves of contraction, which become more pronounced posteriorly, pass alternately down the myomeres of opposite sides of the body so that the posterior part of the trunk and tail undulate from side to side and propel the animal through the water.

Locomotory musculature

The myomeres are folded in a complex zigzag fashion. The apex of each "zig" and "zag" is roughly cone shaped so that it extends farther forward or backward than appears on the body surface (Figure 8B). Although most muscle fibres in the myomeres extend longitudinally, some are diagonal. These complexities appear to enable short fibres to exert their effects over several body segments and also cause the trunk and tail to twist during their undulations in such a way that they exert a thrust downward as well as laterally. The effect is somewhat like that of a sculling oar.

Terrestrial vertebrates, since they are not buoyed up by the water, must have a strong vertebral beam braced by strong back muscles and strong appendages that propel them by thrusting against the ground (Figure 8C). Their trunk muscles play a role different from those of fishes. The powerful epaxial musculature, which braces the back, can be organized into three columns, as seen in the mammals: (1) A median transversospinalis group lies next to the spinous processes of the vertebrae. The deeper parts of the muscle group remain segmented and include short muscles, such as the interspinales and intertransversarii that interlace successive vertebrae. The superficial parts fuse to form more extensive longitudinal muscles, the multifidus and spinalis that act across many body segments. (2) A longissimus dorsi lies lateral to the transversospinalis group, and (3) a long iliocostalis lies lateral to it. The anterior parts of these columns break up into smaller muscles that support and help to move the head and neck. The very long muscles, spinalis, longissimus, and iliocostalis, are often closely associated to form a functional complex called the erector spinae.

Hypaxial musculature in primitive terrestrial vertebrates

The hypaxial musculature remains extensive and segmented in primitive terrestrial vertebrates, such as salamanders (body squirming still plays some role in locomotion); but it becomes much reduced and loses most of its segmentation in higher species. A column of hypaxial musculature lies ventral and lateral to the vertebral column and helps to support and move the back.

Most of the rest of the hypaxial musculature helps to form the thoracic and abdominal walls, and most of this has an important role in breathing in higher vertebrates that ventilate their lungs by changing intrathoracic pressure. The muscular diaphragm of mammals is considered to be hypaxial because it develops from the ventral parts of cervical myotomes. It forms a dome-shaped partition between the thoracic and abdominal cavities, which moves posteriorly when the muscle contracts and reduces intrathoracic pressure. The elastic recoil of the abdominal viscera, assisted by the contraction of muscles in the abdominal wall, restores the diaphragm to its resting position. The abdominal wall contains a longitudinal rectus abdominis muscle on either side of the central line and, laterally, three broad, thin sheets of muscle: external oblique, internal oblique, and transversus abdominis. Comparable layers occur in the thoracic wall: external and internal intercostals lie between the ribs; a reduced transversus thoracis lies deep to the sternum, and a reduced rectus thoracis occurs near the front of the sternum. In addition, a serratus dorsalis inserts near the verte-

bral attachments of the ribs, and several scalenus muscles extend from the neck to the ventral portions of the anterior ribs. All these muscles assist in changing thoracic size and intrathoracic pressure by moving the ribs forward during inspiration and backward during expiration.

A final group of hypaxial muscles is associated with the pectoral girdle in tetrapods. Posteriorly, there is an articulation between the pelvic girdle and sacral vertebrae, but none exists anteriorly. Body weight is transferred from the trunk to the pectoral girdle and appendages by a muscular sling. A major component of this complex is the serratus ventralis (Figure 8D), which extends from the vertebral border of the scapula to the ventral ends of the ribs. Other hypaxial muscles, belonging to the rhomboideus group, extend between the scapula and spinous processes of the vertebrae. A levator scapulae ventralis extends between the skull and scapula.

Appendicular muscles. The paired fins of a typical fish do not have a role in body support; rather, they are used as stabilizing keels and rudders for turning. Appendicular musculature is correspondingly simple and relatively weak. Many fishes have only a dorsal abductor or extensor muscle that pulls the fin dorsally, and a ventral adductor or flexor that pulls it ventrally. Certain fibres of these muscles spread far enough fore and aft so that they can also pull the fin forward or backward slightly. The appendicular musculature is derived primitively from the mesenchyme that originates in the ventral portion of the myotomes.

The tetrapod limb

The limbs of terrestrial vertebrates become the primary supporting and locomotor organs, and the appendicular muscles become correspondingly complex. An early stage in the evolution of tetrapod limb muscles is seen in salamanders. The proximal segment of each limb lies and moves primarily in the horizontal plane, and the distal segment extends perpendicularly from the elbow or knee to the ground. There are many appendicular muscles, but they can be grouped into a dorsal and a ventral series that have evolved, respectively, from the abductor and adductor series of fishes. Dorsal muscles abduct, or lift away, the proximal segment of the limb and extend the lower segment and foot, thereby raising the limb from the ground during the recovery phase of a stride. Ventral muscles are more active during the propulsive phase; for they adduct, or pull in, the limb and flex its distal segments, thereby placing the foot firmly on the ground. Both dorsal and ventral muscles are involved in moving the limb forward (protraction) and backward (retraction). Although limb muscles are numerous in salamanders, they are not very powerful, and lateral undulations of the trunk help in limb placement and movement. When the anterior portion of the trunk bends to the left, for example, the right pectoral appendage is protracted to some extent because it lies on the convex side of the trunk fold. As a wave of contraction spreads down the right side of the body, the right appendage, now on the concave side of a fold, exerts a posterior thrust.

By the mammalian stage of evolution, the appendages have rotated so that they extend ventrally perpendicular to the trunk. This arrangement provides better support and makes for a long fore and aft swing of the legs. Lateral trunk undulations are no longer important in locomotion, although there is some extension and flexion of the back in certain fast-running mammals such as carnivores. Mammalian limb muscles as a group are very powerful, and although there has been a further subdivision and increase in their number, dorsal and ventral groups can still be recognized. Since the body is supported by vertical limbs, the ventral group is relatively less powerful than in primitive tetrapods that need to raise the body from the ground. Some ventral muscles shift during embryonic development from a ventral to a dorsal position, where they can participate in the swing of the legs. The supraspinatus and infraspinatus, which lie on the lateral surface of the scapular bone, are examples.

Dermal muscles

Fibres from some of the appendicular muscles fan out beneath the skin and form integumentary or dermal muscles that can pull the skin. Largest and most common of these is the panniculus carnosus, which originates from the pectoralis and latissimus dorsi in the shoulder region and spreads out beneath the skin of the trunk. Integumentary muscles beneath the skin of the neck and head are branchiomeric in origin.

Branchiomeric muscles. The bronchiomeric group of visceral muscles is very well developed in fishes, in which the visceral arches are prominent structures. All of the arches support gills in primitive jawless fishes, and the posterior ones still do in jawed fishes. The musculature of one of the posterior arches in a shark probably comes close to the primitive condition of the musculature for all of them at an early stage in their evolution. Most of the musculature extends as a sheet laterally and posteriorly from a gill arch and spreads over the top and bottom of a gill pouch, forming the dorsal and ventral superficial constrictors (Figure 8A). Deeper parts of the musculature extend between segments of an arch. All these muscles compress the gill pouches and drive water out of the external gill slits during expiration. Primitively, there probably was a dorsal levator for each arch that helped to expand the gill pouches during inspiration; but the levators of the last four or five arches have aggregated to form a triangular-shaped cucullaris, most of whose fibres act on the pectoral girdle. The gill pouches are expanded by the elastic recoil of the gill arches aided by the coracobranchial muscles of the hypobranchial group.

The visceral arches in sharks

The first visceral arch of sharks forms the jaws, and hence it is referred to as the mandibular arch. The second, or hyoid arch, helps to suspend the jaws; its upper segment, known as the hyomandibular cartilage, extends as a prop from the ear region of the skull to the posterior end of the upper jaw, or palatoquadrate cartilage. The ventral part of the hyoid arch extends into the floor of the anterior pharynx and mouth cavity. Muscles of these arches are naturally somewhat modified. The levator of the hyoid arch supports the hyomandibular, and most of the rest of the hyoid musculature forms constrictors that compress the gill pouch lying posterior to the hyoid arch. The levator muscle of the mandibular arch supports the palatoquadrate, and most of the rest of the mandibular musculature forms a large adductor mandibulae that closes the jaw. The most ventral part of this musculature forms the intermandibularis lying between the two halves of the lower jaw. Certain of its fibres incline posteriorly enough to help certain hypobranchial muscles open the jaw. With few exceptions, jaw-opening muscles are always relatively weak in comparison with jaw-closing muscles. Muscles of the various visceral arches are innervated by specific cranial nerves, and the pattern established in fishes is maintained throughout the vertebrate series.

During the evolution of terrestrial vertebrates, branchial respiration is replaced by pulmonary respiration; the jaws are formed of more superficial dermal bones that develop around the mandibular arch, the upper jaw is self-supporting and firmly united with the skull proper, and some changes occur in methods of feeding. Profound changes take place in the visceral arches and their muscles. Most of the mandibular musculature continues to act on the jaws, and the bulk of it forms the jaw-closing muscles, which in mammals are the deeply situated pterygoid muscles and superficial temporalis and masseter muscles (Figure 8D). The jaws are opened primarily by the digastric muscle, which extends from the lower jaw to the hyoid bone and thence to the base of the skull. The front half of it has evolved from mandibular muscles; the back half from hyoid muscles. Each part retains its characteristic innervation. A mylohyoid compresses the floor of the mouth, a tensor veli palatini lies in the soft palate, and a tensor tympani attaches to the malleus bone in the middle ear and regulates tension of the eardrum. It may seem odd that a mandibular muscle should attach to an auditory bone, but the malleus is a derivative of the mandibular arch.

Fate of the jaw muscles in mammals

The hyoid bone of mammals is moved primarily by the hypobranchial muscles. Only two small hyoid muscles remain associated with this arch; a stylohyoid extends to the hyoid bone from the skull base, and a stapedius muscle attaches onto the stapes bone in the middle ear cavity.

Most of the hyoid musculature has shifted superficially and spread out beneath the skin of the neck and face as the platysma and facial muscles of expression (Figure 8E).

Muscles of the third arch contribute to the musculature of the pharynx wall. The last arch is lost in mammals, but arches four to six form the laryngeal cartilages. Intrinsic laryngeal muscles, including those of the vocal cords, have evolved from the muscles of these arches. The primitive cucullaris expands and forms a group of muscles that act on the pectoral girdle; *i.e.*, the trapezius and sternocleidomastoid complexes.

FUNCTION AND REGULATION OF MUSCLE ACTION

Postural muscles, fast and slow. Less variation is found in the physiology and regulation of vertebrate muscle than in that of invertebrates, yet several distinct conditions are found. Most vertebrate postural muscles, which are the striated somatic muscles of the skeleton, are composed of muscle fibres belonging to the fast system described earlier. Each fibre receives one neuron terminal, and the fibre is activated only when the junction potential reaches a threshold that sets off an all-or-none action potential. Although any given fibre has a single neuron terminal, a single neuron branches and supplies a number of fibres. Groups of fibres activated simultaneously by one neuron constitute a motor unit, and there are many such units in a single muscle.

Coarse and fine control of muscle

Additional control of tension development derives from the number of motor units that are involved. Only a few motor units are contracting during tonic activity, but as more force is needed during phasic activity, more motor units are recruited. Muscles in which only coarse control over tension development is needed have few motor units, each is made up of many fibres, often 100 or more. Many leg muscles belong in this category. If finer control is needed, as in the extrinsic ocular muscles, the muscle contains many motor units; each is made up of only a few fibres, sometimes no more than ten.

All vertebrates have muscles containing fast-acting fibres in which a maximum tension can be quickly developed. These fibres are supplied by relatively large neurons having a diameter of 12 μm (micrometres). Some muscles of amphibians are known to contain fibres supplied by smaller neurons only 5 μm (micrometres) in diameter; these fibres belong to the slow system. They are supplied by many nerve terminals, and graded junction potentials can directly elicit a gradual contraction. Although some muscles are composed almost entirely of slow fibres, slow and fast fibres are intermingled in others; *e.g.*, the iliofibularis in the leg of the frog. Stimulation of both the large and small neurons can cause fast, all-or-none-type twitches to be superimposed upon the graded contractions of the slow system.

Visceral smooth muscle. When smooth muscle is active, there is a fall in its membrane potential and an increase in the frequency of small, spinelike action potentials. This is accompanied by an increase in tension development. Both electrical and mechanical events are graded. The lower the membrane potential, the greater is the frequency of action potentials and the greater is the tension.

Spontaneous muscle action

Unlike postural muscles, smooth muscle displays spontaneous and rhythmic activity that is independent of nerve action. This activity can be observed in nerve-free tissues, such as the amnion of a chick embryo or when nerve action is blocked in other tissues. Excitability spreads from fibre to fibre, in part, by the pull exerted by contracting fibres on their neighbours and, in part, by current flow from the membrane of an active cell to those of other cells through areas of close membrane contact where resistance to flow is low. Most conduction is along the long axes of the fibres because the fibres have an extensive and intimate overlap in this direction. Conduction is slow, often on the order of five centimetres per second.

Smooth muscle in different vertebrates, or in different organs of the same animal, varies greatly in its response to stretch, nerve stimulation, chemical mediators, and hormones. Parasympathetic (vagus) stimulation in mammals for example, is excitatory to the stomach and sympathetic (splanchnic) stimulation is inhibitory, but both are excitatory to the stomach of elasmobranch fishes, such as sharks, rays, and chimeras. In most mammals adrenalin, which is similar to the neurotransmitter of the sympathetic nervous system, inhibits and relaxes the entire intestinal region, but in adult guinea pigs, it excites and contracts the lower ileum (small intestine). Adrenalin relaxes the uterus of a rat; it also relaxes the uterus of a nonpregnant cat, but contracts that of a pregnant one. The hormone oxytocin specifically contracts smooth muscle.

Multi-unit nonstriated muscle. Muscles that erect the hairs, adjust the cornea and the iris of the eye, move the eyelid, and control the size of many arteries are morphologically smooth. They do not, however, show any of the intrinsic activity characteristic of visceral smooth muscle, and they are capable of rapid and direct nervous stimulation. Some can also be activated by hormones. They are often referred to as multi-unit nonstriated muscles.

ELECTRIC ORGANS

Electric organs are an unusual modification of muscle tissue that has evolved independently in several groups of fishes. The muscles involved may be extrinsic ocular muscles as in the marine stargazer (*Astroscopus*); branchiomeric muscles as in the marine electric rays (*e.g.*, *Torpedo*); or trunk muscles as in the electric eel of South America (*Electrophorus*) and the mormyrid knife fishes of Africa (*e.g.*, *Gymnarchus*). The electric catfish of Africa (*Malapterurus*) has an extensive electric organ beneath the trunk skin, but its derivation from muscle is not certain.

In the electric organ in *Torpedo*, each muscle fibre, or its motor end plate, is modified as a disk-shaped structure called an electroplax. During development the incipient muscle cell, or myoblast, flattens and loses its contractile apparatus. The surface receiving the nerve supply usually remains rather flat, but the opposite surface usually develops many protruding papillae. The motor neurons branch extensively and have many points of contact with the electroplaxes (see BIOELECTRICITY).

Museum

As institutions developed by modern society to stave off for as long as possible the deterioration and loss of objects treasured for their cultural value, museums do for such objects what libraries do for books and what archives do for official documents. Society does not save these things just to hoard them but to use them. Museums accordingly are organized to use their treasures for cultural purposes.

There are many kinds of museums. They all collect, preserve, study, and exhibit objects, but, within the common framework of these basic functions, they differ widely in what they do and why they do it. Though the museum as it is known in the 20th century is of relatively modern conception, its name was used for a different kind of institution, though of not dissimilar character, in ancient classical times: the word museum, derived, through Latin, from the Greek *mouseion*, "seat of the muses," was defined by Guillaume Budé in his *Lexicon-Graeco-Latinum* (1554) as "a place dedicated to the muses and to study, where one engages oneself in noble disciplines." Thus, the museum at Alexandria, Egypt, created at the beginning of the 3rd century BC in the Ptolemaic era and later destroyed, was not a museum in the modern sense but an institution of research, a library, and an academy. (Nearer to modern notions of museum is the Greek *pinakothēkē* [French *pinacothèque*, German *Pinakothek*], which Budé defined as the place where painted panels, objects of jewelry, standards, and other ornaments are kept.)

Notion of a museum

The notion of a museum springs from the passion for collecting, which is deeply rooted in human nature. All civilizations, from the most primitive to the most advanced, share the desire to accumulate objects that are beautiful, costly, rare, or merely curious. Religious communities, rulers, and magnates set up the first collections, open to the public or at least to certain members of it; examples are seen in the treasury of the Athenians at Delphi and later in the cathedral treasuries of the Middle Ages, as well as in the acquisitions of the Roman emperor Hadrian and, before him, of the Roman provincial governor Gaius Verres; similar examples are also found in the primitive civilizations of Africa and Oceania, at a stage of development comparable to that of the Neolithic Period or the European Bronze Age. From the basic satisfaction of the collector's instinct, one proceeds in time to the making use of assemblages of objects to suit the needs of study. Since society became organized, museums have opened their doors ever more widely to those sections of the population that have had access to knowledge through education. More recently, with the spread of university education, museums have begun to assimilate and make use of techniques of mass communication.

Today the museum is an institution that assembles, studies, and conserves objects representative of nature and man in order to set them before the public for the sake of information, education, and enjoyment. By this definition, the term museum includes not only those institutions known as such but also art galleries (noncommercial), picture galleries, secular and ecclesiastical treasuries, certain historical monuments, permanent open-air exhibitions, botanical and zoological gardens, aquariums, and libraries and archives in so far as they are open to the public.

This article is divided into the following sections:

I. Museum operations

FUNCTIONS OF MUSEUMS

The museum as a reflection of cultural and social environment

Social role. A museum is above all a reflection of man and his activity, of his natural, cultural, and social environment. It speaks a language that is specific, that of the object, the "real thing." In this way it exerts its influence on the illiterate visitor as well as on the visitor steeped in visual impressions from two-dimensional objects (pictorial images, reproductions, texts). Because of this, the museum has always played a social role; reflecting the might of church or state, offering a feast of research to the university and to the lone scholar, mirroring the varied interests of a local learned society, symbolizing the wealth and social status of a collector, and standing as a cultural monument to the glory of a city. In the contemporary world, a museum tends to be both an expression of the community and an instrument to serve it. Nonetheless, it often happens, particularly in the countries of Europe where it was born in the 18th and 19th centuries, that the museum remains a treasure-house frequented more by foreign tourists than by its immediate community. This mummified kind of museum, however, must disappear in the face of the needs of education and cultural activity in contemporary society. Indeed, through its collections, a museum above all presents the past, in everything that concerns natural history, art, archaeology, ethnology, or anthropology. That is to say, it presents the values of a vanished or vanishing society or, even further, focusses attention on permanent natural values endangered by modern progress. It marks out these values for the public as a "heritage" because of their importance for the continuity of culture. The values exemplified are moral, religious, aesthetic, historical, and biological, and interested visitors and research workers alike are reminded of forgotten ideas and are made aware of a starting point for an enhanced life. A window opens on the world, whether the infinitely small one of the electron microscope or the infinitely large one of the astronomical telescope, whether that of a neighbouring people or that of the inhabitants of the most faraway countries.

Preservation of cultural values. Through the values that it embodies and expresses in visual terms, a museum conveys an objective view of the three-dimensional world to its visitors, allowing them to exercise their critical spirit over their own heritage and that of other peoples, shaping their taste and arousing their curiosity. In the aristocratic world extending from Renaissance times to the end of the 18th century, collections of curiosities made by universities and wealthy individuals were the source of much scientific development. In the 19th century, young painters quite often received their training in the galleries of paintings of royal palaces. Twentieth-century civilization, insofar as it turns to the past for cultural values, is perhaps more than ever based upon the museum.

Role as an instigator of new cultural trends

The museum has an even more important role: it can stimulate artistic ability and intellectual purpose, awakening the creative spirit latent in each of us. As examples of spectacular success in this respect may be cited the Polytechnic Museum of Moscow, the Birla Industrial and Technological Museum, Calcutta, the East Harlem Art Studio (Neighbourhood Museum), the A.R.C. section

(Animation, Research, Confrontation) of the Musée d'Art Moderne de la Ville de Paris. Research undertaken by sociologists at Toronto, Tel Aviv, and Munich confirms this as does the success achieved by children's museums. A guarantor of the continuity of culture, the museum thus plays its part in the permanent creation of new cultural habits.

Service to the community. The museum serves primarily its community. The latter may be the nation as a whole (as in the case of the national central museums—British Museum, Louvre, Museum of History and Technology, Washington, D.C.) or be provincial or local. A community is perhaps also metropolitan; major cities have museums, which, like the Metropolitan Museum of Art of New York, have a principal responsibility to serve the population of the huge area surrounding them. The first duty of a museum is, therefore, to define its community, to understand its needs, as a whole and in its diverse parts —social classes, minorities, and so on. On this basis a museum's program, including the size and scope of its collections, the spread of its activities, and the material means to give them effect, will be established. Furthermore, the program must take into account the existence of the community's other cultural centres, the needs of teaching syllabi, from primary school to university, and lastly the reaction of the community itself, studied and evaluated at each level of museum activity.

Exhibition. Naturally, a museum's principal activity is the use of the "language" peculiar to itself—that is, of presentation—to display the objects belonging to its collections or occasionally lent to it for temporary exhibition. The aim of presentation is to provoke and facilitate direct contact between the individual and the object, whether the individual be a child member of a school group or an adult alone, whether the object be a work of art, a specimen belonging to natural science, or a working model in a gallery of technology. The science of the museologist and the art of the museographer (museology meaning the philosophy and theory of museums, while museography is the description of practical museum work) will convey the message simultaneously to diverse categories of persons. The object will be presented in the light of scientific, aesthetic, and psychological criteria and will be displayed in association with other objects in an explanatory and documentary display incorporating a coherently related group of things and ideas. This group of objects will be set in the larger context of the natural or cultural heritage. In the case of a work of art, the message of which is above all aesthetic and therefore individual, contemplation and assimilation will be made easier by a layout whereby a significant number of persons may without mutual hindrance enter into intimate contact with the work and benefit from what have been called the "tactile values" by the art historian Bernard Berenson. Recollection of the content will thus be more pliant and more allusive. The diversity of the public obviously gives rise to the greatest difficulty in the choice of display. After the static and quantitatively exhaustive displays favoured in the 19th century and in some "elite" museums of the 20th (crowded objects and fading labels unchanged for years in their showcases), the time has at last arrived for a division into permanent displays in great public galleries that are more or less educational, study galleries for the well-informed art lovers, and reserved material accessible to qualified researchers only. At the same time, a formula of flexible architecture permits frequent changes of display and the multiplication and rapid succession of temporary exhibitions, thus making it possible to serve all sections of the community simultaneously or successively, as is done, for example, in the Museum of Modern Art, New York, the Victoria and Albert Museum, London, the Musée National des Arts et Traditions Populaires, Paris, and the National Museum of Victoria, Melbourne.

Museology and museography

Collection. The problem of collection has likewise changed, since a museum now serves the community and no longer the cultivated social group that brought it into being. Most museums, with the exception of recently created institutions and university museums, have acquired their collections a little haphazardly, depending upon the taste of the donors and the particular scientific interest of the staff. For some years, it has been stated that a museum should have an acquisition policy defined by two criteria: the state of scientific knowledge and the needs of the community—thus a work of art should be acquired not for its rarity or price but to fill a vacuum in the existing collection's representativeness. For the same reason, a field expedition or an expedition for purchase will be a profitable enterprise for a museum of archaeology or ethnology. Museums often create new departments in order to respond better to public demand; for example, the Department of Architecture of the Museum of Modern Art, New York, the Department of Biology of the Moravian Museum at Brno, Czechoslovakia, and departments of city planning in a number of city historical museums.

Acquisition policies

Educational and cultural roles. Even if a museum has its specific form of address, or "language," and its particular effect on the public, it is not the only institution of education and culture at the heart of the community; it should cooperate closely with others, especially to become some sort of teaching institution itself. The École du Louvre, centre of the teaching of the history of art, set up at the end of the 19th century in the same building as the Louvre, is undoubtedly the foremost example of a popular university attached to a museum. Since then, a number of museums, particularly in the U.S., have initiated series of lectures and have organized a permanent cooperation with schools and universities. From the organization of guided tours, still widespread in France and the U.S.S.R., has arisen the creation of many-sided educational services, which have tended to become departments of education. The advent of audiovisual methods has compelled museums to present, in special projection rooms, programs of films complementing the displays of exhibits. In many central museums and in certain regional museums, teaching chairs at university level have been founded, principally in art history, anthropology, natural sciences, and museology, notably at Paris (Musée de l'Homme), at New York (Metropolitan Museum of Art), at Brno (Moravian Museum), and at Accra, Ghana (the Ghana National Museum). In an increasing number of countries, schoolteaching is closely linked to a museum. In Mexico, a visit to the museums of Mexico City is required annually for all secondary school pupils in classes of history, archaeology, and natural science. In Great Britain and in New Zealand, future teachers or headmasters of primary schools receive a special introduction to museum teaching. East Germany has produced school textbooks that continually refer to museum collections and provide a guide to a systematic tour of them; science museums have been most active in this field. The Museo Nazionale della Scienza e della Tecnica "Leonardo da Vinci" in Milan puts its laboratories at the disposal of senior high school classes.

The extension of direct educational activities of the museum and the growth of its social role to the benefit of the community have been such in the second half of the 20th century that it has appeared necessary to make museums extend outside their walls. In practice, they do not lend themselves to indefinite expansion; too great a flood of visitors prejudices the effectiveness of the instruction provided, by making it difficult to achieve that essential intimate contact between the visitor and the object on display. From this there have developed, during the 1950s, loan services to schools and travelling educational exhibitions to be succeeded by mobile museums (Richmond's Art Mobile, the science exhibitions on "museobuses" organized by the Birla Industrial and Technological Museum, Calcutta, the United Nations Educational, Scientific, and Cultural Organization [UNESCO] pilot museobus in Nigeria). Likewise, since the 19th century, and particularly in France, the great central museums have made use of their important collections in order to effect long-term loans and deposits in provincial museums to enable them to establish collections representative of all periods. More recently, particularly in the United States, opinions have been voiced calling for the decentralization

Mobile museums and museobuses

of traditional museums, established in city centres, for the benefit of suburbs and city neighbourhoods deprived on the cultural plane. The Smithsonian Institution has shown the way by establishing the first neighbourhood museum, at Anacostia, in Washington, D.C. The first colloquium of experts on the subject was held in 1969 in Brooklyn, New York, in another neighbourhood museum (Muse, located in the Bedford-Stuyvesant area), set up by the Brooklyn Children's Museum. In Sweden, in 1965, the government founded Riksutställningar, a pilot scheme for travelling exhibitions, to serve schools, urban and rural cultural centres, and provincial museums by using the collections of museums of the large cities. In countries such as France, where multipurpose cultural centres with up-to-date equipment have been created, museums have undertaken to cooperate with these centres by providing them with all types of exhibition.

Conservation and restoration. In order to be in a position to play its social, educational, and cultural role to full advantage, a museum should not only collect but should also cherish that part of the heritage of which it is in possession and for which it assumes responsibility. That is where the function of conservation, one of the more ancient of a museum, is so important. Museums and picture galleries have always had restorers attached to their staff to maintain their works of art in a good state of preservation, while science museums have at their disposal technicians able to mount specimens carefully. With advancement of scientific knowledge, more and more thorough research has been undertaken in laboratories, dealing with the conditions of conservation required for different kinds of exhibit. There has come to be a distinction between conservation and restoration. Conservation concerns the care given to collections as a whole, to protect them against three causes of alteration: environmental (temperature, humidity, atmospheric pollution, lighting); internal (biological, physical, chemical, or mechanical action within the object itself); and human (handling, transportation, etc.).

Distinction between conservation and restoration

Restoration is the work of repairing and reconditioning deteriorated objects; this requires manual skill and considerable scientific knowledge. The specialized services undertaking conservation and restoration can be classified under three categories: scientific laboratories employing research personnel with elaborate equipment (Institut Royal du Patrimoine Artistique, Brussels; Conservation Center, New York; Centraal Laboratorium voor Onderzoek Van Voorwerpen van Kunst en Wetenschap, Amsterdam; Istituto Centrale del Restauro, Rome); technical laboratories employing personnel of average qualifications under the direction of a scientist, using simpler equipment; and workshops devoted entirely to restoration work, in which the personnel consist of expert workmen. Such services can handle all materials comprising museum collections or deal with one specific material (*e.g.*, iron, wood, or paper). They are national or attached to a particular museum. The first great institutes go back to the 1930s; in the meantime, restoration workshops, which have always existed, have equipped themselves with apparatus for examining early works of art—X-ray, spectroscope, and so on. Training schools for specialists in conservation and restoration have been set up in Rome, Warsaw, New York, Brussels, Mexico, New Delhi, and Tokyo. Furthermore, the problems of conservation are now written into the programs of all courses of museology and museography. An international professional organization, the International Institute for Conservation of Historic and Artistic Works (IIC), with its offices in London, was founded in 1950. In 1958 UNESCO established the International Centre for the Study of the Preservation and the Restoration of Cultural Property, with headquarters in Rome. This organization, which is intergovernmental, was composed of 53 member states in 1971.

Research and publications. Research workers must be counted as a particularly important group of the public served by a museum; for a museum must obviously base its activities on thorough studies of its collections. Research, therefore, forms an integral part of a museum's life, whether it is research undertaken by the museum's own scientific personnel or by outside researchers making use of the museum's documentary resources. These resources ought, therefore, to be developed in a manner to respond to these needs. A first requirement is that inventories and catalogs of the collections should be as complete as possible. Unfortunately, few of them have been able to proceed beyond the level of accession registry or rudimentary card indexing. The reason lies in the shortage of personnel and also in the ceaseless curiosity of conservators, who will often give new acquisitions priority over old ones. The more advanced museums have catalogs or card indexes that include, besides essential identificatory information, complete, scientific documentation of the object. Some have even considered the utilization of computers for the systematic treatment of information concerning collections (for example, the University of Oklahoma's project for cataloging the state's ethnographic collections; Museum Computer Network, consolidating more than 20 museums in the U.S.; a Swedish project in the process of realization around the Livrustkammaren and Skokloster). Few museums, however, are likely to be able to assume the cost of such a system, and its introduction presupposes a good deal of preliminary groundwork yet to be done. Lastly, it appears difficult to envisage computers answering all the questions raised in the domain of the humanities, especially those about aesthetics.

Inventories and catalogs of collections

Besides documenting their collections, museums should afford to their own personnel and to outside researchers complementary facilities such as study rooms and accessible reserves, libraries, archives (particularly for museums of modern art) and occasionally even, as in the case of developing countries, make provision to house foreign visitors. Museums of archaeology or site museums in such countries as India, Pakistan, Peru, and Senegal usually put rest houses at the disposal of foreign researchers. Lastly, reserves and documentation of collections clearly ought to be readily accessible to all researchers, and this involves demands on such things as classification, furniture, and service personnel. Museums should be more and more considered as the normal places for the results of field expeditions—written, graphic, visual, and audiovisual objects and documentation—to be deposited. Thus the museums of natural science of Mexico (Museo de Historia Natural) and of San Francisco (California Academy of Sciences) have received in trust nearly all of the natural science collections from neighbouring universities, so that these shall be taken care of. To conclude the subject, one must mention particular university museums that have a more acknowledged research vocation than others, and the most important of these is without doubt the University Museum of the University of Pennsylvania at Philadelphia; most of the universities of the world, and the greatest of them, such as Oxford, Cambridge, Moscow, Ibadan, Harvard, and Yale, created such museums long ago.

Museum publications do not all fall under the heading of research. Many are of an educational and cultural character or are popular; however, the scientific resources of a museum obviously ought to be made available not only to research workers who are able personally to visit the collections but also to specialists all over the world. That is why scientific publications, periodical or other, are important. If the first are usually devoted to the research work of museum personnel, the others generally comprise exhaustive publication of collections, prepared with care and illustrated. The cost of such productions makes demands on a museum's limited budget, the more so because they cannot be presented as spectacular undertakings to the authorities or those otherwise responsible for finance.

Museum publications

MUSEUM PROCEDURE

Legal and financial arrangements. *Statutes.* Concerning their statutes, museums may be classified in two major groups: public museums and private museums. If they are state museums, the first group generally comes under the ministry of national education or the ministry

of culture, more rarely under the "technical ministries" (*e.g.*, museums of communications under the ministry of communications, army museums under the defense ministry, etc.) or under the ministry of tourism. If they are provincial, they come under district or municipal administration. This is the case of the great majority of museums of Europe and of the developed countries of Asia, Africa, and the Americas. Their personnel have the status of civil servants, and their management is ultimately controlled by the national administration. In certain cases, most notably in Great Britain, a committee appointed over the museum administers its funds and guides its policies. The collections belong to the national patrimony and are normally inalienable. In certain very centralized countries, such as France, even the municipal museums are placed under the technical control of a central administration that selects the scientific personnel and proposes nominations to the municipal administration. Private museums are totally or partly independent of the central administration. They are generally under the authority of a board of trustees or a council that is renewed by co-optation. The director, chosen by the council or the board, is responsible to it for the management of the institution and selects the senior members of the staff with its approval. This is the usual situation in the United States, where only the dependent museums of the Smithsonian Institution and the National Park Service have national statutes. The same is true of Canada, in such cities as Montreal and Toronto. In other countries, only a few isolated private museums come under national regulation, and it is the same with company museums.

Organization of private museums

Foundation. Historically, museums have been founded by individuals, by organizations, and by governments, but generally without special planning. A museum is established to house a collection that has been bequeathed or confiscated, in memory of a celebrated person, to protect archaeological discoveries at a site, or to raise a monument to the glory of a regime or a town. This procedure still applies except for a few great undertakings, such as those of the National Museums of Canada, the National Park Service of the United States, the open-air museums of Romania, and the national and provincial museums of Mexico. This has generally led to undesirable proliferation: in 1964 the rate of creation of new museums in the United States was estimated to be one every 3.3 days. For this reason many poor countries, with the support of UNESCO, now aim at long-term planning, while some European countries are preparing to consolidate their museums according to discipline or to province. It seems desirable not to discourage creative enthusiasm, while maintaining the principle of a minimum of planning, taking account of the needs of communities, and imposing on them a multidisciplinary program, indispensable in the present state of knowledge in order to avoid the old errors that had led to the division (sometimes even administratively) of museums into museums of science, art, history, and technology.

Resources and funding

Finance. Museums' resources can be ranked under four headings. Allocations and subsidies received from public funds constitute the main element of the budget of public museums regulated by statute and often form a not inconsiderable part of that of private museums. The drawback of such resources is a lack of flexibility in the application of their funds and the effect of fluctuation in the political order, through which museums come to receive a low priority in terms of budgetary considerations. A museum's own revenues, which only apply in the case of private or at least largely autonomous museums (notably in the United States), are sometimes considerable, but they seldom suffice to cover the expense of current running and only in exceptional circumstances allow augmentation of activities and acquisitions. Subsidies, gifts, and private legacies are often the sole means whereby a museum can pursue a policy of expansion, acquisition, and development; unfortunately, these resources are somewhat unstable, being often accompanied by conditions incompatible with the museum's freedom of action and susceptible to the effects of economic circumstances. A museum's receipts of a commercial nature are not of considerable importance except in the case of large institutions, and then only when they are statutorily permitted to retain what they receive for their own use, which is not the case with many national museums.

Until latterly, public museums had only public resources at their disposal (gifts could be used only for acquisitions), while the essential element in the budgets of private museums had been set up through private funds, thanks primarily to favourable tax legislation. Meanwhile, it has become apparent that museums, if they are to expand, must be able to benefit at the same time from both public and private funds in order to permit an administrative flexibility that can match the increase in educational activities, research, and conservation.

Entrance fee revenue

There is a tendency to believe that entrance fees to a museum constitute an important source of income. They are in fact negligible for a number of reasons. For one thing, in many countries, the sum of admission charges reverts to the public treasury; for another, a museum worthy of its name should keep admission charges as low as possible if it wishes its collections to be accessible to all and wishes to admit certain classes of visitors free of charge: children, groups, military personnel, students, and friends of the museum. This explains why many museums have given up charging entrance fees, after having established that their receipts hardly covered the salaries of staff employed to sell tickets and control them. They have turned rather to admission fees to temporary exhibitions, at a much higher charge, and to the proceeds of the sale of catalogs to these exhibitions, which are generally used to meet part of the cost of organizing the exhibitions. The British government decided in 1971 to charge admission to the national museums of England and Scotland. This move has been strongly criticized in political and professional circles because public collections are usually donated under the condition that museums and art galleries be accessible to all free of charge.

Personnel. Museum personnel may be classified as scientific, technical, and service. The scientific personnel—director, curators (keepers, assistants), specialists in education, conservation, and restoration—have had university training adapted to the museum's needs and, if possible, a complementary professional training in museology, teaching, conservation, and restoration. According to the international doctrine established at the ICOM seventh general conference, New York, 1965, such personnel should be recognized as having the status and advantages equivalent to those of members of the teaching profession with similar qualifications and responsibilities. This principle is, unfortunately, still far from being universally applied, which explains the difficulties in recruiting encountered by museums. Technical staff—draftsmen, museographers, documentalists, librarians, security specialists, preparers or restorers of the middle range—should possess the professional qualifications of their respective crafts. Museographers should have received, in principle, special training in the techniques of presentation, cataloging, and so forth. Service personnel include attendants, maintenance workers, and secretaries.

Specialized training of personnel

Specialized training of scientific personnel is a recent development. Since the day of the earliest museums, directors and curators have been recruited from among amateurs or from researchers in the disciplines represented in the museum. In the 19th century, some patrons were even put in charge of directing great institutions. In the course of the 20th century, it has become the practice to call on specialists in the scientific disciplines the museum is concerned with: a museum of art will be headed by an art historian, a department of archaeology by an archaeologist, and so forth. Unfortunately, the unfavourable status of museum staff and, above all, the salaries—inferior to those of universities—sometimes prevent the engagement of persons of the highest qualifications and in any case tempt such a person to leave after a few years to find a better situation elsewhere. On the other hand, this system is not suitable for museums of average importance, which are generally provincial and the collections of which are dependent upon a number of disciplines. That is why, under the impetus first of na-

tional professional organizations, then of international organizations, specialized training has been created; a hundred courses existed in 1970 throughout the world, of which half were in the United States. Many of these courses are of interest only to museums of art and history, few covered the generality of museums, and only some offered an advanced degree or diploma. Among the latter, one may mention the centres or courses at Brno, Leicester, Baroda (India), New York, Boulder (Colorado), and Rio de Janeiro. The École du Louvre at Paris is above all a teaching institution for the history of art. Some national museum associations have their own courses, of which the best known and most outstanding is the museum diploma awarded by the British Museums Association. An international committee of ICOM is endeavouring to establish norms for programs and diplomas. On the average, such training is postgraduate, lasts one or two years, and is directed toward university graduates in various disciplines.

Courses also exist for museum technicians, notably at Jos, Nigeria, and Santiago, Chile. These courses specialize in museographic techniques and are directed toward high school students.

Collection. Three questions can be asked in connection with museum collections; they concern program, acquisition, and management. The program is essential: established scientifically and in accordance with the aims of the museum and the needs of the community, it determines the type of objects that ought to be acquired to serve the objectives of research and exhibition. Acquisition itself depends above all on the available means (special budgets, field expeditions, and gifts and legacies); it can be made in two ways, directly and indirectly. Direct acquisition is essentially the collection of objects from the field by means of excavation and ethnographic or natural-science expeditions. The objects or the specimens recovered are scientifically documented and immediately available for research, education, or exhibition. Indirect acquisitions are brought about with the aid of one or more intermediaries: collectors and art and antique dealers. This is generally the only method for the acquisition of works of art, but its disadvantage is absence of documentation and the risk of illegality. In fact, since World War II, illegal traffic in cultural assets has become of great magnitude—theft, clandestine excavation, illicit export from developing countries, and pillage of poorly guarded monuments. Furthermore, an industry of fakes and copies has developed. Another means of acquisition is exchange with another museum or the deposit on loan of pieces belonging to a collector or scientific institution. UNESCO has successfully adopted a variety of international instruments on these subjects: recommendation on archaeological excavations (1956), recommendation on the illicit export and import of cultural property (1964), and a convention on the same subject (1970). Furthermore, a number of conferences have been held, notably in 1967 at the Metropolitan Museum of Art, New York, on fakes, and in Paris (ICOM) in 1970, on ethical rules of acquisition. No satisfactory solution has yet been found to facilitate the enrichment of the museums of Europe and North America while protecting the cultural patrimony of countries of the developing Third World.

Direct and indirect acquisition

The management of collections begins in the course of field expeditions (summary identification) or with their entrance into the museum. It includes primarily the registration on the museum inventory register. An inventory number will thus identify the object and will be marked on the object itself or attached to it. This number usually follows a code that includes, as a minimum, an indication of the museum or department, the year of accession, and the accession serial number during that year. The next step is the cataloging procedure of the collections, which usually consists of two cards: a museographical card carrying essential information on origin, composition, author, use, title, location in the museum, type of acquisition, price, state of conservation, etc.; the other a scientific card carrying all the information that may be useful to investigators. Depending upon the museum, these cards are written, typed, perforated, or computerized.

Documentation of collections

Museum collections are made up not only of original objects but also of documents referring to them, original audiovisual materials (ethnographic films, recordings, photographs), specially constructed models (above all for scientific and historical museums), and generally all documents referring to the museum's program that are of scientific or didactic interest.

Exhibition. From the church treasures of the Middle Ages to the museums of various categories of the end of the 19th century, exhibition or presentation hardly varied: as much as possible of the collection was shown to the public. The latter, belonging to the cultivated classes, was expected to be capable of finding what it was looking for among a medley of incongruous objects that came to be classified after a system inspired by the science of the epoch. During the first half of the 20th century, the notion of aesthetic presentation prevailed even in museums not dedicated to art. Since the 1950s, a rapid revolution has made itself felt, toward a presentation of items in relationship to one another, rather than in isolation, for everything that is not strictly artistic. Notwithstanding this, all the various schools still coexist: documentary presentation (eastern Europe), aesthetic (Italy and France), ecological (Mexico), and others. At the risk of arbitrary schematization, one can, however, distinguish three types, corresponding to three principal categories of museum. The first, aesthetic presentation, applies to art collections and seeks to isolate a work so that it may be totally perceived; it places the accent on backgrounds, lighting, space, and volume, while the documentary and didactic apparatus is either abandoned or placed as an introduction to the display or on an optional circuit parallel to the display. The complex historical presentation finds application in museums of history, archaeology, anthropology, and ethnology; it seeks to bring to life a cultural ensemble display by a combination of visual and audiovisual means with documentation prominently integrated; it generally brings into conjunction display galleries for a large public and study galleries; it integrates elements belonging to a number of disciplines—geography, economics, sociology, art, religion, and urban-development studies. The ecological presentation is applied to collections of natural sciences and recreates the environment of each species, of the kingdoms of plants, animals, and man. The latter tends to influence the historical presentation, associating man to his environment.

Types of presentation

Exhibition techniques have likewise evolved considerably in the past 100 years. Under the influence of technical progress, the static exhibitions of the past, tied to monumental architecture, have yielded place to much more varied display arrangements. To take only a few examples, in the field of modern art light and sound complete the object; in scientific and technical museums the animated model that can be manipulated by the visitor is being further perfected; the documentary apparatus, strongly influenced by the graphism of the Bauhaus (the name given to the group of modern architects and designers working first at Weimar and then at Dessau, Germany, in the 1920s), becomes an element of the aesthetic framework; temporary and travelling exhibitions have also become increasingly complex. Theatre staging has influenced the conception of exhibition space, and modern museums such as the National Gallery of Victoria, Melbourne, are only empty volumes in which the covering on floors, walls, and ceilings can be modified in a few hours. Complex lighting effects can be achieved by the modulated and controlled use of natural and artificial light sources. Guided instruction, formerly undertaken by guides conducting homogeneous groups in parties, is now becoming incorporated in the form of record machines as part of the display framework in support of the objects. Research and literature on display methods and techniques for all types of exhibition have proliferated, and during the 1960s the first private firms specializing in museography appeared, while the most important museums greatly strengthened their workshops in matters of exhibition design and mounting. Similarly, research on the museum public has led to the constant adaptation of display to meet the needs of the visitor.

Exhibition techniques

Travelling exhibitions

The improvement of transport facilities and the development of the museums' cultural role, with the diversification of their activities, have led to a multiplication of temporary and travelling exhibitions on a national and international level. The latter can be prestige enterprises, organized, say, on the occasion of world fairs (New York, Montreal, Osaka), or sponsored on a bilateral basis by two states. Most of them, however, have a purely scientific and cultural character, or they may be educational. In this last case, the program of the exhibition is drawn up by an expert or experts, who also take charge of the display as a whole, while the details are taken care of by the museums taking part. The principal problems are insurance, the increasingly prohibitive cost of which (due to the influence of the art market on the estimated value of the works to be insured) is a heavy burden for the museums concerned and gives government-organized exhibitions an advantage; and also security and transport, particularly with regard to the packing and unpacking of the crates.

Other operations. *Public relations.* In the past the public was simply a security problem, and little else, to a museum, because of the risk of vandalism and theft. These risks still exist, of course, and have multiplied with the growing popularity of museums and the increase in the value of their collections, above all those of art museums. But growing consciousness of their social role has led museums to create new services: publicity, public relations, information, documentation. The increasing flow of visitors has begun, especially in the tourist towns of Europe and North America, to pose problems of space and surveillance, on the one hand, and of air conditioning of galleries, on the other. Specialists have begun to realize that these problems are not very different from those affecting other institutions dealing with a mass public, such as theatres, operas, cinemas, and supermarkets. It is also the case that transport and visitor parking assume increasing importance in the site plan of a museum, while up-to-date electronic systems of surveillance have been widely adopted.

Assistance to research. For obvious reasons of conservation and management, a museum cannot lend its collections out for people to consult, as a lending library does. The problem of research, one of growing importance in a museum's everyday life, has already been mentioned. Every museum is also a documentation centre where objects, photographs, films, recordings, texts, and index cards ought to be readily available and be looked after by qualified staff. The library, formerly reserved for the exclusive use of the museum's own scientific personnel, has become a general library covering the range of disciplines represented at the museum. The film, photograph, and phonograph libraries fill a threefold role: as archives, as museographic reserves for use in display to the public and for cultural activity, and as centres for consultation. It is not unusual, especially in developing countries and some provinces without research institutions, for a museum to be a headquarters for archaeological and ethnographic expeditions, for the inspection of historic monuments, for local learned societies, and sometimes even for teaching at the university level.

Conflicts of interest in museum operations. It stands to reason that the development of a museum's social and scientific missions involves internal tensions in the heart of the institution and its personnel. Whereas in the past a museum was a temple, a depository of objects and works for the enjoyment of a minority, it must now satisfy conflicting needs: to educate, to entertain, and to contribute to the development of knowledge. Too many museums still consider that research is their essential job and attach little importance to their cultural and social role. These museums appear static, shut-in upon themselves for the benefit only of their scientific personnel who can devote themselves to basic research without sufficient justification, vis-à-vis the community. Other museums, in increasing numbers, have devoted all their means to education and culture, becoming many-sided cultural centres without the necessary scientific basis. In fact, like a university, a museum should reconcile the requirements of science, which cannot proceed beyond research, and of culture, which should be oriented toward as large a public as possible. Various writers, moreover, see the museum's future as an institution situated at the city centre and housing its collections and its research and conservation activities there but decentralizing itself over the entire urban conglomerate or rural area in carrying out its cultural and educational activities.

II. Types of museums

The origin of museums is found either in the royal or ecclesiastical treasures of the Middle Ages or in the cabinets (little rooms) of curiosities and specimens first kept from the 16th to the 18th centuries. In a general way, art museums may be said to have sprung from the treasures, including royal or princely collections, while science museums have inherited the cabinets of curiosities. It was at the end of the 18th century, under the influence of the French philosophes and the Enlightenment, and at the beginning of the 19th under that of scholars that the classification of museums into categories, according to the terminology of the disciplines to which their collections belonged, was born. This first typology, which remains in force in a number of countries and which is still reflected in the names of the specialized committees of ICOM, distinguished between the museums of fine arts, applied arts, archaeology, history, ethnography, natural science, science and technology, regional and local museums, and specialized museums. Meanwhile, the evolution of museums since World War II has made the barriers between the disciplines and types of collections disappear progressively. It seems more justifiable now to divide museums into three categories: artistic or aesthetic, historical, and scientific.

ART MUSEUMS

Kinds of art museums

Art museums are those whose collections are conceived and displayed essentially for their aesthetic value, even if the objects they enclose are not all works of art in the intention of their creator. In this way, in addition to the museums of painting, sculpture, decorative arts, applied and industrial arts, one may include most museums of antiquities, of folklore, and of primitive arts. Some museums, generally those of more recent creation, demonstrate such arts as those of film, music, and theatre. As has been said above, the work of art is displayed for its own sake in order that a direct and intimate contact between the visitor and the object may be established. The state of preservation of the work, the quality of restoration, the environment it is given, notably the background and lighting, assume special importance. The didactic character of the display has disappeared almost entirely, since enjoyment carries the day over acquisition of knowledge. Concerning the fine arts, the masterpiece is the rule, and here temporary exhibitions allow the public to become familiar with collections that the museum could not acquire because of the rarity and high price of masterpieces. For the other arts, it is the objects as a whole that are important: series of tapestries, period rooms, services of silver plate, and so on. Regarding primitive art or folklore material, this art tends to link itself with the fine arts, to the extent that the modern socialization of culture no longer allows the art of the elite, in the European sense of the term, to be considered the only valid art. In all circumstances, the significance of the work of art, its functional or religious intention, is hardly important: a 15th-century virgin and child are not presented as a cult object any more than is an African mask. The danger of this separation of beauty from function is that the display risks becoming theatrical, all the more as museography attaches as much importance to the aesthetic beauty of the framework as to that of the object. In Italy, for example, in the museums of antiquities, stands and showcases are often works of art in themselves, but they therefore hamper contact with the objects they contain. Artificial light is usually considered preferable for paintings, natural light for sculptures. Precautions need to be taken to avoid alterations resulting from the lighting (*e.g.*, the level of

lighting, infrared and ultraviolet radiation). Museums of modern art occupy a separate place among art museums. They are, in effect, given up to art in the process of development and to the aesthetic environment of contemporary life. So it is natural that their activities are of a character that is above all temporary, reflecting the diversity of aesthetic movements and the problems of the moment. The museums of modern art of Stockholm and New York, the Musée d'Art Moderne de la Ville de Paris, the Stedelijk Museum, Amsterdam, among others, are also places of experimental action, open to all forms of art, comprising the theatre and music. The open-air sculpture museum is a recent form of exhibiting contemporary art, as for example, the Billy Rose Art Garden of Jerusalem and the Hakone Open Air Museum of Japan.

Museums of modern art

The public of a museum of art is essentially a public of amateurs and the curious, and this type of museum is of particular importance in the framework of leisure and tourism. The question of education raises specific problems: when the system of primary, secondary, and higher education gives art a large place in it, the art museum becomes an integrated part of such a school system, bringing it the help of its visual resources, as is the case in Great Britain; if a school does not teach art or does not teach it well enough, the museum should alleviate the deficiency and find new methods—whence the creation of children's museums and of rooms of aesthetic initiation.

HISTORICAL MUSEUMS

All museums where collections are conceived and presented in a historical perspective should be classed as historical museums, their object being essentially to document a chronological sequence or an ensemble representative of a moment in an evolving pattern. The Musée de l'Histoire de France, created by King Louis-Philippe (1773–1850) at Versailles, displays, with the aid of pictures, the outstanding events and persons in the country's history during more than 1,000 years. Few museums, however, are devoted entirely to the history of a country, although that formula is being used by some countries that have recently become independent in order to arouse national consciousness and a sense of cultural–historical unity. In the countries of Europe and America, history museums of provinces and towns are found frequently: the Musée de Bretagne (Brittany) at Rennes (France), city museums at Warsaw, Dresden, Stockholm, Amsterdam, Rotterdam, London, New York, and the Heimatmuseum in Germany. The great national historical museums are the Museo Nacional de Historia of Mexico City, the Museum of History and Technology of Washington, D.C., the Musée National de Versailles et des Trianons, the Muzium Negara of Kuala Lumpur, Malaysia, the National Museum of Budapest, and the national history department of the Rijksmuseum, Amsterdam, which was inaugurated in October 1971. The most modern of these museums display the whole history of a country, region, or town from its origin (including natural history and geography) to the present age, without neglecting the perspectives of actual development, such as land acquisition and urban growth. They integrate science and art, call upon all kinds of audiovisual media, and give a large place to written graphic documents, to ecological reconstructions and models, and to maps. The exhibitions are often housed in an ancient building, itself a historic symbol.

National historical museums

Other kinds of history museums include those at archaeological sites, museums installed in a historic monument or on a battlefield, and personal memorial museums. Examples of these include Mount Vernon (Virginia, for George Washington), Archaeological Museum (Taxila, Pakistan), Lenin Museum (Ulyanovsk), and Museo Arqueológico de Teotihuacán (Mexico). These museums are often didactic and comprise reproductions and models; sometimes, and especially in the case of memorials, they appeal to the feelings of the visitor by respecting the actual setting of a person's life and the simplest objects that belonged to him there: this is the case with museum homes, such as that of the writer Ernest Hemingway (1899–1961) in Cuba.

Finally, there is the historical museum, dedicated to a period in the history of a country or region: such are ethnographical museums, better named in Scandinavia as museums of cultural history, whether they are presented in traditional fashion in a building or in the open air. These museums—for example, the Skansen of Stockholm, Colonial Williamsburg of Virginia, the Musée National des Arts et Traditions Populaires of Paris, the Village Museum of Bucharest, Romania, and the Museum of English Rural Life of the University of Reading, Berkshire—retrace the preindustrial or protoindustrial epoch. Attractive to the public, especially in open-air form, these museums contribute notably to the understanding of and respect for the human environment and fast-vanishing cultural traditions. Developing countries attach importance to them in their efforts to reconcile the survival of traditional values with industrialization. One of the most successful examples is undoubtedly the National Museum of Niamey (Niger), which combines a zoological garden, an open-air museum, and an ethnographic exhibition.

Museums of cultural history

The problems of display that arise for museums of the historical type are specific, in that objects are shown for their functional and historical significance, and the written or recorded commentary, the relationship between groups of objects, the scientific rigour of the program, and the flexibility of display take on a determining importance. In the same way, reserves and study galleries take up a great deal of room in these buildings because the breadth of the subjects treated is such that knowledge about them makes continual progress. Frequent temporary exhibitions, modifications of permanent displays, and scientific activity at the museum and on field expeditions are vital for the museum, except where very specialized museums (*e.g.*, memorial museums) are concerned.

SCIENCE MUSEUMS

Museums of natural science, of exact or applied science, and technical museums (except for museums of the history of science and technology, which are counted as historical) are classified as science museums. The task of science museums is to communicate in three-dimensional form a scientific spirit and mentality, to arouse natural inclination for science, to give information on research and progress, to give each person a sense of sharing in technological development, to make people wish to understand, appreciate, and conserve nature and man's natural environment in an ecological and historical perspective, so as to demonstrate the evolution of nature and man. The museums of natural science that were created first were the Muséum National d'Histoire Naturelle of Paris, at the end of the 18th century, and the British Museum (Natural History), of London. They multiplied considerably during the 19th century with the development of natural science, and, in the United States and Latin America, they have absorbed physical anthropology and then social anthropology. If their evolution has been slow during the first half of the 20th century, they have been transformed quickly enough since 1950: witness the renovated sections (since 1960) of the American Museum of Natural History, New York, and the Museo de Historia Natural, Mexico City. In Europe, their rise has been less, although mention may be made of "pilot" museums such as the Moravian Museum at Brno, which combines biology, genetics, and other sciences, and the Museum of Zoology of the University of Copenhagen.

The functions of science museums

Museums of the applied sciences and technical museums, of which the most celebrated example is the Deutsches (German) Museum of Munich, are more recent. Some of them are devoted solely to the sciences, such as the Palais de la Découverte (Palace of Discovery) of Paris. Others are essentially technical, such as the Museum of Science and Industry of Chicago. Developing countries are anxious to establish these museums for the sake of popular education; and India has succeeded in establishing three, at Calcutta, Pilani, and Bangalore. Large industrial companies see in these museums a means of publicizing their production and applied research.

Use of models in science museums

All of these museums associate the real object (natural specimen, machine) with the model (diorama, dummy, or animated model) and with demonstration (physical experiments, planetarium exhibitions, field trips). Their aim is essentially didactic, and their educational activities are very important and decentralized. Some museums organize travelling dismountable exhibitions to serve distant regions and those least developed technologically; others use mobile museums, as at Calcutta; still others offer various facilities to schools that do not possess laboratories and workrooms, as at Milan. More recently, the tendency has been to renounce the name of museum and adopt instead the expression centre of science and technology, which is the case with institutions sponsored by UNESCO and the new Ontario Science Centre.

Science museums are probably the best attended and the most active of museums. They have made the most vital progress in museology and in the techniques of presentation. Within the framework of positive efforts to conserve the environment, museums of natural science have a particular role to play in informing and persuading the public. On a scientific level, these museums have also supplied researchers with documentation (millions of specimens) permitting the advancement of knowledge in a multidisciplinary perspective.

SPECIALIZED MUSEUMS

Open-air museums. Mention should be made of museums that have not been established in a classic exhibition building but that have been created instead within the bounds of a garden or park, the exhibited objects being set up in the open air. These museums are dependent upon all the scientific disciplines but raise special museological and museographic problems. One finds, thus, ethnographic museums (Skansen at Stockholm, National Museum of Niamey, Rijksmuseum voor Volkskunde "Het Nederlands Openduchtmuseum" at Arnhem), museums of natural science (zoological or botanical gardens), archaeological museums (Prehistoric Museum at Moesgård, Denmark, archaeological sites considered to be museums), museums of art (sculpture gardens), and museums of the history of technology. Though the administration, services, and reserves are lodged in spacious buildings, special problems of conservation and of the circulation of the public remain. Because of their character as parks, these museums are very attractive and are often described by visitors as "more lively" than traditional museums. Furthermore, their dimensions permit the reception of a greater number of visitors than any other kind of museum. It is probable that their future is unlimited, above all in developing countries, where the land is not dear, even in the centre of cities. From the point of view of presentation, one finds here the means of artificially creating a more satisfactory environment than the ecological reconstructions of indoor museums. There is, however, a danger that exists in the temptation to "fake," especially in open-air ethnographic museums. These museums should in fact obey extremely strict rules, on the scientific level, for collection and presentation. Finally, conservation is made difficult by climatic conditions, for the collections are left outdoors under the open sky and are subjected to variations in temperature and humidity, without the possibility of control or correction.

Though they can all be fitted into the categories already described, their specialization itself poses particular problems for specialized museums. Some among them are of great importance and have contributed much to the development of museology: like the regional museums, they are usually obliged to call on a wide range of techniques and to integrate many scientific disciplines. A transport museum, for example (such as those of Budapest, Lucerne, and Dresden), will make reference to geography, economics, history, and sometimes even to art if ancient or modern artists have illustrated aspects of transportation. Thus one finds museums of wine, clock making, fabrics, hygiene, musical instruments, ceramics, fishing, and other subjects. Many of these museums describe limited economic activity (mineral exploration, the shoe industry) and, in this case, are more or less tied to the industry they illustrate; others treat of an artistic activity (theatre, marionettes, music, cinema) and have a threefold aspect—historical, artistic, and technical.

Children's museums

For want of something better, one may classify under this heading museums that appeal only to one section of the public, as do children's museums, when the latter are not simply a section for children in a big museum. The Brooklyn Children's Museum of New York, the Bāl Bhavan of New Delhi, and the Children's Museum of Algiers have their own collections and their own activities, which make appeal only to children. It is the same with museums for the blind and with some university museums that serve only an already very specialized student public. These museums have their systems of presentation and collection and have programs of activities determined in their application by the homogeneity of their public and, except for university museums, not generally undertaking any scientific research.

Regional museums. Regional, or local, museums devoted to all aspects (natural, historical, and artistic) of a region or district, such as are found in western or eastern Europe, India, Mexico, Chile, and Canada, are of interest through their multiplicity of values. At the same time, they serve a community that is culturally homogeneous or is destined to become so. Their first responsibility is therefore to reflect this community and to give value to its traditions and its creative spirit; the second is to open the community to the outside world, particularly in serving as a relay station for the central museums, which can send them exhibits or collections on deposit that illustrate the cultural and natural, national and international, heritage. Their usual handicap is to have been founded by a patron or by a local learned society that imposes obligations that are incompatible with the development of a modern museum. The majority of them still consist of departments or sections representing scientific disciplines: this setup, which is indispensable for reserve collections and for research, should gradually disappear to give place, on the level of public exhibition, to a better integration as a museum of history. Some have already taken this step, such as the Kanagawa Bunko Museum of Yokohama.

Other institutions functioning as museums. Besides museums properly speaking, numerous institutions employ the same language of presentation regarding the object itself, sometimes with a directly cultural aim, sometimes with a view to publicity or the diffusion of various aspects of knowledge. In the first category are institutions such as archives and libraries, whose collections are not intrinsically of the same nature as those of museums but whose role is equally cultural and educational and, indeed, scientific, and also cultural centres and exhibition halls (such as Kunsthalle in Germany) that do not have permanent collections. These last are not recognized by the American Association of Museums, whose rules of accreditation are very strict, but they are recognized by the International Council of Museums (ICOM), which seeks to associate them with museums in order to make them observe the professional regulations established for museums, in the interest of the collections and the public. One must not neglect these institutions, which in many cases constitute useful and natural staging posts for museums, particularly for their travelling exhibitions.

Archives and libraries

Distinct from those above, many enterprises have been created by business and industry, whether they be company museums such as the Evoluon, built by Philips N.V. at Eindhoven, The Netherlands, exhibition fairs, or small specialized displays, not to speak of international fairs and exhibitions the contents of which are partially cultural and partially scientific, technical, and economic. It is difficult to say, in each case, which of them is an activity of museum type and which is simply publicity or a commercial event. Nonetheless, their techniques of display, use of animation, and contact with the public are often worth the attention of the museologist. That is why, in 1969, the museums of The Netherlands organized their country's museums fair, called Musement, in the halls that house the commercial fair of Utrecht; this allowed a number of tests of public reactions and of methods of presentation to be made.

III. Museum architecture

Influence of the past on museum architecture

Just as with the content of a museum, the container itself is largely fashioned by the past. First, a museum's history conditions its architecture; the religious treasures of the Middle Ages were kept in churches and monasteries, and the royal collections were lodged in palaces or castles; art itself was closely linked to the dwellings of the social class that generated its creation. When the relics of feudalism made room for the political and cultural democratization that developed progressively during the 19th century, many palaces, symbols of the old order, were transformed into museums, while, in countries or towns without palaces, the new museums imitated, with greater or less exactness, temples, palaces, and castles. So it is that the first great U.S. museums adopted Neoclassical or Palladian architecture and that the museums established by the British in India reproduced Neo-Gothic or Victorian architecture. In the Soviet Union, after the Revolution of 1917, the royal or aristocratic dwellings were transformed into houses of culture for the people. In central and western Europe, this tendency was prolonged and still continues for other reasons: the great number of historical monuments left to the state or to local administrations, following their abandonment by their traditional owners or their confiscation by a new political regime, obliged those responsible for them to find new uses for them; and their transformation into museums became the customary method to preserve and reanimate them.

Since World War II change in museological theory has caused the theory of museum architecture to evolve, at least in advanced countries, and national and international meetings of experts have attempted to define a doctrine of functional architecture for museums. Successively now will be examined: the traditional temple museum; the monument transformed into a museum; the architectural style of recent museums; the most advanced theories actually put into effect; the problem of aesthetics versus function in modern museums.

TEMPLE OR PALACE MUSEUMS

The British Museum in London, the complex of the "Museum Island" in East Berlin, the Metropolitan Museum of Art in New York, the National Gallery of Art in Washington, D.C., the National Gallery, London, and many others are structures of monumental character, generally imitating Greek temples in their exterior appearance: colonnades, pediments, heavy classicizing decoration. Within are rooms covered with marble or hard stones, with lofty ceilings, vast staircases sometimes occupying a third of the available space, inconvenient circuits for visitors, lighting as high up as possible—all elements designed to emphasize the value of the collections of masterpieces in a solemn and almost religious atmosphere. The visitor has to be impressed, dazzled by the splendour of past centuries. It is a curious thing, for the same phenomenon can be found in museums of natural sciences, such as the American Museum of Natural History in New York or the Muséum National d'Histoire Naturelle in Paris. In all these edifices, the space devoted to reserves and services is insufficient, inadequate, and impractical. This type of museum, born at the end of the 18th century and in the 19th, continued to be built thereafter. In some way, one can think of the Israel Museum in Jerusalem and the Nationalgalerie in West Berlin—this last the work of the German architect Ludwig Mies van der Rohe —which date from the 1960s, as representing the modern conception of the temple museum. Such museums are generally constructed in the centre of old towns, and their adaptation to the needs of the modern world is inconvenient and costly. In other respects, they often become historical monuments themselves, and their extension raises difficult problems, as with the Tate Gallery in London. Educated traditionalists are attached to them, while the "new public" and the contesting groups take exception to a stultifying consecration of the heritage. The solutions adopted for the transformation of these edifices to turn them into modern museums are generally radical: installation of false ceilings or mezzanine floors, suppression of natural light by obscuring windows and glass roofs, subdivision of rooms, suppression of decorative painting and sculpture, and so on. In many cases interior courts have been covered over in order to install reserves there, and extensions have been constructed on adjacent land. Among the most spectacular achievements of modernization may be cited the covered courts at the Rijksmuseum of Amsterdam, the projects being carried out at the Metropolitan Museum of Art of New York, the new installation of Greco-Roman rooms at the British Museum of London, and the internal remodelling of the whole of the National Museum of Budapest.

The modern temple-museum

MONUMENTS TRANSFORMED INTO MUSEUMS

The great majority of museums created between 1800 and 1950 have been housed in existing historical monuments: the Louvre in Paris, the Hermitage in Leningrad, the Uffizi in Florence, the Prado in Madrid, and innumerable provincial museums. Developing nations forgoing construction of new buildings as museums have also followed this trend: the Queen's Palace at Tananarive (Malagasy Republic), the National Museum at Libreville (Gabon), the Fort Jesus Museum at Mombasa (Kenya), the National Museum at Bangkok, the Museu Nacional of Boa Vista at Rio de Janeiro. These museums offer problems of great architectural interest, for the buildings utilized are no easier to transform than the temple-like edifices, and they also impose restrictions in respect of their aesthetic and historical character. Their restoration and equipment for use as a museum are carried out by the same architect, who is seldom chosen by the museum director but is more often imposed by the administration responsible for historical monuments and public works. Italy and France have gathered experience from these problems, for which it is impossible to lay down rules, the building being a work of art in itself (*e.g.*, the case of the Petit Palais at Avignon, France, which is to become a museum of Italian primitive art).

Limitations of historic buildings

The position of this sort of museum is seldom good, it being situated in the historic centre of town, with attendant problems of traffic circulation and access. The humidity of the walls and the internal atmosphere are often damaging to the collections. The natural lighting is either insufficient or too dazzling, in which case one must either add or suppress windows. Space is not flexible enough, and the museographic equipment needs to be adapted to work on inconvenient surfaces. Generally speaking, their intimate character makes these monuments better suited for museums of painting, for memorial museums, for specialized history museums, and even for the installation of private collections. The didactic aspect of contemporary museography is not at ease there, and, with the exception of a few vast buildings like the Louvre and Versailles, these museums cannot receive more than a limited number of visitors at a time. One notes, however, the great success of the Historical Museum of the city of Warsaw, installed in eight bourgeois houses joined together. It is usually necessary, as in the example above, to make the program of the museum coincide closely with the character of the monument and to avoid installing a folklore museum in a royal palace or a museum of secular art in an old church. Another important element to take into consideration is that of the security of the collections, to the extent that historical monuments are, in general, more susceptible to fire or theft than other museums.

Nevertheless, the tendency to make use of this type of building will continue in countries rich in monuments, and it is a question then of a form of museum that permits the safeguarding, for cultural aims, of important evidences of the heritage.

RECENTLY CONSTRUCTED MUSEUMS

It is necessary now to distinguish again between museums of private or semiprivate status (endowed with a board of trustees or a council) and museums of public status. In the first, the influence of the director and the scientific personnel in the choice of architect and those over him is often weighty: those responsible for the museum must establish a program in accordance with which the architect will be chosen and by which he himself will then

have to abide. In the case of the publicly run museum, the personnel do not possess the same liberty. The architect is chosen either from among the official architects of the administration or municipality or by a national or international public competition; it is then very difficult for the museum personnel and for the director to bring influence to bear on the work of a technician who has been more or less imposed upon them. Moreover, the decision to build a publicly regulated museum always has, in one form or another, a political character in the widest sense, and the appearance of the building does not belie it.

Museums designed by modern architects

Among the most modern museums, many are in themselves monuments, heirs to the concept of museum-temple or museum-palace. The great modern architects, such as Le Corbusier of Switzerland and Mies van der Rohe and Frank Lloyd Wright of the U.S., in the museums of Tokyo, Chandīgarh, Berlin, and the Solomon R. Guggenheim Museum, in New York, seem to have intended to show in practice their own ideas of museology and thereby to express enduringly their own artistic genius. This kind of solution has seldom led to museums that are really effective, even if their aesthetic character assures their fame. These buildings are, in fact, conceived from the outside, and their interior space, though occasionally suitable for an artistic exhibition according to the norms of the time of their construction, cannot be adapted to the incessant changes in museological concept. Other museums, less prestigious and less celebrated, seldom situated in capital cities, owe their construction to architects who are less well known but who have been willing to collaborate closely with museological personnel capable themselves of preparing a precise program. Some examples, among many others that have been completed or are in course of construction, are the museums of Edmonton (Canada), of the Abegg-Stiftung at Riggisberg (Switzerland), of Arts et Traditions Populaires at Paris, of Antiquities of Sicily at Syracuse, and, above all, the complex of modern museums of Mexico, at Mexico City and in the provinces. They are characterized by the systematic use of the most modern material and techniques, the spatial division of service areas and zones open to the public, the creation of flexible space in volume for permanent and temporary exhibitions, the extent of the reserves and of research facilities, and by a carefully studied ground plan to work in conjunction with all-round urban planning and with means of transportation and parking (many levels of parking, for example, under the National Gallery of Victoria in Melbourne). If museums of this type are still found situated at the centre of a city, there has been a tendency in favour of museums in the country (Rijksmuseum Kröller-Müller at Otterlo; Louisiana Museum near Copenhagen) or in new towns.

In developing countries, for want of means, new building is rare and the lack of qualified personnel sometimes allows great freedom to the architect, who is usually appointed by the administration (public works department). The result is mediocre more often than not, because a program is lacking or else because it has been prepared by an expert strange to the country and ignorant of the community's requirements. The architecture itself scarcely differs from that of a school or a hospital built by the same architect. In the richer developing countries, the wish to construct museum-monuments linked to prestige urban planning (Abidjan, in the Ivory Coast; São Paulo in Brazil) has begun to make its appearance.

THEORY OF MUSEUM ARCHITECTURE

Collaboration between architect and museum directorate

Several international meetings have studied the problems of architecture, especially the relations between the architect and those responsible for the museum. Two of them, organized by ICOM in 1961 (Milan) and in 1968 (Mexico), have contributed greatly to the laying down of the main lines of an international code linked to the development of museology and museography. The director, assisted by his scientific personnel, is considered as the "master of the work"; by this title he lays down the program and chooses the architect (or gives his approval to the choice). The architect is the "master of the workmanship" and prepares the project in accordance with the program, with which he is provided. Then, the master of the work and the master of the workmanship cooperate in perfecting the program and the project derived from it until the building is completed and the collections and displays are installed. Increasingly, specialists of other disciplines—urbanists, sociologists, climatologists, specialists in conservation—are added to the basic team and intervene at various stages of preparation and completion.

The building should be flexible and extensible: interior and exterior circuits should separate the public from the service personnel and the unexhibited collections as far as possible. Environmental conditions (lighting and climate) should be studied before the adoption of the project and at the same time as the museological program. The interior fittings and displays depend, at least in their main lines, upon the cooperation of the director and the architect, since the choice of technical solutions will be conditioned by the architecture and the program. When the museum is functioning, it should be the subject of an evaluation through a study of the public and the personnel to discover their reactions. This is why it is desirable that the architect responsible for the construction should remain in charge of the building after its inauguration, in order that he may be in a position to correct his work should the need arise.

The program's importance should be emphasized. Its quality will condition that of the building. Its establishment is long and exacting labour, which relies on a clear idea of the aims and functions that it is desired to give the museum, the needs of the community and of research, the nature of the collections, the requirements of display and conservation, and the scientific conditions. The program must be prepared and discussed, not only with the scientists of the disciplines concerned but also with those who will be responsible in the future for conservation and education, representatives of the regular users, and the museographers who will be in charge of displaying the collections.

AESTHETIC AND FUNCTIONAL ARCHITECTURES

Until the 1950s it was more important, as has been noted, that the architecture of museums should reflect the concept of a museum as the sanctuary of beauty and of the past: the building reflected a striving for the monumental to the exclusion of real architectural creation for the sake of striking the imagination and providing a jewel case worthy of the treasures enclosed in it. In the same way, newly constructed museums in several developing nations still go on imitating traditional architecture: the Muzium Negara of Kuala Lumpur and the National Palace Museum of Taipei. Since 1950, influenced by modern architectural trends and the development of museology, two theories have emerged: a museum will either be a cultural monument in itself, whose siting, external appearance, and materials employed will be a symbol of its role at the centre of community and as a key element of the new city; or it will simply be a box concentrated on its interior and conceived strictly in terms of its collections and the intellectual satisfaction of its visitors. The first concept applies to some of the most celebrated museums built since World War II: the Solomon R. Guggenheim Museum, Oakland Museum (California), the Nationalgalerie of West Berlin, the Israel Museum in Jerusalem, and others. Such edifices are in general neither flexible nor capable of extension, even when they are in complete accord with the program designed for them in terms of current museological doctrine. Consequently, in conceding that they may even become classics of 20th-century architecture, it is unlikely that they can be easily adapted to the museum's development needs. The second concept is illustrated by the Musée National des Arts et Traditions Populaires of Paris, the principal new museums of Mexico, the National Gallery of Victoria of Melbourne, and the Louisiana Museum of Copenhagen, as well as others. These museums, which can sometimes also be considered as masterpieces of architecture, are essentially conceived in terms of the collections, and their aesthetic character is secondary, without being altogether excluded.

Modern architectural trends

Though the functional museum is clearly the more de-

sirable, there is no disguising that it will be difficult to escape from the museum-monument, often insisted on for reasons of prestige by the authorities on whom it depends. The real solution lies, as has been mentioned already, in the close cooperation between the museum director and the architect.

Concerning the interior of the museum, which is often entrusted to the architect, and the special museum fittings, the principles are the same. The aesthetic should be a secondary consideration in the decor, in the furniture, and in the lighting; the most important thing is to begin by giving attention to the objects and to facilitate the visitor's contact with them. This is particularly true of the design of showcases and stands, the forms and materials of which still too often have aesthetic pretensions, so that the collections they contain or support can no longer be "seen" for themselves.

IV. History of museums

The history of museums and of the institution "museum" through the ages is linked closely to the history of society and to the evolution of knowledge. In fact, every museum is the work of one or more founders, it addresses itself to a well-defined public, and it is dependent upon one or more sciences. In the paragraphs that follow, the history of museums will be presented from an essentially sociological point of view. The influence of the history of sciences on museums will also be glanced at.

THROUGH THE 17TH CENTURY

Medieval museums

The museum was born, so far as collections are concerned, in the geocultural area defined by the Mediterranean Basin and in the countries situated immediately to the north, in the zone of Greco-Latin civilization. Several phases can be distinguished. First, the Middle Ages, characterized by feudalism and Christianity, saw the first collections appear in three institutions dominated by the clergy as the sole custodians of art and science: the church, the monastery, and the university. Works of art, manuscripts, apparatus, and curious specimens were kept for their religious, scientific, or economic value, seldom for aesthetic reasons. They were certainly not museums as such, for the collections were neither for public display nor for systematic research. The dates of foundation are not known, but the religious treasuries of the Abbey of St. Maurice in Valais, Switzerland, of Aachen, Germany, and of Monza, Italy, comparable, moreover, to the collections of Japanese temples, contain objects extending from the late Roman Empire to the late Middle Ages. The transformation of these treasuries into modern museums is recent and dates practically from the development of international tourism.

From about 1400 to 1700—that is, from the beginning of the Renaissance to the apogee of Classicism—the rediscovery of Greek and Roman antiquity, the fragmentation of Christiantity and the secularization of education, the general emergence of an aristocratic and bourgeois cultivated class, and the great discoveries resulted in a great increase in collections, at first in royal collections (explorers' spoils, diplomatic presents) and then in the private in emulation. The collections of Vienna and of the Escorial, near Madrid, succeeding those of the dukes of Burgundy and the kings of Spain, those of Versailles and of Florence and of the Vatican, gave birth to the greatest museums of our time. Naturally, the collections were open at that time only to members of the cultivated class, if and when they could enter their owners' palaces. There was no desire to collect systematically nor any attempt at conservation or valuation—merely curiosity, a taste for luxury and prestige, but also the birth of a sense of beauty and a consciousness of the scientific value of certain specimens. One finds during this period only one exception, that of the creation of the Ashmolean Museum at Oxford (1683), the first museum deserving of the name and the first university museum.

THE 18TH CENTURY

The 18th century saw a rapid evolution and the birth of the principal public collections at the instance of artists and naturalists; among these were the British Museum, the Louvre, the Muséum National d'Histoire Naturelle, the Vatican Museum, and others. This was due, in the most important countries of Europe of this time, to the growth of the bourgeoisie in importance and numbers, to the broadening of public education, to the rise of research, to the birth of a first form of tourism, to the movement of the Enlightenment and the Encyclopaedic spirit, and to the growing taste for the exotic. The aristocracy began to lose importance as a governing class, the aristocratic, intellectual, and cultural life began to become democratized, and things from abroad and of the past were becoming appreciated. It was at this time that the collections from Siberia and Alaska were set up at St. Petersburg (Leningrad), which created the great collections of natural science in parallel with the first attempts at systematic classification. The opening of salons of painting and of the royal galleries of pictures and sculptures placed past and present art within view of a fairly large public. The most distinct movement toward the creation of museums proper was to be found in Great Britain, in spite of numerous restrictions that still limited access to collections. Meanwhile, a public had been called into existence, authority was given for research on museum objects, and concern for conservation showed itself in the many restorations carried out on works of art, by distinguished artists, not necessarily for the best. Simultaneously, the area of the collections, if not yet themselves museums, broadened with the dissemination of ideas and extended to the Slavonic world and to North America.

The first public collections

1790–1850

The first half of the 19th century (which began in fact with the French Revolution, in the last decades of the 18th) saw the rise, in Europe and in the United States, of the middle classes, the advent of revolutionary ideas, and the development of the sciences, henceforth set free from religious constraint. From the first the French Revolution opened the Louvre to the people. (The Russian people had to wait for their Revolution of 1917 for the same privilege.) During that period France and Great Britain opened the way to the museums: not only were the great museums of today opened, but many provincial museums were created on the initiative of local learned societies of intellectuals wishing to serve their community. The private collections, formed since the beginning of the 18th century, became museums in their full right, either as the result of political events that brought about the nationalization of the property of the former governing classes or by voluntary gift of their owners, won over to new ideas; the architectural type of museum-temple became widely diffused, and the feeling for the past, awakened by the discoveries made by the first archaeologists in Egypt, in Italy, and the Near East as well as by the fashion for Gothic art (this word covering all the art of the Middle Ages), absorbed the public. For the first time, the museums came to play a major role in the creation of styles, such as the Neoclassical and the "troubadour" style. Artists and men of culture went on pilgrimage to Rome, where the Vatican Museum offered a vast range of aesthetic experiences. During and after the Napoleonic era (following probably the infatuation of Napoleon I and his court for works of art) all the great cities of Europe opened museums. Princess Czartoryska even organized in the park of her castle at Pulawy, near Warsaw between 1801 and 1809, the first Polish museum, embellished with the motto "the past for the future," in imitation of such patrons as Alexandre Lenoir, who opened his Musée des Monuments Français in Paris in the middle of the Revolution, seeking to preserve for the future the most remarkable monuments of the past that were in danger of being destroyed by the political and popular upheavals. The museums of this era were essentially of an artistic and historical–archaeological character and were to play a considerable part in developing a consciousness of the intrinsic value of European or Western civilization, at the time of the rise of European nationalism and the imperialism that accompanied it. On the other hand, this

Nationalization of private collections

museological explosion, coinciding with the Industrial Revolution, was to preserve an important part of the cultural values of the ancient world, which otherwise would undoubtedly have been destroyed by technical and economic progress and new aesthetic fashions.

1850–1950

The hundred years from 1850 to 1950 saw a number of phenomena, which, influencing one another, led to the formation of a "world of museums" that carried the germ of the present situation: the continuing development of the Industrial Revolution in Europe and the United States; the institution of democratic regimes (in spite of dictatorial regimes, mostly short-lived); fundamental transformations in the sciences and accelerated technical progress; extension of European–American colonialization, economic or political, to the whole world; a rise of the means of communication; and the democratization of education and culture. On the level of museums, the larger institutions created in the course of the preceding periods were reformed and enlarged; national centralized administrations were organized in Belgium, France, Italy, and the Soviet Union; they ran the central museums directly and controlled the provincial ones. These last were enriched notably by deposits from the central museums and improved their management by throwing off the tutelage of local learned societies composed largely of amateurs. In the United States and in Canada, the multiplication of private museums commenced and has not yet ceased: Royal Ontario Museum (Toronto, 1912), Metropolitan Museum of Art (New York, 1870), American Museum of Natural History (New York, 1869), Museum of Fine Arts (Boston, 1870), Museum of Modern Art (New York, 1929), Art Institute of Chicago (1879), and many others. In the colonial countries, under the influence and often on the initiative of the colonial powers and their scientific institutions or their patrons, museums were created after European models: Prince of Wales Museum of Western India, Bombay; Indian Museum, Calcutta; Coryndon Memorial Museum, Nairobi. In Latin America, which was liberated earlier from political colonization but remained closely linked with Europe and the United States intellectually and economically, numerous museums of art appeared, devoted principally to the more classic European art, while local arts, pre-Columbian and colonial, were neglected.

New types of museums

This same period saw, in addition, the birth of new categories of museums—of anthropology and ethnology, of science and technology, of the history of cities, of archaeological sites. It saw the discovery of the educational role of museums and the birth of a professional consciousness, with the creation of national associations of museum professionals (British Museums Association, American Association of Museums, Association Générale des Conservateurs des Collections Publiques de France, Scandinavian Museums Association, Deutscher Museumsbund), the publication of professional journals and books, the creation of the first international organization, the International Museums Office, dependent on the League of Nations, but enjoying a mixed statute, being at the same time both governmental and professional. The first researches on what is now called museology and museography were undertaken on the initiative of the great museums or professional organizations: studies on conservation, display, management, international cooperation, and the history of museums.

The evolution of the museum during this epoch reflects perfectly that of the society that gave it birth. Civilization, threatened by technical progress, sought to affirm the permanence of its intellectual values: the Western world, ruined spiritually by world wars and engaged in the "work" of colonization, tried to justify and maintain its fundamental unity. In the face of the difficulty of creating new forms of life and culture, a growing importance was attached to the preservation of the past; new ruling classes born without much past, especially in North America, adopted the past of classes that had disappeared and yet remained sentimentally attached to forms of popular cultural expression. Scientific knowledge became stricter and more systematic and was no longer content to speculate about ideas but sought the support of concrete things. Finally, in the artistic domain, a market was created, and of this museums were both origin and end product: the origin because they awoke the taste for collecting and "connoisseurship" and the end product because ultimately collectors give what they have assembled to museums, for economic, social, and prestige reasons.

The three principal facts of the century from 1850 to 1950 may be defined thus from the point of view of the museum concept: the idea that culture is for the people, as expressed by Lenin and by every action of the Soviet government since 1917; the patronage of a wealthy class at the service of the community, as can be seen in the United States in both large and small towns; the development of tourism, which has brought into favour museums of art and archaeology in countries of great cultural riches in the Mediterranean Basin and western Europe.

Effect of World War II on museums

World War II terminated this period, with upheaval in the museum world as elsewhere. In Europe, museums and art treasures were destroyed, and entire collections were transferred from one country to another; political and economic changes involved profound modifications in the conception of culture for some countries, while the United States, less affected on the domestic plane, was able to continue developing its museums and acquiring collections that had become too expensive for war-devastated and impoverished countries to buy or sometimes even to preserve.

1950–70

The two decades that elapsed from 1950 to 1970, once the wounds of war had been attended to, saw a renaissance of museums, which, without breaking with the major trends of the preceding period, required their adaptation to a world that was largely new. Most of the museums of Europe had first to be reconstructed or restored and to reconstitute collections that had disappeared or had been sent away to shelter during the war. The unprecedented development of tourism in the countries of the Mediterranean Basin, led, under governmental pressure, to a reorganization of the museum as an institution, which now no longer concerned itself with the national public, at least in the larger centres, but endeavoured to attract a mobile, sheeplike public of tourists, who "followed the guide." By contrast, in northern Europe and in the Socialist countries, museums turned resolutely toward education, cultural invigoration, and the service of the community: it was a time of great development of regional museums, open-air museums, exhibition centres, "museum forums," and museums of modern art. In the United States, the expansion of museums proceeded at an accelerated rate (as noted earlier, a new museum every 3.3 days in 1964). The price of objects in the art and antique market became such that a constant flood of imports from all over the world found its way to the shops and sale galleries of New York, by the mediation of sales rooms or the traffickers in London, Paris, and Zürich. More recently, between 1965 and 1970, social and racial problems have stimulated the appearance of a new type of museum, the neighbourhood museum, a sociocultural community centre, a virtual relay station for the great museums at the centre of the metropolis, which are increasingly criticized for their elitist and centralizing character.

Museum organizations

In the same period a profession or, rather, group of professions was created around international, national, and sometimes provincial associations and organizations. On the international plane, UNESCO, the International Council of Museums (ICOM) and its specialized international committees, the International Institute for Conservation (IIC), and the International Centre for the Study and the Preservation and Restoration of Cultural Property in Rome (governmental) organize the cooperation of institutions and professionals, diffuse information, and assist in exchanges and contacts. On the national plane, nearly every country equipped itself with a professional organization that sometimes has a permanent structure

and a secretariat, publications, and training activities. In some very large countries possessing numerous museums, provincial, regional, and specialized organizations were founded. In the United States, their proliferation is astonishing; alongside the American Association of Museums, one finds an Association of Art Museum Directors, an Association of Science Museum Directors, and regional conferences. The training of personnel has assumed considerable importance: chairs have been created in the universities of Brno, Leicester, Paris, Colorado (at Boulder), New York, and elsewhere. On the initiative of national associations and of ICOM and UNESCO, centres for museographic training have been created, and attempts are being made to unify and standardize their diplomas and programs.

Museological and museographical research, conservation studies, and sociological surveys carried out on the public have multiplied, expressing both anxiety and desire—anxiety of a museum that feels itself challenged, criticized, and overtaken by the progress of culture and society; desire, on the contrary, to adapt itself and find new methods.

Museums in Asia and Africa

As in Europe, but to a lesser extent, numerous people of Asia and Africa have known the idea of collecting. The Shōsō-in of Nara and the royal collections in Japan and China bear witness to this, going back to the 1st millennium of the Christian Era. Certain African tribes and secret societies have always possessed treasures of religious and genealogical significance. But the concept of museum, properly speaking, only appeared late, usually under Western colonialism or at least under the influence of Western ideas. In the 19th century, important museums were created in Latin America and Asia. European researchers in Africa assembled collections that were sometimes dispatched to museums in European cities and sometimes kept on the spot in embryo museums or, rather, depositories and centres of study. In most of these countries, however, genuine museums only appeared with political independence, the necessary condition of political and cultural autonomy. Only a few countries have succeeded in endowing museums that can be compared with similar European institutions and yet do not imitate them but find instead original solutions to problems of presentation, communication, and animation. Mexico, Japan, India, and Malaysia are excellent examples of success in this respect. In these countries, history, exact and natural sciences, and technology most often constitute the core of the most modern museums, because of the needs of education. Africa, more backward because less culturally independent, owes its only successes in museums to their systematic use as a factor in national unity and cultural identification, as at Niamey (Republic of the Niger), Kampala (Uganda), and Accra (Ghana).

In the less developed nations, problems of museum modernization, training of personnel, research, conservation, and studies on the public pose themselves with far more acuteness than they do in the industrialized countries of Europe and North America. If Japan and Mexico have discovered original methods of presentation, if India possesses three university departments of museology (at the universities of Baroda, Calcutta, and Vārānāsi), they are exceptions. The action of international organizations has been applied to putting at the disposal of these countries the means of undertaking the necessary reconversion of the museum (UNESCO training centres at Jos in Nigeria, Mexico, and Honolulu; of ICOM at Santiago, Chile, and soon at Kuala Lumpur). It is certain, however, that the aim will be reached only through the integration of museums into the struggle toward sociocultural development, which means their largely forsaking the tradition of the great European museums, the historical evolution of which has taken place in an entirely different context.

In these countries, the profession has begun to organize itself: there are powerful museum associations in Brazil and in India, a Museums Association of Tropical Africa, regional activities initiated by ICOM in Asia and in Latin America. But there is much to do, and the national heritage is impoverished continually, for the very reason that swelling collections and museums in rich countries have encouraged an export drain of such items as African sculptures, Maya stelae, Indian bas-reliefs, and Chinese ceramics.

Since World War II the determining factors of museum development in all countries are the countless meetings, conferences, and seminars organized by professional groups or by UNESCO at the national, regional, and international level. Publications, periodical or otherwise, play an equally essential part. Recently, there has been launched the idea of creating institutes of museology that would permit professionals to think together about institutional and professional problems. All these phenomena, all these movements tend to unify the world of museums and eliminate discrimination in museological matters between developed and developing countries, between the West and the rest of the world. The innovative and progressive activity of Japan, Mexico, and India is significant in this respect because the achievements of these countries now offer examples and models to those where the museum was once born.

PROSPECTIVE

A cursory balance sheet of the situation of the museum in the world of 1970 may be presented. Every time a museum, in accordance with its vocation and with the support of public authority and influential private sources, has given its public leadership and has integrated itself into society and served it, while at the same time drawing upon intensive and systematic scientific research and attending both to the requirements of conservation and those of social communication, it has given proof of its indispensable character and its value as a fundamental institution in the modern world. When, on the contrary, a museum refuses to modify its routines or to accept the revolution in museum concepts, devoting itself to an elite or a basically tourist public, it cuts itself off from the mass of society and from the young. There are countries where the museum's role does not cease to grow, but there are others where, without the intervention of radical transformation, the museum is condemned to vegetate and perhaps even to disappear.

Continuing problems

Certainly, there are obvious obstacles and limitations. Museums that have the greatest success can no longer handle the flow of visitors easily. To set against this, too many of them, and sometimes the same ones, appear as "centralizers," monopolizing a wealth of exhibits in too confined a space at the centre of a metropolis. Thus, in a period of multidisciplinary research and action, their rigorous specialization, their disdain of reality and their contempt for the reasonable requirements of an increasingly well-read and well-informed public lead one to think that they are hardly capable of further adaptation. In fact, nothing in all this is ultimately of grave danger to the museum, so long as it maintains an active and constant pursuit of the revolution that began during the last few decades. The museum, which alone can speak the language of real things, will more and more become an antidote to the culture of the image and the word. If it did not exist, it would be necessary to invent it. In scientific matters, it is the centre of a three-dimensional documentation of the history of the world and of man, which no publication can replace. As an instrument of education and culture, provided that it adopts an integrated vision of science and humanism and provided also that it decentralizes itself physically and intellectually, the museum is a centre of development for all men through their participation in the creation and continuity of culture. Socially, the museum does not accept distinctions of class nor those of race or age. It invites an opening of the spirit, an enduring insight into the problems of yesterday, today, and tomorrow. It is, finally and above all else, an essential element of the cultural environment of man, present and future.

BIBLIOGRAPHY. Few books have been published on museum matters, but a large number of periodicals, national and international, contain articles of widespread museological or museographical interest. Among them are: *Museum* (quarterly); ICOM *News* (quarterly); *Studies in Conservation* (quarterly); *Art and Archaeology Technical Abstracts* (biannual);

Museum News (monthly); *Curator* (quarterly); and *Museums Journal* (quarterly). The major bibliographical works are: *Bibliographie muséologique internationale/International Museological Bibliography* (annual); STEPHAN F. DE BORHEGYI, ELBA A. DODSON, and IRENE A. HANSON (comps.), *A Bibliography of Museums and Museum Work, 1900–1960* (1960, suppl. 1961); FREDERICK A. RATH and MERRILYN ROGERS O'CONNELL (comps.), *Guide to Historic Preservation, Historical Agencies, and Museum Practices: A Selective Bibliography* (1970).

The most recent history of museums is GERMAIN BAZIN, *Le Temps des Musées* (1967; Eng. trans., *The Museum Age*, 1967). A controversial study of museum history with an attempt to show the future developments of the institution may be found in S. DILLON RIPLEY, *The Sacred Grove* (1969). On general organization of museums, see: UNESCO, *The Organization of Museums: Practical Advice* (1960, reprinted 1967); INTERNATIONAL COUNCIL OF MUSEUMS, *Les Problèmes des musées dans les pays en voie de développement rapide* (1964); and G.H. RIVIERE, *Report of the* UNESCO *Regional Seminar on the Educational Role of Museums* (1960). The most comprehensive book on recent museum architecture is MICHAEL BRAWNE, *The New Museum* (1965). On museum techniques for management administration, registration, and acquisition, see the booklets published by the Smithsonian Institution; the Canadian Museums Association, especially G.B. MACBEATH and S.J. GOODING (eds.), *Basic Museum Management* (1969); the British Museums Association; and DOROTHY DUDLEY and IRMA BEZOLD WILKINSON, *Museum Registration Methods*, rev. ed. (1968). On conservation, although the amount of technical literature is extensive, UNESCO, *The Conservation of Cultural Property* (1968), is the most up-to-date work. An effort has been made recently to make available to all curators basic information on important features such as lighting: ROBERT L. FELLER "Control of Deteriorating Effects of Light upon Museum Objects," *Museum*, 17:57–98 (1964). On research and museum collections, the best theoretical study is J. NEUSTUPNY, *Museums and Research* (1968). The largest amount of museum literature concerns education and communications methods. Among many titles: DUNCAN F. CAMERON (ed.), *Are Art Galleries Obsolete?*, a report of the proceedings of Seminar 2, organized by the Art Gallery of Ontario (1969); and "A Viewpoint: The Museum As a Communications System and Implications for Museum Education," *Curator*, 11:33–40 (1968); ERICK LARRABEE (ed.), *Museums and Education* (1968); HANS L. ZETTERBERG, *Museums and Adult Education* (1968); ALMA S. WITTLIN, *Museums: In Search of a Usable Future* (1970).

Training of qualified personnel has recently become a major issue although little has been published yet, except the ICOM, *Training of Museum Personnel* (1970). All countries with a sizable number of museums have published directories, and a complete list of them cannot be given here. Special mention must be given to AMERICAN ASSOCIATION OF MUSEUMS, *The Official Museum Directory* (1971); and to the BRITISH MUSEUMS ASSOCIATION, *Museums Calendar* (annual), including information on countries other than the U.K.

(H.de V.-B)

Music, Art of

Both the simple folk song and the complex electronic composition belong to the same activity, music. Both are humanly engineered; both are conceptual and auditory, and these factors have been present in music of all styles and in all periods of history, Eastern and Western. What follows is an examination of the accounts of music that have been given by philosophers and musicians from earliest times to the present. The historical role of music as an adjunct to other human activities and its gradual emergence as an activity in its own right will be observed, along with the forms through which it found expression. Attention will then be directed to the situation of music in the world today.

Music is an art that, in one guise or another, permeates every human society. Modern music is heard in a bewildering profusion of styles, many of them contemporary, others engendered in past eras. Music is a protean art; it lends itself easily to alliances with words, as in song, and with physical movement, as in dance. Throughout history, music has been an important adjunct to ritual and drama and has been credited with the capacity to reflect and influence human emotion. Popular culture has consistently exploited these possibilities, most conspicuously today by means of radio, film, television, and the musical theatre. The implications of the uses of music in psychotherapy, geriatrics, and advertising testify to a faith in its power to affect human behaviour. Publications and recordings have effectively internationalized music in its most significant, as well as its most trivial, manifestations. Beyond all this, the teaching of music in primary and secondary schools has now attained virtually worldwide acceptance.

But the prevalence of music is nothing new and its human importance has often been acknowledged. What seems curious is that, despite the universality of the art, no one until recent times has argued for its necessity. The ancient Greek philosopher Democritus explicitly denied any fundamental need for music: "For it was not necessity that separated it off, but it arose from the existing superfluity." The view that music and the other arts are mere graces is still widespread, although the growth of psychological understanding of play and other symbolic activities has begun to weaken this tenacious belief.

SPECULATIONS ON THE NATURE OF MUSIC

Music, then, is everywhere to be heard. But what *is* music? Commentators have spoken of "the relationship of music to the human senses and intellect," thus affirming a world of human discourse as the necessary setting for the art. A definition of music itself will take longer. As Aristotle said, "It is not easy to determine the nature of music or why anyone should have a knowledge of it."

Early in the 20th century, it was regarded as a commonplace that a musical tone was characterized by the regularity of its vibrations; this uniformity gave it a fixed pitch and distinguished its sounds from "noise." Although the view may be supported by traditional music, it would be an unacceptable yardstick today, when "noise" itself may be treated as an element in composition, to say nothing of the random sounds incorporated (without prior knowledge of what they will be) by modern composers, like the American John Cage, and others in works having aleatory (chance) or impromptu features. Tone, moreover, is only one component in music, others being rhythm, timbre (tone colour), and texture. Electronic machinery has enabled some composers to create works in which the traditional role of the interpreter is abolished and to record, directly on tape, sounds that were formerly beyond human ability to produce, if not to imagine.

Non-Western ideas. From historical accounts, it is clear that the power to move men has always been attributed to music; its ecstatic possibilities have been recognized in all cultures and have usually been admitted in practice under particular conditions, sometimes stringent ones. In the civilization of India, music was put into the service of religion from earliest times; Vedic hymns stand at the beginning of the record. As the art developed over many centuries into a music of profound melodic and rhythmic intricacy, the discipline of a religious text or the guideline of a story determined the structure. Even today the narrator is central in most performances of Indian music, and the virtuosity of a skillful singer rivals that of the instrumentalists. There is very little concept of vocal or instrumental idiom in the Western sense. The vertical dimension of chord structure—that is, the effects created by sounding tones simultaneously—has never been developed in South Asian music; the divisions of an octave (intervals) are more numerous than in Western music, and melodic complexity in Oriental music goes far beyond that of Western practice. Moreover, an element of improvisation is retained that is vital to the success of a performance. The spontaneous imitation carried on between an instrumentalist and narrator, against the insistent rhythmic subtleties of the drums, can be a source of the greatest excitement, in large measure because of the faithful adherence to the rigid rules governing the rendition of ragas—the ancient melodic patterns of Indian music.

Indian music in religion

Chinese music, like Indian, has traditionally been an adjunct to ceremony or narrative. Confucius (551–479 BC) assigned an important place to music in the service of a well-ordered moral universe. He saw music and government as reflecting one another and believed that only the superior man who can understand music is equipped to

Confucius and music in China

govern. Music, he thought, reveals character through the six emotions it can portray: sorrow, satisfaction, joy, anger, piety, love. According to Confucius, great music is in harmony with the universe, restoring order to the physical world through that harmony. Music, as a true mirror of character, makes pretense or deception impossible.

Ancient Greek ideas. Although music was important in the life of ancient Greece, it is not now known how that music actually sounded. Only a few notated fragments have survived, and no key exists for restoring even these. The Greeks were given to theoretical speculation about music; they had a system of notation, and they "practiced music," as Socrates himself, in a vision, had been enjoined to do. But the Greek term from which the word music is derived was a generic one, referring to any art or science practiced under the aegis of the Muses. Music, therefore, as distinct from gymnastics, was all encompassing. (Much speculation, however, was clearly directed toward that more restricted meaning with which we are familiar.) Music was virtually a department of mathematics for the philosopher Pythagoras (*c.* 550 BC), who was the first musical numerologist, and who laid the foundations for acoustics. In acoustics, the Greeks discovered the correspondence between the pitch of a note and the length of a string. But they did not progress to a calculation of pitch on the basis of vibrations, though an attempt was made to connect sounds with underlying motions.

Plato (428–348/347 BC), like Confucius, looked on music as a department of ethics. And like Confucius he was anxious to regulate the use of particular modes (*i.e.*, arrangements of notes, like scales) because of their supposed effects on men. Plato was a stern musical disciplinarian; he saw a correspondence between the character of a man and the music that represented him. Straightforward simplicity was best. In the *Laws*, Plato declared that rhythmic and melodic complexities were to be avoided because they led to depression and disorder. Music echoes divine harmony; rhythm and melody imitate the movements of heavenly bodies, thus delineating the music of the spheres and reflecting the moral order of the universe. Earthly music, however, is suspect; Plato distrusted its emotional power. Music must therefore be of the right sort; the sensuous qualities of certain modes are dangerous, and a strong censorship must be imposed. Music and gymnastics in the correct balance would constitute the desirable curriculum in education. Plato admitted and valued music in its ethically approved forms; his concern was primarily with the effects of music, and he therefore regarded it as a psychosociological phenomenon.

Aristotle's views

Yet Plato, in treating earthly music as a shadow of the Ideal, saw a symbolic significance in the art. Aristotle carried forward the concept of the art as imitation, but music could express the universal as well. His idea that works of art could contain a measure of truth in themselves—an idea voiced more explicitly by Plotinus in the third century AD—gave added strength to the symbolic view. Aristotle, following Plato, thought that music has power to mold human character, but he would admit all the modes, recognizing happiness and pleasure as values to both the individual and the state. He advocated a rich musical diet. Aristotle made a distinction between those who have only theoretical knowledge and those who produce music, maintaining that persons who do not perform cannot be good judges of the performances of others.

Aristoxenus, a pupil of Aristotle, gave considerable credit to the human listener, his importance and his powers of perception. He denigrated the dominance of mathematical and acoustical considerations. For Aristoxenus, music was emotional and fulfilled a functional role, for which both the hearing and the intellect of the listener were essential. Individual tones were to be understood in their relations to one another and in the context of larger formal units. The Epicureans and Stoics adopted a more naturalistic view of music and its function, which they accepted as an adjunct to the good life. They gave more emphasis to sensation than did Plato, but they nevertheless placed music in the service of moderation and virtue. A dissenting 3rd-century voice was that of Empiricus, who said that music was an art of tones and rhythms only that meant nothing outside itself.

The Platonic influence in musical thought was to be dominant for at least a millennium. Following that period of unquestioned philosophic allegiance, there were times of rededication to Greek concepts, accompanied by reverent and insistent homage (*e.g.*, the group of late 16th-century Florentines, known as the Camerata, who were instrumental in the development of opera). Such returns to simplicity, directness, and the primacy of the word have been made periodically, out of loyalty to Platonic imperatives, however much these "neo" practices may have differed from those of the Greeks themselves.

In the 20th century, the effects of Greek thought are still strongly evident in the belief that music influences the ethical life; in the idea that music can be explained in terms of some component such as number (that may itself be only a reflection of another, higher source); in the view that music has specific effects and functions that can be appropriately labelled; and in the recurrent observation that music is connected with human emotion. In every historical period there have been defectors from one or more of these views, and there are, of course, differences of emphasis.

Christian ideas. Much of the Platonic–Aristotelian teaching, as restated by the Roman philosopher Boethius (*c.* 480–524), was well suited to the needs of the church; the conservative aspects of that philosophy, with its fear of innovation, were conducive to the maintenance of order. The role of music as accessory to words is nowhere more clearly illustrated than in the history of Christianity, where the primacy of the text has always been emphasized and sometimes, as in Roman Catholic doctrine, made an article of faith. In the varieties of plainsong, melody was used for textual illumination; the configurations of sound took their cue from the words. St. Augustine (AD 354–430), who was attracted by music and valued its utility to religion, was fearful of its sensuous element and anxious that the melody never take precedence over the words. These had been Plato's concerns also. Still echoing the Greeks, Augustine, whose beliefs were reiterated by St. Thomas Aquinas (*c.* 1225–*c.* 74), held the basis of music to be mathematical; music reflects celestial movement and order.

Martin Luther (1483–1546) was a musical liberal and reformer. But the uses he envisioned for music, despite his innovations, were in the mainstream of tradition; music must be simple, direct, accessible, an aid to piety. His assignment of particular qualities to a given mode is reminiscent of Plato and Confucius. Calvin (1509–64) took a more cautious and fearful view of music than Luther, warning against voluptuous, effeminate, or disorderly music and insisting upon the supremacy of the text.

Music as mathematics

Later Western ideas. In reviewing the accounts of music that have characterized musical and intellectual history, it is clear that the Pythagoreans are reborn from age to age. The German astronomer Johannes Kepler (1571–1630) perpetuated, in effect, the idea of the harmony of the spheres, attempting to relate music to planetary movement. René Descartes (1596–1650), too, saw the basic of music as mathematical. He was a faithful Platonist in his prescription of temperate rhythms and simple melodies so that music would not produce imaginative, exciting, and hence immoral, effects. For another philosopher–mathematician, the German Gottfried von Leibniz (1646–1716), music reflected a universal rhythm and mirrored a reality that was fundamentally mathematical, to be experienced in the mind as a subconscious (unfelt) apprehension of numerical relationships.

Immanuel Kant (1724–1804) ranked music as lowest in his hierarchy of the arts. What he distrusted most about music was its wordlessness; he considered it useful for enjoyment but negligible in the service of culture. Allied with poetry, however, it may acquire conceptual value. Georg Wilhelm Friedrich Hegel (1770–1831) also extolled the discursive faculties, saying that art, though it expresses the divine, must yield to philosophy. He acknowledged the peculiar power of music to express many

nuances of the emotions. Like Kant, Hegel preferred vocal music to instrumental, deprecating wordless music as subjective and indefinite. The essence of music he held to be rhythm, which finds its counterpart in man's innermost self. What is original in Hegel's view is his claim that music, unlike the other arts, has no independent existence in space, is not "objective" in that sense; the fundamental rhythm of music (again an aspect of number) is experienced within the hearer.

Subjectivism in Hegel

After the 18th century, speculations upon the intrinsic nature of music became more numerous and profound. The elements necessary for a more comprehensive theory of its function and meaning became discernible. But philosophers whose views have been summarized thus far were not speaking as philosophers of music. Music interested them in terms extrinsic to itself, in its observable effects; in its connections with dance, religious ritual, or festive rites; because of its alliance with words; or for some other extramusical consideration. The only common denominator to be found, aside from the recognition of different types of music, is the acknowledgment of its connection with the emotional life; and here, to be sure, is that problematic power of the art to move men. Various extramusical preoccupations are today the raison d'être of "contextualist" explanations of music, which are concerned with its relation to the human environment. The history of music itself is largely an account of its adjunctive function in rituals and ceremonies of all kinds—religious, military, courtly—and in musical theatre. The protean character of music that enables it to form such easy alliances with literature and drama (as in folk song, art song, opera, "background" music) and with the dance (tribal, ethnic, "social," ballet) appears to confirm the wide range and influence that the Greeks assigned to it.

PROBLEMS OF MUSICAL MEANING

Musical theorists

Before the 19th century, musicians themselves seldom were theorists, if theorist is defined as one who explicates meaning. Musical theory, when it was something other than the exposition of a prevalent or emerging style, was likely to be a technical manual guiding vocal or instrumental performance, a set of directions for meeting current exigencies in church or theatre practice, or a missive advocating reforms. Prolific masters, such as Bach, produced not learned treatises but monuments of art.

The 19th century saw the emergence of composer–critics (Carl Maria von Weber, Robert Schumann, Hector Berlioz, Franz Liszt), versatile artists with literary proclivities who were not, to be sure, propounding comprehensive theories or systems of thought. Richard Wagner, an active theorizer, presaged a new species, the composer–author. But he did little to advance musical theory. He proposed a unity of music and drama (*Gesamtkunstwerk*)—a reflection of the "programmatic" preoccupations of 19th-century composers—but its multiplicity of musical and extramusical elements only added to the confusion of musical thought. The distinctly musical character of Wagner's genius, clearly discernible in *The Ring*, is in no way explained by his discursive credos. Igor Stravinsky, Arnold Schoenberg, and other composer–authors of the 20th century were to be somewhat more successful in elucidating their techniques and aims.

Origins of modern theories. Present-day ideas of music as a symbolism owe much to two German philosophers, Arthur Schopenhauer (1788–1860) and Friedrich Nietzsche (1844–1900), who brought to the theory of music a new concept, articulated by each in different ways and in divergent terms but faithful to the same principle—dynamism. Both saw in music an art that is not "spatialized" (hence not "objective") in the way that other arts are by the very conditions of their manifestation. Music is closer to the inner dynamism of process; there are fewer technical (and no concrete) impediments to immediate apprehension, for an entire dimension of the empirical world has been bypassed.

Schopenhauer looked upon Platonic Ideas as objectifying will, but music is

> by no means like the other arts, the copy of the Ideas, but the *copy of the will itself*. This is why the effect of music is so much more powerful and penetrating than that of the other arts, for they speak only of shadows, but it speaks of the thing itself.

In contrast to Kant he accords a special efficacy to music:

> The effect of music is stronger, quicker, more necessary and infallible. Men have practiced music in all ages without being able to account for this; content to understand it directly, they renounce all claim to an abstract conception of this direct understanding itself.

Schopenhauer acknowledged a connection between human feeling and music, which "restores to us all the emotions of our inmost nature, but entirely without reality and far removed from their pain." Music, which he is presenting an as analogue of the emotional life, is a copy or symbol of the will.

Nietzsche posed an Apollonian–Dionysian dichotomy, the former representing form and rationality, and the latter drunkenness and ecstasy. For Nietzsche, music was the Dionysian art *par excellence*. In *The Birth of Tragedy from the Spirit of Music*, Nietzsche anticipated the 20th-century discovery that symbol making (whether in dreams, myth, or art) is a necessary and to some extent even automatic human activity. The rich suggestiveness and prescience of his insights embraced the concept of the "symbolical analogue"—the artistic function of ordering and heightening the ingredients of the actual world—and the polarities of experience symbolized in the Apollonian–Dionysian conflict itself, which Stravinsky also explored. Nietzsche gave short shrift to mathematical aspects of music, and like Schopenhauer he deprecated blatantly programmatic music that abounds in obvious imitations of natural sounds. Discerning a power in music to create myths, he looked upon mere "tone painting" as the antithesis of its essential character.

Conflicting views about meaning. Efforts of theorists to account for the universal appeal of music and to explain its effects have, since the 19th century, been various, contradictory, and highly controversial. In pointing out the chief points of view that have emerged, it must be emphasized that there are no completely isolated categories and there is usually considerable overlapping; a single spokesman, the 19th-century English psychologist Edmund Gurney, for example, may incorporate formalist, symbolist, expressionist, and psychological elements, in varying proportions, to explain the phenomenon of music. Although some disagreements are more apparent than real because of the inherent problems of terminology and definition, diametrically opposing views are also held and tenaciously defended.

Referentialists and Nonreferentialists

Among those who seek and propound theories of musical meaning, the most persistent disagreement is between the referentialists (or "heteronomists"), who hold that music can and does refer to meanings outside itself, and the nonreferentialists (sometimes called formalists or absolutists), who maintain that the art is autonomous and "means itself." The Austrian critic Eduard Hanslick, in his *The Beautiful in Music* (German edition published 1854), was a strong proponent of music as an art of intrinsic principles and ideas; yet even Hanslick, ardent formalist though he was, struggled with the problem of emotion in music. Hanslick's views have been classified as a modified heteronomous theory.

One looks in vain for an extremist of either persuasion, referentialist or nonreferentialist. Stravinsky first achieved fame as a composer of ballet music, and his works throughout his career have been rich in extramusical associations. It would be a nice simplification to ally referentialism with "program" music and nonreferentialism with "absolute." But the problem cannot be resolved by such a choice, if only, first of all, because extramusical referents can vary in complexity from a mere descriptive title to the convolutions of the Wagnerian leitmotiv, in which a particular musical phrase is consistently associated with a particular person, place, or thing. The referentialist does not require an explicit program (which may, when present, be altogether too meagre by his canons), and the nonreferentialist does not necessarily denigrate program music, though he makes a point of distinguishing between the extramusical pro-

gram and the musical meaning. The contemporary U.S. theorist Leonard Meyer, in his *Emotion and Meaning in Music* (1956), speaks of "designative" and "embodied" meanings; he recognizes both kinds in music, but appears to give equal weight to the extrinsic and intrisic.

If there is intrinsic, or embodied meaning, one may well ask what meaning is embodied and how it is to be apprehended. An extreme formalist would say that the acoustic pattern itself and nothing more is the sense of music; Hanslick, indeed, said this, though he did not hold consistently to the view. But most nonreferentialists regard music as, in one way or another, emotionally meaningful or expressive. Referentialists, too, find expressive content in music, though this emotional content may be extramusical (even if not explicit) in origin, according to the American theorists John Hospers in *Meaning and Truth in the Arts* (1946) and Donald Ferguson in *Music as Metaphor* (1960). Meyer has made the observation that while most referentialists are expressionists, not all expressionists are referentialists. He makes the useful distinction between absolute expressionists and referential expressionists and identifies his own position as "formalist-absolute expressionist." In acknowledging that music can and does express referential (designative) meanings as well as nonreferential ones, Meyer exhibits an eclectic and certainly permissive view. But he has been criticized for failing to make clear the *modus operandi* of this referential meaning in music.

Intuition and intellect

Most theorists agree that music is an auditory phenomenon and that hearing is the beginning of understanding. Beyond this there is little agreement. There is bad blood especially between proponents of intuition, like Benedetto Croce, and champions of intellectual cognition, like Hospers. Gurney was constrained to postulate a special musical faculty that need not reside exclusively either in the mind or the heart. The main problem for theorists arises from the inveterate tendency to dichotomize thought and feeling. Henri Bergson (1859–1941) broke with this tradition when he spoke for "an intellectual act of intuition." Recently, a reawakened philosophic and artistic concern for the concept of organic unity has revealed strong affinities among such disparate works as Gurney's *The Power of Sound* (1880); the U.S. philosopher Susanne K. Langer's *Philosophy in a New Key* (1942) and her later works; John Dewey's classic *Art as Experience* (1934); and the U.S. composer Roger Sessions' *The Musical Experience* (1950).

It is apparent that music is connected in some way with the emotional life of man, but the "how" continues to be elusive. Sessions (echoing Aristotle) states the problem fairly:

> No one denies that music arouses emotions, nor do most people deny that the values of music are both qualitatively and quantitatively connected with the emotions it arouses. Yet it is not easy to say just what this connection is.

It was long fashionable to speak of the "language" of music, or of music as the "language of the emotions," but since a precise semantics is wanting in music, the analogy breaks down. Two or more listeners may derive very different "meanings" from the same piece of music, and since written and spoken language cannot render these musical "meanings," whatever they may be, in consistent and commonly recognizable terms, verbal explication often seems to raise more questions than it settles. Philosophic analysts who hold that all meaning is capable of rendition in language therefore pronounce music—unless it can be saved by the referentialists—without meaning, confronting the thoughtful listener, thereby, with a proposition that seems clearly to contradict (and trivialize) his own experience. The difficulty, of course, is a semantic one, and explains why some theorists substitute such terms as import, significance, pattern, or gestalt for meaning. Recognizing an incompatibility between the modalities of nonverbal arts and their treatment by discursive thought, it is hardly surprising that musical aestheticians have been few.

Symbolist contributions

Significant contributions to musical theory have been made in the 20th century by several investigators who may be classified as symbolists, though most of them exhibit formalist, expressionist, and psychological elements as well. The most influential (and controversial) work has been done by Langer. Her most adamant critics (such as John Hospers) have objected to her use of the term symbol that must, in their lexica, stand for something definite; she takes pains to ascribe this more limited usage to the term signal. The more general use of the term symbol that she endorses has a long history, notably in such 19th-century figures as Goethe, Carlyle, and the French Symbolist poets. Mrs. Langer is accused of having somewhat weakened her argument through a vacillating terminology, and she has described the musical symbol as "unconsummated" because of its ambiguity. But the validity of her theory does not depend upon the term symbol; her thought, indeed, has much in common with that of Edmund Gurney, who does not employ the term, and whose "ideal motion," if substituted for symbol, would remove most of her critics' objections. Her use of symbol is nevertheless defensible; she construes art as a "symbolic analogue of emotive life," rendering the "forms of sentient being" into intelligible configurations. She is a naturalist; she sees art as organic in origin and she echoes the view, long held among symbolists, that artistic form and content compose an indissoluble unity that each art manifests according to its peculiar conditions. The symbolism of music is therefore tonal (or, at its broadest, auditory) in character and can be realized only in time; in psychological experience, time assumes an ideal guise. (Painting and sculpture, in their distinctive modalities, embody ideal space.) Mrs. Langer embraces all the arts in her purview. The U.S. musical theorist Gordon Epperson's *The Musical Symbol* (1967) is an application of her concepts, with modifications, intensively to music.

In moving from symbolic to contextualist explanations of music, it is well to note that a source of great confusion, in the former, is the fact that tone painting (with explicit signals that yield, when the code is understood, designative meanings) is widely regarded as musical symbolism. An example of such tone painting is Bach's introduction of musical notes, corresponding to the letters of his own name, as a theme in the unfinished final fugue of the *Art of Fugue*. And surely it may be argued that this qualifies on one level. But the contention that there is an intrinsic symbolism in the musical meaning itself is a claim that referentialists are generally unwilling to honour. Yet many theorists, whose concern is with the sociological or psychological effects of music, are not so much opposed to the idea of inner or profound meaning as indifferent to such meaning per se. Even an absolutist, however, is unable to examine music in isolation from its human environment. Meyer deliberately eschews logical and philosophical problems of music and makes "no attempt to decide whether music is a language or whether musical stimuli are signs or symbols." (He does not defend the inference that such concerns are irrelevant to meaning.) Musical meaning and communication, he maintains, cannot exist in the absence of the cultural context. The statement is hardly open to dispute; a theorist is classified according to his proximity to the referential or nonreferential pole. If a referentialist emphasizes explicit aims and associations of a particular work (as in varieties of *Gebrauchsmusik* or "utility" music, written for specific social or educational purposes), the formalist can maintain that there is also an intrinsic or embodied meaning to which he attaches the greater aesthetic value.

Psychological approaches

Among contextualists, however, a simple referential view is the exception rather than the rule. Any theorist who examines musical perception is making a study of a complex human activity. He is dealing with the psychology of music, in which certain elements—*e.g.*, music, listener, mode of apprehension, cultural context—are indispensable, and in which characteristic processes recur. Specialists will emphasize one element or another: formalists the music itself, sociologists the listener and his milieu, psychologists the how of perception. Though psychology could survey the whole field, in practice psychologists, according to their persuasions, investigate the perception of measurable acoustic phenomena, the physical–mental

effects of musical sound, or—more rarely—the functional role of music in human experience; and pragmatists and analysts alike may leave something out of account. But it remains for the comprehensive theorist, probably one who, like Langer, is equipped to discern relationships among many departments of thought, to construct a valid hierarchical structure of musical meaning in all its ramifications.

Deryck Cooke, the British musicologist and the author of *The Language of Music* (1959), who may be classified as a referential expressionist, has offered a sophisticated argument for the notion of music as language. Concepts, however, may not be rendered by this language, only feelings. Cooke reaffirms the possibility, long disputed by many theorists, that such feelings may be recognized, identified, and even classified. But he confines his investigation to the last few hundred years of the Western tradition.

Information theory

The French theorist Abraham Moles's *Information Theory and Esthetic Perception* (1966), brings the new science of information theory to bear on musical perception, emphasizing that the concept of form is the essential thing; the "sonic message," whose dimensions vary from one composition to another, is a whole. Information theory thus proves to be a novel ally for organicists. The message, which is subjected to "atomistic" study of its components is (thanks to recording) concrete; there is a temporal sonic material, a *materia musica.* Moles gives reinforcement to the aesthetic theory of distance:

> The esthetic procedure of isolating sonic objects is analogous to the sculptor's or decorator's isolating a marble work against a black velvet draping: This procedure directs attention to it, alone and not as one element among many in a complex framework.

Information theory, which Leonard Meyer also discusses, begins its investigations without the help of traditional theory, which it finds to be untenable for its procedures. Musical messages discerned through information theory are not referential, yet Moles chooses to term the measurable elements in the sonic repertoire symbols: "each definable temporal stage represents a 'symbol' analogous to a phoneme in language." According to Moles, music must, as an art, obey rules; the role of aesthetics is to enumerate universally valid rules, not to perpetuate the arbitrary or merely traditional. He foresees experimentation with a much richer repertory of sounds, transcending musical instruments and drawing on whatever sources—certainly electronic ones—are available for realizing the "most general orchestra." A host of composers have set out to fulfill this desideratum. In order to increase the compass of possible sounds, various electronic "synthesizers" were constructed. In electronically synthesized music, the medium itself is indistinguishable from its message.

The quest for some distillation of musical meaning may be foredoomed to failure. Meanings, intrinsic and extrinsic, abound; meanings of all kinds, moreover, are revealed in and through the social setting. Church, theatre, and broadcasting affect music in characteristic ways. The modern concert is a device whereby formal, autonomous meanings are emphasized; further, the scope and available repertoire of the concert have been enormously increased through recordings, for any suitably equipped room may become, at the turn of a switch, a recital hall.

A number of important psychological and sociological considerations, closely related to problems of musical meaning, remain. These are discussed, in the context of 20th-century practice, in the following section.

Considerations related to performance practice. Listening to music for its own sake, apart from ritual or storytelling, is a recent historical development. There have always been impromptu song and dance; and performances of music in home, church, and theatrical productions have a long history. But there was no public opera house until 1637 when the first one opened in Venice; the first public concerts for which admission was charged appeared in London in 1672. During the next 50 years there were beginnings in Germany and France also, but the modern concert was not a significant feature of musical life until the late 18th century.

Of the forms that have characterized distinct periods of musical history, it is sufficient to remark here that the chief Renaissance forms—mass, motet, the polyphonic chanson, and madrigal—were allied to texts that strongly influenced their structure. Instrumental music was for the most part in the service of the voice, though instrumental church compositions, dances, and chansons arranged for organ were not uncommon. A strong alliance between voices and instruments has continued into the present, with musical theatre, the art song, and religious music. Instrumental music as a separate genre emerged in the 16th century, gaining considerable momentum in the 17th through a variety of idiomatic pieces. Increased attention to technical fluency was accompanied by greater complexity and sophistication in the instruments themselves. In response to stylistic demands for greater resonance and power, the modern forms of the violin appeared in the late 16th century, only gradually supplanting the earlier viols. The harpsichord did not finally yield to the pianoforte until the 18th century. The once-prevalent idea that early stringed and keyboard instruments were primitive precursors of their modern counterparts has been effectually demolished by research in medieval and Renaissance music and by dedicated performers, who seek to restore the sounds and spirit of those eras.

The development of opera, oratorio, and the cantata gave a prominence to vocal music throughout the Baroque era (*c.* 1600–1750) that made it equal in importance to instrumental music, with which these forms were closely allied. But instrumental-chamber and independent-orchestral ensembles, as they exist today, also had their beginnings during this period. A highly significant development of the late 18th century was the definitive appearance of the modern sonata (whether in the form of the solo and duo sonata, piano trio, string quartet, concerto, or symphony) with the Viennese classicists Haydn and Mozart and, later, Beethoven.

Since a vocal text is likely to be confused with intrinsic musical meaning, or at least to divert attention from a preoccupation with it, it is not surprising that modern aesthetic theory followed on the emergence of an autonomous instrumental music requiring greater concentration on the sound itself; its colour and intensity, and the intelligibility (in terms of tonal organization alone) of a composition. Moreover, the very concept of listening as an attentive (and sometimes rigorous), serious, and necessary activity of the music lover gained acceptance only slowly, following the inauguration of public concerts, and is still vigorously resisted. The expectation that the art should provide enjoyment without effort is, indeed, widespread and accounts for much of the opposition to new and demanding idioms. But even for the well-disciplined and eager listener there is the problem of quantity: he must cope as best he can with what Langer has called "the madhouse of too much art." If more effort is required, more discrimination is also needed. In music education, articulate voices ask that teaching be centred more upon qualitative aspects of the art ("aesthetic education"), less upon music making as an activity. This concern for musical value appears to reflect a more intensive search for meaning, which is not likely to be the exclusive property of a particular style or era; nor is it to be sought in an indiscriminate acceptance or rejection of novelty per se. A pronounced pedagogical interest developed in such contemporary popular music as "rock," "soul," and similar folk idioms with great numbers of followers, especially among the young, whose gigantic festivals generated feelings of religious exaltation. The texts of the songs are highly emotional and often deal with "protest" themes; accompaniments are provided by guitars, keyboard and percussion instruments, and are electronically amplified. Music educators became attracted by the intrinsic structural values of this music, especially its distinctive rhythmic and modal characteristics, its texts, and the qualitative levels that may be distinguished. A music so vital and widespread, moreover, was deemed by many to be worth studying in school. The "rock" movement became a musical-sociological phenomenon of large proportions.

Implied world views

Again, music proves its protean susceptibilities in the service of disparate world views. Among humanist psychologists (such as the Americans Gordon Allport and Abraham Maslow) music may be one among other means toward self-fulfillment, integration, self-actualization; for aesthetic Existentialists (such as the philosopher Jean-Paul Sartre) it is yet another crucial department of choice and freedom; for spiritual Existentialists (such as the philosophers Karl Jaspers and Martin Buber) it transmits transcendent overtones. For expressionists (such as the composers Schoenberg, Ernst Krenek, and René Leibowitz) music carries austere, and sometimes doctrinaire, moral imperatives. Theodor Adorno, a composer-philosopher and pupil of Alban Berg, writes powerfully of these and speaks for an awareness of dazzling lucidity, but the tone, notwithstanding his humour, is one of obligation. Only the expressionists, among those mentioned here, are committed primarily to music, though Adorno, in particular, considers music and musicians always in interaction with their environments. The aesthetic concept of play is virtually absent, except among such humanists as Maslow. With Sartre, no less a humanist, the tone is one of responsibility. Many educators long held the explicit aim (at least in part because of a misinterpretation of John Dewey) of presenting the content of a discipline as "fun"; the present concern for aesthetic education, an area of great interest to Dewey himself, eschews this trivial view. But play, in the aesthetic sense, follows rules, as information theory has demonstrated; even "controlled aleatory" composition observes some limits. And the play may be very serious indeed, as in the important 20th-century atonal style known as "12-tone technique," practiced by the Viennese expressionists and their successors.

Tonality and meaning

The most troublesome problem not only for the untutored listener but also for the professional musician has been, in much contemporary work, the loss of explicit tonality; and this accounts for the tardy popular response to Schoenberg and his school: the vocabulary is esoteric. Nineteenth-century compositions did, indeed, stretch the tonal system to its outer limits; but it is now clear that Wagner and Richard Strauss, and even the early Schoenberg, had not broken from it. As for Debussy, his use of "exoticisms" was filigree upon a secure tonal base. So were such practices as the juxtaposition of keys by Stravinsky. This is not to say that the tonality of the Western world, fecund though it has been, is superior or more natural than other systems. Ethnomusicology and comparative musicology have proved this to be a parochial view, though there are still those who champion harmonic practices based on the physical laws governing overtones—as Western tonality is—as the only "natural" source of development. It should not be irrelevant, however, to inquire if any folk music has been discovered that exhibits atonal characteristics.

Tonality in Western music, though a significant aspect, cannot be considered the crux of musical meaning. The tone-rows that are used in the 12-tone compositions of Schoenberg, like major–minor tonality in earlier music, are a technical substratum and must be no more explicit in the finished work than the chemical makeup of pigments in the "Mona Lisa." The devices selected may affect the comprehensibility or accessibility of the work, but they are not, per se, the determinants of its worth or quality. Similarly with musical colour, or timbre; the 19th century produced a great profusion of compositions, particularly in the orchestral repertoire (*e.g.*, works by Liszt and Berlioz) that exploited the unique sonorities of instruments; control of volume was, in itself, a rich source of colour. Works with literary or other extramusical associations were excellent vehicles for sonorous effects, but colour, like tonality, must be evaluated in musical context. Langer, among present-day aestheticians, regards words themselves as musical, rather than discursive, ingredients; they are "assimilated" by the song.

MUSIC TODAY

Music and the mass media. In the same way that recordings extended the concert, television and film enlarged the scope of musical theatre and the dance. Experiment characterized both media, though film makers became more enterprising. Television, being the later arrival, borrowed from its predecessor, and its own unique possibilities remained largely undeveloped. In the occasional "live" (though more often taped) concert or musical film, the medium functioned as a large theatre. In England and Canada, subsidized broadcasting made possible a comparatively large musical offering. But in the United States, television's tie with commercial advertising produced meagre fare, though some promise could be seen in developments in educational television and university broadcasting centres.

Creative ferment lagged in the musical theatre despite the success of works by Leonard Bernstein (*Fancy Free, On the Town*)—with their emphasis on ballet—and by Gian Carlo Menotti, which demonstrated the popular appeal of original and sophisticated composers and loosened the rigid distinctions once thought to prevail between "concert" and "commercial" music. Except in European countries, with a vigorous tradition or government support or both, the enormous expense of staging opera and ballet in metropolitan centres discouraged not only experiment but even new repertory, except in relatively obscure theatres and on college campuses. The belated fanfare for Alban Berg's opera *Wozzeck*, which was completed in 1921 but not extensively performed until mid-20th century, only emphasized the difficulties experienced by radical new works. Evidences of operatic vitality and imagination such as Germany exhibited—in repertory, staging, choreography—became important, even if not global, developments.

Music in films

In film making there was more widespread evidence of musical vitality, as well as public response. Here the Wagnerian ideal of the music-drama in which all the arts reach their apotheosis, was proclaimed by some practitioners, who held, as Wagner had, that the arts of music, dance, and theatre as separate entities would be absorbed and superseded in the new form. If this proved so, Wagner's Bayreuth would be of much greater compass and far more fluid than the one he envisioned. It seemed more probable, however, that the emerging art film, in which such unity is demonstrated, would achieve a place of its own, while in no way dispossessing other genres. Many British and American composers wrote music for commercial films, notably William Walton (*Henry V*, 1944; *Hamlet*, 1947; *Richard III*, 1954—all featuring Olivier); Virgil Thomson (*The Plow That Broke the Plains*, 1936; *Louisiana Story*, 1948); and Aaron Copland (*Our Town, Of Mice and Men*, 1939). Among Soviet composers Shostakovich scored music for *Hamlet*, and Prokofiev for *Alexander Nevsky* (1938) and *Ivan the Terrible* (1944), both directed by Sergey Eisenstein.

A more or less obtrusive "background music," to be sure, accompanied most commercial films; what Eisenstein envisaged (and what present-day art films strive to achieve) was "a unity of fused musical and visual images, *composing the work with a united audio-visual image.*" Ingmar Bergman, in whose films such a unity of sound and sight was often attained, believed that music and film have much in common because both affect the emotions directly, and are not mediated by the intellect: "Film is mainly rhythm; it is inhalation and exhalation in continuous sequence." Many observed that music and film are both arts of time and movement, with myriad possibilities of unification.

Recording, television, and film have their own potentialities as media; all are devices, as well, for extending the range of concert hall and theatre. The global communication that now takes place with such rapidity by means of these media weakened those cultural barriers, which long isolation imposed on human societies. East Indian and African music, and art, the Japanese Nō Theatre, the sounds of medieval viols—all these and much more were placed within reach of anyone who would take a little trouble. What further revelations lie ahead?

Future prospects

Leonard Meyer, in *Music, the Arts, and Ideas* (1967), suggested that a great many kinds of art and music would continue to exhibit vitality and even flourish, side by side,

in fluctuating equilibrium. For historical precedent, Meyer pointed to ancient Egypt, where a cultural "steady state," favourable to art but without radical innovation, endured for millennia. He thought that further experiment would follow avenues already opened up and that radical novelty in the media of art could hardly be expected after what has transpired in recent years. This was a recognition of possible "outer limits" of the human physiology and psyche, but imposed no moratorium on novelty.

It has happened again and again that music at first considered revolutionary is later regarded as conventional or passé. "The sated ear forever demands new harmonies, which it will fast learn to tolerate and then dismiss as threadbare and uninteresting," said the British physicist James Jeans (1877–1946). Debussy was once "modern" and Stravinsky avant-garde; later even Bartók was regarded as old hat. Impressionism (Debussy, Ravel) and Expressionism (Schoenberg, Berg, Webern) were contemporary manifestations of the early 20th century, succeeded by the Neoclassicism of Stravinsky and Hindemith in the third and fourth decades. Neoclassicism, stylish before 1940, was itself one illustration of the eclecticism that permeated 20th-century composition. The use of jazz idioms by Stravinsky and Hindemith (as well as Copland and many others) was another. After World War II, there was a belated upsurge of Expressionism; occurring not so much in its original spirit, however, as in the preoccupation with 12-tone technique as a compositional device. This was followed by experiments with other aspects of serialism (described as "total" in some contexts) and the bewildering proliferation of new idioms in which electronic music in its various manifestations played an ever more dominant role. The British critic Donald Francis Tovey foresaw this development with extraordinary prescience; but his confident prediction that the human voice (and its echo in the singing instrument) would never be superseded may be open to question.

But if highly abstract and perhaps dehumanized art music—conceived and consummated electronically—is already in process of realization, it need not be concluded that other modes of composition will or must therefore be replaced or invalidated. Though a prominent composer of electronic music may say that Bartók has had his day, it is also a fact that there are millions of listeners who have not "caught up" with Bartók. Many music lovers today, even among professional musicians, find the last Beethoven string quartets hard going. The same composer may be expected to produce works that differ in their dimensions and accessibility. Beethoven, for example, wrote easy short pieces for piano, as well as lengthy sonatas; and Bartók composed not only six demanding string quartets but also the carefully graded *Mikrokosmos,* designed for the instruction of beginning pianists.

Although a particular musical style, such as Impressionism, may reach its peak and cease to evolve, a change of fashion—to Neoclassicism or whatever—does not consign Debussy to the ash heap. The concert-hall repertory is testimony to the persistence of disparate styles; and it is evidence, what is more, of a preference for the old over the new. Public taste in classical music is conservative. There are, however, fluctuating allegiances in regard to established repertoire, as may be seen in the shifts in taste affecting a composer such as Liszt.

Folk music, popular music, jazz. The persistence of viable music is especially remarkable in the universal phenomenon of folk music. Essentially anonymous in character, folk music, transmitted orally, is often a repository of ethnic and cultural idiosyncrasies and affords them a precarious immortality. With the ending of the cultural isolation that geography for so long has imposed, whole traditions are now threatened with extinction. Meanwhile, comparative musicologists are busy recording those traditions, as Bartók and Zoltán Kodály did in their extensive collection of Hungarian folk music. Precisely because recording instruments were developed only recently, the origins and early characteristics of folk music, both vocal and instrumental, are largely conjectural. But present practice, in this domain, may be a good, if not altogether reliable, indication of what preceded it. There is a problem, however, in keeping genres distinct, since "folk" and "art" music have greatly influenced one another. In more than one instance, a composed song has found its way into the vernacular; and it is necessary only to recall a number of Schubert's songs to realize how slight the distinction between folk and art music can be.

Reciprocal influences

Authentic folk music is characterized by melodic and rhythmic directness and simplicity—a compass that will not tax the normal voice—and accent and repetition corresponding closely to indigenous speech patterns; all qualities that make folk tunes easily transferable from voices to instruments. But composed music may also (and often does) exhibit these characteristics. In the 19th century there was much intentional exploitation of native music (a symptom, not infrequently, of nationalistic loyalty) by such composers as the Bohemians Dvořák and Smetana; the Russian "Five" (Balakirev, Cui, Rimsky-Korsakov, Borodin, and Mussorgsky); and Chopin in his polonaises and mazurkas. But this was more often an aspect of eclectic skill and cosmopolitanism than of patriotic sectarianism. Dvořák, for example, wrote many melodies in the style of American Indian and Negro music as he understood them. German composers created melodies of unmistakable folk quality and sometimes made use of well-known tunes not only from their own folk tradition but from other countries also, as Brahms bears witness to in his Hungarian dances, and Beethoven in the "Russian theme" of his string quartet (*Razumovsky*) Opus 59, No. 2. Similar examples abound. Folk music has been a source of nourishment and inspiration for art music and its composers. It is a truism that every artist draws sustenance from his own culture; some composers, notably the Hungarians Bartók and Kodály, absorb and reflect regional musical idioms to an extraordinary degree in their work.

But if folk music finds its way into art music, the converse is also true. Every civilization in which music is highly developed exhibits sophisticated elements (structural, melodic, rhythmic) in its folk music. This has made it difficult to establish the authenticity of much European folk music, and many "examples" are undoubtedly of recent origin. A high degree of musical literacy in a culture influences every level of music making. In the United States, for example, the growing sophistication of "popular" music (and especially jazz) has been effected both by knowledgeable and imaginative practitioners and by a listening public made ready for their innovations.

In a broad sense, folk music best deserves the epithet "popular." But in common usage the term denotes a more ephemeral, commercially successful music; introduced, in many cases, in stage or film musical comedy, or by a reigning vocalist through nightclub and television performances or recordings, and disseminated by the varied and far-flung resources of the entertainment industry. The quality of much of this music is very high. Composers, arrangers, and performers devote considerable talents to its production, often combining in one person two or even three of these functions in a manner reminiscent of "serious" composers, until a fairly strict division of labour (though only within the past century) became the rule. The cohesive force in all this has been the dance band in its varied manifestations; "hit tunes" originate and are perpetuated in that setting.

Popular music, so identified, does represent a viable, though short-lived, folk music throughout much of the civilized world. But few "hits" hold their own for more than a few months against the relentless production of new tunes. Some of the best ones are revived, periodically, out of nostalgia or simply from the quest for variety; when more than a few years old, however, they sound "dated," though they may be highly evocative of another era and possessed of an archaic charm. Newness is one of the principal values of the genre. Such "all-time" favourites as "Dinah," "Stardust," and the "St. Louis Blues" only underscore this point.

Every human calling has its peculiar vocabulary. The speech of jazzmen is highly esoteric, with nuances that cannot be rendered in any terms whatsoever to outsiders.

Meanings, moreover, are often seasonal, and some words change their meaning altogether or become obsolete. Jazz itself defies definition. Nevertheless, some of the elements that have gone into jazz can be identified; they are largely folk elements, indigenous to the United States. Because the Negro contribution to jazz has been enormous, the appellation Afro-American has often been used; but the presumption that jazz is a genetic or ethnic phenomenon is a big one. African melodic patterns found their way, certainly, into plantation slave songs, spirituals, and the distinctive and emotionally fervent blues. As a cultural phenomenon, jazz, in its origins and in its evolution in the 20th century, is uniquely American, though its dissemination has been worldwide. The characteristic syncopation, the undeviating beat, and frenetic energy were constituents of ragtime, an important "jazz" manifestation early in the 20th century. But harmonic accompaniment is essentially European. Jazz was a hybrid art from the start; in the decades since its emergence, it has become increasingly complex. Two distinctive features have been present: the element of improvisation—at one time every skilled musician's stock-in-trade—which has otherwise virtually disappeared from Western musical practice; and, related to improvisation, melodic and rhythmic rubato, or fluctuation, over a steady beat.

Elements of jazz

New Orleans was the first important jazz capital; "Dixieland" and "Chicago style" were early variations of New Orleans jazz. Swing, the predominant popular style of the 1930s and early 1940s, was an aspect of jazz, though purists might wish to disclaim it. (Jazz influence, nevertheless, has been pervasive in all 20th-century popular music, not excluding "rock" and "soul.") Later decades saw the development of "hot" jazz, "cool" jazz, and the growth of a serious audience of intellectual analysts with a special jargon and stringent (though unofficial) requirements for membership in their ingroup. Jazz, like music itself, is exceedingly protean.

One of the most exciting manifestations among jazzmen is the jam session, in which a group of players improvise together, sometimes for hours at a stretch. At its most successful, the jam session produces that happy fusion—rare in modern music making—of rigorous discipline and spontaneous—even inspired—creativity. The complexities of such performance cannot be rendered in notation; nor are they repeatable.

Non-Western counterparts

The foregoing description of the jam session can apply, with little modification, to renditions of East Indian ragas —music adhering to strict traditional melodic patterns; there, too, skillful improvisation is essential to good performance, within prescribed limits. Vocalist, percussionist, and instrumentalists resemble the makeup of the "dance band"; and the lengths of performances (and the Dionysian atmosphere generated) are often strikingly similar. Another interesting parallel is seen in the capacity of jazz instrumentalists to suggest East Asian microtonality, using intervals smaller than half tones.

This interesting similarity between American jazz and East Indian "classical" practice, made even more striking by the rhythmic complexity of both, need not be given exaggerated importance, though it calls for a reappraisal of concepts of "new" and "old." Cultural exchange may be expected, among its other benefits, to effect just this kind of examination. The appetite in the West for East Asian (and other "exotic") music is a recognition of its intrinsic value. Of course, the influence is reciprocal; and the use of Western musical techniques, particularly in film scores and broadcasting, is steadily increasing; India and Japan offer dramatic evidence of this. East meets West, musically speaking, and both are changed. The rapprochement, moreover, proceeds on several levels, not only on the people to people, or "folk" level, but also among ethnomusicologists, a less numerous and more highly disciplined breed who ply their researches across the continents and are jealous in the preservation of traditional patrimonies. In between are those musicians (and active listeners) who are gradually becoming aware of a confrontation of cultures: sometimes dramatic, as in the musical dialogue that ensued when the Indian sitar player Ravi Shankar and the violinist Yehudi Menuhin met, but more often in the form of a subtle infusion of newly published works, recordings, public concerts, and the unrehearsed music of the streets.

BIBLIOGRAPHY

Historical purview: JULIUS PORTNOY, *The Philosopher and Music* (1954), gives a chronological account of what philosophers have contributed to musical theory; and GORDON EPPERSON, *The Musical Symbol*, ch. 2 (1967), discusses philosophical musical thought from classical antiquity through the 18th century. LIN YUTANG (ed. and trans.), *The Wisdom of Confucius* (1938, reprinted 1958), gives attention to ancient Chinese music.

Problems of musical meaning: ARTHUR SCHOPENHAUER, *Die Welt als Wille und Vorstellung* (1883; Eng. trans., *The World as Will and Idea*, 1961); and FRIEDRICH NIETZSCHE, "The Birth of Tragedy from the Spirit of Music," trans. by CLIFTON P. FADIMAN in *The Philosophy of Nietzsche* (1954). EDUARD HANSLICK, *Vom musikalisch Schönen* (1854; Eng. trans., *The Beautiful in Music*, 1957), remains the best single exposition of the formalist (or nonreferentialist) position in musical aesthetics. EDMUND GURNEY, *The Power of Sound* (1880, reprinted 1966), maintains a similar point of view but with considerably greater amplitude and subtlety. For background of the contemporary symbolist views of musical meaning, see ALFRED NORTH WHITEHEAD, *Symbolism* (1959); SUSANNE K. LANGER, "On Significance in Music," in *Philosophy in a New Key*, 2nd ed. (1951), and *Feeling and Form* (1953). LEONARD B. MEYER has made an important contribution to the aesthetics of music. His interest in the relevance of information theory to music has been evidenced in two articles: "Meaning in Music and Information Theory," *Journal of Aesthetics and Art Criticism*, 14:412–424 (1957), and "Some Remarks on Value and Greatness in Music," *ibid.*, 17:486–500 (1959), reprinted in his *Music, The Arts, and Ideas: Patterns and Predictions in Twentieth-Century Culture* (1967). JOHN DEWEY, *Art as Experience* (1934, reprinted 1959); and KARL JASPERS, *Von der Wahrheit* (1947; Eng. trans., *Truth and Symbol*, 1959), have given reinforcement to organic and symbolic theses, respectively.

Performance practice, styles, and musical forms: The best historical accounts of musical forms, styles, and performance practice are to be found in DONALD J. GROUT, *A History of Western Music* (1960); GUSTAVE REESE, *Music in the Middle Ages* (1940), and *Music in the Renaissance*, rev. ed. (1959); MANFRED F. BUKOFZER, *Music in the Baroque Era* (1947); ALFRED EINSTEIN, *Music in the Romantic Era* (1947); and WILLIAM W. AUSTIN, *Music in the 20th Century, from Debussy to Stravinsky* (1966). SIR DONALD FRANCIS TOVEY, *The Forms of Music* (1956), contains informative and engaging short pieces. ROBERT SCHUMANN, *On Music and Musicians*, ed. by KONRAD WOLFF (Eng. trans. 1947), is an example of the work by a 19th-century precursor of the phenomenon of the present-day composer-authors who have contributed to aesthetic theory by elucidating their own works and commentating on other composers and on the scene in general. See also IGOR STRAVINSKY, *Poetics of Music in the Form of Six Lessons* (1947); PAUL HINDEMITH, *A Composer's World* (1952); AARON COPLAND, *Music and Imagination* (1952). Discussion of music and film may be found in LEWIS JACOBS (ed.), *The Emergence of Film Art* (1969). Twelve-tone technique and varieties of serialism deriving from it are treated in ARNOLD SCHOENBERG, *Style and Idea* (1950); and RENE LEIBOWITZ, *Schoenberg, et son école* (1947; Eng. trans., *Schoenberg and His School*, 1949). Short pieces on electronic music appear often in periodical literature. See LEJAREN HILLER and JAMES BEAUCHAMP, "Research in Music with Electronics," *Science*, 150:161–169 (1965); CARLOS CHAVEZ, *Toward a New Music* (Eng. trans. 1937), anticipated by several decades the electronic revolution that is now in progress. On folk music, a classic work is BELA BARTOK, *Amagyar Népdal* (1924; Eng. trans., *Hungarian Folk Music*, 1931). Jazz is treated in LEONARD FEATHER, *The Book of Jazz* (1957); and in LEROY OSTRANSKY, *The Anatomy of Jazz* (1960), a balanced and comprehensive analysis of the subject.

(G.E.)

Music, East Asian

A study of the music of East Asia covers historical periods of changing styles from at least 2,000 BC to the present time, set in a context of regional cultures located as far south and west as Vietnam, Tibet, and Central Asia, north to Mongolia, Manchuria (Northeast Provinces), and Korea, and east to Japan. From this rich and varied offering the present article will centre primarily on the music of three countries: China, Korea, and Japan. After

a general introduction each country will be discussed separately in chronological order. Historical relations and musical similarities will be pointed out along with striking musical differences. This article is divided into the following sections:

I. The nature of East Asian music
  East Asian music vis-à-vis that of other major cultures
    Concepts of music
    Theoretical systems
  Musical traits common to East Asian cultures
II. The music of China
  Formative period
    Ancient artifacts and writings
    Aesthetic principles and extramusical associations
    Tonal system and its theoretical rationalization
    Classification of instruments
    Han dynasty: musical events and foreign influences
  T'ang dynasty
    Thriving of foreign styles
    Courtly music
  Sung and Yüan dynasties
    Consolidation of earlier trends
    Music theatre
  Ming and Ch'ing dynasties
    Further development of opera
    Other vocal and instrumental genres
  Developments since 1911
    Period of the Republic of China and Sino-Japanese War
    Communist period
III. The music of Korea
  Shaman music
  Court music
  Vocal music
IV. The music of Japan
  Music before and through the Nara period
    Early evidences
    Predominant musical traits
    The Nara period
  The Heian period
    Music of the left and of the right
    Musical notation
    Tonal system
    Vocal music
    Shintō music
    Buddhist music
  Kamakura, Muromachi, and Edo periods
    Nō music
    Koto music
    Schools of shakuhachi flute music
    Samisen music
    Kabuki theatre
    Biwa, vocal, and folk music
  The Meiji period and subsequent music
    Sources of Western influence
    Traditional styles
    Composers in Western styles

I. The nature of East Asian music

EAST ASIAN MUSIC VIS-A-VIS THAT OF OTHER MAJOR CULTURES

East Asian music can be viewed as one of the big four among the generally urban, literate cultural groups of the world. The other three are South Asia, the Near East, and Europe. Around each of these major regional cultures one can find many satellite musical systems known as national forms. In most cases, the fundamental musical concepts of such national forms reflect the basic ideals of the cultural core. For example, the musics of Iran and Egypt are of one family, as are those of France and Sweden or of China and Japan. A possible fifth addition to the "big four" concept is the Southeast Asian musical culture characterized by the use of knobbed gongs. Although it lacks the extensive written documents on music history and theory characteristic of the other four, it shares with them certain distinctive types of instruments and musical styles. Using instrument type alone as a measure, it is sometimes possible to note cultural influences and mixtures of the major traditions in smaller units. For example, the physical structure and playing positions of various bowed instruments in mainland Southeast Asia can often mark clearly Chinese influence, as in Vietnam, or Muslim and Chinese forms in confluence, as in the various bowed lutes of courtly ensembles in Cambodia and Thailand. By the same token, the appearance of flat gongs in mainland Southeast Asia shows Chinese connections, while the knobbed gongs clearly stem from Southeast Asian culture proper.

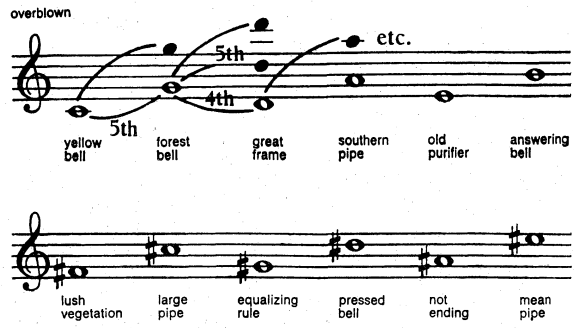
Intercultural influences

Concepts of music. If one turns to distinctions in musical style one of the first questions to arise is "What is music?" Two basic definitions will suffice for this article. The first definition is cultural: a sonic event can be called music if the people who use it call it music, regardless of one's own reaction to it. Similarly, certain events that sound musical to foreign ears are not music culturally if they are not accepted as such by native culture carriers. A good example of such a situation is found in the Near East, where singing is never allowed in the mosque, though one may hear performances and even buy records of "readings" from the Qur'ān. Such cultural and functional problems of definition seldom arise in East Asian music, and a more neutral definition is appropriate. A sound event may be considered and studied as music if it combines the elements of pitch, rhythm, and loudness in such a way that they communicate emotionally, aesthetically, or functionally on the levels that either transcend or are unrelated to speech communication. Those who have been moved by a love song or a lament can well appreciate some of the implications of such a view of music. When listening to "exotic" music—*i.e.*, that of a tradition outside one's own background—it is important to remember that such transcendental values are at work for the alien listener as well as for listeners familiar with the particular musical language in use.

There are many kinds of music in the world, the three most common terms being folk, popular, and art music. Folk and popular music have their special indigenous and mixed forms in Asia (as in all the world today), but it is in the literate art traditions of Asia that historical and musical distinctions can be made most clearly. In the context of this discussion, art music is defined as a tradition having, to some degree, a conscious theoretical basis and a sense of repertoire that is played against the highest standards of excellence held by informed native listeners. The performer is often—though not always—a professional, and there may be a known historical depth to the traditions. Thus, there may be art music in many nonliterate cultures such as that of the Australian Aboriginals and that of the tribal courts of Africa. In this article, however, the major concern is with one of the large urban, literate cultures and its three national variants. Before looking at these musical systems in detail, it is useful to compare the entire culture with those of the other major "big" three, South Asia, the Near East, and Europe.

Theoretical systems. It has already been implied that all four major literate cultures have written histories and music theories. All four, in their ancient forms, laid a strong emphasis on the extramusical qualities of music. For example, the study of such concepts as the power of vibrations (in ancient Indian music theory), and the relationships between music and other elements in the universe (found in Assyrian records as well as in the writings of medieval European scholars) can be matched in East Asia by the joint efforts of Chinese musicologists and astrologers to bring the music of the empire in tune with the universe. In addition, all four developed mathematically and acoustically based music theories. The Chinese system used end-blown bamboo tubes (*lü*) as the source of pitch data, whereas the other three systems tended to rely on the divisions of a string (thus the pictures of Pope Gregory I or monkish European scholars strumming a monochord). Although their Chinese equivalents are pictured with panpipes instead, one of the most fascinating facts is that both Chinese and Western systems, unlike the other two, emerged with a cycle of fifths (the fifth being a musical interval such as C to G in the West; see also below under *The music of China*), creating 12 tones that were mathematically correct (in their acoustical relationships) but not equidistant musically (shown in the musical notation labelled I). Thus it would seem that the two geographical ends of ancient urban music cultures came up

I



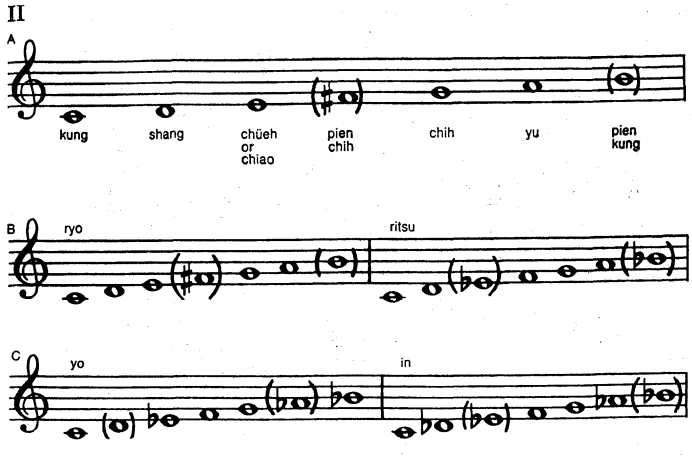
with very similar systems. One of the reasons that they do not sound the same today is that in the 17th century, Western musicians and acousticians found a formula that allowed them to bypass the "natural" system and hence make all pitches equidistant. The same formula was discovered by a Chinese, Hsü Tsai-yu, about 1596; but such "well-tempered" tuning was not accepted in Chinese music practice until very recent times. There are, of course, many other differences in the sound, the instrumentation, and the forms of Western and Eastern music. Many will be noted in the subsequent chronological study of East Asian music. But if the wonder of such variants is to be fully appreciated it must be understood that music is not in fact an international language. It consists of a whole series of equally logical but sometimes very different closed systems. The word closed is used to mean that the musical facets mesh perfectly within a given system, but they often may prove difficult or impossible to transfer to another system. In this light, a given passage of Chinese music when analyzed or judged with the logic of Beethoven is chaos, but Beethoven seems equally illogical when viewed in the context of Chinese, or for that matter Indian, music theory. Such intercultural clashes can be constructed between almost any of the larger systems. In this context, one can see that Chinese music is tonally more foreign to Near Eastern or Indian music than to Western, though historically it had closer relations with the other two. There are, of course, many other musical concepts and styles that travelled over the silk route between China and other parts of Asia; but these must be held aside until the discussion of the history of Chinese music.

Internally logical, closed systems

MUSICAL TRAITS COMMON TO EAST ASIAN CULTURES

In these primary considerations a view of some general aesthetic traditions common to much of East Asian music is also requisite. The tonal vocabulary of 12 tones generated in a cycle of fifths is the first common factor. From this tonal vocabulary various scales of five to seven notes are chosen, as they are in the West. The total number of

II



notes in an East Asian scale is often seven, but each tends to have what could be called a five-tone (pentatonic) core, as seen in notation II. The one scale in which no half steps appear (the so-called anhemitonic pentatonic; the first scale in II-A) is common all over the world, although casual listeners often mistake it as being characteristically "Oriental." A study of other East Asian scales, such as the *yo* and *in* scales shown in II-C, in addition to a few moments spent listening to authentic East Asian recordings, will reveal clearly that Oriental music comprises a great deal more than the black notes on the piano augmented by a few bangings of cymbals or gongs.

Although gongs and cymbals are well-known elements in much modern Chinese opera music (*i.e.*, after 1500), such instruments are not particularly common to East Asia in general. Indeed, there are a great variety of combinations, many of them historically related. Perhaps the only fundamental parallels between the multitude of East Asian performance practices lie in two common characteristics: (1) the emphasis on melody supported by rhythm, with little interest in harmonic accompaniment such as is found in the Western Classical style; and (2) a preference for the chamber-music sound ideal. The latter term means that no matter how large an ensemble may be, the individual instruments are meant to be heard. This differs from the orchestral sound ideal, popular in 19th-century Western music, in which the intention is to merge the sounds of the individual instruments into one musical colour.

Melodic and sonic ideals

The degree to which the melodic and sonic ideals are applied in East Asian music will become evident in the examination of specific genres. At this point it is necessary only to note the rather common tendency for East Asian music to be word or pictorially oriented. Such orientations are obvious in the many vocal and dance forms of Asia; but with a few notable exceptions one also finds that purely instrumental music will be attached through its title to a literary moment or a scene. Perhaps this relates to a general sensitivity to nature in East Asian culture as a whole. Whatever its source, it has produced many sonorous and pleasing results.

II. The music of China

One always approaches any survey of Chinese music history with a certain sense of awe—for what can one say about the music of a varied, still active civilization whose archaeological resources go back to 3000 BC and whose own extensive written documents refer to endless different forms of music in connection with folk festivals and religious events as well as in the courts of hundreds of emperors and princes in dozens of different provinces, dynasties, and periods? If a survey is carried forward from 3000 BC it becomes clear that the last little segment of material, from the Sung dynasty (960–1279) to today, is equivalent to the entire major history of European music. For all the richness of detail in Chinese sources, it is only for this last segment that there is information about the actual music itself. Yet the historical, cultural, instrumental, and theoretical materials of earlier times are equally informative and fascinating. This mass of information will be organized into four large chronological units: (1) the formative period, from 3000 BC through the 4th century AD; (2) the international period, from the 4th through the 9th century; (3) the national period, from the 9th through the 19th century; and (4) the world music period of the 20th century.

FORMATIVE PERIOD

Ancient artifacts and writings. Chinese writings claim that in 2697 BC the emperor Huang Ti sent a scholar, Ling Lun, to the western mountain area to cut bamboo pipes that could emit sounds matching the call of the phoenix bird, making possible the creation of music properly pitched for harmony between his reign and the universe. Even this charming symbolic birth of music dates far too late to aid in discovering the melodies and instrumental sounds accompanying the rituals and burials that occurred before the first historically verified dynasty, the Shang (1766–1122 BC). The beautiful sounds of music are evanescent, and before the invention of recordings they disappeared at the end of a performance. The remains of China's most ancient music are found only in those few instruments made of sturdy material. Archaeo-

logical digs have uncovered globular clay ocarinas (*hsün*), tuned stone chimes (*ch'ing*), and bronze bells (*chung*); and the word *ku*, for drum, is found incised on Shang oracle bones. The earliest surviving written records are from the next dynasty, the Chou (1122–221 BC). Within the famous five classics of that period, it is in the *Li chi* ("Collection of Rituals") of the 2nd century BC that one finds an extensive discussion of music. The *I Ching* ("Classic of Changes") is a diviner's handbook built around geometric patterns, cosmology, and magic numbers that indirectly may relate to music. The *Ch'un Ch'iu* ("Spring and Autumn" Annals), with its records of major events, and the *Shu Ching* ("Classic of History"), with its mixture of documents and forgeries, contain many references to the use of music, particularly at court activities. There are occasional comments about the singing of peasant groups, an item rare even in the early historical materials of Europe. The *Shih Ching* ("Classic of Poetry") is of equal interest, for it consists of the texts of 305 songs that are dated from the 10th to the 7th centuries BC. Their great variety of topics (love, ritual, political satire, etc.) reflect a viable vocal musical tradition quite understandable to modern radio or record listeners. The songs also include references to less durable musical relics such as the flutes, mouth organ (*sheng*), and, apparently, two forms of the zither (the *ch'in* and the *se*).

Chou dynasty musical documents

Aesthetic principles and extramusical associations. Despite the controversial authenticity and dates of ancient Chinese written sources, a combined study of them produces tantalizing images of courtly parties, military parades, and folk festivals; but it does not provide a single note of music. Nevertheless, in keeping with the prehistoric traditions of China, the philosophies of sages, such as Confucius (K'ung-fu-tzu, 551–479 BC) and Mencius (Meng-tzu, 371–289 BC), and the endless scientific curiosity of Chinese acousticians furnish a great deal of rather specific music theory as well as varied aesthetic principles. The straightest path to this material is found on the legendary journey, mentioned earlier, of Ling Lun in search of bamboo pipes. The charm of such a tale tends to cloud several interesting facts it contains. First, it is noteworthy that the goal of the search was to put music in tune with the universe. This extramusical need was noted earlier in the general discussion of world music history. It is upheld in theory in the "Annotations on Music" ("Yüeh-chi") section of the *Li chi* with such comments as "Music is the harmony of heaven and earth while rites are the measurement of heaven and earth. Through harmony all things are made known, through measure all things are properly classified. Music comes from heaven, rites are shaped by earthly designs." Referring back to the previously given general definition of music, it can be seen that such cosmological ideals may be not merely ancient superstitions but actually cogent insights into the cultural function of music in the societies of men. Confucius, as pictured in the *Analects* written long after his death, had a similar view of music, including a concern for the choice of music and modes proper for the moral well-being of a gentleman. It is an open question as to how much performance practice followed the admonitions and theories of the scholars; but centuries later one finds numerous pictures of the wise man standing before some natural beauties while his servant follows closely behind him carrying his seven-stringed zither (*ch'in*) for proper use in such a proper setting.

Another point to be noted in the legend of the origin of music is the fact that Ling Lun went to the western border area of China to find the correct bamboo. It shall be noted as this article progresses how often cultures from Central and West Asia or tribal China influenced the growth and change of music in Imperial China. Finally, it is significant that, although the emperor in the myth was primarily concerned with locating pipes that would bring his reign into harmony with the universe, the goal was also the creation of precise, standard pitches.

Tonal system and its theoretical rationalization. The cyclic creation of a 12-tone system in China has been mentioned before. Under the Chinese classical system this cycle began from a basic first pitch called yellow bell (*huang chung*), produced by blowing on the first bamboo tube (*lü*). This concept is of special interest because it is the world's oldest information on a tone system concerned with very specific pitches as well as the intervals between them. The precise number of vibrations per second that created the yellow bell pitch is open to controversy (between middle C♯ and the F above) because the location of this pitch could be changed by the work of new astrologers and acousticians in behalf of a new emperor, in order that his kingdom might stay in tune with the universe. (The note C was used in the previously given example in deference to Western readers; it should not be assumed that a pitch identical to C♯ was necessarily central to ancient Chinese music). The choice of the primary pitch in China had extramusical as well as practical applications, for the length of the yellow bell pipe became the standard measure (like a metre); and the number of grains of rice that would fill it were used for a weight measure. Thus, the pipe itself was often the property not of the Imperial music department but of the office of weights and measurements.

Practical applications of Chinese music

Mathematical relationship of pitches. The bamboo *lü* pipe is closed at the bottom by a node in the bamboo, with the result that another pitch a fifth and one octave higher could be produced on it by blowing more strongly (overblowing) as shown in notation I. This new pitch could be produced an octave lower by constructing a separate pipe two-thirds the size of the first one. If one then continued to construct pipes alternately four-thirds and two-thirds the length of the previous ones, an entire system of 12 notes could be generated, which is, with the exception of the means of creation, acoustically and proportionately in the same relation as is found in the Greek Pythagorean system. The English versions of the Chinese names for the 12 pitches seem quite fanciful; but they represent theoretically correct pitches, as do terms used in the Western traditional system, such as C or A♭. The source of each name in the Chinese system is conjectural; but Chinese classical acousticians, like modern Western scientists, no doubt found value in creating a professional nomenclature that was divorced from everyday speech and potentially descriptive of the nature of the object. For example, the use of bell names may relate to the gradual preference for tuned bells over pipes in the music division of the courts. Names like "old purifier" and "equalizing rule" may refer to aspects of the fact that, in both the Greek and Chinese "pure" systems, tones created beyond the first 12 will be out of tune with the original set. In the West, the degree of out-of-tuneness—the famous so-called Pythagorean comma—caused great problems as music became more involved in harmonic textures and modulations. Chinese academicians toyed with the same mathematical and acoustical problems of the comma, but in general they were not of a major concern for practicing musicians because the Chinese did not use the 12 tones in the same way as did the Westerners.

Scales and modes. For both traditions, the 12 pitches are merely a tonal vocabulary from which a specific ordering of a limited number of pitches can be extracted and reproduced on different pitch levels. Such limited structures are called a scale. With a set scale it is possible to emphasize different notes in such a way that they seem to be the pitch centre. Such variations of pitch centre within a scale are called modes. In the Western traditional systems most scales use seven tones that can be transposed and that contain modes. For example, C major (C–D–E–F–G–A–B) can be made a Dorian mode by using D as the pitch centre without changing the pitches used (D–E–F–G–A–B–C); and the whole scale and its modes can be transposed to a higher or lower pitch level (F major, E♭ major, etc.). The Chinese system concentrates in a similar way on a seven-tone scale but with a five-tone core (*wu sheng*) plus two changing (*pien*) tones, as shown in notation II-A.

Pitch centre

The notes of a scale (a set of intervals not tied to specific pitches) are often indicated in Western music with syllables such as *do re mi*. The Chinese equivalent terms for

notes in their classical scale are given in notation II-A. As in the Western system, modes can be constructed in Chinese music, and the scale can be transposed. From these comments it can be seen that the mythical emperor Huang Ti seems to have founded a very thorough system indeed. Throughout the Ch'in (221–206 BC) and Han (206 BC–AD 220) dynasties Imperial systems were tuned and retuned to meet Imperial and heavenly needs. Theoretical sophistications and experimentations continue on to the present day. How far back they may go in time is unknown, but in recent times there have been discovered stone chimes from the 2nd millennium BC that imply by their tunings that the Chinese classical tone system tradition may actually be as ancient as the legends claim. It is a pity that the music was not equally durable.

Extramusical associations. Returning to the extramusical aspects of the Chinese system, one finds that the five fundamental tones are sometimes connected with the five directions or the five elements, while the 12 tones are connected by some writers with the months of the year, hours of the day, or phases of the moon. The 12 tones can also be found placed in two sets of six on Imperial panpipes (*pai-hsiao*) in keeping with the female–male (Yin and Yang) principle of Chinese metaphysics. Their placement is based on the generation of the pitches of each pipe by its being either four-thirds larger or two-thirds smaller than the previous one, the smaller ones being female.

Classification of instruments. The Chinese talent for musical organization was by no means limited to pitches. Another important ancient system called the eight sounds (*pa yin*) was used to classify the many kinds of instruments used in Imperial orchestras. This system was based upon the material used in the construction of the instruments, the eight being stone, earth (pottery), bamboo, metal, skin, silk, wood, and gourd. The sonorous stones, ocarinas, and flutes mentioned earlier are examples from the first three categories. The bells are obvious metal examples. Another ancient member of the metal category is a large bronze drum (*t'ung ku*), which is of special interest because of the widespread distribution of archaeological examples of it throughout Southeast Asia. Equally intriguing are the designs and sounds of the bronze head of the drum as well as the frequent statues of frogs around the rim of the head. Han dynasty military expeditions to the south report that bronze drums among southern peoples represented the spirit of rain and water and rumbled like bullfrogs. The possession of such bronze drums or later gongs was, and still is, prestigious among tribal groups in Southeast Asia.

Stringed instruments of ancient China belong to the silk class because their strings were never gut or metal but twisted silk. Drums are skin instruments, whereas percussive clappers are wood. The most enjoyable member of the wooden family is the *yü*, a model of a crouching tiger with a serrated ridge or set of slats along its back that were scratched by a bamboo whisk in a manner recalling the various scratched gourds of Latin American bands. The Chinese category of gourd is reserved for one of the most fascinating of the ancient instruments, the *sheng* mouth organ. Seventeen bamboo pipes are set in a gourd or sometimes in a wooden wind chest. Each pipe has a free metal reed at the end encased in the wind chest. By blowing through a mouth tube into the wind chest and closing a hole in a pipe with a finger the reed will be made to sound, and melodies or chord structures may be played. Many variants of this instrumental principle can be found in Southeast Asia, and it is not possible to know with assurance where this wind instrument first appeared. Western imitations of it are found in the reed organ and, later, in the harmonica and the accordion.

The mouth organ

Han dynasty: musical events and foreign influences. The extensive work in theory and classification in ancient times implies that there must have been an equally large amount of performance practice. Modern information on all of these elements of music has suffered because of the destruction of many books and musical instruments under the order of Ch'in Shih Huang Ti, emperor of the Ch'in dynasty (246–209 BC). Yet there are several survivals from the Han dynasty (206 BC–AD 221) that do give some insight into how the musical events took place. In the court and the Confucian temples there were two basic musical divisions: banquet music (*yen yüeh*) and ritual music (*ya yüeh*). Dances in the Confucian rituals were divided into military (*wu wu*) and civil (*wen wu*) forms. The ensembles of musicians and dancers could be quite large, and ancient listings of their content were often printed in formation patterns in a manner analogous in principle to those of football marching bands in America today. Rubbings from Han tomb tiles show more informal and apparently very lively music and dance presentations at social affairs. The early Chinese character for dance (*wu*) implies movement by the body more than by the feet. The folk sources of many of the songs from the *Shih Ching* and later books show that courtly musical life was not without its gayer and more personal and secular moments. The stringed instruments, notably the seven-stringed *ch'in* zither, apparently were popular as vehicles for solo music.

The Han dynasty empire expanded and at the same time built walls between its national core and western Asia. But these actions were paralleled by an increasing flow of foreign ideas and materials. Buddhism entered from India to China in the 1st century AD, whereas booty, goods, and ideas came from Central Asian Gandharan, Tokharian, and Iranian cultures along the various desert trade routes via the cities of Khotān to the south (3rd to 5th centuries), Kucha in the centre (4th through 8th century), and Turfan to the north (5th through 9th century). Desert ruins and Buddhist caves from this period and later reveal a host of new musical ensembles and solo instruments. Two stringed instruments of particular interest are the angle harp (*k'ung-hu*) and the pear-shaped plucked lute (*p'i-p'a*). The harp can be traced back across Central Asia to the ancient bas reliefs of Assyria. The lute also seems to have West Asian ancestors but is a more "contemporary" instrument. Variants of this instrument have continued to enter or be redesigned in China down to the present day. A delightful symbol of the long-term musical and commercial value of such a plucked lute is found on a 10th-century clay statue of a caravan Bactrian camel with two different styles of *p'i-p'a* tied to the saddle post on top of the rest of the cargo.

Diffusion of instruments in the Han dynasty

New percussion instruments are evident in the celestial orchestras seen in Buddhist iconography. One apparent accommodation between old Chinese and West Asian tradition is the *fang-hsiang*, a set of 16 iron slabs suspended in a wooden frame in the manner of the old sets of tuned stones. Knobless gongs related to the present-day Chinese *lo* seemed to have entered the Chinese musical scene before the 6th century from South Asia, while the cymbals (*po*) may have come earlier from India via Central Asian groups. One of the most sonorous Buddhist additions was a bronze bell in the form of a basin (*ch'ing*) that, when placed rim up on a cushion and struck on the rim, produces a tone of amazing richness and duration. Among the varied new instruments pictured in heavenly ensembles one can still find occasional "old time" instruments such as a set of narrow wooden clappers (*ch'ung-tu*) tied together on one end like ancient wooden books. The clappers were sounded by compressing them quickly between the hands. Variants of this Chou dynasty instrument are still heard in all three major East Asian countries.

Not all of the new influences in China came via religious or trade activities. During the Six Dynasties period (AD 220–589) China was rent by internal strife and border wars. The constant confrontations with the Tatars of the north caused an increased interest in the musical signals of the enemy via drums, trumpets, and double reeds. Although related instruments were equally evident to the south and west, there can be little doubt that the creation of cavalry bands with double kettledrums are direct imitations of the musical prowess of the horseback terrorists against whom the walls of China were built. With great effort and much blood, China gradually reunified under the Sui dynasty (581–618), and older courtly music and the latest musical fads were consolidated.

T'ANG DYNASTY

Thriving of foreign styles. The few centuries of T'ang dynasty existence (618–907) are supersaturated with brilliant Imperial growth and cultural flourishing as well as military and natural disasters. Such a rich loam of good and bad nourished one of the most fascinating eras of music history in the world. The more formal Imperial ceremonies revitalized the ancient orchestras of bells, stone chimes, flutes, drums, and zithers plus large bands of courtly dancers. In reality, Imperial power was based perhaps less on the Mandate of Heaven than on the "liberation" of neighbouring countries, a development of more thorough tax systems and more and more trade cities and harbours. Into all these power sources flowed foreign goods and foreign ideas. Persians, Arabs, Indians, and Malayans were found in the foreign quarters of port towns, while every trade caravan brought in masses of new faces and modes of living. Perhaps it is not surprising that an 8th-century poet, Yüan Chen, should lament about air pollution created by western horsemen, about the ladies who studied western fashions and makeup, and about the entertainers who devoted themselves to only "western" music. (One must remember that the term western refers to the land west of the China wall.)

Tavern entertainers

There was hardly a tavern in the capital of Ch'ang-an (now Sian, Shensi Province) that could compete without the aid of a western dancing or singing girl with an accompanying set of foreign musicians. Popular tunes of the period included "South India" and "Watching the Moon in Brahman Land," while beautiful, exotic dancing boys or girls were ever the rage. One set of girls from Sogdiana (centred in modern Uzbek Soviet Socialist Republic) won the support of the emperor Hsüan Tsung by being costumed in crimson robes, green pants, and red deerskin boots and twirling on top of balls. Other girls from the area today called Tashkent inspired a poet of the 9th century, Po Chü-i, with their dance, which began by their emergence from artificial lotuses and ended by the pulling down of their blouses to show their shoulders, a style not unfamiliar to old Western burlesque connoisseurs. A study of the lithe bodies and flying sleeves on T'ang clay dancing figurines is an even more compelling proof of the style of the era. In such a context one can understand how eventually an additional character was added sometimes to the word for dance to indicate the movement of the legs as well as of the body.

In addition to all the commercial musical enterprises of the T'ang dynasty period, there was another equally extensive system under government supervision. The T'ang emperor Hsüan Tsung (712–756) seemed particularly keen on music and took full advantage of the various musical "tributes" or "captives" sent to him by all the nations of Asia. This plethora of sounds was further enriched by the special area in Ch'ang-an called the Pear Garden (Li Yüan), in which hundreds of additional musicians and dancers were trained and in which the emperor himself was most active. Such trainees were naturally often female. They followed in an earlier tradition of court girls (*kung nü*) whose basic duties were to entertain distinguished guests. A remnant of this tradition is found in the Japanese geisha girl of today.

The mass of different foreign musical styles in the capital was too much for the government musical bureaucracy. A distinction already had been made between court music (*ya yüeh*) and common music (*su yüeh*); but T'ang nomenclature added a third kind—foreign music (*hu yüeh*). Eventually officials organized Imperial music into the ten kinds of systems (*shih pu chi*). Of these categories, one represented instrumentalists from Samarkand, whereas another group came from farther west in Bukhara. Kashgar, at the mountain pass between the East and West, sent yet a different group. Musical ensembles also were presented to the emperor from the eastern Turkistan trade centres of Kucha and Turfan. India and two recently defeated kingdoms of Korea provided still other musicians. Chinese and Kucha music were blended by different musicians. One group was supposed to maintain the old styles of Chinese folk music, and there had to be one special group for the performance of formal Chinese court music. These ten types by no means completed the picture, for nearly every Asian culture took its chance at musical goodwill in Ch'ang-an. Nothing from further west appears in T'ang China, for culture hardly existed in Europe at that time. Nevertheless, one can sense in T'ang musical culture an internationalism not matched until the mass communications of the mid-20th century provided radio and phonograph owners with the delights of a similarly exotic and extensive choice.

Courtly music. The only music that can be discussed in a survey of a repertoire so large is the more official courtly music. Ritual presentations are generally divided into two types: so-called standing music, performed without strings and apparently in the courtyard; and sitting music, for a full ensemble played inside a palace. There are lists of the names of some pieces in these categories with their authorship usually credited to the emperor or empress of the time. For example, "The Battle Line Smashing Song" was said to be by the T'ang emperor Tai Tsung (626–649). The accompanying dance is listed for 120 performers with spears and armour. A similarly grandiose piece is the "Music of Grand Victory" credited to the next T'ang emperor, Kao Tsung (649–683). Empress Wu (died 705) is said to have written "The Imperial Birthday Music," in which the dancers form out the characters for "Long Live the Emperor" in the best modern marching-band tradition. Music inside the palace includes a concert version of "The Battle Line Smashing Song," with only four dancers, "A Banquet Song," and a piece supposedly composed by Empress Wu in honour of her pet parrot, who always called out "Long Live Her Majesty." Those familiar with music in the courts of Henry VIII and Louis XIV or with the songs always ending in praise of Queen Elizabeth I may recognize the cultural context of such music.

Courtly extravaganzas

Later dynasty copies of T'ang paintings show ladies entertaining the emperor with ensembles of strings, winds, and percussion; and many of the choreographic plans of the larger pieces are also available in books. According to some sources, court orchestra pieces began with a prelude in free rhythm that set the mood and mode of the piece and introduced the instruments. This was followed by a slow section in a steady beat, and the piece ended in a faster tempo. Documents also tell much about the instrumentation and the colour and design of each costume of the musicians and dancers. No orchestral scores are to be found, however. One solo piece for *ch'in* survives and 28 ritual melodies for *p'i-p'a* were discovered in the hidden library of the Tun Huang (Cave of the Thousand Buddhas), but the grand musical traditions of T'ang remain frustratingly elusive. Major clues to their actual sounds will be found in marginal survivals of such music, which will be discussed in the Korean and Japanese sections. The original traditions waned with the decline of T'ang good fortune, and the conflicts of the Five Dynasties and Ten Kingdoms period (907–980) brought the international period to an end.

SUNG AND YUAN DYNASTIES

Consolidation of earlier trends. Despite the chaos of kingdoms in the 10th century, or perhaps because of it, cultural traditions solidified, so that by the Sung dynasty (960–1279) one can speak of a national rather than an international cultural mood. Many of the short-lived usurpers of regional governments were of "barbarian" (*i.e.*, Turkish) origin, but their general cultural efforts were to appear Chinese rather than to import further foreign fads. But one significant foreign musical addition of the period was from the northern Mongols in the form of a two-stringed fiddle, or bowed lute—the "foreign lute" (*hu-ch'in*). It became an important feature of the plebian theatre and teahouse world, which grew stronger and larger as more musicians and dancers were dropped from government payrolls. With the establishment of the Sung court, Confucian ceremonies and similar "old-fashioned" musical events were revived; but Imperial contributions to music of the period were primarily in the creation of gigantic historical or encyclopaedic works. For example, the official *Sung shu* ("Sung History," 1345) contained

496 chapters, of which 17 deal directly with music, and musical events and people appear throughout the entire work. The *Yü hai* encyclopaedia (*c.* 1267; "Sea of Jade") has 200 chapters, with ten on music. It is interesting that the *lü* pipes are discussed separately under the topic of measurements. Manuals on how to play the seven-stringed *ch'in* zither also survive, as well as rare music collections such as the "Songs of Whitestone, the Taoist," based on the poems and songs of Chiang Kuei (1155–1221) and first printed in 1202. Many Sung poets continued to use the five- and seven-syllable-line *shih* form perfected by T'ang writers, which was believed to have been chanted to tunes strictly adhering to the word tones of the Chinese language. The singing girls (*chi kuan*) of the teahouses and brothels and the general growth of urban, mercantile life inspired the creation of *tz'u* poems, which were free of word-tone restrictions, filled with colloquial phrases, and capable of freewheeling musical settings. A major source for music based on both the old and new forms is found in the rising world of public theatre.

Music theatre. Chinese drama can be noted as far back as the Chou dynasty, but it was really the T'ang period Pear Garden school that quite literally set the stage for Chinese opera. Regional music-drama flourished throughout the Sung empire, but the two major forms were the southern drama (*nan ch'ü*) and the northern drama (*tsa ch'ü* or *pei ch'ü*). The *tz'u* poetical form was popular in both, although the southern style was held to be softer, with its emphasis on five-tone scales and flute and percussion accompaniments. The northern style is said to have preferred the seven-toned scale, to have used more strings, and in general to have been bolder in spirit. According to period writers, each of the four acts of a northern drama was set in a specific mode in which different tunes were used, interspersed with dialogue. The southern style was more lyrical.

Northern and southern styles

The Mongols under Genghis Khan and later Kublai Khan finally succeeded in invading China, and the foreign Yüan dynasty (1279–1368) was founded. The two styles of drama noted above continued and intermixed under Yüan drama (*Yüan ch'ü*), while the basic poetical form became *san-ch'u*, popular songs of even freer style. On stage there appeared standard songs for specific situations or emotions that could be used in any opera, thus making it easier to communicate a story to mass audiences who may have spoken in many different dialects. Additional appeals to the general public were made by bringing onto the stage several forms of dancing and acrobatics, events that had been, along with several forms of puppet theatre, such gay parts of Chinese city life during the Sung dynasty.

MING AND CH'ING DYNASTIES

Internal Mongol struggles, natural disasters, and peasant revolts permitted the return of Chinese rule and the founding of the Ming dynasty (1368–1644). It in turn gave way to Manchu invasions from the north under which the last dynasty, the Ch'ing (1644–1911) was formed. Though there is much history and much blood involved in all such changes, one can view the music of these eras together under their two most active styles—theatre music and instrumental pieces.

Further development of opera. *Forms of the 16th–18th centuries.* The flourishing of regional music-drama has continued throughout the centuries since the Sung dynasty until the present day. Musically they vary greatly in their instrumentation and particularly in their voice qualities. But all tend to follow a tradition of using either standard complete pieces (*lian ch'ü*) or stereotyped melodic styles (*ban ch'iang*) in every opera. The complete-piece approach of Yüan drama survives today primarily in a 16th-century form called *k'un ch'ü*. Nurtured in a more aristocratic form of theatre, the music of *k'un ch'ü* was less bombastic than that of the popular theatre. The major instruments were the horizontal flute (*ti tsu*) and the notched vertical flute (*hsiao*). The flutes often produce a special mottled tone by the presence of one hole that is covered by thin rice paper that buzzes quietly as one plays. The *sheng* mouth organ and the *p'i-p'a* plucked lute could also be found in *k'un ch'ü*, along with a single free-reed pipe, *kuan*. The term *kuan* usually stands for one of several forms of double-reed woodwinds with cylindrical bore and no bell. Survivors of its ancient forms are found in Korean and Japanese court music. Variants of the single-reed *kuan* are found throughout Southeast Asia, where it is equally appreciated for its mellow, clarinet-like tone. A plebian instrument found in some *k'un ch'ü* is the three-stringed plucked lute (*san-hsien*) with a snakeskin soundboard. Plucked with a bone pick, it enjoys great popularity in folk music as well as theatre music, and it developed in two sizes, the shorter one prevalent in the south and the longer one in the north. The shorter form is of particular historical interest, for it was imported into the Ryukyu Islands as the jamisen and from there moved to Japan, where it evolved into a samisen.

The *k'un ch'ü* form

The vocal style of *k'un ch'ü* matched the mauve accompaniment and was usually performed by a male singing falsetto. Another style of opera from the same period, *i-yang ch'iang*, seemed more appealing to the general public and is noteworthy for its use at some point in its development of a chorus (*pang-ch'iang*) as well as of soloists. In addition, passages in colloquial speech were often interpolated between lines of classical poetry in order to explain them. Such lines were often sung. Still another Ming music-drama genre of considerable influence in the myriad regional forms is the clapper opera (*pang-tzu ch'iang*). In addition to the rhythmic importance of the clappers, the instrumental accompaniment of this form is noted for its emphasis on strings, the principal form being the moon guitar (*yüeh-ch'in*), a plucked lute with a moon-shaped wooden body and four strings in double courses. An interesting addition to this instrument is the presence of a thin strip of metal tied at both ends inside the body to give the instrument a richer tone. Among the endless variants of style and accompaniments in Chinese regional opera one must add the sounds of the extremely large flat gongs heard in the southwest and the *yang ch'in* (western zither), particularly popular in Cantonese music. The latter is often called a butterfly harp, though it is neither a harp nor a butterfly but a hammered dulcimer derived from a Near Eastern instrument (*santūr*) brought into China in the 18th century. For the rest of the materials concerning theatre music it is best to turn to the primary music-drama form since the 18th century, Peking opera (*ching-hsi*).

Peking opera. Credit for the beginning of Peking opera is given to actors from Anhwei appearing in Peking in the 1790s. But Peking opera really combines elements from many different earlier forms and, like Western grand opera, can be considered to be a 19th-century product. In addition to all the instruments mentioned above, many others may be found. Barrel drums with tacked heads (*ku*) and a double reed with a conical bore and bell (*so-na*) are used in military scenes, along with cymbals (*po*) and large flat gongs. The two most common percussion instruments are a small flat gong (*lo*) and a *pan ku* drum. The small gong is some eight inches in diameter; the face is slightly curved except for a flat centre spot. It is designed in this manner in order that the tone and pitch of the gong will rise quickly each time it is hit. This "sliding" gong effect is characteristic of the Peking sound. The *pan ku* or *tan-pi ku* is equally unique in construction. The skin is stretched over a set of wooden wedges strapped in a circle with only a small spot in the middle completely hollow. This allows the performer to produce a very dry, sharp sound. Such a tone is practical as well as aesthetic, for the *pan ku* player is the leader and his signals are essential to the coordination of the performance. In combination with the large and small gong, cymbals, and a clapper, the *pan ku* also controls the very important rhythmic elements of the drama. In all East Asian music one must remember that harmony and harmonic progression are not parts of traditional music. The functions of harmony—such as underlining expression, providing sonic contrast, and creating a sense of forward motion—are handled with equal efficiency by rhythm in

Role of rhythm

East Asia, although the methods and sounds are very different. In both traditions, the choices are not arbitrary, and with cultural exposure one comes to recognize the musical intention, even though it is not necessary to know precisely what chord or what rhythm pattern produces an appropriate musical effect. For example, very few listeners to Western music know that a doubly diminished chord (C–E♭–G♭–A) played tremolo means danger, although all would recognize the danger signal by ear. By the same token, a Peking opera fan hearing the large gong played alone in the rhythm

would know that the situation is a similar moment of confusion but probably would not know that the pattern is named the scattering hammer (*luan-chueh*). Pattern names are for specialists, but pattern sounds and "meanings" are for attuned listeners. Other aspects of the functions of rhythm in East Asia will emerge in the examination of other cultures. For the moment, attention will be given to the melodic side of Peking opera.

Like any theatrical music, the tunes of Peking opera must conform with the text structure and the dramatic situation. In the latter case, one finds that a majority of Peking aria texts are based on series of couplets of seven or ten syllables each. Although there may be several verses set in strophic form (*i.e.*, music repeated for each strophe, or stanza), part of the musical tension is maintained by the interjection of comments or short dialogue between the two lines of each verse. These leave the listener waiting for the completion of the line. The tune aids in this forward motion and tension by playing what could be considered an incomplete melodic cadence (point of resolution) at the end of line one, which is brought to a final resolution at the end of the second line. From a dramaturgical standpoint, the arias of Peking opera can be categorized into different types whose style is recognizable in the same way that one can tell, without language ability, the mood of a love, farewell, or vengeance aria in Italian opera.

Prototypes of Peking melodies

Peking melodies themselves tend to fall into two prototypes called *hsi p'i* and *erh huang*. Within each of these general types there are several well-known tunes, but the word "prototype" has been used to define them, as each opera and each situation is capable of varying the basic melody greatly. For example, if the scale shown in notation II-A is used as the tonal vocabulary of a given scene, one will find that *erh huang* melodies in it will tend to cadence on G or the C above it, whereas a female aria in the *hsi p'i* style will prefer E and A. It is not possible in a short explanation to refine the musical details further, except to add that the particular rhythm in which a melody is set will also allow its character and meaning to change. There are also other classes of melodies (as there are in Western opera of any one historical period), and there are action pieces (as there is ballet in some Western opera) and borrowings from other traditions (as there is church music in Western opera). In all, Chinese opera is filled with a musical and dramatic logic that, even at first introduction, helps to explain why it remains more popular than Western forms for more than a fourth of the world's population.

Other vocal and instrumental genres. The emphasis here has been on opera because it is best known, but there are many other popular forms from the Ming and Ch'ing periods. Musically, the various shadow- and hand-puppet plays are similar to the opera tradition except that, like Southeast Asian puppetry, a manipulator must often be the singer-narrator as well. The most common melodic instrument for both opera and puppetry is some form of fiddle, or bowed lute. It comes in several different forms, such as the *hu-ch'in, erh hu,* and *nan hu*. Although the shape of the body may be different, all traditional Chinese fiddles exhibit certain specific structural characteristics. The small body has a skin or wooden soundboard and an open back. The two strings pass over a bridge and then are suspended above a pole to the pegs, which are inserted from the rear of the scroll (not from the sides as on a Western violin). Such a system places one string above the other rather than parallel to it (as on a banjo or a *p'i-p'a*). Because of this, the bow passes between the strings, playing one string by pressing down and the other by pulling up. The fingerings of tunes are done by sideways pressure, along the strings; they are too far from the pole for it to serve as a fingerboard, which, because of the vertical stringing, would be a nuisance in any case. It is this unique manner of fiddle construction that helps one determine the source of many of the bowed lutes of Southeast Asia.

A simpler form of vocal accompaniment is found in a popular narrative idiom called *ta ku tz'u,* which uses a small flat drum with an occasional plucked string instrument such as the *san-hsien.* A *p'i-p'a* player may also be heard accompanying himself in a *tan tz'u* narrative. Leaving the endless forms of vocal music, it is appropriate to turn briefly to the instrumental. The 25-stringed *se* zither, with movable bridges, and the seven-stringed *ch'in,* with permanent upper and lower bridges (like a piano), were well-known for solo music in ancient times. During the last dynasty collections of *ch'in* music and instruction books flourished as part of certain neo-Confucian revivals. Many musical notations were developed, perhaps the most interesting variety for the *ch'in* being one in which Chinese characters were artificially constructed by combining symbols for the notes with indications of fingering technique, such as up strokes, down strokes, or harmonics. Although most of the music was based on vocal pieces or evoked some scene, there were several examples of variation forms that had an important influence on Korean and Japanese forms that followed. The *p'i-p'a* likewise developed an extensive repertoire of solo pieces, many of them quite virtuosic and pictorial. For example, anyone hearing a *p'i-p'a* battle piece needs to know very little Chinese to recognize the musical interpretations of the action. In recent times there has been a considerable revival of solo literature for the *cheng,* a zither with 16 strings and movable bridges whose popularity spreads as far south as Vietnam. The strings are apparently influenced by the Near Eastern dulcimer mentioned above (*yang ch'in*), for they are metal.

Music for the *ch'in* zither

Chamber music exists in many styles, functions, and locations. Some of it can be considered folk music played by farmers or working people for festivals or private entertainment, as in the American bluegrass tradition. Music of this type can still be heard at weddings or funerals in Chinese communities all over the world. During the Ming and Ch'ing periods, small ensembles of courtiers or professional musicians could be found at palaces, but the major sources for this kind of chamber music were in the world of the musically inclined businessman or trader. Because of this, certain regional forms of chamber music such as Amoy "southern pipe" and Shantung music survive in such locations as Taiwan, Manila, Singapore, and San Francisco. In this context it is noteworthy that even during Japan's isolation period (1600–1868) Chinese vocal and chamber music, known in Japanese as *minshingaku* (Ming and Ch'ing music), was played in Nagasaki, the only open port in Japan. Examples of such dispersed regional music are of great value in the study of the oral history of Ming and Ch'ing music and of the distribution and development of various musical instruments. Much of the repertoire of such stylistic groups is derived from theatre music, but there are many examples that may imply the sounds of older lost traditions. There are a variety of notation systems, particularly for the solo music. The one most commonly used in tune books of the last dynasties is *kung ch'ih,* which

III

indicates notes in a scale as shown in notation III. This system is still popularly used, although mainland sources prefer the number system shown in the first line of notation IV. It is based on the 19th-century French *chevé* system (which used numerals 1–7 for the notes of the scale) and, unlike other Chinese notations, shows rhythm by the use of dots and beams borrowed from Western eighth and 16th notes. Percussion accompaniments can also be found in a similar style, as can larger ensemble scores, but both are more characteristic of 20th-century China.

IV

DEVELOPMENTS SINCE 1911

Period of the Republic of China and Sino-Japanese War. Under the influence of missionary and modernization movements, many musical experimentations occurred in the last dynasty, but these were greatly increased by the rise of the first republic in 1911 and the establishment of Communist rule in 1949. During the period of the republic and of the Japanese war, a plethora of new songs were created in "modern" style, the most famous being shown in notation IV. The piece was written in 1934 by Nieh Erh to text by the modern Chinese playwright T'ien Han as a patriotic march and was adopted as the national anthem in 1949. It is an excellent example of a mixture of new and traditional Chinese music. The first phrase implies a major mode with its use of F♯. But after that point the entire piece is Chinese pentatonic. The first phrase also leads one to expect symmetrical four-bar phrases, but the tune quickly takes a more flexible Chinese course. Chinese and Western composers continued to try out bits of each other's traditions with only occasional success, and individual Chinese artists have become famous for their performance on Western instruments. Chinese instruments in turn have been subjected to many modernizations, such as the building of a family of *erh hu* fiddles by the creation of bass and alto versions. In conjunction with this movement there was the appearance of concertos for such instruments accompanied by a mixed Western and Chinese orchestra.

The "modern" style

Communist period. As was noted earlier, many completely traditional forms continued, particularly in foreign Chinese communities. The special point of interest since 1949, however, is the application of Marxist doctrine to the musical scene of China. The first obvious area of change is found in the ever popular forms of regional and Peking opera. Although the appeal of traditional tales of emperors, princesses, or mythological characters could not be suppressed, the emphasis of all new operas was on workers, peasants, soldiers, and Socialism. Thus, the *Romance of the Three Kingdoms* (*San Kuo chih yen-i*) or the *Ruse of an Empty City* tend to be replaced by the *Raid on the White Tiger Regiment* or *The Red Guards of Hung Lake.* Aria topics also vary, such as "Looking Forward to the Liberation of the Working People of the World" or "Socialism is Good." The accompanying orchestra is usually larger than the traditional one and is set in families of instruments, sometimes with complete violin sections. Choruses often appear, representing the people or the army in the victorious advance of Socialism. Acrobatics are still popular, but one also sees ballets strongly influenced by the more energetic sections of Soviet productions. Ballet shoes are combined with peasant or Red Army uniforms, and nearly every finale includes large numbers of red flags and a portrait of Mao Tse-tung. For all these modernizations, a surprising large number of new operas follow the previously mentioned musical forms of prototype melodies set in appropriate rhythms.

As part of the encouragement of people's music the national government emphasized regional folk music. But, in general, folk music was "reconstructed" away from its former individualistic nature into collectives of choruses or folk orchestras. The topics of such regional songs were also reconstructed so that they reflect the new Socialist life. The most famous new folk song from Shensi Province is "Red is the East," while the Miao people are credited with "Sing in Praise of Chairman Mao." Every "minority" group in China has at least one song directly in praise of Chairman Mao, while other songs deal with local industries and accomplishments. Such songs are sometimes performed in regional style with traditional accompaniments, although they may often be found arranged Western-style for use in the public schools of the nation. This effort, in addition to the number of recordings that are also available, make it possible for a Chinese citizen to become aware, perhaps for the first time in history, of the great variety of local music traditions in his large country, even though such music appears now in Marxist reconstructions. Marxist defense of this changed folk music is that music of a given period must reflect the views and aspirations of the masses (as understood by the government) and must be based on idioms of the people. Composers of concert music have produced many folk orchestra compositions along with symphony, piano, and military band music based on this basic Marxist musical principle, called Socialist realism. When dealing with traditional instruments and vocal styles the composers have sometimes created extremely original and interesting pieces despite the general conservatism of government aesthetics policies. Vocal and choral music are preferred because of their ability to communicate specific national goals more efficiently than, for example, *The Sacred War Symphony*. Two excerpts from the words of "My Home Is the Collective Farm" represent typical goals of Socialist realist music:

Socialist realism

> Our land strips are fused into one, No boundaries, no distinctions of 'yours' or 'mine'; If you ask me what my name is, All of us are named collective farmers, All of us are named collective farmers. . . . People present us with prize certificates and banners, We hang them all up in our parlour; In the centre is a portrait of Chairman Mao. His heart must be glad. His heart must be glad.

The social philosophy implied in this message may not be appealing to all peoples, but it is as real and meaningful to 20th-century Chinese as was "A Mighty Fortress Is Our God" to 17th-century German Protestants, "A Hymn to Reason" to 18th-century French revolutionists, or "We shall overcome" to 20th-century American protesters. Most modern Western musical sales are for material goods, but China has concentrated its musical media on national messages.

It must be remembered that music exists in a cultural context and that it has never remained static since the world began. In the late 20th-century, music of all periods from every society is available to those with sufficient mass communication sources, although China has wished

to suppress what is called capitalist formalistic arts. It does seem unlikely that the tuning of the *lü* pipes for rulers will ever be a major concern of Chinese musicians again, but the ability of China to preserve so many historical facts, materials, and idioms along with modern changes is sufficient to keep the musical world in awe for some centuries to come.

III. The music of Korea

On a map Korea looks like a finger pointing from the top of China down to the lower part of Japan. Thus, one would expect its music to reflect its "bridge" position between two such powerful traditions. The movements of foreign, particularly Chinese, armies and cultures are indeed major factors in Korea's tradition. But beneath these reflections lies a deeper core of indigenous musical styles that, at first hearing, seem most strange to the ear of listeners with preconceived notions as to what East Asian music sounds like. A possible additional factor in the growth of Korean music is the country's position as a peninsula jutting out from Manchuria and from the spawning ground of many Mongolian hordes. It may be that part of Korean music is the result of a cultural cul de sac left by the Mongolian hordes as they dashed across the steppes of Asia to their eventual demise in the mountains of Europe. Archaeological sources indicate that various Mongol peoples from north Asia did indeed occupy areas of Korea from at least 2000 BC, and Chinese writings show that their people and armies were active in Korea from the period of the Chinese Han dynasty (206 BC–AD 220) on. Obviously, a study of Korean music contains riches extending far beyond its geographic borders.

SHAMAN MUSIC

The earliest references to music in Korea are found in a 3rd century AD Chinese history book that comments about agricultural festivals (*nong-ak*) with singing and dancing among the tribes of northwestern Korea. Such events are still a strong part of Korean life. Another ancient but long-lived tradition in Korea is shamanism, or communication with the unseen world by medicine men in a state of trance. This is of special interest because such a belief is characteristic not only of all north Asian tribes but also of other peoples (such as Eskimos) who live in the northernmost regions of the world. Korea is one of the few countries south of the Arctic area that maintain strong shamanism in the face of several foreign religious adoptions such as Buddhism, Confucianism, and Christianity. A few Korean shamanistic events, however, show still other possible prehistoric connections. For example, sometimes the head of an animal may be placed in the centre of a Korean ritual ground, and mythology says that the first ruler of Korea was created by the union of god and a bear. Divine origin is part of Japan's Imperial mythology, and the head of a bear is central to the important rites of the Ainu tribal culture in northern Japan.

Today, a Korean shaman (*mudang*) may use many combinations of musical instruments. The simplest and potentially most significant accompaniment is a small, flat gong with a slight rim. It brings to mind the single-headed pan drum with a wooden or bone hoop found in the shamanism of most of Central Asia and in the Arctic Circle as far away as Lapland and Hudson Bay. A drum sound itself is produced in Korea by the most popular percussion instrument, the *changko*, an hourglass-shaped, two-headed drum struck by the hand and a stick. In Korean shaman rituals flutes, double reeds, fiddles, and other gongs and drums may be used that at first sight may appear rather Chinese. The sound, however, creates a totally different impression. The music shown in notation V represents a flute and gong excerpt from a shaman ensemble that also contains a drum, zither, fiddle, and oboe in a driving polyphony (combination of simultaneous voices, or parts) that seems closer to Dixieland jazz than to Chinese music. The seven pitches of the flute tune, plus its microtonal slides, its use of a fourth (c♯″–g♯″) "out of tune" with the Chinese *lü* pipes, and its rhythm, produce a very un-Chinese, jazzlike sound. The style is totally traditional and is notated to show the special Korean proclivity for a six-beat unit, which in this excerpt is particularly strong in the accompaniment of the other instruments. The dotted bar lines in the transcription imply a kind of polymetric syncopation that often gives Korean folk and popular music its special appeal. One part seems to be in four whereas others are in six, so that they come together only after 12 beats. Triplets and even five-beat forms are found as well. Thus, it is evident from a brief look at one example from one type of Korean shaman music, in addition to a discussion of other forms and characteristics, that Korean cultural materials continue to reflect fascinating mixtures and mysteries. The total style cannot be called purely Chinese or north Asian but simply Korean. The characteristics of the first example are typical of the kind of music best known and loved by the general Korean populace. Studies in Korean music, however, have tended to concentrate on the less familiar styles of court music, which are maintained by dedicated national music institutes and Korean scholarship.

Polyphony, tuning, and rhythm

V

COURT MUSIC

The three kingdoms of Koguryŏ in the north, Paekche in the southwest, and Silla in the southeast were established in the century before AD 1 along with a small Japanese-related enclave (Kaya or Mimana). The organization of courts and introduction of Chinese religions resulted in an ever-increasing importation of Chinese musical materials. Indications of this can be found in such sources as paintings in an AD 357 tomb near An-ag, a colony of China at that time. A horseback band of the Chinese Han dynasty style is seen with drums and a small bell hit with a hammer. One brave rider apparently is able to play the Chinese panpipes in transit. Deeper in the tomb a zither, lute, and a very long end-blown flute can be seen accompanying a dancer whose long nose and costume imply that central Asian traditions may have travelled even as far as Korea by the 4th century. The Silla dynasty domination coincided closely (668–935) with the heyday of the Chinese T'ang period, and the subsequent Koryŏ (935–1392) and Yi dynasties (1392–1910) also tended to match parallel Chinese periods. Thus, Korea's court-music traditions tended to reflect those of China.

Being on the border of Chinese culture, Korea was able to maintain certain ancient traditions during periods of barbarian domination in China proper. Such marginal survivals are of particular importance because many have continued to the present day, thus giving extremely rare examples of music traditions long gone from the land of their origin. For example, in the Silla period, court music was divided into *hyang-ak*, Korean music; *T'ang-ak*, T'ang Chinese music; and *a-ak*, Confucian ritual music. The instruments used for these ensembles were those described earlier in the discussion of Chinese music, such as sets of tuned stones (in Korean *teuk kyeng*) and bells (*pyen chong*), mouth organ (*saing*), and instruments in all the other eight categories of Chinese classical traditions (*e.g.*, those based on the materials used in construction; see above). Unlike China, ensembles using such

Survivals of ancient Chinese music

instruments can still be heard in the national institutes of north and south Korea and in Confucian rituals. Among the many instrumental treasures still played in Korea is the *a-chaing*, a zither—with seven strings and movable bridges—that is not plucked but, more remarkably, is bowed with a resined stick of wood. The globular flute (*hoon*), mentioned as one of the very earliest artifacts of Chinese music, has been played in Korean Confucian temples since the 12th century, as has a *tchi* flute, which has a bamboo mouthpiece plugged into the blow hole with wax. In addition to five finger holes it has a cross-shaped hole in what on other flutes is the open lower end. The lower end of the *tchi* can thus be closed by the little finger of the left hand. This unique flute is known to have been in Korea by at least the 11th century and, like the previous two examples, has totally disappeared from the rest of East Asia. By contrast, the *piri* cylindrical double-reed aerophone (wind instrument) has many relatives in Asia, but the rich saxophone-like tone produced by its deceptively narrow tube body and large reed are not heard elsewhere. It is heard in many other forms of Korean music, from folk festivals to party music.

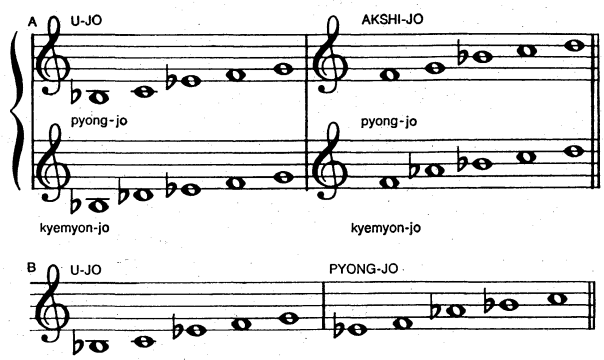
Indigenous instruments

Not all the instruments of Korea are Chinese imports. The *taekeum* flute with six finger holes, a membrane-covered hole for a buzzing sound, and open holes near the end would seem to be a Chinese instrument, except for its spectacular length of two feet five inches (74 centimetres) and its gigantic blow hole. A Korean musician, Wang San-ak, is credited with the invention in the 7th century of a *komungo* zither with six strings. Two strings on one side and one on the other have movable bridges, whereas the central three strings pass over 16 bridges. It is played by striking the strings with a wooden stick clenched in the fist with the thumb stretched along the top of the plectrum. One of the other mysterious Korean instruments is the *haekeum* two-stringed fiddle. It would seem to be an obvious relative of the Chinese equivalent, with the bow passing between the strings, except that the neck is bent toward the strings (rather than away from them, as in the rest of the world), and the pegs seem to be inserted backward, so that the strings are wrapped around the large round part of the pegs instead of the narrower end, which sticks out, unused, from the back of the neck. The *kayakeum* board zither with 12 strings and movable bridges is surprising in sound to those accustomed to Chinese and Japanese zither melodies. It is held that the instrument was created in the 6th century in the Japanese-dominated Kaya area—thus the survival of one example in the 8th-century Japanese Shōsō-in treasure house. The *kayakeum* is regarded as Korea's favourite native instrument and it can be heard in all levels of Korean music and dance. The *sanjo* variation forms for this zither represent one of Korea's most famous purely instrumental genres.

Much of what is known about the origin of instruments is derived from Chinese and Korean historical books and administrative documents, such as the grand list of presents sent by the Chinese Sung emperor to Korea in the year 1111. The list includes ten sets of stone chimes and ten bell sets, along with five iron equivalents and numerous other instruments. Korean musicians performed successfully at the Chinese court, and Korean monks attended the international training centres in China to learn Buddhist chant. During the reign of Sejong (1419–50), new Imperial shrine music and traditional Confucian ritual music were emphasized along with musical settings of epics written in the newly developed Korean alphabet. The grand traditions of China were preserved under the guidance of the court master of music, Pak Yon (1378–1458).

Proof of the diligence and concern of these and later efforts are found in the *Akhak kwebon* ("Music Handbook"), first appearing in 1493. The nine volumes of this work contain pictures of all the court instruments along with their fingerings or tunings, costumes and accessories for ritual dances, and the arrangements of dance designs and orchestral seatings. The first three volumes deal with music theory and contain ample evidence of the continuation of the complete Chinese classical tradition discussed earlier. The only differences are the pronunciations given to the Chinese characters in which the terminology is written. There are, however, additional explanations of tone systems that reflect Korean-created idioms. For example, the tone systems for Imperial shrine and banquet music are given in modes and transpositions of the pentatonic scale as shown in notation VI-A. The specific manner in which Korean pentatonics are described varies from period to period. Later theories tend to make *pyong-jo* the same mode as *u-jo* transposed a fourth higher (notation VI-B), considering the *kyemyon-jo* variants to be the other mode on those two pitches (analogous to the pattern in VI-A). The exact pitch on which these modes start also varies over the centuries.

VI



Balance of Korean and Chinese traditions

From the short theoretical discussion above it should be evident that Korean musicians maintained a balance between native and Chinese traditions. Such a balance is seen in the standard instrumentation of the three major court orchestras. By the 15th century the Chinese-style *T'ang-ak* and the Confucian *a-ak* ensembles concentrated on Chinese instruments such as bell and stone chime sets, and the texts of surviving *T'ang-ak* pieces such as *Lo-yang-chun* (*Spring in Loyang*) follow the Chinese *tz'u* poetical form. Processional military music (*chui-ta*) begins in the style seen in ancient drawings, with drums, gongs, accompanying conch shell and straight trumpets, in addition to a "barbarian" oboe with a conical body. This ensemble is followed by a softer one with the more typical Korean hourglass drum (*changko*) and cylindrical oboe (*piri*), the unusual Korean fiddle (*haekeum*) and flutes (*taekeum*). The softer ensemble can also be heard in dance music (*sam-hyon*), whereas chamber music (*chong-ak*) softens this group further by using a smaller oboe along with the later addition of the Chinese "Western" dulcimer (*yang ch'in*, or in Korean, *yang-keum*). The most famous suite of movements in this and in orchestral traditions is the *Yongsan Hoesang*, which consists of nine to 11 pieces taking some 30 minutes to play. The title is based on a former religious chant about Buddha preaching on Mt. Yongsan, but the pieces attached to this general name have since lost their vocal tradition. When the Korean ensemble (*hyang-ak*) plays pieces like *Su-je-chon* (*Long Life as Immeasurable as the Sky*), one hears a more indigenous combination of the hourglass drum, oboes, flutes, fiddles, and the special bowed zithers (*a-chaing*). Though the style is still slow and "ancient," the sounds seem less Chinese.

The survival of so many old traditions is partly due to the preservation of notation books. Many are in the traditional Chinese forms. In the late 15th century, however, a Korean mensural system (*i.e.*, a notation showing time values) was created that, through the use of columns of 16 squares, gave a clearer indication of rhythm and tempos than do most Chinese notations. This system, usually with modifications into six- or 12-square groups, is used today to notate the six-beat rhythms and can be read as easily as Western notation if one can read Korean.

VOCAL MUSIC

Vocal music is another important side of the Korean tradition. One of the longest and rarest older forms is the

kagok, in which a man and a woman sing 26 songs, each with five lines of different lengths (32 beats, 27, 37, 27, and 41). Accompaniments and interludes are provided by a small ensemble. *Sijo* is a classical three-line form of Korean poetry that also can be sung to the accompaniment of the hourglass drum. Narrative songs are found in the genre called *kasa* accompanied by a flute and drum. The dominant narrative form today is *p'ansori*. It was originally performed simply to the accompaniment of a barrel drum (*puk*), but today a small ensemble is used. In addition, the performer moves in a stylized dance form, holding a fan in a manner vaguely similar to Japanese Nō drama. It may be that this music-drama tradition emerged from ancient shamanistic entertainments of the gods, although it is now purely a classical narrative. As with so much Korean folk music and songs of the teahouse girls (*gishang*), the most striking aspect of the *p'ansori* sound is the female voice quality and melodic ornamentation. It reminds one more of traditions at the Arabic end of the long trails of Mongolian movements, such as North Africa and flamenco Spain, than it does of other East Asian traditions. Korean music is indeed an enigma but a very beautiful and exciting one.

Voice quality and ornamentation

IV. The music of Japan

A reader of the previous sections of this article will know already that Japanese music can be considered as a national tradition set in the satellite category of the general East Asian music culture. One also knows that Korea served as a bridge to Japan for many Chinese musical ideas as well as exerting influence through its own forms of court music. A comment has been made as well about the presence of north Asian tribal traditions in Japan in the form of Ainu culture surviving on Hokkaido island and the Shakalin islands. It should further be pointed out that the island isolation of Japan allowed it to develop its own special characteristics without the intense influences of the Chinese giant and the Mongols so evident in other mainland cultures. Therefore, in the ensuing discussion all the "foreign" elements will be placed in the matrix of traditions and styles that are characteristically Japanese.

MUSIC BEFORE AND THROUGH THE NARA PERIOD

Early evidences. As in the case of the history of mainland traditions, ancient Chinese sources and modern archaeological data provide the earliest surviving insights into Japanese music. Archaeologists have discovered materials of Stone Age people in Japan and pottery remains of the so-called Jōmon culture dating back as far as the 3rd millennium BC. Among the items recovered from the subsequent Yayoi period (3rd century BC–3rd century AD), the musically most significant finds are *dotaku* bronze bells. They show that the native population had adopted Chinese metallurgy. The shape of the bells and the locations of their remains indicate that they may have entered the Japanese islands with tribes migrating from north Asia. The gradual domination in Japan of one group called the Yamato clan became more evident in the Tumulus period (*c.* AD 250–*c.* 500) and led to the present Imperial system. Specific evidence of its musical life is found first in certain tomb figurines (*haniwa*), which were substitutes for the earlier Asian tradition of human sacrifices at the death of a leader. One *haniwa* has been found playing a barrel drum with a stick, while another figure is seated with a four- or five-stringed board zither across his lap. Crotal bells (pellet or jingle bells) are found on costumes, and some statues seem to be of singers. The zither is of special interest, for it is related to the Korean *kayakeum* mentioned earlier as appearing in the Japanese section of Korea (Kaya) by at least the 6th century. It also may be the earliest example of the *wagon*, or *Yamato-goto*, a six-stringed zither with movable bridges found in Japanese Shintō music. The crotal bells survive in the form of the *suzu* bell tree, an instrument characteristic of Shintō dances only. The interpretation of another figure as a singer and the presence of a drummer are rather too general for conclusions, although a Chinese history book of the 3rd century (*Wei chih*, AD 297) does speak of the natives of Japan as singing and dancing during a funeral. This source also notes two actions well-known in Shintō today: a concern for purification and the use of hand claps in praying before a shrine. The mention of shamanism is also found in Chinese accounts and is of particular interest in those concerned with the north Asian aspects of Japanese culture. In this context it must be remembered that the Ainu were as populous and strong as the new Japanese people at the time of the founding of the Yamato dynasty. Battles between the Japanese and Ainu are noted in 6th-century Chinese books such as the *Sung shu* (513) and, rather like 19th-century American Indians, Ainu were found as mercenary troops in a group of Japanese forces sent to assist the Korean Silla dynasty in the 7th century. The Chinese *Sui shu* history book (630) mentions tatooed people like the Ainu, as well as a five-stringed zither and a flute. Ainu culture today maintains a Jew's harp and no flutes, but it does have a *tonkori* zither with two to five strings. It is unlike the zither on the lap of the earlier tomb figure in both its shape and playing position, being held like a banjo and played open stringed with both hands. The surviving shamanism of the Ainu has equivalent forms in early Shintō and in a few surviving Japanese folk "mountain women" traditions. But the guttural vocal style and the frequent polyphonic textures of modern Ainu music today seem culturally to point north rather than south or west. Perhaps the Ainu are a living link between present-day civilization and the life pictured in ancient Chinese documents.

Archaeological evidence and early references

As the Japanese people gradually drove the Ainu northward they solidified their own internal structure and established stronger ties with continental culture. Records show that a Korean Silla (in Japanese, Shiragi) emperor sent 80 musicians to the funeral of a Japanese ruler in 453. Chinese Buddhism was officially accepted as a religion in Japan in the 6th century, selected converts being sent to China for proper training in the rituals (hence the music) of that faith. In 612 a Korean musician, Mimashi, is believed to have introduced masked dances and entertainments (*gigaku*) and southern Chinese music (*kuregaku*) into the Japanese court. Finally, by the 8th century Japan produced its own first written chronicles, the *Koji-ki* (713) and the *Nihon-gi* (720), which recount the mythological origin of music as the form of an entertainment used by the gods to tempt the sun goddess out of her hiding in a cave. Indirect references to music appear in semi-historical accounts of early court activities in the books. In addition, the *Nihon-gi* contains the texts of some 200 poems, many of which seemed to have been derived from the oral musical tradition.

Predominant musical traits. It is apparent that by the 8th century the documentary history of Japanese music had begun. Although this claim predates an equal state of Western music history by some 100 years, certain interesting parallels between the two traditions can be made. Both seem more clearly established in the same general 200-year period, a short time when compared to Chinese music studies outlined above. Both developed a musical nomenclature heavily influenced by the music of religious organizations: the Roman Catholic Church in the West, Buddhism in Japan. Both traditions were equally influenced by theories of a foreign culture from over the nearest sea: Greece in Italy and China in Japan. Herein many differences arise, one of the most significant being that in the Japanese case, the foreign tradition of China at the time of its first major influence was alive and strong and could apply practical musical information and instrumentations as well as theories, whereas the Greek tradition was long dead by the same period, when the European monks turned to it for guidance. Nevertheless, one can see that the general length and beginning of each history is comparable. Before discussing Japanese music in chronological detail, an attempt should be made to envision general characteristics, realizing that in doing so the tendency is to apply aphorisms to music that stretches over a series of styles as old and varied as the music of Europe from Gregorian chant through Claude Debussy. With that caveat, general guidelines for the appreciation of Japanese traditional music can be put forth.

Aesthetic and formal ideals. These guidelines fall under three general concepts: (1) the sound ideal, (2) the structural ideal, and (3) the artistic ideal; but these three things are not clearly separate in any musical event.

In general one can say that the most common sound ideal of Japanese music is to produce the maximum effect with a minimum amount of material. For example, the *taiko* drum of the Nō drama consists of a barrel-shaped body over which are lashed two cowhide heads some 20 inches in diameter stretched over iron rings. Wooden sticks are used to hit one head. Obviously, the sound potentials of the drum are many, but they are deliberately suppressed. For example, the sticks are made of very soft wood, and the strokes are applied only to a small circle of soft deerskin in the centre of the head. The *taiko*, like Japanese ink paintings, accomplishes a great deal by concentrating on very carefully chosen limitations of the medium.

Instrumental potential and tone colour

Another feature of much Japanese traditional music could be called the chamber music sound ideal. No matter how large an ensemble may be, one finds that the various instruments are set in such a way that the timbre, or tone colour, of each can be heard. This can be understood in Western chamber music and contrasts with the Western orchestral sound ideal, in which the primary intention is to merge all the instrumental sounds into one glorious colour. The colour separation of Japanese music is quite evident in the large court ensemble (*gagaku*), as well as in drama music and actual chamber ensembles such as the *sankyoku*, for koto zither, samisen plucked lute, and the end-blown *shakuhachi* flute.

The structural intents of Japanese music are as varied as those of the West, but one of special interest is the frequent application of a three-part division of a melody, a section of a piece, or an entire composition. This is in contrast with the more typical two-part division of Western music. Of course, examples of both ideals can be found in the music of both cultures; the concern here is with broad generalities. The fundamental terminology of the Japanese tripartite form is *jo-ha-kyū*, the introduction, the scatterings, and the rushing toward the end. A Western musician might wish to compare this with sonata allegro form and its three parts (exposition, development, recapitulation). But the Western example relates to a complete event and involves the development of certain motives or melodic units (such as first and second theme), whereas the Japanese concept may be applied to various segments or complete pieces that are generally through-composed (*i.e.*, with new material for each segment). Japanese music reveals its logic and its forward motion not by themes but by a movement from one section to another different one until the final section is reached. Forward motion in motivic Western music was often derived during the classical periods from the tension created by chord progressions. In Japanese music, such sonic events generally are not used. Nevertheless, the need for aurally recognizable patterns falling into a progression that the informed listener can anticipate is necessary in all music. In Japan such stereotyped patterns are melodic or rhythmic, not harmonic. They will be discussed in detail later; but the recognition, whether intellectual or aural, of the existence of such recurring patterns is essential to the appreciation of any music.

Word orientation. One of the artistic ideals of Japanese music is equally clear in all of East Asia. It is the tendency for much of the music to be word oriented either through actual sung text or through pictorial titles to instrumental pieces. With the exception of variation pieces (*danmono*) for the Japanese koto zither, one can seldom find a purely instrumental piece in the spirit of, for example, the Western sonata or symphony. Japanese ensemble pieces, like those mentioned earlier in China and Korea, are either dance pieces, instrumental versions of songs, or descriptive. This ideal in all of East Asia was not weakened until recent times, when such music was forced to compete with Western idioms.

Guilds. By the same token, the ideal of the composer as genius, so dear to 19th- and 20th-century Western hearts, had little place in earlier East Asian music. In Japan, as in China and Korea, the names of many composers are known, but the actual setting of their music was and still is often done by a group of fairly anonymous people. One may know who was helping out at a given time and in a given place; but in any written form of the music their names, or even the name of "the" composer, may often be missing. In the Orient, particularly in Japan, the performer is often the person remembered and noted. Such an ideal is understood in the West by fans of popular music. Although this ideal has given way to the Western composer "star" system in modern Japan, it does depict an important social setting for any appreciation of the older Japanese classical traditions. In keeping with this artistic ideal, one should add that often there is not one "correct" version of a given piece. Most traditional music is organized under guild systems, and thus each guild may have its "secret" version of a well-known piece. A given guild will play its version precisely the same way in each performance, for improvisation has practically no role in any of the major genres of all East Asian music. Differences are maintained between guild versions, however, in order to identify a given group's musical repertoire as separate from all the rest. A fascinating example of the tenacity of this ideal is found in the present-day Imperial court orchestra. It was formed in the late 19th century by the combination of previously separate ensembles from the courts and temples. The musicians played the same-named pieces but could not always agree on many musical details, so they continued to play their disparate versions at the same time, creating a kind of polyphony that is now accepted as the "correct" ancient tradition in Japan, although, as with the U.S. composer Charles Ives, it sometimes actually represents two things going on at once. The separation of guild styles can be carried further to one more artistic ideal, which holds that it is not just what one plays on an instrument, it is how one plays it. For example, in the case of the *taiko* drum mentioned above, the manner in which a player sits, picks up the sticks, strikes the drum, and puts the sticks away will reveal the name of the guild to which he belongs and also can be used to judge his skill in performance. No Japanese instrument is merely played. One could almost say that its performance practice is choreographed. Such distinctions exist in the music of other East Asian cultures as well, although the clues to their understanding have not yet been revealed to outside listeners and viewers. This brief discussion of their existence in Japanese music will serve to enhance the appreciation of at least one Asian tradition as the discussion turns to a chronological study of its many styles.

Manner of handling instruments

The Nara period. *Codification of court music.* The previously mentioned documents from the Nara period (710–784) demonstrate how very active music was in the newly established capital in Nara. The general term for court orchestra music, *gagaku*, is merely a Japanese pronunciation for the same characters used in China for *ya yüeh* and in Korea for *a-ak*. As Japan absorbed more and more of the outside world, the music of the court, like that of T'ang dynasty China of the same general centuries, received an increasing variety of styles. In 702 these styles were organized under a music bureau (*gagaku-ryō*) and by the early 9th century an additional *Ōuta dokoro* (the "Big Song Hall") was created for handling Japanese-composed additions to the repertoire. Among foreign genres, the musical styles of the nearby three kingdoms of Korea have already been shown to be some of the first imports, Silla music being called in Japanese *shiragi-gaku*, Paekche music, *kudaragaku*, and Koryŏ music, *kōkurigaku*. Music from these three kingdoms was sometimes called collectively *sankangaku*. Under all these terms were found still other Chinese and north Asian traditions, in addition to music purported to have come from India as early as 736. Evidence of such a distant import can be found in a surviving court dance (*bugaku*) called "Genjōraku," whose story about the exorcising of a snake can be traced to an ancient Indian Vedic tale. The date of 736 is also assumed for the entrance of music from Indochina, which survived for several centuries in a form of music called *rinyūgaku*. Al-

though this tradition is now lost, there are extant detailed pictures of the ensemble along with other ancient instruments and a variety of dances in sources such as the 14th-century copy of the 12th-century *Shinzeigakuzu* scroll.

Influence of T'ang dynasty China. The dominant musical style of early *gagaku* was, naturally, from China and was called T'ang music (*tōgaku*). In Japan, as in Korea, the establishment and maintenance of such a music has made it possible for modern listeners to hear foreign versions of famous pieces long forgotten in the country of their origin. For example, there are names of pieces played and dances performed in Japan that are also found in T'ang Chinese lists. Unlike China, however, many of these works are still played in Japan, and a few of the original costumes and masks used at that time are preserved. Perhaps the most valuable treasure in Japan for such materials from the ancient traditions of all of East Asia is the Shōsō-in, a storehouse built for the household goods of the emperor Shōmu after his death in 756. In this collection (which includes a few later additions from temples) one can find some 21 percussion instruments, 12 strings, and 12 winds, in addition to dance masks, notation, and drawings. Some of the materials are Chinese or Korean imports, while others are Japanese-made. The Chinese variant of the arched harp of the ancient Near East (in Japanese the *kugo*) is best preserved here. The very decorations of certain instruments can also be historical gold mines. For example, the protective cover across the face of one plucked lute (*biwa*) contains the picture of a performer riding a camel near a palm-treed oasis. Another such cover depicts a group of foreign (*i.e.*, not East Asian) musicians accompanying an energetic dancer, all on the back of an elephant. Etchings along a hunting bow show scenes of dancing and music performances connected with a popular imported art of acrobatics and juggling called *sangaku*.

Instruments preserved in the Shōsō-in

THE HEIAN PERIOD

Music of the left and of the right. Further images of Japanese musical life can be captured from the Heian period (794–1185). In the very first chapter of the 10th-century *Ochikubo monogatari*, Japan's earliest novel, the sad fate of the heroine is noted by the fact that she was never able to learn how to play the Chinese seven-stringed *ch'in* zither, although she did have some training in Japanese koto zither music. The famous 11th-century works, such as Murasaki Shikibu's *The Tale of Genji*, are filled with romantic koto, *biwa*, and flutes, as well as *gagaku* and *bugaku* performances and the singing of many songs. Diaries also show that the courtiers, now moved to Kyōto, found music to be a useful and frequent adjunct to their insular courtly life. It was in this period that the many forms of official court music were organized into two basic categories. The so-called music of the left was called *tōgaku* and contained the Chinese- and Indian-derived pieces. The music of the right was called *komagaku* and contained all Korean and Manchurian examples. In both categories there were pieces that by this time may have been Japanese arrangements or original compositions. The terms left and right were derived from the Confucian-based administration system of the new capital, which divided the entire government into such categories. In *bugaku* they controlled the costumes of the dancers, left dances emphasizing red, right dances, green. In *gagaku* these two major divisions standardized the instrumentation of the ensembles. When playing dance accompaniments, stringed instruments were deleted, but the two orchestras for purely instrumental performances were complete. Each used plucked 12-stringed zithers with movable bridges called *gaku-sō* or by the generic term koto. The string section was completed by a four-stringed plucked lute, the *gaku biwa*. A small hanging gong (*shōko*) and a large hanging drum (*tsuri daiko*) were found in both. The leader of a *tōgaku* piece would use a barrel drum (*kakko*) with two lashed heads struck with sticks, while a *komagaku* piece would be led by an hourglass *san no tsuzumi* drum similar to the Korean *changko*. The standard melodic instrument for both was the double-reed *hichiriki*, a *komabue* flute being added in *komagaku* and a *ryuteki* flute in *to-gaku*. The Japanese *shō* mouth organ appears in both.

Dance costume and instrumentation

Musical notation. In modern performances the *shō* plays a fascinating cluster of harmonies, although there is some feeling that the original Chinese interpretation of its notation was melodic, with little or no harmonic addition. Part of the performance problem, outside the impressive age of the music, is that *gagaku* notations came only in part books, which were often rather like Western "lead sheets"; *i.e.*, they served as memory aids rather than detailed guides. For example, the *shō* notation gives only one note for every four beats of a standard piece. The modern interpretation is that each note represents the bottom of a chord, but the notes might actually have been the skeleton of a melody. The earliest surviving form of instrumental notation in Japan is a book, dated 768, of lute (*biwa*) music found in the Shōsō-in. The earliest flute part book is dated 966, and a few additional wind or string books remain from the 10th to the 13th centuries. More frequent sources can be found from the last 300 years. Scores did not exist until modern times. The traditional part-book notations reflect the importance of oral, rote learning and the guidance of a teacher. For example, flute and *hichiriki* notations in their standard forms consist of columns first marked off by dots representing major percussion time markers (usually every four beats, though there are five- and six-beat pieces). Next, one finds a column of syllables called *soga*, which were used to help one memorize the instrumental part by singing it. With this system it was even possible to substitute a vocal rendition of one part in an ensemble if that instrument were missing. Finally, there is another parallel column that contains a skeleton of notes or fingerings on the instrument itself. Obviously one can comprehend fully the subtle ornamentations and nuances of any melody notated in this manner only through the guidance of a teacher. In the case of the string notation, one generally finds only the names of stereotyped patterns along with occasional notes. The percussion notations likewise consist of names for stereotyped patterns. If both the strings and percussion are played as written, they appear to be merely time markers, in accordance with the colotomic principle found in much East and Southeast Asian music (the demarcation of time intervals by the entrance of specific instruments in prescribed order, a procedure contributing to the musical structure and imparting a sense of progression).

But as in jazz, there must have been more to the music hidden in the oral tradition. Further clues as to the performance practice of this music in addition to its underlying music theory and its practical uses are found in several important sources. In 735 an ambassador, Kibi Mabi, brought back from China a 10-volume *Digest of Musical Matters* (in Japanese *Gakusho yoroku*), which implies the Chinese foundation of the art. In 1233 a court dancer, Koma Chikazane, produced another 10 volumes—the *Kyokunsho*, describing Japanese *gagaku* matters. Of equal value is the *Taigen-shō*, written by a *gagaku* musician, Toyohara Sumiaki, in 1512, when court music seemed on the verge of extinction.

Tonal system. By a combination of these sources—Buddhist music-theory tomes, part books, and present-day performance practice—it is possible to understand many of the basic principles upon which ancient Japanese music was founded. From what has already been said about the beginnings of Japanese court and religious music it is not surprising to find that the complete tone system of both consists of the Chinese 12 tones shown in notation I, the only difference being the Japanese pronunciations of the characters for each pitch name. The scales in II-B show that Japanese ancient music followed the East Asian tradition as well in the use of two seven-tone scales, each with a pentatonic core. The *ryo* scale (set on C for the sake of comparison) shows no great difference from the Chinese scale in II-A; but the *ritsu* scale seems to reveal the early presence of an indigenous Japanese tonal ideal with the placement of its half steps. Japanese *gagaku* and Buddhist music theories contain most of the

Principal tonalities

classical Chinese ideas concerning transpositions and modes, but in practice the two scales shown in II-B could be constructed on only three pitches each: *ryo* on D (*ichikotsu*), G (*sōjō*), E (*taishiki*); and *ritsu* on E (*hyōjō*), A (*ōshiki*), and B (*banshiki*). Note that the pitches for such transpositions form a classic pentatonic (D–E–G–A–B). The two names for the pitch E are present in order to make a distinction between the two scales possible on that same tone. In the unaccompanied court songs and the chants of Buddhism one can observe the use of other transpositions, for all oral traditions in the world "adjust" notated pitches to the preferences of given singers. In *gagaku* instrumental music, the six tonalities are observed, part books for each instrument being organized in sections by the tonalities of the compositions. A few pieces are found in more than one tonality. A transcription of part of the basic melody for such a composition, "Etenraku," is shown in notation VII-A/B. Although set in two *ritsu* tonalities (*hyōjō* and *banshiki*; VII-C), it is obvious from this example that the piece, which is a "crossover" (*watashimono*), is more than merely transposed.

Although the scale has been transposed, yet the pitch centre of the melody also has been changed (from E to C♯). This is one of the few clear examples in performance practice of the mode systems spoken of in music theory. A glance at the related folksong "Kuroda-bushi" (VII-D; see below) and at the *in* scale (II-C) provides a preview of an emphasis on such a different mode centuries later.

VII

Vocal music. In the poetry-oriented court life of Japan, secular vocal music would obviously be important. Many of the poems in classical collections seemed originally to have been song texts. One of the oldest secular song forms is *saibara*, which was first inspired by the singing of pack-train drivers. Among the new fads of Heian period vocal music (called collectively *eikyoku*) were *rōei*, songs based on Chinese poems or imitations of them, and *imayō*, contemporary songs in Japanese. Many *gagaku* melodies were given texts to become *imayō* songs, while others were derived from the style of hymns used by Buddhist missionaries. Little of these vocal traditions remain, but memories of their importance are preserved in nearly every novel and diary of the period. For larger surviving repertoires it is necessary to turn to religious music.

Shintō music. The indigenous religion of Japan, Shintō, was closely connected with the legendary legitimacy of the emperor. Thus, special Shintō music was devised for use in Imperial shrines, a tradition already familiar from the discussion of China and Korea. In Japan such Shintō music is called *kagura*. The kind of music and ritual used exclusively in the Imperial palace grounds is called *mi-kagura*, that in large Shintō shrines, *o-kagura*, and Shintō music for local shrines, *sato-kagura*. The *suzu* bell tree, mentioned before as among the earliest known Japanese instruments, is found in all such events; and the equally ancient *wagon* zither can be heard in the palace rituals and sometimes in the larger shrines. General Shintō chanting (*norito*) is rather straightforward, whereas the surviving music of *mi-kagura* is more complex. Unison choruses of men are accompanied by the *hichiriki* oboe, a *kagura-bue* flute, the *wagon* zither, and the periodic rhythmic markings of a pair of long, thin *shaku-byoshi* clappers. The music for *mi-kagura* ceremonies is divided into two types: one to praise the spirits or seek their aid (*torimono*), the other to entertain the gods (*saibari*) in the tradition, mentioned earlier, of the mythological amusements given before the sun goddess. Perhaps the most famous surviving dance suite from the Shintō tradition is *Azuma asobi* (*The Entertainment of Eastern Japan*), which can be seen as a courtly reflection of the agricultural base of Japan in its annual performances during the spring equinox and the summer solstice. The work is said to be an imitation of the dance of a heavenly maiden who performed on the beach of Suruga in the 6th century. *Azuma asobi*, along with *bugaku* dances, may be seen at many other Imperial, national, and shrine occasions—dim but nevertheless impressive reflections of the colourful courtly life of Japan of centuries ago. *Mi-kagura* is exclusively a male event, but Shintō female dancers (*miko*) are found in other shrines. Historical documents show that the Heian court, like ancient China or, for that matter, all other affluent societies of the world, appreciated the value of female dancers and their music. In later times the Heian-originated *shirabyōshi* female dancer-musicians became important elements in the transfer of courtly and religious traditions into later theatrical forms. The major source of religious musical influence is found elsewhere in the Buddhist temples.

Buddhist music. There are many forms of Buddhist hymns, such as *saimon*, as well as semireligious dance songs, such as *goeika*, *nembutsu odori*, and the *bon odori* performed to folk festivals. But the basis of Buddhist classical music and hence the core of Buddhist influence on Japanese art music is found in the theory and practice of chanting known generically as *shōmyō*. Such a tradition came originally from foreign Buddhist missionaries and next from Japanese converts studying in China. Noted sources from the many Japanese interpretations of this tradition are the *Shōmyō yojinshu* by Tanchi (1163–1237) of the Tendai sect and the *Gyosan taikaishu* (1496) of the Shingon sect. The theoretical bases of these studies are similar to the ones already discussed under the topic of *gagaku*. Here need be added only comments about Buddhist notation systems. Most early chant notations used neumes, squiggle-like signs that, like those of the early Christian traditions, served primarily as memory aids with which an initiate could recall the de-

Systems of notation

tails of a given melody. The most influential system was the so-called *go-in hakase,* attributed to Kakui (born 1236) of the Shingon sect. Under this method the five notes of each of three octaves of a pentatonic scale were indicated by the angle of a short line, rather like the hands on a clock. Variations of this method were of great influence in the notation of all vocal music of the period and continue to be used in Buddhist chant today. It has been conjectured that the system may be based on the positions of hand *mudra* (ritual gestures) in ancient Indian Buddhism. Whatever its true origins, it remains as one of Japan's more novel innovations in the preservation of music. Of equal value is the continuing vitality of Buddhist classical chant in modern Japan.

KAMAKURA, MUROMACH, AND EDO PERIODS

Nō music. The Kamakura period (1192–1333) marks the end of Heian court splendour and the start of a new military government located in Kamakura, far away from Kyōto. In such a context it is not surprising to find the development of long narratives of military history and the flourishing of plebian theatricals. The story of the defeat of the Heike clan (the *Heike monogatari*) was known in mansions, war camps, and temple grounds primarily as sung by *biwa*-playing bards. As in the traditions of ancient Greece and Europe, these minstrels were often blind or built their style in that of the blind priest lute tradition (*moso biwa*) in which mendicant monks used to recite sutra (scriptures) from house to house or at temples. More lucrative forms of entertainment grew under the circus acts that developed out of the *san-gaku* (folk theatricals) mentioned above, its companion comic acts, *saru-gaku* (literally, monkey music), and theatricals derived from folk rice-planting dances, *den-gaku.* Street parades (*fūryū*) and Buddhist entertainments (*en-nen*) also were part of the colourful scene. By the subsequent Muromachi period (1338–1573) the terms *saru-gaku-no-Nō* and *den-gaku-no-Nō* had become the dominant terms for temple and shrine pantomime and dialogue dramas, while the comic interludes of such plays were called *kyōgen.* Through the support of the military rulers and the efforts of individual artists such as Kan-ami (1334–85) and his son, Zeami Motokiyo (1363–1443), the first major form of Japanese theatre developed. It became known eventually as Nō.

The music of Nō as it is performed today consists of vocal music (*yōkyoku*) with an instrumental ensemble known collectively as the *hayashi.* The singing is done by the actors or by a unison chorus (*jiutai*). The four instruments of the *hayashi* are a flute (*Nō-kan*), the *taiko* stick drum described earlier, a small hourglass drum (*ko tsuzumi*) held on the right shoulder and a larger one (*o tsuzumi*) placed at the left hip.

Melodic principles. The writings of Zeami, such as the *Kaden-shō,* contain terms reflecting the traditional tone systems and terminologies of former times. A distinction was made between the recitative section (*kotoba* or *serifu*) of a play and melodic parts (*fushi*). The melodies of Nō can be categorized into two basic styles, the strong (*tsuyogin*) and the lyric (*yowagin*). Their differences are most evident in the placement of fundamental tones and the use of auxiliary tones around them. In the lyric style the three basic tones (*jo, chu,* and *ge*) are a fourth apart (see notation VIII-C, below). The movement to and from each note is regulated in a manner comparable to the regulated approach to certain intervals in 16th-century Western counterpoint. Similar but different laws are applied to the strong style, the fundamental tones of which are much closer, the standard procedure today being that *jo* and *chu* are one pitch and *ge* is approximately a minor third below (VIII-B). Melodies contain various formulas and ornamentations the names of which often reflect earlier traditions in Buddhist chant and court secular songs. The choice of combinations depends on the musical needs of the given dramatic text as well as the position of the music in the general form of the piece. Once more, such restrictions in an "exotic" music should seem reasonable to students of Western art music with its needs for stylistic restraints. The notation of Nō singing (sometimes called *utai*) is derived from simpler Buddhist and early *biwa* forms that used teardrop-shaped neumes along with important pitch names to remind singers of the performance practice of a given passage. This so-called sesame-seed notation (*goma-ten*) remains basic to Nō vocal music today, and there are many detailed books in modern Japanese to help the initiate follow the music with the aid of a teacher. Variations in notation style and in the interpretation of specific passages are maintained by the various schools of Nō along with the "secret piece" tradition basic to much of Japanese traditional music since its beginnings.

Fundamental and auxiliary tones

Song types. The musical-dramatic form of Nō has as many variations as any other creative genre, such as an opera or a symphony. Table 1 shows the outline of the form of one play, "Yuma Yawata." In it one can see the manner in which the concept of *jo-ha-kyū* or tripartite form, is applied in the context of sections (*dan*) along with typical placements of Nō musical styles within such a form. The *shidai* is usually an introduction and the *na-nori* allows the first character to identify himself. The travelling song (*michiyuki*) is followed by a song emphasizing higher tones (*ageuta*). Songs with lower melodic emphasis (*sageuta*) and other styles (*issei, kuri,* and *rongi*) mix with more recitative sections (*sashi, kotoba*) and with entrances (*deha*), closings (*kiri*), and dances (*kuse* and *mai*).

Table 1: Tripartite Form Concept (Jo-Ha-Kyū) in the Nō Drama "Yumi Yawata"

sections (dan)	placement of musical styles
Jo (mae-dan)	shidai na-nori michiyuki (ageuta)
Ha	
First dan	issei sashi sageuta ageuta
Second dan	kotoba sashi ageuta kotoba
Third dan	kuri sashi kuse rongi
Kyū (ato-dan)	ageuta deha sashi issei mai rongi kiri

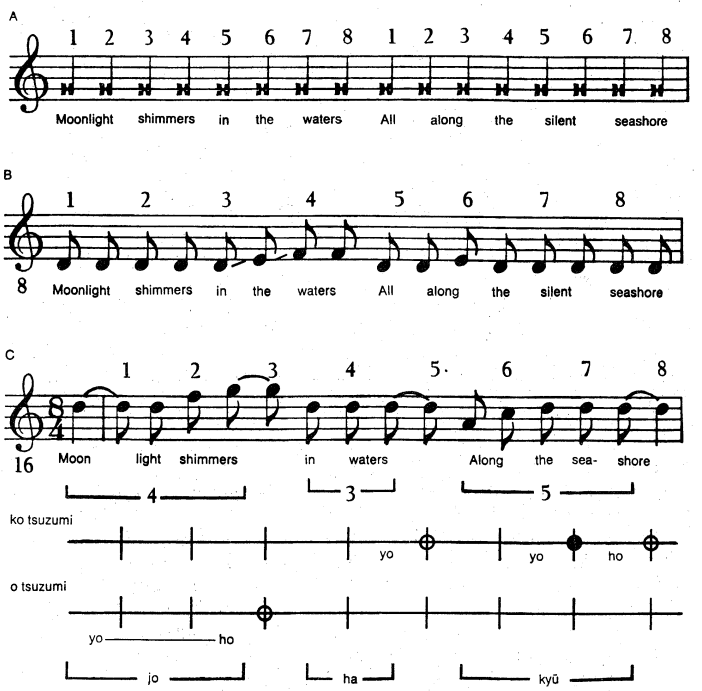
Setting of texts

Within each of these sections and subsections one must remember that drama and text have their influence as well. Though the drama is not all poetic, the earlier discussion of Chinese theatre should prepare one for the fact that many lines of the text are indeed actually poems or are influenced by poetic form. Although there is great variety in the syllable lengths and combinations, the most common divisions in Nō are into lines of seven or five syllables. Such a 12-syllable line has been constructed in English in notation VIII along with a 16-syllable variant so that the reader can compare certain basic principles in the settings of Japanese Nō texts. The placement of a text rhythmically can be done in three major ways: *o-nori,* with one syllable per beat (VIII-A); *chu-nori,* with two syllables per beat (VIII-B); and *hira-nori,* in which 12 syllables are worked into an eight-beat frame (VIII-C). The setting shown in VIII-A is in the spoken (*kotoba*) style, VIII-B, in the strong (*tsuyogin*) singing, and VIII-C is lyric (*yowagin*).

Note in VIII-C that, although there are two sections of seven and five syllables, the actual division of their presentation (4 + 3 + 5) is tripartite; *i.e.,* in the form of *jo, ha,* and *kyū.* Lines of greater numbers of syllables in *hira-nori* require more beats, and 12-syllable lines themselves can be handled in many other ways. Thus, one must not take this artificial example to be representative of the only style of Nō text setting any more than one can consider a given eight-beat phrase from one Mozart opera as being sufficient to show all there is to aria form. Nevertheless, the settings given in notation VIII show in their syllable displacements and melodic contours that such "Oriental" music, like that of all cultures, does have a thorough internal logic. Nō music shares with Western art music the extra convenience of a complete written music theory, of which this short example demonstrates only a few elementary principles. The principles may be taken one step further by constructing a typical drum accompaniment for the *hira-nori* version of the texts.

Function of drum patterns. The lower portion of VIII-C represents one possible setting of the text by the

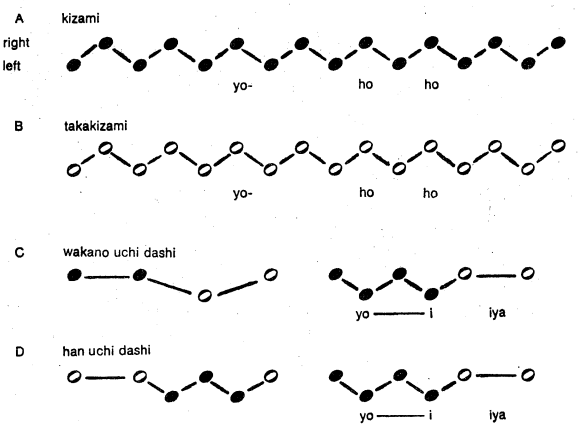
VIII



music of the two *tsuzumi* drums. The music of the Nō drums consists of a series of named, stereotyped patterns that are aurally perceivable and that tend to progress in given orders. The pattern supporting the vocal line in VIII-C is called in both drum parts *mitsuji*, although they do not always play a pattern with the same name. The circles represent moments in which the drum is struck, and the words are drum calls (*kakegoe*) uttered by the drummers. These calls are as essential to the performance and recognition of a given pattern as are the drum sounds themselves. They help to give each pattern a unique aural image. Also, the manner in which the calls are performed by the player helps to signal and control the timing of each beat in a music that is often very elastic in rhythm. Note in addition that, in VIII-C, the first call of each drummer builds up to his first actual striking of the drum, which in turn marks the divisions between the three parts; *i.e.*, the *jo, ha,* and *kyū* phrasing of the vocal line. In short, the vocal line and text have been "rhythmicized" in a manner analogous to the way in which Western music might harmonize a given moment in a song. There are no chords in most Japanese music, but this example shows one way in which many of the basic functions of harmony are handled in a totally parallel yet sonically different

Rhythmic patterns and listener expectation

IX



way. This point may be taken one step further by showing (in notation IX) a set of named patterns for the *taiko* stick drum, an instrument used only in dance sections of a play. Placement of the dots shows right- and left-hand strokes; black dots indicate the softer—and light dots the louder—strokes. The few patterns (*tetsuke*) in the example are from a set of 59 found in a *taiko* instruction book. A study of them shows that they belong to families (*tegumi;* the *kizami* family in A and B and the *uchi dashi* group in C and D). Once more the principles of harmony in Western music come to mind; *i.e.*, a C-major and C-minor chord are related because they share some common aural traits (the tones C and G in this case). If one looks into a lesson book of *taiko* music one will find that, as in many Western harmony books, the student will be told what patterns may appear before or after each item. In Western music one learns in a similar way that certain chords may be preceded and followed by others. In both the Japanese and Western cases there is a selection of permissible choices of earlier or following events for each pattern. Thus, it would seem that the concept of prediction and anticipation is fundamental to the listener's sense of logical progression in the music of both. The major difference in this case is that the aurally perceivable, named, stereotyped pattern of Western traditional music is a vertical sonority called a chord, whereas in Nō music it is a horizontal time unit called a *tetsuke.*

Role of the flute. The music of the Nō flute (*Nō-kan*) has many stereotyped patterns, but it functions in rather different ways from the drums of the *hayashi.* Although it seems originally to have related to the vocal line, today it does not play the singer's melodies. The Nō flute looks like the *ryuteki* flute of *gagaku*; but a short cylinder has been inserted inside its tube so that the upper holes of the flute overblow a seventh (as A–G) rather than the octave, as with all other flutes. This unique characteristic of the flute seems to reflect the tonal principles of Nō mentioned earlier, whose basic notes outline a seventh (A–D–G in notation VIII-C). The flute may give a specific pitch to set the tonality of a vocal entrance, but its normal functions today are to signal sections of the form and to play one of the dozen standard dance pieces used in various Nō dramas. The dance pieces are set in sections (*dan*). Each piece is learned by rote or by a notation consisting of flute mnemonics placed in a frame of eight squares representing beats in a manner rather like the Korean notation mentioned earlier. The flute's seven holes are fingered by the middle joint of the fingers instead of the tips, producing an impressively fluid melody that would not fit into the graphic notation system of traditional Western music. At the same time, it does not compete with the Nō vocal line by being too melodically clear. Indeed, a discussion of the Nō flute seems to be a particularly appropriate finale in this brief survey of Nō music (*Nō-gaku*); for it shows that the form of each musical item—whether performance practice, pitch relations, structure, or notation—follows the needs of its functions. The music of Nō drama seems on first hearing to be one of the most puzzling of East Asia's exotic sounds, but a study of its principles can make it become as reasonable and as beautiful as a Bach cantata.

Koto music. *Schools and genres.* The 13-stringed zither with movable bridges called the koto has been mentioned as one of the basic instruments of the court ensembles as well as a common cultural accoutrement for court ladies. The development of independent solo and chamber music genres for this instrument becomes more evident as one moves into the Muromachi period. One of the earliest schools of solo koto music is the *Tsukushi-goto,* supposedly founded by a priest, Kenjun, in the latter half of the 16th century on the southern island of Kyushu. Its repertoire was first based on the *imayō* song tradition and thus seems to reflect the presence of refugees from the court who fled south during the difficult civil wars. Sets of songs accompanied by the koto and sometimes by the three-stringed plucked lute, or samisen (*shamisen* in Tokyo dialect), were part of the tradition. They were called *kumiuta,* a term applied to much of the early chamber music that developed in subsequent years. The *Tsukushi-goto* school was restricted to priests and Confucian scholars. But Hosui, a samisenist and student of Kenjun on koto, took the tradition to Kyōto in the early 17th century, combined it with more popular music, and

Roots in earlier song traditions

taught it to more lowly people, such as blind men, as he was himself. In Kyōto he founded a new school, *Yatsuhashi-goto*, which mixed the older repertoire with many new compositions. The title *Yatsuhashi* was adopted later by another apparently unrelated school to the far south in the Ryukyu Islands.

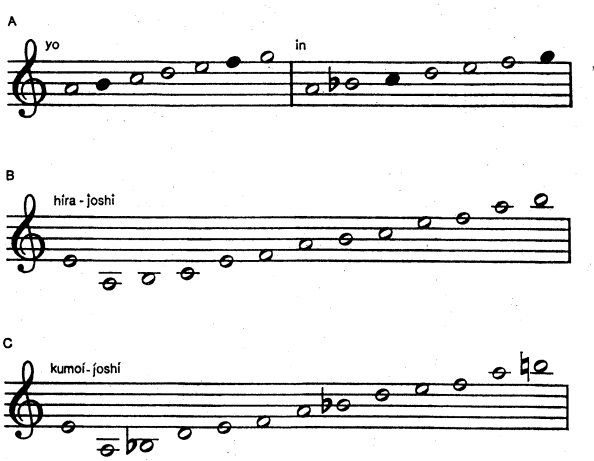
The new schools of popular, or "vulgar," koto (*zokuso*) are proper reflections of the mercantile life of the new Edo period (1603–1867). In 1695, a student of one of Hosui's students took the professional name Ikuta Kengyō and founded another school, the Ikuta. The term *kengyō* had been one of the basic ranks of musicians under the guild system and so is frequently found in professional names, but the name Ikuta remained as one of the primary sources of koto music until the creation of still another school by Yamada Kengyō (1757–1817). In present-day Japan, the Ikuta and Yamada schools remain popular, whereas the earlier traditions have faded considerably. Both schools have provided famous composers; and there are several pieces from their schools, as well as a few earlier works, that are now shared by the guilds as part of the classical repertoire of the koto. The slightly longer and narrower shape of the Ikuta koto produces a tone easily distinguishable from that of the Yamada school.

Koto music is known in general as *sokyoku*. In the koto solo instrumental music (*shirabemono*), the most important type is the *danmono*, a variation piece in several sections (*dan*), each normally of 104-beat length. The term for koto chamber music, *san-kyoku*, means music for three. The standard instrumentation today consists of a koto player who also sings, along with performers on a three-stringed plucked samisen lute and an end-blown *shakuhachi* flute. In earlier times a bowed variant of the samisen called the *kokyū* was used more often than the flute. The basic genre of chamber music is called *jiuta* and combines the earlier *kumiuta* tradition of accompanied song with instrumental music by alternating sections with singing (*uta*) and instrumental interludes (*tegoto*). After the 19th century a second embellishing koto part (*dana-wase*) often was added to the instrumental interludes. Twentieth-century innovations will be covered later.

Tunings and notation. Each school of koto music from the courtly tradition to the present time involves changes in the structure of the instruments, and changes in playing method and notation. The ancient court koto (*gaku-so*) is similar to the modern koto and is played with picks (*tsume*) on the thumb and first two fingers of the right hand or with bare fingers, although, unlike the Ikuta and Yamada styles, the left hand is not used to alter the tone by pressing the string on the other side of the movable bridges. Its notation consists primarily of the names of basic patterns in addition to occasional melodic fragments and the text. The survival of such music is dependent on a continuing viable rote tradition; thus, most of the tradition is lost.

The tunings of the 13 strings of the court koto were derived from the modes of the *ryo* and *ritsu* scales of the earlier periods. The tunings used in the Edo koto traditions, however, reveal hitherto new, apparently indigenous, tonal systems. These concepts were eventually categorized under the two scales called *yo* and *in*, shown in notation X-A. The tunings in X-B and X-C reflect the new kinds of pentatonism of the period with their use of half steps. The *hira-joshi* tuning appears in such famous early works as *Rokudan* (*Six Dans*) ascribed to Yatsuhashi Kengyō, the "founder" of the modern koto styles. In all, there are some 13 standard tunings for the koto and many variants. Like all the other popular music in Japan from the 17th century on, these koto tunings are based either on the older tradition preserved in part in the *yo* form or on the more "modern" *in* scale. One can note in the 19th century occasional pieces deliberately written in the previous *gagaku* mode style as well as the use of the Holland tuning (*oranda-choshi*) that the Western major scale derived from the Dutch business area on Deshima in Nagasaki. Nevertheless, the *yo–in* system remains the fundamental tonal source for new Japanese music from the 17th century on, exceptions being revived court music, new Nō plays, and the work of avant-garde composers after World War II.

X



The earliest printed notations of koto, samisen, and flute pieces from the Edo period are found in the *Shichiku shoshinshu* (1664), the *Shichiku taizen* (1685), and the *Matsu no ha* (1703). Although many sections of such collections contain only the texts of songs, one can find certain pieces that parallel the line of words with numbers representing strings on the koto or finger positions on the samisen, names of stereotyped koto patterns, or mnemonics for the particular instrument with which the piece is learned. In the late 18th century both the koto and the samisen traditions developed more visually accurate notations. The koto version (first seen in the *Sokyoku taisho*, 1779) used various sized dots to indicate rhythm. In the early 19th century, string numbers were placed in columns of squares representing rhythm, as in the system mentioned earlier in Korea. The numbers and squares eventually were combined with the $\frac{2}{4}$ bar-line concept of the West; so that the notations of both schools today, although separate systems, maintain a balance of traditional and Western ideas. Their modern compositions attempt to do the same as well; but before they can be treated, attention must be given to the traditions connected with the other major instruments of the Edo period.

Printed collections

Schools of shakuhachi flute music. The *shakuhachi* end-blown flute is a variant of the Chinese *hsiao*, and examples of it can be found in the famous 8th-century Shōsō-in storehouse mentioned earlier. During the Muromachi period (1338–1573), a smaller Japanese version called the *hitoyogiri* became popular as a solo instrument, but the best known form of the *shakuhachi* is the one developed in the Edo period. The instrument was used by *komusō*, priests who begged or sometimes spied while wandering through the streets playing the flute incognito, their heads covered by a special wicker basket hat. With the changes in Edo society, many former warriors no longer carried their swords, whereas young merchants carried more money. One curious side effect of such changes was the occasional appearance of a *shakuhachi* tucked in the back of one's belt for use as a musical device or as a club.

The major schools of *shakuhachi* music today come from guilds, the Meian and Kinko, whose origins derive from two sects of an earlier Fukeshu guild of *komusō* priests. The Meiji era (1868–1911) abolished the monopoly rights of the various Edo music guilds; and a Tozan school was founded for teaching the music to amateur musicians, a custom soon adopted by the other guilds. The instruments of all schools may vary in size and the number of finger holes for the purpose of pitch as well as differences in timbre ideals. The standard *shakuhachi* has four finger holes along the front and one thumb hole behind. A bell is formed by the bamboo root stems at the end of the flute. The mouthpiece is cut obliquely outward, and a small piece of bone or ivory (*a tsu*) is inserted at the blowing edge in order to help produce the

great subtle variety of tones typical of *shakuhachi* music. The basic repertoires of the music are divided into three types. Original pieces (*honkyoku*) are those claimed to be composed by the founders or early teachers of a given school, whereas outside pieces (*gaikyoku*) are taken from other genres or other schools of *shakuhachi* music. New pieces (*shinkyoku*) continually appear and are kept in that category. *Shakuhachi* notation varies with each school, but all are based on mnemonics with which the music is taught. Given the exceptional subtlety of tone changes and ornamentation in all traditional *shakuhachi* music, such a notation system seems quite logical. The beautiful introverted sounds of *shakuhachi* music seem closer to Buddhist chant than to other instrumental forms and are best learned by the ear and heart rather than the eye and brain.

Samisen music. The three-stringed plucked lute of Japan is known as the *shamisen* in the Tokyo area or the samisen in the Kansai district around Kyōto. It seems to have arrived in Japan as an import of the *sanshin*, or jamisen, from the Ryukyu Islands in the mid-16th century. The Ryukyu form of the instrument, with its oval body and snakeskin, is obviously derived in turn from the Chinese *san-hsien*. Such an origin is reinforced by collections of early Ryukyu music, which use a so-called *kukunshi* notation similar to the Chinese symbols shown in notation III. The Japanese samisen underwent considerable physical change, its body being rectangular and the skins coming from a cat or dog. Apparently under the influence of contemporary *biwa* lute traditions, the plectrum of the instrument was changed from the talon-like pick of the Ryukyus to a wooden *bachi* with a thin striking edge. In addition, the lowest string was kept off the small metal upper bridge near the pegbox so that it produced a buzzing sound (*sawari*) reminiscent of the tone of a *biwa*. The three basic tunings of the Japanese instrument are *hon-chōshi* (b–e′–b′; b = the B below middle C, b′ the B above); *ni agar* (b–f♯′–b′); and *san sagari* (b–e′–a′). They have remained standard to the present day, although there are occasional variants.

Greater variety is found in the many genres of samisen music. The earliest types seem to have been played by old *biwa* entertainers around Ōsaka, a city then called Naniwa; hence the name of the new genre was naniwa-bushi. Samisen was used for folk music and party songs, but, in keeping with the *biwa* origin of the first performers, narrative music was of prime importance. Such music became known as *jōruri*, the term derived from the title of a famous story of the princess Lapis Lazuli (*Jōrurihime monogatari*). As different guilds of samisen evolved it was possible in modern times to divide them into two basic styles: narrative traditions (*katari-mono*) and basically lyrical musics (*uta-mono*). Table 2 is an outline of the development of these two styles in terms of genre names. *Sekkyō* was an earlier form of Buddhist ballad drama for the general populace and thus is placed at the beginning of the narrative style, for *sekkyō-bushi* was eventually done with samisen accompaniment. The term *jiuta* has already been mentioned as one of the early chamber music forms and thus starts the lyrical list. Turning to the narrative list first, one finds a mass of names, most of which after *naniwa* and *jōruri* are derived from the professional name of the musician who began the style. Except for the term *ogie* and *utazawa*, the names for the lyrical styles are more descriptive. It has already been noted that *kumiuta* means a set of songs. The terms *hauta* and *kouta* stand for short lyrical pieces such as would be heard in a teahouse or at a banquet. *Nagauta* means a long song and represents the major genre in this category, which will be described presently. Each of the styles listed in Table 2 uses a samisen of different size with different weight bridges and design of plectrums. The voice quality of the singers is quite different as well. For example, a professional *shinnai* singer would find the performance of *gidayū* as difficult as would a French opera specialist attempting to sing Wagner. The most famous and perhaps most demanding of the narrative styles is *gidayū*, named after Takemoto Gidayū (1651–1714), who worked with Chikamatsu Monzaemon in the founding of the most popular puppet-theatre tradition (known as *bunraku*) of Ōsaka. The *gidayū* samisen and its plectrum are the largest of the samisen family, and the singer-narrator is required to speak all the roles of the play, as well as to sing all of the meditations and commentaries on the action. The part is so melodramatic and vocally taxing that the performers are often changed halfway through a scene. There is little notated in the books (*maruhon*) of the tradition except the words and the names of certain appropriate stereotyped samisen responses. The samisen player must know the entire drama by heart in order to respond correctly to the interpretations of the text by the singer. The two musicians sit on a platform to the stage left of the theatre and through the intensity and skill of their performance help bring life and pathos into the wooden characters who move with frighteningly realistic gestures in the hands of three puppeteers. The power of *gidayū* is such that it can be heard in concert versions as well. In the 19th century, a school of female performers (*onna-jōruri*) carried on the concert tradition with equal ability.

Jōruri, or narrative, music

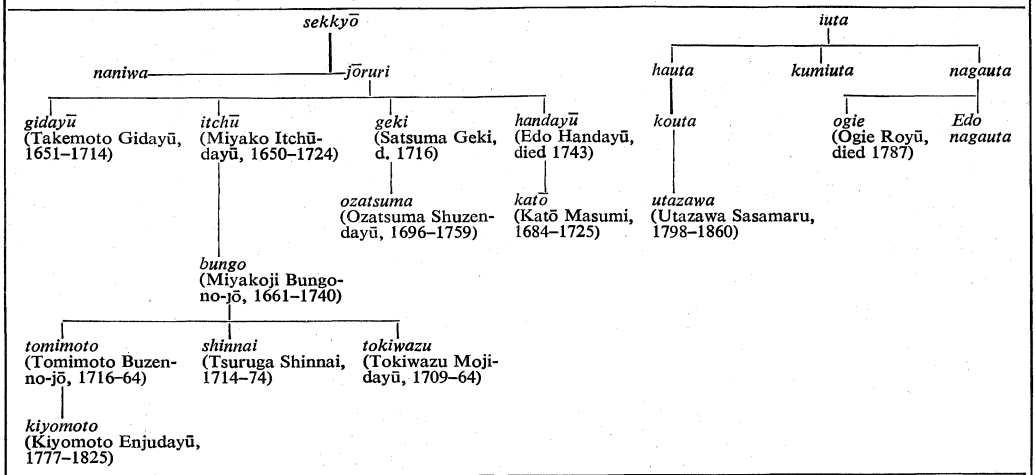
Music for the puppet theatre

Kabuki theatre. The *nagauta* form of lyric music, like most of the other narrative forms, began with a close relation to the Kabuki popular theatre of the Edo period. The first Kabuki performances used instruments (*hayashi*) from the Nō drama. Because Kabuki was related to the flourishing demimonde of the major cities, however, the music of the party houses and brothels was soon added to the theatre. By the mid-17th century the names of *nagauta* singers and samisen players were listed on posters along with the cast. In the same manner, the names of musicians in many of the other genres listed in Table 2 were adopted to denote parts of a play. Although nearly all of the music listed can be heard in concert forms today, the major genres still included in Kabuki productions are *gidayū*, *tokiwazu*, and *kiyomoto* from the narrative styles, and *nagauta* from the lyrical. Rather than discussing them individually they will be viewed in the total theatrical context and later brief reference will be made to their concert forms.

Onstage music. Kabuki as theatre is discussed elsewhere in the encyclopædia. Its musical events can be divided into onstage activities (*debayashi*) and offstage groups (*geza*). In plays derived from puppet dramas, the *gidayū* musicians, called here the *chobo*, are placed on their traditional platform offstage left or behind a curtained alcove above the stage-left exit. If other genres are used, the performers are placed about the stage according to the scenery needs of the play. There are some plays in which several different kinds of onstage music are required, a situation called *kake-ai*. The most common dance scene today, however, is one in which the onstage group consists of *nagauta* musicians and the Nō *hayashi*. The samisen and singers are placed on a riser at the back of the stage, and the *hayashi* sit before them on floor level —thus, their other name of the *shitakata*, meaning "the ones below." There are as many different types of dances that require different kinds of music as there are in Chinese or Western opera. In a general view, perhaps the most intriguing side of this variety is the relation of the older drum and flute parts to the Edo-period vocal and samisen melodies. In totally Kabuki-style pieces, the *tsuzumi* drums play a style called *chirikara* after the mnemonics with which the part is learned. The patterns of this style follow closely the rhythm of the samisen part. If the Nō flute is used as well, it is restricted to cadence signals; or a simple bamboo flute (*take-bue* or *shino-bue*) is substituted, which plays an ornamented (*ashirai*) version of the tune. There are many sections, however, in which the drum patterns and Nō flute melodies discussed earlier are combined with samisen melodies. In a classical repertoire of hundreds of set pieces, there are many different combinations, but to many listeners these situations seem rather puzzling at first hearing, with apparently two kinds of music going on at the same time. If the situation is from a play derived from a former Nō drama and uses the full *hayashi*, one notes first that the flute is not in the same tonality as the samisen nor is it playing the same tune. The drums in turn do not seem to relate

Tension between simultaneous styles

Table 2: Genres of Shamisen Music*



*Names of founders of some styles are given in parentheses.

rhythmically to the melody, as they do in the *chirikara* style. If one analyzes a given situation in detail it is found that the drums and flute are playing named stereotyped patterns normally of eight-beat length as in the Nō. The essential difference between them and the samisen melody is that they do not seem aurally to have the same first beat. Many times a given samisen melody will make room through silence for an important vocal call in the drum patterns, but the deliberate lack of coordination of beat "one" creates a vital rhythmic tension that makes the music drive forward until resolve is accomplished at a common cadence. This important compositional device can be called a slide-rule effect: each part is internally rigid and progressive, but its conflict with the other parts forces the music (and the listener) to move the musical event through a time continuum toward a mutual completion. The Nō flute music is frequently related to the *taiko* stick-drum rhythm, so that they can be considered as a common unit rather than separate parts. There are situations in which the *tsuzumi* play *chirikara* patterns in support of the samisen melody, while the *taiko* and Nō flute play either Nō patterns or later Kabuki-named drum patterns "out of synchronization" with the other music. At such moments one can see that in Kabuki dance music, as in Western Classical music, there are three kinds of musical needs. In the West they are melody, rhythm, and harmony. In this music they are melody, rhythm, and a third unit of one drum and a flute that functions like harmony although its sound is totally different. If this third Japanese feature is called the dynamism unit, then it can be said that *nagauta* dynamism and Western traditional harmony both serve to colour the line, to create tension that drives the music onward and help to standardize the formal design of the piece by clarifying cadences or by creating the need for them. All of this brings back the earlier point that music is not an international language. The equally logical but different aspect of this music is certainly most obvious and striking.

The formal aspects of Kabuki music are as varied as the plays with which music is connected. In dance pieces derived from Nō plays, many of the sectional terms of the Nō mentioned above are found. The classical Kabuki dance form itself often consists of sections divided into the traditional tripartite arrangement as shown below:

deha or *jo*
oki michiyuki
chūha or *ha*
kudoki, monogatari, odori ji
iriha or *kyu*
chirashi, dangire.

Generally speaking, the *oki* represents all kinds of introductory instrumental sections (*aigata*, or in this case *maebiki*) or vocal parts (*maeuta*) before the entrance of the dancer. The *michiyuki* usually incorporates the percussion section as the dancer enters. The term *kudoki* is found in the early history of samisen music as a form of romantic music and is used here for the most lyrical section, in which the percussion is seldom heard. The *monogatari* (story) relates to the specific plot of the dance, and the *odori ji* is the main dance section, rather like the *kuse* or *mai* of the previous Nō form. During this section, the bamboo flute may appear for contrast and, in Nō style, the *taiko* drum may be important. The *chirashi* contains more active music, and the final cadence occurs during the *dangire*. There are endless variations and extensions of this form, but the many specific instrumentational and stylistic traits found in each of these sections help the listener to become aware of the logical and necessary progression of a given piece through a moment of time to its proper ending.

Changes in notation in the 18th century

Most early collections (*shōhon*) of onstage music consisted of the text and samisen mnemonics (*kuchi-jamisen*, mouth samisen) of instrumental interludes (*ai-no-te*). In the 18th century some of the lyrical forms began to use syllables to represent fingering positions on the instrument, a system called the *iroha-fu*. In 1762 a set of circles with various extra markings along with the string number were combined in a book called the *Ongyoku chikaragusa* to create a more accurate if complicated system. Further rhythmic refinements were created in the 1828 *Genkyoku taishinsho*, but it was not until the modern period that Arabic numbers in the French *chevé* style (apparently learned in Germany by Tanaka Shōhei) were combined with Western rhythmic and measured devices to create notations that could be sight-read without the aid of a teacher. Three variations on this technique form the basis of most modern samisen notations, although occasional pieces can be found in Western notation as well. Thus, it is possible to purchase large repertoires of *nagauta, kouta*, or *kiyomoto* music for performance or study alone. Motivating such notational changes was the increased interest during the mid-19th century in samisen music composed for concert performance (*ozashiki*) rather than as dance accompaniment. Such a tradition is common practice for all the samisen genres today.

Music and dramatic content

Offstage music. Returning to the theatre, one finds rather different music offstage. This *geza*, or *kagebayashi* (shadow *hayashi*), music is normally placed in a small room on stage right with a view of the drama through a bamboo curtain. The music consists of special samisen and vocal pieces and a great variety of percussion signals. For example, a huge *o daiko* barrel drum with two tacked heads signals the beginning of a program, in keeping with the sounds given by the same drum from a tower over the entrance of very early Kabuki

theatres. Other drums, bells, gongs, and clappers are used to reinforce stage action, and special offstage songs may set the mood or location of a scene, particularly in those scenes in which onstage musicians do not appear. For example, the singing of the offstage song "Eight Miles to Hakone" will tell an audience that the scene is set along the old Tokaido road, whereas the sound of waves (*nami-no-oto*) beat on the *o daiko* drum indicates that the scene is on the road near the sea. A type of offstage song called *meriyasu* may be used to reflect the silent thoughts of the stage character, while the call and response of occasional beats offstage of two *ko tsuzumi* drums will place a scene in a mountain area with its echoes. As in Western musical theatre and films, many of the sounds are naturalistic, whereas others are traditional means of evoking desired responses from an audience. Theatregoers in both traditions are often unaware consciously of the means used for such reactions even though familiarity has made their dramatic value very real indeed. The specific musical devices used in a given Kabuki play are under the control of a headman, *hayashi gashira*, who works with the first samisenist, the actors, and the director to produce the desired results. Thus, the musical contents of a given play may change with different productions. In Kabuki, the combination of offstage and onstage music creates a total atmosphere that has few parallels in other world theatres. Perhaps it comes as close as anything to the composer Richard Wagner's ideal of the all-embracing art form (*Gesamtkunstwerk*).

Biwa, vocal, and folk music. During the late 19th century the *biwa*-accompanied narratives enjoyed a revival. The blind-priest *biwa* (*moso biwa*) tradition had originally been divided into two schools named after the provinces in Kyushu from which they came, Chikuzen and Satsuma. The tradition declined greatly over the years. When the Imperial restoration began in the Meiji Era (1868–1912), many members of the new administration were from those provinces. Thus new schools of narrative *biwa* music arose under those two names, influenced at this time by several samisen narrative traditions. The topics of the new *biwa* pieces were often military and appropriate to the modernization period. The 19th century also was one of Japan's periodic revivals of interest in things Chinese, reduced somewhat with the advent of the Sino-Japanese War of 1894–95. Another late Edo period style was *shigin*, the singing of Chinese poems in an intense solo style quite unrelated to the Heian *rōei* tradition of Chinese-based songs. *Shigin* was later accompanied by *shakuhachi*, and during the increased military spirit of the Meiji era it was combined with a posturing sword dance, *tsurugi-mai*. It also appeared in *biwa* concerts and could still be heard on rare occasions in the early 1970s.

Work songs, theatricals, and festivals

Courtly writings have left little information about the music of the peasants in any detail, but some folk songs and theatricals of the Edo period remain for modern study. The rice-planting, harvesting, and other work songs that survive may retain ancient melodies and may also be evidence of the indigenous origins of the *yo–in* scale systems to which most such music belongs. In this context, the first phrase of the folk song "Kuroda-bushi" is shown in notation VII-D as it is said to have been derived originally from a Heian period *imayō* based on the *gagaku* piece shown in VII-A. Most folk songs are, of course, regionally functional but historically vague and subject to the normal changes of any oral tradition. Viewing as a whole both the performance practice and voice qualities of Japanese folk music, one finds a great variety of styles. Such richness may reflect the long periods of Japanese feudalism, which fostered many different musical dialects.

The many processionals and pantomimes of folk theatricals are accompanied by flutes and percussion, the generic term for such ensembles being *hayashi*. During the Edo period, the Shintō shrines of Tokyo developed festival ensembles (*matsuri bayashi*) for the various major districts of the city. Most of these combine a bamboo flute with two folk-style *taiko* stick drums, an *o daiko* barrel drum, and a small hand gong called the *kane*, or *atarigane*. When such groups are playing general festival music, they all use a suite of five pieces: *yatai, shoden, kamakura, shichome*, and another *yatai*. But their versions of each piece can be very different. When dance or pantomime is involved, the *sato-kagura* music implied earlier is used. There are in addition many forms of folk festival dances (such as the *bon odori*) that either have a *hayashi* ensemble, are unaccompanied, or, since the Edo period, use a samisen. Given the oral base of all folk music, many songs are lost with the demise of another old farmer or worker. There has been a considerable revival of interest in national songs in Japan since World War II, however, and there are hopeful signs that such colourful traditions will survive.

THE MEIJI PERIOD AND SUBSEQUENT MUSIC

Sources of Western influence. The period of Japanese history after 1868 is often thought of primarily in terms of its Westernization. The three major sources of Western music in Japan were the church, the schools, and the military.

Religious and military music. Christian music had, in fact, been introduced into Japan as early as the mid-16th century with the arrival of Portuguese merchants and Roman Catholic priests. With this importation came Catholic music and Western musical instruments, the most lasting of which was the double-reed shawm, which survives today as the tuneful accessory of itinerant noodle sellers. The bowed *rebeca* lute may have combined with the Chinese *hu-ch'in* in the creation of the bowed *kokyū* of 17th-century Japan. But the suppression of Christianity in that century destroyed the bamboo organs, choirs of mass singers, and most of the other direct Western musical imitations until the Meiji restoration. The official doctrine of new religious freedom in 1872 brought large numbers of Protestant missionaries into action, and collections of hymns with Japanese text were printed by 1878. Interdenominational editions were necessary by the 1890s. Since that time, standard Catholic and Protestant musical activities can be found and, with the international growth of Tokyo, one can even add the sounds of synagogues and a mosque. But the growth of musical acculturation in Meiji Japan is better seen in its other foreign imports.

Band music, as part of a military table of organization, had already been tried in Dutch style at a military school in Nagasaki during the early 19th century. After Adm. Matthew C. Perry's arrival in 1853, every foreign delegation to Japan did its best to impress the natives with marching bands (Perry added a minstrel show). Thus, the various Japanese regional and national military leaders were quick to add such organizations to their modernized armies. The Emperor was equally aware of the Western musical values displayed by the first foreign missions and ordered that the *gagaku* musicians be trained in band music as well. A navy band from the Satsuma clan gave the first Japanese public performance of this new music at the opening of the railroad in 1872, and in 1876 *gagaku* musicians made their debut as band musicians on the occasion of the Emperor's birthday. The training of the many new ensembles was in the hands of English, French, and German bandmasters, and new music was created by them or by their Japanese students to match the spirit of Meiji modernism. The most famous case is the national anthem, "Kimi ga yo," which was one of the few successful early attempts at combining Western and Japanese traditions. A British bandmaster, William Fenton, teaching the Japanese navy band, worked together with *gagaku* musicians through several unsuccessful versions; and the search continued through his German successor Franz Eckert. A court musician, Hayashi Hiromori (1831–96), is credited with the melody shown in notation XI, which was given its premiere in 1880 and has remained the national anthem since that time. Hayashi first wrote it in traditional *gagaku* notation; and Eckert "corrected" it with Western harmonization, noting that it fit in both a *gagaku* mode (*ichikotsu*) and one from the Western church tradition (Dorian). As Japan's military prowess grew, standard Western-style marches and patriotic pieces dominated the repertoire. They also influ-

Collaboration of Western and traditional Japanese musicians

enced popular music with such genre as *rappa-bushi* (literally, "bugle songs") as well as music in the schools.

XI

Music education. Public-school music in Japan was organized by a member of a Meiji educational search team, Izawa Shūji (1851–1917), and a Boston music teacher, Luther Whiting Mason (1828–96). Mason was brought to Japan in 1880 to help form a music curriculum for public schools and start a teacher-training program. Though there was much talk of combining the best of East and West, the results of the sincere efforts of an American late-Victorian and a Japanese bureaucrat were less than glorious. The first children's songbook, the *Shogaku shokashi shoden* (1881), contained either Western pieces with Japanese words or songs newly composed by Mason. The primary sources of Western tunes were those pieces from Boston school books that appeared to be pentatonic. Through this method songs like "The Bluebells of Scotland" spoke of beauty ("Utsukushiki"), "Auld Lang Syne" concerned fireflies, and Stephen Foster became the major composer of songs known to educated Japanese children. The newly composed songs with their artificial tunes and moralistic words quickly faded away and eventually were replaced by more popular children's school songs based on military music (*gunka*) from the Sino- and Russo-Japanese wars. The teacher-training school became the Tokyo Music School by 1890 and included instruction in koto and, because of the lack of proper violins, the bowed *kokyu*. The music department of the modern University of Fine Arts is still located at the spot of the original school in Ueno Park, Tokyo, with a bust of Beethoven beside the entrance. Koto, samisen, Nō music, and Japanese music history are now found there along with extensive offerings in Western music. But until very recent times music education was totally Western in orientation. Japanese music was presented in middle-school music appreciation courses only some ten years after World War II. The teaching of Western-style singing and the use of choruses have become fundamental to a proper education in Japan, with the results that youth and workers' choruses of the 20th century are cut off from original Japanese music. It was only with the rise all over the world in the mid-20th century of searches for cultural or ethnic identities that the Western nature of Japanese music education has been bypassed by some youth. Such a move should be quite clear to followers of Euro-American folk- and minority-group music revivals. In Japan, 20th-century activists, right or left, have attracted youth by the use of the public-school choral tradition in new textual contexts. Behind the robust volume of such functional, harmonized tunes lies the equally viable if quieter sounds of older, traditional music.

Traditional styles. The pre-Meiji period of 19th-century Japanese traditional music, known generically as *hōgaku* vis-à-vis Western music (*yōgaku*), was generally strong. It has been noted that certain styles of samisen music had been able to create concert repertoires disconnected from dance or party accompaniment. Koto teachers and composers also flourished; and *biwa* music began to return along with court music, paralleling the restoration of Imperial power. The most devastating effect of the restoration was the cancelling of monopoly privileges previously held by the various guilds, including those in the music fields. This temporary economic–social setback was overcome by admitting students from all classes of people and, at the same time, by a concerted effort on the part of more imaginative musicians to make some compromise between their old traditions and the new sounds flowing in from the West. In general, the evaluation of Western music by Japanese traditionalists showed that it differed from *hōgaku* in the following ways: it used other tone systems; it was thicker in texture, with more high and low notes going on at the same time; part of this thickness was sets of chords; it was generally considered better if it were faster and louder and the instruments were played more fancifully; it used more instruments at a time; it used different kinds of metres; and it had other forms, often organized by the concept of first and secondary themes. A survey of late-19th-century and early-20th-century musical experiments in Japan shows that every one of these characteristics was tried out, particularly in koto and samisen music. Perhaps the most obvious and successful composer in the new traditional music (*shin hōgaku*) following World War I was Miyagi Michio (1894–1956), a blind koto teacher in the Ikuta school. In 1921 he composed a piece "ochiba no odori" ("Dance of the Falling Leaves"), which used two koto, samisen, and a 17-stringed bass koto of his invention. Later works by Miyagi combine orchestras of traditional instruments, sometimes with strikingly successful results, although concertos for koto by some composers, with their mass koto and *shakuhachi* accompaniments, rather negate the entire sound ideal of the original idioms. The 1929 duet for *shakuhachi* and koto, "Haru-no-umi" ("Spring Sea"), has proven Baroque-like in its performance practice, for it is often heard played by the violin, with koto or piano accompaniment. Its style equals the French composer Claude Debussy in his most "orientale" moments. The Japanese traditionalist's view of Western music listed above continued to be employed after World War II with such works as multimovement pieces using mixed orchestras in other contemporary idioms, including electronic manipulations. Such trends are best seen in the context of Western-style Japanese composers.

Evaluation of Western music by Japanese traditionalists

Composers in Western styles. Although graduates of the Tokyo Music School and modernized court musicians were involved in many of the first concerts and compositions in Western classical music, the major Japanese forces in this direction came from young men who studied in Europe. The most famous surviving composition of this era is *Kojo-no-tsuki* (*The Ruined Castle*), written in 1901 by Taki Rentarō after his training in Germany. The first line, shown in notation XII, reveals, with its use of E or E♯, a conflict between the Western minor and the Japanese *in* scales. In its piano-accompanied version it recalls the style of Franz Schubert, and as sung in the streets it sounds Japanese. Yamada Kōsaku was training in Germany when the Meiji Era ended (1912) and returned to Japan with a new, more composer-like name, Koscak, and a strong interest in the founding of opera companies and symphony orchestras, as well as in the teaching of Western music. His famous 1940 opera, *Kurobune* (*The Black Ships*), deals with the opening of Japan to the West and reflects his knowledge of Wagnerian style. Attempts at nationalistic operas can be represented better by the 1952 work *Yuzuru* (*Twilight Crane*) by Ikuma Dan. The plot is a Japanese folktale, and, although the musical style is a mixture of the music of Maurice Ravel and the late works of Giacomo Puccini, one finds as well deliberate uses of folk songs and idioms. Shimizu Osamu is perhaps more successful nationalistically in his choral settings of Japanese and Ainu music, in which the style of vocal production and chordal references seems to be a more honest abstraction of Japanese ideals. Mamiya Michio combined

XII

traditional timbres with 12-tone compositional technique in a koto quartet. Mayuzumi Toshirō has produced many clever eclectic results in such works as his *Nirvana Symphony* (1958); Buddhist sutra texts mix with a combination of choral writing in the style of Igor Stravinsky, orchestral tone clusters, and sweeping vocal lines derived from Japanese Buddhist chant style.

20th-century musical internationalism

It has often been felt that no true combination of Japanese and Western music would be possible until there was some composer who was equally knowledgeable in both Western and Japanese traditional styles. Until recent times such a musical, aesthetic barricade seemed unbroken. But the international musical styles of the last third of the 20th century seem to make culturally transcendental eclecticism a viable medium for those composers with enough talent and insight to control the infinite idioms available to them. In Japan, Takemitsu Toru seems a likely candidate for such an accolade. His music is totally contemporary and never directly "orientale," yet some of his senses of timing, texture, and structure are characteristically Japanese.

In modern Japan all styles of music are available, from the traditional to the most avant-garde. Fully professional performances of Kabuki music are matched by complete Beethoven symphonic series. Huge choruses singing polemics of every type and mass bands of children bowing violins in the widely imitated method of instruction developed by Suzuki compete for audiences with intimate recitals of Heike *biwa* music and hundreds of other events. Research in Japanese traditional music has flourished among native scholars as well as among an increasing number of foreign devotees. National, private, and academic organizations have been founded for the collection, study, and publication of material dealing with all aspects of Japanese musical life; and the commercial record companies periodically enter into prestige contests that result in stunning, well-documented albums concerning nearly every type of Japanese music from Buddhist chant and folk songs to electronic music and prewar popular tunes.

From the outline of Japanese musical culture given above it should be evident that old traditions can still be heard along with the newer ones. For the most part, the older forms probably do not sound the same today as they did in their heyday. Such changes in traditions are inevitable, however, and are common to music in most other world cultures, including the Western. For example, present day *gagaku* performances are undoubtedly different from those of 1,000 years ago, but Mozart symphonies as well do not sound the same as they did in the 18th century. Now modern technology has made it possible to "freeze" a given performance of some musical event through a recording. But each musician in each generation may choose as he desires to add fresh flavour to such earlier items or leave them "pure." Part of the charm and fascination of Japanese music is that it still offers so many stylistic listening and studying choices to anyone curious or energetic enough to want to know them better. A major point of this entire article is that none of the various styles of Oriental music is any more mystical or incomprehensible than is Bach or Beethoven. Each tradition is simply different. All of them are also logical and—perhaps of greater importance—they are beautiful to those who learn their special forms of musical language.

BIBLIOGRAPHY

Music of China: For Western-language sources see FREDRIC LIEBERMAN, *Chinese Music: An Annotated Bibliography* (1970). Excerpts from basic historical Chinese texts are in *Chung-kuo ku-tai yin-yueh shih-liao chi-yao* (1962). See also RULAN CHAO PIAN, *Song Dynasty Musical Sources and Their Interpretation* (1967); ROBERT H. VAN GULIK, *The Lore of the Chinese Lute*, rev. ed. (1969); L.E.R. PICKEN, "The Music of Far Eastern Asia," in *The New Oxford History of Music*, vol. 1 (1954); FRITZ KUTTNER, "The Music of China," *Ethnomusicology*, 8:121–127 (1964); and "A Musicological Interpretation of the Twelve Liis in China's Traditional Tone System," *ibid.*, 9:22–38 (1965); and DANIEL S.P. YANG, "Censorship: 8 Model Works," *The Drama Review*, vol. 15, no. 3 (1971).

Music of Korea: The major sources for Korean music study are in Korean or other Asian languages. LEE HYE-KU, the major scholar, has provided a few items in English such as *Korean Classical Music Instruments* (n.d.) and *Topics in Korean Music* (1967). A mimeographed *Glossary of Korean Music* by CHANG SA HOON was printed by the Korean Radio Management Bureau, Ministry for State Council Administration (1961). The Korean Broadcasting Corporation (KBC) has produced several excellent LP records with English notes of value. See also DONALD SUR, "Notes on the Yongsan Hoesang Source," in *Essays in Ethnomusicology* (1969); and ALAN HEYMAN, "Pansori," in *Essays on Asian Music and Theater* (1971) and his "Comparative, Critical Study of Korean Traditional Music Today," *Korea Journal*, vol. 2, no. 9 (1962); and BANG-SONG SONG, *An Annotated Bibliography of Korean Music* (1971).

Music of Japan: General introductions are FRANCIS T. PIGGOTT, *The Music and Musical Instruments of Japan* (1909, reprinted 1971); WILLIAM P. MALM, *Japanese Music and Musical Instruments* (1959); and SHIGEO KISHIBE, *The Traditional Music of Japan* (1966, Nippon Victor record album JL 32–4). Studies of special topics are HANS ECKARDT, *Das Kokonchomonshu* (1956); TOYOTAKA KOMIYA, *Japanese Music and Drama in the Meiji Era* (1956); WILLIAM P. (W.P.M.)

Music, Recording of

Because music evaporates as soon as it is produced, men, seeking permanence in life's ephemera, have long sought ways to record and reproduce it.

Man's efforts to capture the fleeting sounds of music have followed two basic methods: that of symbols and that of signals. The former—musical notation—matured earlier, and in one form or another it virtually monopolized the recording of music for centuries; the latter had to await the emergence of technology for its development. In notation, symbols are written down as a message to a trained performing musician who understands them and reinterprets them into sound. Signals, on the other hand—being direct physical impressions of, and potential stimuli to, sounds—bypass the performer in their reproduction and, in some electronic compositions, even in their recording. This essay will concern itself solely with the latter, nonsymbolic, method. Information on the former method will be found in the article MUSICAL NOTATION. For a longer discussion of the technical aspects of the reproduction of sound, the reader is referred to SOUND RECORDING AND REPRODUCING.

Types of reproduction. The physical reproduction of music has been accomplished in three major ways, which can be designated the mechanical, the acoustical, and the electrical. In the mechanical, an automatic instrument, such as the barrel organ, plays music that has been built, or programmed, into the mechanism by the designer; the resulting sound is that of the apparatus. In the acoustical and electrical methods of reproduction, sonic vibrations themselves are captured in performance and reproduced—by purely mechanical means in the acoustical method and by the use of vacuum tubes, transistors, and other such devices in the electrical. In both cases, the resulting sound is expected to be that of the independent performance.

Mechanical, acoustical, and electrical methods

Until the end of the 19th century, music was reproduced primarily by means of the mechanical method. There are reports of other methods, probably based on the action of wind or forced air, dating as far back as about 1500 BC, in the 18th dynasty of ancient Egypt, when a colossal statue of the god Memnon at Thebes made some sort of sounds to greet his mother, the goddess of the dawn. (Toppled by an earthquake in the year 27, the statue seems to have lost this ability upon reconstruction.) Friar Roger Bacon is reported to have invented some sort of talking head in the Middle Ages, and Josef Faber created in Vienna in 1860 a

talking man with ivory reeds for vocal cords, a rubber tongue and lips, and with a keyboard that altered the mouth cavity to control word formation. The most common technique, however, called for a human hand or clockwork to turn a cylinder embedded with pins that would strike or otherwise operate some sound-producing apparatus, such as the metal teeth of a music-box comb; the hammers, quills, or pipes of a keyboard instrument; or the clappers of a set of bells. Automatic carillons are known from the 1300s, automatic harpsichords and organs, from the 1500s. King Henry VIII of England owned an automatic virginal; his daughter Queen Elizabeth I in 1593 sent the sultan of Turkey an elaborate musical clock. Every six hours it played a tune on 16 chimes, followed by a two-trumpet tantara, then by an organ tune and performance by "a holly bushe full of birds and thrushes, which at the end of the musick did singe and shake theire winges." In the 19th century, Queen Victoria of Great Britain owned a bustle that would play "God Save the Queen" when she sat down.

Some of the most illustrious composers in the history of music wrote for mechanical devices. Haydn wrote tunes for musical (pipe organ) clocks; Mozart wrote several pieces for mechanical organ; and Beethoven wrote his *Wellington's Victory* (or *Battle Symphony*) for the panharmonicon, a full mechanical orchestra invented by Johann Nepomuk Maelzel (Mälzel), a German musician who specialized in mechanical musical devices of this type.

At the end of the 19th century, two inventions superseded the barrel-and-pin mechanism. One was the player piano, which used a perforated cardboard roll to control a stream of air that activated the piano's hammers. This had the advantage of enabling pianists to record their performances for future playback, and many virtuosos and composers took advantage of this device, among them Ignacy Jan Paderewski, Edvard Grieg, Claude Debussy, and Sergey Rachmaninoff. Some composers, including Igor Stravinsky and Paul Hindemith, wrote music especially for the piano roll, using devices such as combinations of as many as 30 notes played simultaneously; while impossible for two hands, such chords could readily be played by the perforated paper.

The player piano

The second invention, which was to make obsolete all previous music-reproducing apparatus (except in toys and cuckoo clocks), was the phonograph.

The impact of recording. *On composition.* In 1967 a survey of hundreds of American composers indicated that they were almost unanimous in regarding the recordings of their works as being more important than either printed publication or live performances. Through recordings, composers gained not only an easy familiarity with the music of others but also a new medium for their own works.

The contemporary American composer and teacher Milton Babbitt, in a conversation in 1965 with the Canadian pianist Glenn Gould (who maintained his own reputation largely by means of records and broadcasts, rather than by concert performances), said:

> We have all been affected as composers, as teachers, as musicians by recordings to an extent that cannot possibly be calculated as yet. . . . I don't think one can possibly exaggerate the extent to which the climate of music today is determined by the fact that the total Webern is available on records, that the total Schoenberg is becoming available.

The use of the record as a medium had superficial beginnings as early as 1904 in Ruggero Leoncavallo's song "Mattinata," specifically written for the record according to the label. Later, in 1925, Igor Stravinsky composed a piano piece, *Serenade in A Major,* expressly for the record medium, though it is also perfectly capable of being performed live. Ottorino Respighi's *Pines of Rome* (1924) incorporates a recording of a nightingale's song in its third movement. Much more important use of recording as a medium occurred toward midcentury, in works fundamentally relying on recorded tape, such as Edgard Varèse's *Poème électronique,* an 11-channel tape played through 425 speakers at the 1958 Brussels World Fair, and Morton Subotnick's *Silver Apples of the Moon* (1967), an electronic work playable only as a recording.

On teaching. In music education the phonograph was early adopted as a tool in teaching both serious students and laymen. Teachers who could not adequately illustrate musical examples at the piano found in records a means of demonstration. They could also bring entire orchestras into the classrooms by means of the phonograph.

In 1930 the *Columbia History of Music by Ear and Eye,* a phonographic survey that became popular in music history classes, enabled many students—as well as many of their teachers—to hear for the first time such instruments as viols, lutes, virginals, clavichords, and harpsichords, together with the then little-known music written for them. A half dozen years later another educational recorded project, *L'Anthologie sonore,* added impetus to this specialized field. By the 1960s, the Baroque music of the 17th and 18th centuries—as well as the earlier music of the Renaissance and medieval era—increasingly was recorded in performances using the instruments for which it was written. Such music found a wide audience beyond educational institutions; this audience was developed in large part by the phonograph.

Recorded histories of music

By the 1970s many conservatories, colleges, universities, and even some secondary schools had constructed recording studios to enable students to analyze their own performances or to rehear their own compositions.

On criticism. Records also enabled music critics to expand their knowledge, and for the better critics their perspective, of music and performance practices. Unfortunately, a record collection also allows reviewers to write on superficial differences between performances with very little expenditure of intellectual energy. New music has suffered especially from the resulting loss of the ability of many critics to expostulate on music for their readers.

On concerts. The impact of recordings on the concert hall has also been enormous, both for classical and for popular performances. Performers today can hardly hope to attract a concert audience if they have not produced distinguished recordings; usually, their audiences, both at home and abroad, consist of persons who know the performers' work through recordings. In the popular music field especially, many performers cannot compete in live appearances with recordings in which they depend heavily on technical aid. There are some who feel that the phonograph may cause the demise of the concert hall, which, if it survives at all, will do so for social rather than musical reasons. A possible indication of this trend is the disappearance of independent nonacademic nonprofessional classical music magazines in America; instead, there are record magazines. Their name changes are significant. *The American Record Guide,* established in 1935 as *The American Music Lover*; *High Fidelity,* established in 1951 (in 1965 it incorporated the last major concert–opera trade magazine, *Musical America,* into a combined edition); and *Stereo Review,* established in 1958 as *Hi Fi/Music Review.* The record magazine is not a peculiarly American phenomenon; England has *The Gramophone* and *Records and Recording*; France, *Diapason Microsillon* and *Harmonie*; Germany, *HiFi-Stereophonie* and *Fono Forum*; Italy, *Discoteca*; Holland, *Luister*; Belgium, *La Revue des Disques*; Sweden, *Musikrevy;* and Japan, *Record Geijutsu,* among many others.

On musicology. The entire field of comparative musicology—*i.e.,* the study of the relationships between Western, non-Western, and primitive music—depends upon disc and tape recordings. Although the discipline may be traced to the 18th century, it did not emerge from a primitive state until it acquired phonographic tools. Primitive music is generally transmitted orally rather than through a written tradition, and as such its performance practices—certainly in rhythm and intonation—cannot be accurately transcribed into Western notation. Since World War II, anthropologists and musicologists have visited the most remote parts of the world with tape machines to record aboriginal music before it was either tainted or wiped out by Western civilization. The most recent studies have been conducted as a race against time or more specifically against the transistor radio, a ubiquitous commodity that is homogenizing the world's musics.

The role of the producer. Although the record producer has at times become an equal partner with the musicians in creating the recorded performance of classical music, in the popular field he is frequently in total command. Here, in fact, the sounds produced by the musicians may simply be the raw material for the producer to work with; artificial sounds, overlays of sound upon sound, electronically introduced reverberation, multichannel effects with directional interplay and moving instruments, all may serve as vital ingredients of the recording. Paradoxically, as technological advancement brought the recording beyond the mere imitation of live performances, popular musicians began to bring complex electronic equipment into the concert halls to imitate the sounds of their recordings.

In productions of classical music, serious thought is given to whether the recording should faithfully capture the performance as heard from the optimum position in the concert hall or studio or whether the recording setup should be used to "enhance" the performance. Few question any longer the common practice of correcting actual mistakes. Ever since magnetic tape made detailed editing possible, extra takes have been made of sections in which musical problems are evident. The best taping of each section is spliced into a master tape. Even in recordings made during an actual concert, performers sometimes return to the hall afterward to emend any blemishes. The improvements in recorded performances made possible by tape splicing, however, often mislead audiences into anticipating the same perfection in live performances. Also, although tape editing facilitates the excision of poor passages that, while acceptable in the heat of a concert, would become irritating upon repeated hearings, it also has been said to hamper the continuity of the performance. It is unlikely, however, that a listener can spot the rare movement that has required no splicing from the majority that have. This alleged lack of continuity, however, was much worse when music had to be recorded in five-minute segments, for recordings at 78 revolutions per minute.

Microphone placement

Microphone placement has been perhaps the major criterion in separating the "natural" or "re-creative" from the "creative" technique of large-scale classical recordings. In a natural setup, microphones are placed in the optimum positions in the hall—often directly over the conductor—in order to re-create the concert-hall or opera-house effect. In the natural arrangement, the conductor is responsible for instrumental and vocal balances.

Some record-producing companies prefer to put microphones closer to the performers—the so-called close-miking technique. Here the record producer—generally with the final approval of the conductor or leader—is responsible for balances, for bringing out particular instrumental or vocal lines, in other words, for participating in the interpretation. Studio-made popular recordings —other than those of a lush semiclassical nature—have generally used the close-miking technique; in some cases, each performer in a small musical group is assigned his own microphone. In a close-miked symphonic recording session, 18 microphones may be used: three for violins; one for cellos and basses (sometimes one for each); one each for woodwinds, brasses, timpani, snare drum and triangle, bass drum and cymbals, celesta or harp, and soloist; and from three to six for a chorus. Several separate recordings, or "tracks," each comprising the inputs of several microphones, generally are made at the same time, and the producer must balance the strength of these various inputs during the recording session. Until about 1960, two-track machines were ordinarily used; by 1970 eight-track recorders were in use, allowing much more subtle mixing of channels during the editing sessions subsequent to the actual recording. For popular music sessions, 16-track recorders are sometimes used. For stereophony, all the recording tracks must be edited and mixed to make the final two channels.

The record producer also determines the degree of separation between those two channels, and during a dramatic recording—an opera, for example—he may function as stage director in guiding the performers around the aural stage. In quadraphony (quadriphony), which has four channels, the controversy between natural and close-miked recordings persists; in classical music, when the two rear channels are used mainly for hall ambience, the arguments centre on the placement of the two front channels. Some companies, however, have begun to use the four channels as equal partners even in the classics. Columbia Records pioneered in this technique by placing the conductors Leonard Bernstein or Pierre Boulez in the middle of the orchestra, which is seated for optimum quadraphonic array rather than for optimum concert-hall effect. The introduction of quadraphonic discs in the early '70s found several systems competing for prominence, most notably Columbia's SQ disc, Japan Victor Company's CD-4 disc (RCA's Quadradisc in the U.S.), and Sansui's RM (also called QS) disc.

The development of musical recording. In 1877 the U.S. inventor Thomas Alva Edison heard "Mary had a little lamb" emanate from a machine into which he had just spoken the ditty. It was the first time a recording of the human voice had been reproduced, and the event signalled the birth of the phonograph. There was, to be sure, a long gestation period.

Edison sent representatives, machines, and cylinders to Europe almost as soon as he had invented the phonograph, and between 1888 and 1894 recordings were made by such notables as Alfred Tennyson, Robert Browning, and even Johannes Brahms, who played a Hungarian rhapsody. The first "celebrity" recording, however, was made in Edison's West Orange, N.J., laboratories when the Polish pianist Josef Hofmann, then a 12-year-old prodigy, paid a visit to Edison's studio in 1888. The German musician Hans von Bülow followed shortly after with a recording of a Chopin mazurka on the piano.

The first "celebrity" recordings

In 1894, Charles and Émile Pathé built a small phonograph factory in a suburb of Paris and began to record singers as eminent as Mary Garden. Within a decade their catalog boasted some 12,000 items, and their name became almost synonymous with the cylinder phonograph in Europe. Meanwhile, Emile Berliner, a German immigrant living in Washington, D.C., had filed a patent in 1887 for a "Gramophone," using a disc rather than a cylinder, and he began manufacturing Gramophones and discs in 1894. The disc had the commercial advantage of being more easily manufactured than the cylinders. One of his representatives established a branch in London, the Gramophone Company (in 1898), a branch in Berlin, Deutsche Grammophon A.G., and one in France, the Compagnie Français du Gramophone, while Berliner's brother set up a disc-pressing facility in Hamburg. Most of Europe's recording industry thus was started by Berliner's representatives, and in the United States the small Berliner organization was to turn into the giant Victor company.

By the beginning of the 20th century, recording industries had been established in Germany, Austria, Russia, and Spain. Much of the managerial and technical talent, not to mention equipment, had been imported from America. (By 1970, the positions would be reversed, with Europe in command of a major portion of the American market.)

During the 1890s, recordings had become popular primarily through coin-in-the-slot phonographs in public places. Talent was incidental to the novelty of the apparatus; most of the recordings were of whistlers, bands, comic numbers, ditties, ethnic routines, and the like. In the first years of the 20th century, Victor and its affiliates raised cultural expectations with its Red Seal series (Red Label in Europe), particularly with discs made, beginning in 1902, by the Italian tenor Enrico Caruso. By 1910, the vast majority of record sales—some estimates are as high as 85 percent—were classical.

The Red Label had been initiated in 1901 in Russia with some of the first ten-inch disc recordings made, and the basso Fyodor Chaliapin was among the first artists to record on the new Russian Red Label.

In 1902, Victor and another major label, Columbia, decided to help the development of the new industry by pooling their patents. Victor was thereby legally able to record on wax (which would then be electroplated) for

the first time, and the new wax discs were then used in recording Caruso in Milan. Caruso's discs were a major catalyst in transforming the amusing gadget of a phonograph into a respected cultural phenomenon. That same year the new series received London-made recordings by stars of the Covent Garden opera house, primarily through the efforts of the Gramophone Company's music director, Landon Ronald, a bona fide serious musician and conductor who was able to convince his colleagues of the musical worth of the Gramophone. One instrumentalist also appeared in the new Red Label series, the Czech violinist Jan Kubelík.

In America, Columbia followed suit in 1903 with its ten-inch Grand Opera Records, recording the Metropolitan Opera stars. Shortly after, Victor began its own celebrity recording sessions of opera stars and others on 3½-minute 12-inch discs. Victor also made many of its associate European companies Red Label recordings—which included Mary Garden singing music by Debussy with the composer at the piano—available in the U.S. on its Red Seal series. Columbia soon dropped its opera series when the recordings did not sell as well as songs and marches, but Victor saw an institutional value in the celebrity recordings. The prestige of the Red Seal rubbed off on Victor's other products: "Victrola" became, in the popular mind, almost a generic term for the (disc) phonograph, and the company practically monopolized the quality-minded market for many years. Indeed, the total Western Hemisphere record market became virtually monopolized by Victor and Columbia, while their London affiliates controlled the rest of the world. The first major break did not come until World War I, when ties were severed with the Deutsche Grammophon of Germany, which emerged after the war as the independent Deutsche Grammophon Gesellschaft (DGG).

Between 1907 and 1910 Columbia tried to approach Victor's cultural prominence by releasing records from Europe, later by reinstating its own recording sessions with operatic singers. Columbia also began issuing double-sided discs, as had already been done in Europe. Victor did not do so until 1923.

During the early days of recording, both the cylinder and the disc were produced acoustically rather than electronically. A singer would sing into a horn, and his accompanist behind him played a piano placed on a platform so that the rear of the instrument—with the back removed—would also be level with the horn. With the development of a sound box to be placed on violins and violas, small orchestras could be used as accompaniment, but bassoons were required to play the cello part and a tuba the double bass part. It was an event worthy of a London newspaper announcement in 1904 when the Czech violinist Jan Kubelík made two records with his own Stradivarius, rather than on a violin with the sound box. When symphonic recordings came to be made, the wind and brass instruments still played or doubled the parts written for the lower strings, which could not be reproduced adequately. Although acoustical recordings were improved by the 1920s, the problems were not overcome until the introduction of the microphone and the consequent electrical recording process around 1925.

Birth of a mass medium

In the decade 1910–20, the phonograph became a truly mass medium for popular music, and recordings of large-scale orchestral works and other classical instrumental music proliferated. The rise of the popular record coincided in the U.S. with the new ragtime, popularized by Scott Joplin's rags at the turn of the century and sensationalized by Irving Berlin's "Alexander's Ragtime Band," written in 1910, which swept the country the following year. It stimulated an unprecedented dance craze at a time when the phonograph was becoming increasingly available. As the fad spread to millions who had never danced before, phonographs were sold to people who had never owned records before. Between 1914 and 1919, phonograph sales increased more than fivefold. In 1917, Victor issued the first jazz recordings, by the Original Dixieland Jass (sic) Band, but few major jazz releases appeared before the 1920s.

The first large-scale symphonic recording, Tchaikovsky's *Nutcracker Suite*, was issued in 1909 in England. The first attempt to record a concerto came the following year, also in London, when Wilhelm Backhaus recorded a cut version of the first movement of Grieg's *Piano Concerto*. In 1913, the first complete symphonies, Beethoven's *Fifth* and *Sixth*, were recorded in Germany under an anonymous conductor; later that year, a celebrity conductor, Arthur Nikisch, led a full-scale symphony for the first time, again the Beethoven *Fifth*. Solo instrumentalists vied with the opera singers for the record-buying public's affection, mainly by recording tidbits. In 1917, Victor began to record with a combination that was to prove its star classical music attraction for decades: Leopold Stokowski and the Philadelphia Orchestra.

The serious recording of serious music became a growing phenomenon as the phonograph matured during the early 1920s. Tidbits and orchestral snatches gave way to a spate of uncut symphonies, sonatas, quartets, and concertos; the music itself came to mean as much as its star performers, and the electrical recording process, from 1925 on, raised the quality of the recordings as well. But the mid-'20s also saw the rise of radio, which provided free music, and this new factor, plus the worldwide economic depression of the '30s, threw the phonograph industry into serious decline.

The companies realigned themselves. In 1929 the Radio Corporation of America (RCA) bought Victor. Later that year, Edison left the phonograph business he had created. In 1931 the English Columbia Graphophone Company divested itself of its near-defunct American progenitor and joined the Gramophone Company to form Electric and Musical Industries, Ltd. (EMI), bringing into the merger nearly every important European firm except Deutsche Grammophon Gesellschaft (DGG) and its export label, Polydor. American Columbia was revived by its purchase, in 1938, by the Columbia Broadcasting System.

During the 1930s, as the American companies relied mainly on dance records in jukeboxes (*e.g.*, coin-operated devices in public dance halls, taverns, and the like) to satisfy a dwindled market, Europe supplied a slow but steady trickle of classical recordings. In 1931 the HMV label in Great Britain began its "Society" issues: a limited public was asked to subscribe in advance to then esoteric releases—the complete Beethoven piano sonatas played by Artur Schnabel or Pablo Casals performing the Bach unaccompanied cello suites. A new British company, Decca, organized in 1929, also began to issue serious recordings. In the United States, Columbia began to record a number of distinguished orchestras, including those of New York, Chicago, Cleveland, and Minneapolis. RCA retained its leadership, however, with the Philadelphia Orchestra under Eugene Ormandy, the Boston Symphony Orchestra under Serge Koussevitzky, and—perhaps the greatest orchestral combination ever assembled—the NBC Symphony under Arturo Toscanini, as well as with the violinist Jascha Heifetz and the pianist Vladimir Horowitz.

British Decca had a far reaching role to play after World War II when its "ffrr" full frequency range recording became internationally known. The frequency range of discs had been dramatically extended, and Ernest Ansermet's recording of Stravinsky's *Petrushka* in the new process was to awaken the unsuspecting ears of many record collectors in 1946 to the future high fidelity, or "hi-fi," possibilities of the phonograph.

Two other late-1940s developments combined with the extended frequency range to produce a radical change in the development of recordings: magnetic recording and the long-playing (LP) record. In 1948 Columbia Records demonstrated 12-inch unbreakable vinyl discs that could play about 25 minutes of music per side. The standard shellac disc had revolved at 78 revolutions per minute, and a 12-inch disc had to be changed, automatically or manually, every five minutes, thus breaking up the continuity of longer works; the 12-inch LP, revolving at 33⅓ revolutions per minute, could hold the average symphony, sonata, or quartet on a single side. And the vinyl discs had quieter surfaces than the shellac. Victor soon countered with its own microgroove records: seven-inch vinyl

discs at 45 revolutions per minute. Each contained approximately as much music as a 12-inch 78-revolution-per-minute disc, but the package was smaller. By 1950, a pattern had been set: 12-inch LPs for classical works and popular albums, 45s for individual popular songs. Extended-play 45s also were developed and successfully merchandized. The LP opened up an entire new market —not only newcomers but older record collectors who could see the advantage of the new technology and were willing to repurchase their collections as LPs. The 78-revolution-per-minute shellac disc followed the cylinder into oblivion.

Tape had a major impact on recording starting in the late 1940s: anyone with a good recorder and microphone could become a record producer. Small companies sprang up in areas of music ignored by the giants: the esoteric and the avant-garde, the music of the periods before and after the highly popular Romantic classics of the 19th century. Chamber music, as well as Baroque works of the 18th century and earlier, which required paying fewer musicians than an entire symphony orchestra, flooded record stores and resulted in an unprecedented Baroque revival among music lovers. All-Vivaldi concerts were sold out, and Bach became a best seller. Orchestral recordings of less familiar works—produced in a Europe that had been ravaged by World War II, where musicians' fees were minimal—crested the flood. New companies recorded for the first time many symphonies, quartets, masses, little-known operas, and many other once esoteric works, some of which were now available in competing versions. The more popular standard works, the symphonies of Beethoven, Brahms, and Tchaikovsky, became duplicated by the dozens. By the mid-1950s it seemed that practically the entire worthwhile musical output of Western civilization—and much from Asia and Africa—had been made available to the average home.

The stereo revolution

For a few owners of some deluxe tape recorders, a new listening experience was available by 1956: stereophonic tape recordings. Within two years, stereo discs made their commercial appearance; every major U.S. company began issuing stereo discs by the end of 1958.

Now a new flood of records hit the market: notably popular were those that displayed the spectacular effects possible with stereo. It was again Decca/London that convinced the serious music lover of the musical benefits of stereo with the release in 1959 of Wagner's *Rheingold*, conducted by Georg Solti, a pioneer work in the "creative" school of classical record production. Within a decade, two complete recordings of Wagner's *Ring* cycle, comprising four complete operas on 19 discs, were available. Again, as with the advent of the LP, a technical advance spurred the record industry into recording an even greater repertoire than was available previously. By the late 1960s, most American record companies had discontinued their monaural recordings, except for "historical reissues."

The 1950s saw a rearrangement of record company alliances, as Europe began its strong invasion of America. By the 1970s not only did Europe own a sizable chunk of the American record industry, but it had taken over the recording, for the first time, of many of the most prestigious U.S. orchestras.

Another far-reaching phenomenon of the 1950s was Elvis Presley, a popular U.S. singer who inspired a new, militantly youth-oriented style of music: rock and roll. It generated a multitude of solo singers and groups as well as a teenage and subteen culture of rabid record buyers. The success of the British rock group the Beatles helped stimulate record sales in the 1960s to an all-time high. The sales of classical records, however, represented a declining portion of the total. It seemed that most people who wanted the standard classics had already bought them and that few new standard works of any length were being written. Rather than new classical recordings, re-releases were issued in new packages (*e.g.*, "Debussy's Greatest Hits") and in the new medium of tape. During the mid-1960s, two small and conveniently packaged tape formats began a steady rise to popularity: the continuous-loop one-reel cartridge and the two-reel cassette.

Cartridges, cassettes, and video-tape

Each obviated the need for threading tape in order to play it. The cartridge first achieved consumer acceptance as an automobile accessory and was designed primarily as a playback-only format; the cassette configuration was first introduced in an inexpensive portable recorder player.

Cassettes had the advantage over continuous-loop cartridges in being rewindable and thus easier to control for selective "spotting" and for amateur recording. For non-selective music or music in which it is not necessary to start at the beginning—background music, for instance —the continuous-loop cartridge had the advantage of not having to be rewound at all. A new potential appeared in recording music with the addition of television. Videotape cartridges and cassettes were studied by most major record producing companies, and a number of artists experimented with video productions, including the U.S. orchestral conductor Leonard Bernstein, who recorded the Verdi *Requiem* for a video cassette, and the Italian opera and film director Franco Zeffirelli, who directed a video production of Beethoven's *Missa Solemnis* at St. Peter's in Rome. Opera appeared to be the most likely musical genre for video, if the size of the television screen could be made commensurate with the grandeur of the productions. The grafting of images onto the great tradition of Western music will probably require genius comparable to that of the great composers themselves.

BIBLIOGRAPHY. ROLAND GELATT, *The Fabulous Phonograph: From Edison to Stereo*, rev. ed. (1966), the best written, general history of the phonograph, particularly good on the complex corporate developments; OLIVER READ and W.L. WELCH, *From Tin Foil to Stereo* (1959), a scholarly and detailed phonographic history with much elucidation of technical matters, including a reproduction of the original Edison patent and a "genealogical" chart of companies; F.W. WILE, *Emile Berliner: Maker of the Microphone* (1926), an adulatory, but worthwhile biography; FRED GAISBERG, *The Music Goes Round* (1942), an autobiographical account of the history of the phonograph by a man associated with Berliner from the earliest days (a valuable source despite many inaccuracies); MATTHEW JOSEPHSON, *Edison* (1959), a thoroughly researched biography of the inventor of the phonograph; JOSEPH BATTEN, *Joe Batten's Book: The Story of Sound Recording* (1956), another personal documentation of early phonographic history, not as far-ranging as Gaisberg's but with much unduplicated material.

(L.M.M.)

Music, Theatrical

Music as an art of the theatre has its roots in primitive ritual and ceremony and its branches in every modern means of theatrical presentation. Its functions are as varied as the forms require and range from being the primary reason for performance, as in opera, to mere noise, filling a vacuum in imagination for some screen and stage presentations. The more significant and universal aspects of theatrical music are considered in this article; opera is the subject of a separate article.

Theatre music is all music composed to govern, enhance, or support a theatrical conception. Music composed for theatrical purposes obeys different laws than does the music for concert performance or conventional opera. Whereas in opera the music dictates the form in which the dramatic visual imagery is presented and governs its development, in other kinds of theatre the music is, at best, an equal partner among its principal elements. In concert, of course, the music is the sole factor that determines the experience.

In the West, the concept of music as an intellectual experience for its own sake emerged only in the second half of the 18th century. Theatrical music is variously related to something other than itself, whether as an enrichment of words (as in operetta), a factor in structure and mood (ballet), or an intensification of situation and feeling (as in incidental music for plays and films).

In some instances music is dominant, in some it is subservient, and in operetta or stage musical the emphasis alternates between speech, song, and dance. In opera and spoken drama, in which words are wholly sung or spoken, a convention once set is consistently sustained and thereby creates its own kind of reality. The constant change of focus in operetta and musical, from music to

speech and back again, emphasizes the artificiality of the illusion they seek to create.

The classical mainstream of theatre music in the West extends from the mid-17th century to the 1930s, and the instances of drama and music meeting on an equal level of imagination are relatively few. More frequently great music was lavished on weak or corrupt theatre, or great drama was embellished with indifferent music. From the early 20th century new dramatic developments were seldom directly matched in music. A German–Italian composer, Ferruccio Busoni, wrote in 1906:

> The greater part of modern theatre music suffers from the mistake of seeking to repeat the scenes passing on the stage, instead of fulfilling its own proper mission of interpreting the attitudes of the persons represented.

The German composer Kurt Weill's score for *Der Silbersee* (1933; *The Silver Sea*) was the last major musical contribution to a serious play requiring a full orchestra and chorus. Thereafter, for economic reasons, the dramatic theatre had to equip itself with small-group music or prerecorded tapes. The orchestra and chorus became the prerogative of stage musicals and films. The more these were commercially debased the more they came to rely heavily on the clichés of 19th-century music, to the exclusion of newer musical developments.

Producers of stage musicals, the choreographers of dance, and the directors of drama need to be wary of the properties of music. It is more demanding of attention than is often thought, and its use should ideally be confined to circumstances where it can provide something that none of the other theatrical elements can offer. The more its qualities are understood and respected, the better it can be guided to an effective theatrical purpose.

Types of theatrical music

MUSIC FOR BALLET

The partnership of choreography and music

During the 20th century the element of music in all forms of ballet has changed and developed its significance to an unprecedented extent. It has acquired the status of an equal partner with the choreography, where once it was entirely the servant of the ballet master. In the 19th century he asked little more than that the music should decorate his ballets prettily and give rhythmic support to the dancers. His modern successors have been made aware that the highest level of balletic achievement now requires the music and choreography to become extensions of each other, to be heard and seen on equal levels of perception.

The finest modern choreographers are not content simply to ride the surface of their chosen music, whether it is specially written, borrowed, or adapted. They seek to exploit the relationship of eye and ear, recognizing that the effect of any danced step can be changed by the stress of the musical rhythm, the degree of loud or soft in its dynamics, the nature of its harmonic character, and the expressive quality of its instrumental timbre. All these factors can make a positive contribution to the balletic image, and they give coherence to the sequence of movement as they merge into its continuous momentum.

Until the end of the 19th century each new ballet customarily had music specially composed for it, but it was rare for any composer of distinction to write ballet music, unless it was part of an opera. There were exceptions—such as Beethoven's score for *Die Geschöpfe des Prometheus* (1801; *The Creatures of Prometheus*), originally a ballet by an Italian choreographer, Salvatore Viganò—but the great era of Romantic ballet from about 1830 was seldom enhanced by music of intrinsic worth. When ballet gained a musical interest the difference was soon apparent; it has been well said that Léo Delibes gave ballet music a heart, Peter Tchaikovsky gave it a soul, and Igor Stravinsky made an honest woman of it.

Stravinsky's influence on music for ballet

Stravinsky was the dominating figure for nearly half a century (beginning in 1910) in composing music for ballet. He gained international acclaim with the first products of his collaboration with the Ballets Russes of the Russian impresario Sergey Diaghilev: *The Firebird* (1910), *Petrushka* (1911), and *The Rite of Spring* (1913). The first two continue to be performed in their original choreography by Michel Fokine, also a Russian, each with a narrative basis illustrated in music notable for its expressive colour and harmonic innovations. *The Rite of Spring* provoked one of the most notorious scandals in theatre history when Vaslav Nijinsky's original ballet reduced its first Paris audience to verbal insult and physical assault; its rhythmic audacity has since remained a recurring challenge to other choreographers.

Largely as a result of the standard set by Diaghilev's flair and artistic success, most leading composers in the 20th century have contributed something to the art of dance. Diaghilev directly commissioned two outstanding examples in the French composer Maurice Ravel's *Daphnis et Chloé* (1912), which the composer defined as a "poème choréographique," and *The Three-cornered Hat* (1919) by the Spanish composer Manuel de Falla. Distinctive original scores for ballet continued usually to be the outcome of specific commissions. Composers do not yet normally think in terms of dance (as they do in terms of song), although in Great Britain the composer Peter Maxwell Davies has incorporated an integral role for solo dancer in his otherwise instrumental work, *Vesalii icones* (1969).

Contrary to what is still sometimes thought by musicians and a section of the public, music for ballet is not necessarily written to be "interpreted" in dance. Stravinsky has emphasized:

> Choreography must realise its own form, one independent of the musical form though measured to the musical unit. Its construction will be based on whatever correspondences the choreographer may invent, but it must not seek merely to duplicate the line and beat of the music.

Stravinsky's collaboration with Balanchine

The composer was writing from the experience of a long collaboration with a Russian-born choreographer, George Balanchine, mainly for what is now the New York City Ballet. Their partnership began in 1928 with *Apollo*, reached a peak in 1957 with *Agon*, and has been to the 20th century what the collaboration of Tchaikovsky with choreographers Marius Petipa from France and Lev Ivanov from Russia was to the 19th.

In the Soviet Union a post-revolutionary equivalent to the classical three-act narrative ballet has continued to be in demand. This form has been furnished by many composers of ballets that have not been performed beyond the U.S.S.R., but it has been chiefly distinguished by the work of Sergey Prokofiev. His full-length scores for *Romeo and Juliet* (1940), *Cinderella* (1948), and *The Stone Flower* (posthumously staged in 1954) have variously succeeded in reconciling an older classical form to new expressive demands. Its offshoots in western Europe have included, in Great Britain, Benjamin Britten's music for *The Prince of the Pagodas* (staged by the Royal Ballet, 1957) and, in Germany, Hans Werner Henze's music for *Ondine* (Royal Ballet, 1958).

The stronger emphasis in western Europe and the United States is currently on one-act ballets, varying from about 15 minutes to more than one hour's duration. Composers continue to show some reluctance to write music specifically for dancing, partly because they are seldom closely involved with the art, and also because they have relatively less control over the finished performance than in opera and in most other forms of musical theatre. Apart from works already mentioned, however, the ballet repertory has been enriched by such scores as the French composer Erik Satie's *Parade* for Diaghilev in 1917; the British composer Vaughan Williams' *Job* (1931) and the English composer Sir Arthur Bliss's *Checkmate* (1937) for the British ballet mistress Ninette de Valois, in Britain; and the U.S. composer Aaron Copland's *Appalachian Spring* (1944) and the American composer Samuel Barber's *The Serpent Heart* (1946; later revised as *Cave of the Heart*, 1947) for the ballet mistress Martha Graham, in the United States.

Creation of modern ballets to existing scores

Nevertheless, the greater proportion of new ballets in the West during the last half-century have been created to pre-existing music, and it is evident that choreographers have felt a greater freedom to experiment visually in the use of such music. The practice dates principally from the first orchestration (by the Russian composer Aleksandr

Glazunov, 1894) of an arbitrary suite of piano music by Frédéric Chopin to which Fokine created *Chopiniana* (1908)—a title retained by Soviet ballet companies for what Diaghilev renamed *Les Sylphides* (1909). More than 60 years later, another arbitrary suite by Chopin, although retained in its piano form, proved to be no less fruitful for the U.S. choreographer Jerome Robbins in *Dances at a Gathering* (1969).

Almost every category of music—from medieval music to advanced electronics and from symphonic compositions to the simplest pop tunes—has now been used for choreographic purposes. The function of music in a dance context has varied almost as much—staining the ballet's surroundings as a kind of aural decor at one extreme, as with the soundscapes of John Cage for Merce Cunningham's dance works in the United States, to the mutual absorption of music and choreography phrase by phrase in such works as British choreographer Sir Frederick Ashton's *Symphonic Variations*, French composer César Franck's music (Royal Ballet, 1946), and the Balanchine–Stravinsky *Movements* (New York City Ballet, 1963).

Sometimes the same music has been used for several different ballets within a short time by various choreographers. An outstanding example is the *Sinfonia* by an Italian composer, Luciano Berio, written originally in 1968 as a concert work. By the end of 1971 it had been taken over for at least eight separate ballets in almost as many countries in western Europe alone.

Another trend in ballet in the second half of the 20th century has been to make ballets apparently more concerned with musical associations than with human personality. Instances include Balanchine's *Agon* and *Movements*, already mentioned, and the British choreographer Kenneth MacMillan's *The Song of the Earth* (1965) to the song-symphony by the Austrian composer Gustav Mahler. The dancers seem required to assume the "personality," or expressive character, of the musical instruments they parallel, as if the choreographers were moving toward a form of "ideal" dance once postulated by a French poet, Stéphane Mallarmé, who envisaged music and dance not only as equals but also equally devoid of human personality.

Ballet concerned with musical associations

In the view of most ballet critics, the antidote lies in the continuing appeal of narrative dance-dramas with their illustrative music, although the success or otherwise of any ballets that engage pre-existing music is basically governed by a single crucial principle: the level of choreographic imagination should never be less than that of the music. A ballet can be better than its music, but it can never afford to be worse. There will always be ballets dependent on music for no more than expressive colour and supporting rhythm, but the "perfect analogous concord between what we see and what we hear," recommended as the ideal nearly 150 years ago by Carlo Blasis, a great Italian teacher, still remains the most desirable aspiration for every kind of ballet music.

STAGE MUSICALS

When, in the 1930s and 1940s, dancing became an integral element in a genre governed chiefly by song—instead of being merely a diversion—the "musical" established itself as the legitimate theatrical heir to "musical comedy" and a form of popular theatre art that dominated the third quarter of the 20th century. It has lately been challenged by the newer "rock musical," using a variation of the common musical vernacular and techniques related more to the recording studio than to the theatre, the effect of which is not yet determined. Meanwhile, what originally started as a democratic counterpart to aristocratic opera reached its fruition as the theatrical association of sentiment with illusion.

The sentiment is usually dispensed by the narrative; the illusion is created by the music. The most potent narratives in stage musicals have often been adaptations of classical drama and literature—for example, *Romeo and Juliet* transformed into *West Side Story*; *The Taming of The Shrew* into *Kiss me, Kate*; *Don Quixote* into *Man of La Mancha*; and *Oliver Twist* into *Oliver*—or the many variations on the *Cinderella–Pygmalion* legend by which rags are transformed into riches (from *The Shop Girl* in 1894 to *My Fair Lady* in 1956). A distinction was at one time drawn between the frivolous musical comedy and the "musical play," denoting a dramatically serious or even tragic narrative, but both are now equally defined as musicals.

Their specifically musical character is born from a marriage of convenience between first and second generation descendants of European operetta and music-hall variety, on the one hand, and American jazz and American music hall, on the other—plus the romantic balladry of both continents. An English musicologist, Wilfred Mellers, asserts that although most successful stage songs contain subtleties unappreciated by the non-musical listener, they all reflect "an illusion that we can live on the surface of our emotions" and that "the world of musical comedy never gets beyond, or wants to get beyond, this illusion."

The first musical comedy so to be called was *A Gaiety Girl*, staged in 1893 by George Edwardes at the Gaiety Theatre, London. A romantic farce, adorned by the songs of Sidney Jones, it was successfully exported to New York in the same year. John Hollingshead (Edwardes' predecessor at the Gaiety Theatre) wrote in 1903:

First musical comedy

> The invention or discovery of musical comedy was a happy inspiration of Mr. George Edwardes's. It provided a new form of entertainment for playgoers who go to a theatre for amusement and recreation, which was more elastic in plot or story than the old burlesque. . . [It] exhibited a little of the old burletta and vaudeville, most of the best elements of farce, a dash of the French revue. . .and much that would not have been out of place in Parisian *opéra-bouffe*.

Some 50 years of development in musical theatre is reflected in the contrast between the foregoing remarks and the following comment in 1952 by Jack Burton, U.S. theatre historian, on *Oklahoma!* (1943), an epoch-making musical by Richard Rodgers and Oscar Hammerstein:

> This phenomenal production set a new pattern in which every line, every song, every dance routine is an indispensable part of a closely-knit whole. It was a show that had dramatic substance and never ran off the plot track, and so real, so simple, so engrossing was its story that its narrative could be safely entrusted to other than big-name stars.

The years embraced by these comments set up a dominant axis of theatrical exchange between New York and London. Success in this field is governed more by economic than artistic considerations, with longer and longer runs of each production becoming necessary to recover increasingly heavy expenditures before profits can be made. The primary requirements for the composer are, therefore, quick assimilation combined with durability. His music should also be easily adaptable to other media such as motion pictures and phonograph or tape reproduction, whereby it becomes a commonplace of experience to a mass audience far beyond the reach of the original theatrical context.

Although musical theatre of this kind has developed toward a closer integration of music and story, its primary feature has remained the individual song. Lehman Engel, a leading conductor of stage musicals in the United States, has defined five types of song basic to the stage musical: ballad—usually but not exclusively romantic in feeling; rhythm song—varied in emotional character but primarily propelled by a prominent musical beat; comedy song—enhancing verbal humour and divided into "short joke" and "long joke"; charm song—generally delicate, optimistic, and lightly rhythmic; and musical scene—in which a song may form part of a continuous dramatic episode. Engel further asserts that the successful impact of any song in the first instance is generally governed by the following considerations: the tempo, the mood of the scene, the song's position in relation to the whole production, the inherent value of the song itself, and the relative importance of the character who delivers it. It will be noted that integral musical quality is subordinate on this scale, although it is specifically the musical appeal that establishes success in the first place, disseminates that success through other media, and may later lead to revi-

val in the country of origin and to reproduction in other countries.

Success of *My Fair Lady*

Probably the most successful specimen to date is *My Fair Lady*, with music by Frederick Loewe, Vienneseborn U.S. composer. This musical had first runs of 2,717 performances in New York (from 1956) and 2,281 in London (from 1958), and it has since been staged in translation in most European countries and in the Soviet Union. It is rare for the English-language dominance of the musical-comedy genre to be breached by other countries, as France did with *Irma la Douce* (1956) or pre-Nazi Germany did with *Die Dreigroschenoper* (*Threepenny Opera*, 1928) and *Im weissen Rossl* (1930; *White Horse Inn*); but in most European countries except Britain the line between musical and operetta (see below) is less distinctly marked.

In Italy such lighter forms of musical theatre are submerged in an already popular taste for the broadest range of opera, while in Spain they manifest themselves in the category of zarzuela (discussed below in conjunction with operetta). Differences of idiom are often more the outcome of theatrical or other conditions in their respective countries than of theatrical or musical distinctions in the work itself. In the Soviet Union, according to Andrey Olkhovsky, a Russian-born musicologist,

> the numerous attempts which have been made to create a Soviet repertory have led to no results. At best the plots of comedies are based on episodes from Soviet life, but musically they are still imitations of the pre-Revolution operettas.

Stage musical comedies in the Western sense have produced their own original talents among composers—notably Jerome Kern, Irving Berlin, George Gershwin, Cole Porter, and Richard Rodgers in the United States; and Noel Coward, Vivian Ellis, Ivor Novello, Lionel Bart, and Sandy Wilson in Great Britain. They have also had occasional recourse to adaptations from classical composers, including Franz Schubert and Edvard Grieg, who are dramatically characterized respectively in *Lilac Time* (originally *Das Dreimäderlhaus;* 1916) and *The Song of Norway* (1944); Georges Bizet, whose music became the basis of *Carmen Jones* (1943); and Aleksandr Borodin, for *Kismet* (1953).

Musicals ought to be adaptable to varied instrumentation, because theatre orchestras can vary considerably in size and composition from place to place. Paradoxically, the looser form of the new rock musical is propelled by a much more rigid instrumentation derived from the ensemble used in pop-music recording, itself determined by studio techniques. In *Jesus Christ Superstar* (1971) the covering of the orchestra pit, the permanent amplification of instruments, and the use of voices entirely dependent on microphones amounts to a replacement of the illusion of theatre in any traditional sense with the actuality of modern recording studio made visible.

The arrival of the rock musical

MUSIC FOR MOTION PICTURES AND TELEVISION

Motion pictures. Many successful stage musicals have become additionally popular through the medium of motion pictures, but music as a basic element in film making has only gained recognition since midcentury as something more than a means to heighten local colour or intensify emotional expression. In the early silent films, all kinds of music were recorded, classified, and adapted to fit different moods (Beethoven overtures for cowboy–Indian chases, for instance). Several talented hacks also wrote short descriptive pieces. A few bigger films, such as *The Birth of a Nation*, had special scores fitted to them. Since the 1960s it has turned a full circle of the wheel back to extensive musical quotation from classical resources for similar ends but in different ways.

Russian film makers first gave serious consideration to the contribution music could make. V.I. Pudovkin, a Russian musicologist, defined a theory and practice of film music in the early 1930s, advocating a close and contrapuntal relationship between sound and sight. The Russian film director Sergey Eisenstein described his careful collaboration with Prokofiev in making *Alexander Nevsky* (1938). His perceptive observations on the potential link between cinematic rhythm and musical rhythm suggested a technique that has influenced others, such as the British composer Sir William Walton in his score for *Hamlet*.

Hanns Eisler's theories of film music

Hanns Eisler, a German-born composer, formed his own theories of film music, based on empirical experience composing in this medium. His published findings recommended: short musical forms in a film context; the composer's conscious awareness of the film's realistic sound element (the "where" and "when" of its location); and music that could suggest an objective, universal character for the film's emotions, rather than being introspective on its own account. Eisler also supported Pudovkin in maintaining that film music should create its own sense of line independently of, although related to, the film narrative.

Film music has travelled through five broad phases: an initial borrowing from existing conventional sources; the use of musical-cliché catalogs, which enabled any musician of modest ability to assemble an emotional or dramatic sequence and which served as the basis for most later background music in films; the active interest of major composers in writing original scores; a subsequent reaction of either near silence or advanced techniques of electronic sound generation and transformation; and the borrowing from classical sources for new purposes.

In the Soviet Union and France, in particular, the regular participation of leading composers in film music has been the rule rather than the exception. The opposite holds true in the United States and Great Britain, although most composers of distinction in both countries between the mid-1930s and the mid-1950s made some original contributions to motion-picture medium. In the United States these included Aaron Copland, Marc Blitzstein, and Virgil Thomson, who received the first Pulitzer Prize awarded to film music—for *Louisiana Story* (1948); in Great Britain, Ralph Vaughan Williams, Benjamin Britten, Sir William Walton, Alan Rawsthorne, and Richard Rodney Bennett.

Isolated experiments to marry films to specific classical music have been made from time to time. These include the Austrian director Max Reinhardt's film of Shakespeare's *A Midsummer Night's Dream* (1935), which varied the cinematic structure to incorporate the complete suite of Mendelssohn's incidental music originally written for the play. The U.S. film maker Walt Disney's celebrated *Fantasia* (1940) adapted the technique of the animated cartoon to illustrate a sequence of musical classics, outraging some people because the visual relationships were held to be irrelevant to the music but continuing into the 1970s to entertain audiences, especially young ones, on an international scale.

When the making of motion pictures became an industry more than a craft, a situation developed in which music was recognized as desirable by the manufacturers, who nevertheless made no claim to "understand" music in the way they would be expected to understand motion-picture techniques. A parallel attitude among musicians unfortunately came to regard the skilled provision of a score tailored to the demands of script and camera as a spiritually impoverished relation of aspiring symphonic or operatic works.

Renewed use of concert music

In the late 1960s original film composition tended to decline in favour of renewed and often extensive borrowing from existing concert music. The slow movement from a Mozart piano concerto served to express the passage of time as well as for emotional mood in *Elvira Madigan*. The U.S. film director Stanley Kubrick's *2001: A Space Odyssey* (1968), led an audience's imagination outward into space by a transition from the diatonic (using the natural scale of five tones and two semitones) C major of the introduction, to Richard Strauss's tone-poem *Also sprach Zarathustra*, to the polytonal Kyrie from the *Requiem* by the contemporary Hungarian-born composer György Ligeti. In the Italian film director Luchino Visconti's *Death in Venice*, four repetitions of a long passage from the Adagietto movement of the Austrian composer Gustav Mahler's *Symphony No. 5* achieved a different expressive purpose in association with the visual scene each time it was heard.

Examples like these achieved an even greater impact than many original scores because they formed an organ-

ic part of the film maker's conception. Conversely, even scores distinguished by their own merits—such as Copland's for *Of Mice and Men* (1939), or Walton's for *Henry V* (1944)—were added only after the film itself was more or less finished. The major hope for the future of this medium lies in what Vaughan Williams urged: the composition of original scores but prepared in conjunction with the director from the film's inception. Film music might then be turned to more constructive instead of merely decorative purposes, without the dramatic license of the British film director Ken Russell's treatment of extensive passages from Tchaikovsky's music in his film *The Music Lovers* (1971).

Television. The screen medium's first law, that the visual element must come first, has been intensified by television. On the home screen, the experience of music performed for its own sake customarily operates under a double disadvantage. First, it runs the risk of being swamped by its visual presentation, which may range in character from the matching of nonmusical images in varying degrees of relevance to the technique of using close-ups of musicians in action. Secondly, it suffers the continuing handicap of inadequate reproduction by the average television receiver.

Limited repertory of television music

Apart from rare exceptions—such as an occasional "television opera," a dance-film, or Stravinsky's mixed media *The Flood* (1962)—original music to television is chiefly confined to the provision of theme passages or supporting music hopefully intended to enhance verbal or dramatic presentation. Like the cinema pianist who played for silent films, television music has a limited repertory of conventional gestures. Even when these are given a more contemporary harmonic or instrumental garb, they remain basically governed by the 19th-century mode of musical thought, to which it is assumed that mass audiences will most easily react.

Programs about rather than of music have obtained a modicum of television success. While the occasional theme quotation has perhaps introduced a famous musical classic to millions who would not otherwise have heard it, the "workshop" program, showing how music and musicians go about their business, has broken down barriers of technique and exposed the raw materials of music in a way that has probably helped to foster a wider interest in the finished product. Television cannot otherwise be accepted as a musical medium, until sets have a higher standard of musical reproduction.

INCIDENTAL MUSIC FOR THE THEATRE

Incidental music in the theatre, whatever its idiom or degree of stylistic emancipation, justifies itself through its exclusive concern with a specific play or theatrical presentation. Its three main uses involve songs, intensified dramatic effect, and interlude filling, and these have been clearly defined in Western theatre since Renaissance drama freed itself from the church in the 16th century.

A major modification of its character since the 1920s has been brought about largely by the wider use of mechanical techniques of amplification and recorded music. This has encouraged short musical fragments rather than fully composed pieces, except where the latter are specifically called for. Examples of this technique were heard during the late 1960s and early 1970s in the musical productions of the National Theatre and the Royal Shakespeare Company in Great Britain. Such carefully planned but more informal use of incidental music has replaced the elaborate suites customary in the 19th and early 20th centuries, which presupposed the complete performance of each piece and required the stage drama to be produced so that the music could be accommodated in it (a characteristic example is Mendelssohn's music for *A Midsummer Night's Dream* at Potsdam, Germany, in 1843).

Informal incidental music

Economic conditions are now the principal factor governing the provision of incidental music. Theatres not concerned with opera or ballet can no longer afford to hire musicians for a pit band. Trade-union restrictions in the musical profession also limit the public use of recorded music in many countries. The trend is consequently for spoken drama either to dispense with music, to restrict it to one or two musicians with a singer, or to make increasingly fruitful use of electronic sounds on prerecorded tape.

Some famous 19th-century suites of incidental music were brought into being by conditions that favoured resident musicians at court theatres in Germany or lavish orchestral resources in Tsarist Russia. The music has since acquired independent status on its own merits and has become part of the classical concert repertory, such as the Mendelssohn just mentioned and Beethoven's music for Goethe's *Egmont* (1810); Schubert's for the German playwright Helmina von Chézy's *Rosamunde* (1823); Schumann's for Lord Byron's *Manfred* (1852); and Grieg's for Henrik Ibsen's *Peer Gynt* (1876).

Earlier theatre music was often, for long periods of time, governed by measures of censorship and legal restrictions that varied greatly from one country to another. In England, for instance, the monopoly of spoken drama was vested by King Charles II in the Theatres Royal in the 17th century, and this continued until 1843. Other theatres that opened during this time—including those catering to a new working class—were licensed only on condition that plays included five musical items in each act or a "musical accompaniment." The latter condition was sometimes held to be satisfied by no more than a chord struck at intervals on a piano during the performance. Such conditions inevitably brought about a profusion of inferior music, which in turn gave rise to the traditions of music hall and burlesque.

The renaissance of secular theatre, from the 17th century onward, led in Italy to the evolution of the predominantly musical forms of opera and oratorio, in France to the court ballet, and in England and Spain to the cultivation of spoken plays with incidental music. The unparalleled achievements of secular drama in the latter two countries are the roots of present-day musical theatre and help to explain why opera failed to flourish in competition. The drama in England expanded into the allied form of masque and involved the participation of such composers of distinction as Henry Purcell.

The masque

The masque in relation to its own period might well have been defined as "mixed media." This term has now come to stand for theatre presentations in a line of descent from Stravinsky's *Histoire du Soldat* (1918; *The Soldier's Tale*), which combines speech, song, mime, dance, and instrumental music with pictorial design. These elements have since been supplemented by the mechanical techniques of film or photographic projection, and of electronic sounds, in almost infinite permutations, together with a free form of expression no longer necessarily shaped by a narrative content.

Most of these manifestations incorporated two different kinds of musical contribution. One has been defined by a 20th-century German composer, Bernd Alois Zimmermann:

> All elements of the theatre of movement, including film, sound, speech, electronic music, must be mobilized into one great time-space structure, whose arrangement will be constituted by music as the most general form of temporal order.

Zimmermann's ideas were embodied in his opera, *Die Soldaten* (The Soldiers). The alternative is described by another composer, John Cage, as "Single sounds or groups of sounds which are not supported by harmonies but resound within a space of silence" and are added more or less at random to the other elements. It remains to be discovered whether the future of theatre music in drama or mixed media lies primarily with the highly organized patterns of interaction postulated by Zimmermann or with Cage's arbitrary combination of simple, disparate activities into a complex whole.

OPERETTA AND ALLIED FORMS

It seems unlikely that any future exists for operetta except as part of a "museum" repertory, because the contemporary musical has taken its place in musical theatre. Operetta in the usual sense of a work of lesser musical pretensions than opera, with spoken dialogue linking the

musical episodes, was a direct descendant of comic opera, overlapping this category, on one hand, and early musical comedy, on the other. It was born as a democratic expression of popular wit and social satire, flourished for almost exactly a century (*c.* 1840–1940), and died from a surfeit of sentiment.

Offenbach. The satirical, romantic operetta emerged primarily in Paris in the mid-19th century with the French composer Jacques Offenbach; two of his works are still widely staged: *Orphée aux enfers* (1858; *Orpheus in the Underworld*) and *La Belle Hélène* (1864; *Beautiful Helen*). The character of Offenbach's operettas established several musical precedents, including the burlesque of Italian opera, the romantic ballad in $\frac{3}{8}$ or $\frac{6}{8}$ metre, and the drinking song and the *ensemble de perplexité* ("ensemble of confusion"). In England, Arthur Sullivan followed in Offenbach's wake with his fruitful partnership with the author W.S. Gilbert, bequeathing a commentary on aspects of Victorian society through music of popular and enduring, if somewhat relentless, charm.

Viennese operetta. Charm is the main ingredient of the more sentimental Viennese operetta, and it usually submerges the rarer shaft of social comment. The younger Johann Strauss made operetta an international entertainment by an expert blend of charm and craft, and his *Die Fledermaus* (1874; *The Bat*) remains a classic of its kind. A second generation in this tradition was chiefly distinguished by Franz Lehár, whose *Die lustige Witwe* (1905; *The Merry Widow*) represents the genre at its peak of romantic elegance, demonstrating a style and craftsmanship that seems in serious danger of being lost altogether.

Johann Strauss's contribution to operetta

Such operettas remain current in today's musical theatre mainly as an indulgence of musical and emotional nostalgia. Their popular style enabled them to take root and flourish far from their native territories, including transplantation to the United States. The indigenous tradition of the U.S. stage musical, already mentioned, first had to compete with European-style operetta. That the latter keeps a tenacious hold on popular affections is demonstrated by figures listing Rudolf Friml's *Rose Marie* (1924) and Sigmund Romberg's *The Desert Song* (1926) as the most frequently performed works in U.S. musical theatre, in terms of both amateur and professional performances.

Zarzuela. Spain was a prominent exception to the wide dissemination of operetta, preferring instead the flourishing native variety of zarzuela. This form customarily incorporates regional songs and dances, sometimes with traditional rather than original music. It continues to some extent as a staple fare in Spanish musical theatre, although the general contemporary trend toward a more universal style of musical expression has meant that the younger Spanish composer has shown much less interest in the zarzuela form as an outlet for his musical imagination.

The Romantic zarzuela has little resemblance to the aristocratic and courtly character of its 17th-century namesake and emerged with French and Viennese operetta during the 19th century. It divided into two forms—the *zarzuela grande* in three acts, equivalent to romantic operetta, and the *género chico* in one act, invariably comic, usually satirical, employing the broadest musical vernacular, and verging on revue. In the former category, the names of Francisco Barbieri, Amadeo Vives, and Federico Moreno Torroba are probably the most significant representatives of their respective generations.

Zarzuelas in South America

The Spanish character and language of the Romantic zarzuelas made them exportable to Central and South America, where they became a model for the limited indigenous musical theatre. The South American centres are otherwise dominated by imports or imitations of the Italian opera tradition or used as transit bases for the latest North American stage musical on its theatrical circumnavigation. Certain examples of the Spanish zarzuela, such as Moreno Torroba's *Luisa Fernanda* (1932), have achieved popular success in Latin American countries, where local contributions to the genre have notably been made by Juan Bautista Massa in Argentina, Andrés Martínez Montoya in Colombia, Luis Delgadillo in Nicaragua, and Teodoro Valcárcel in Peru.

ORIENTAL MUSICAL THEATRE

Theatre music generally serves different purposes in non-Western idioms—usually adding dimension and perspective to song and dance, indicating symbolic associations, suggesting mood, and even inducing a desired response in an audience. Most Oriental streams of music divide between popular music of a folk character and a more sophisticated style for a cultured elite. The distinction is often less clearly defined than in Western music and is now not so firmly maintained in the wake of recent political and social changes.

China. The classical Peking opera (*ching-hsi*) in China is a form of musical theatre in which music is one among several elements rather than a governing factor, as in Western opera. The vocal writing alternates between styles broadly equivalent to recitative and song, distinguished by a forced high falsetto tone required from the male singers. A less stylized variety is the all-female *yüeh ch'ü*, in which natural singing voices perform musical plays in realistic and decorative scenery, and the Manchurian *P'ing Hsi*, which has developed into an operetta-like equivalent, with traditions and subjects derived from strolling players and folk legends.

Since 1964 the performance of classical Peking opera in Communist China has been mainly restricted to festival occasions (although state-sponsored schools continue to train performers especially for it). More emphasis has been put on entertainments closer to Western musicals, involving contemporary dialogue, everyday dress, and less stylized music. As a popular form of musical theatre it has been turned to political and social advantage with a new and adapted repertory of dramatic ballets and musical plays, bearing such titles as *Taking Tiger Mountain by Strategy* and *The Red Detachment of Women.*

Political overtones of modern Chinese opera

Japan. Music is as much a regular part of theatre performance in Japan as it is in China. The highly formal tradition of Japanese Nō drama incorporates music as an integral feature, usually performed by flute, a variety of string instrument called the samisen, drums, and singers. The music varies in content and character with the subject of the play and obeys detailed melodic rules—especially in the central dance episode designed to reveal the spirit of the play's principal character. A less formal counterpart, the Kabuki theatre, has almost as impressive an ancestry as the Nō and continues to be widely performed, with music used to indicate period, place, time, or mood and often functioning by phrase association like the principle of leading motives in Richard Wagner.

India. Japanese theatre also incorporates music dramas of Indian origin, and the Indian theatre tradition is a full combination of poetry, music, dance, and symbolism. The music is often interpolated rather than specially composed and is likely to be drawn from the repertory of widely known songs without aiming at a high classical standard. The close association of music with drama in Indian culture has been carried over into Indian film, which cannot hope to enjoy wide success among its modern audiences unless it is liberally embellished with songs and other forms of music.

The history of theatrical music

FORMATIVE PERIOD

What is thought to be the oldest document of musical history depicts a man wearing an animal mask, manipulating what is possibly a form of musical bow, and dancing in the wake of a herd of reindeer. This is a prehistoric cave painting dating from the Stone Age, discovered at Ariège in France. Masks are tangible signs of that transfer of personality on which every form of theatre is based and in which song and dance have participated since the dawn of communication and animated ritual. Music in dramatic entertainment reached early peaks of development in European and Oriental cultures in, respectively, the ancient Greece of Homer and, some centuries later, the Chinese classical drama.

Early Greek and Roman theatrical music

Descriptive evidence of the earliest Greek theatre indicates that music, mostly sung by a chorus, was essential but not continuous. At drama festivals the poet wrote his own music (as well as being actor, producer, and choreographer), probably based on some kind of traditional repeated formula. Later Greek theatre, after the fall of Athens (404 BC), initiated both the repertory system and a category of musicians trained more highly than the populace. Amateur and professional became separated for the first time, and increasing sophistication brought about its counterpart in popular pantomime expressed in song and dance, often satirical or bawdy in character.

The Roman musical theatre derived directly from the Greek, ousting a short-lived native form with Etruscan actors who also danced to pipe music. Latin versions of the Greek theatre with music were supplemented by a Roman variant of the pantomime as a dramatic solo dance with chorus and orchestra. It implied some prior knowledge on the audience's part of the subject and the dance vocabulary. Amphitheatre shows of gladiatorial contests were regularly accompanied by music, sometimes involving up to 100 horn blowers and 200 pipers, as well as such extra devices as water organs.

About the time the Roman theatre flourished, an Oriental equivalent emerged in China from ritual ceremonies that came to be repeated for their entertainment value. The puppet theatre was a significant intermediate stage in this process, and the forms evolved into different styles of entertainment for courtier and commoner. Strings, flute, and handbells accompanied the songs and dances in upper-class entertainments; a form of mouth organ replaced the bells in shows for the common people. By the time of the Sung dynasty (AD 960–1279), from which the earliest written music survives, a type of musical variety theatre, the *tzarjiuh*, was widely popular.

The Chinese classical opera tradition has already been mentioned as a modern form of musical theatre. It first developed during the Yüan dynasty (1279–1368) and reached its peak of style and classical form in the Ming period (1368–1644). Its evolution was accompanied by a less formal counterpart based on the dramatization of folk songs linked by a thin narrative plot (*Chueichang*). The full-scale opera and its regional variants remained the most significant form of Oriental musical theatre until the modern post-revolutionary times, but throughout the Far East the indigenous forms of music have always played a prominent part in theatrical presentations.

In Europe the vestiges of Greco-Roman culture were submerged by the early Christian Church. By the 6th century the church had suppressed drama and adapted pagan rituals to its own purposes. A small flame of musical theatre was left burning only in the form of religious ceremonial (for example, in the mass). Festive religious celebrations eventually expanded into the liturgical music drama that slowly developed from about the 10th century. This brought in its wake the equally religious "mysteries" and miracle plays of the Middle Ages in Europe, which were performed in the vernacular instead of in Latin, had a strong musical element, and, in due course, a secular counterpart.

Musical elements of the miracle plays

In a pattern that was to repeat itself after the birth of opera 200 years later, the secular theatre in the Middle Ages established itself either as lighthearted interludes in serious moralities or as deliberate parody tolerated by the church as a safety valve to consistent piety. The annual Feast of Fools in 15th-century Paris, for instance, incorporated an obscene parody of the mass performed in song and dance within the church. By the year 1400 numerous comedies and farces had appeared, usually performed on festive occasions in aristocratic houses or on open stages in municipal squares.

These plays often employed musical forces comparable to those of the religious plays and used them for similar purposes. Choirboys from the church sometimes took part, but surviving texts suggest that there was little choral music as such. The individual actors incorporated parts of songs chanted monophonically to embellish or heighten the dramatic effect, and dancing to specific instrumental music also had a regular place in the entertainment. Professional musicians might be hired and might also be required to act; the constituent parts of the entertainment varied widely from place to place.

The fact that, except for songs, documents of the period contain almost no music directly linked with the theatre is thought to indicate that very little original instrumental music was written for theatrical purposes at this time. Whatever was suitable for weddings, banquets, and other feasts perhaps served a theatrical purpose just as well. Musicians probably had little or no acquaintance with musical notation and played pieces from their regular repertory. These seem to have included arrangements of vocal melodies as well as dance tunes, among which the play texts most frequently identify *basses-dances* and branles.

THE RENAISSANCE AND BAROQUE PERIODS

The French court ballet

When Catherine de Médici married King Henry II of France in 1533, she brought from Italy a taste for entertainments in which dancing was prominent. Her encouragement established the court ballet (*ballet de cour*) as the foundation of classical ballet, the source of a new theatrical identity for music and a precursor of French opera. As a unified blend of poetry, music, and movement, the court ballet dates from the performance of the *Ballet comique de la reine* at a court wedding in 1581. The form comprised an optional number of scenes in mime and dance, prefaced by explanatory verses that were either spoken or sung; the scenes were accompanied by solo and choral songs with lute and instrumental ensemble pieces for strings.

In about 1605 a more mannered style of singing had become customary, and by 1620 the court ballet was more a vehicle for display than drama. Unified dramatic plots were restored by the poet Isaac de Benserade in midcentury, and Jean-Baptiste Lully, who entered the service of King Louis XIV in 1652, endowed the music with fresh distinction. He favoured dramatic musical expression with the use of larger choral and orchestral forms and formulated such dances as the minuet, first danced by Louis as "Le Roi soleil" (the sun king), the gavotte, rigaudon, bourée, passepied, and loure—each with its particular rhythmic metre.

Lully collaborated with the playwright Molière in a famous succession of comedy-ballets, of which *Le Bourgeois Gentilhomme* (1670) is probably the best known. Thereafter the character of Lully's work became essentially operatic, and music in the French theatre was left to function in a more subsidiary role. The dramatist Pierre Corneille, for instance, wrote "I have employed music only to satisfy the ear while the eyes are occupied with looking at the machines." In another category, the pastoral comedies derived from Italian models were liberally embellished with songs loosely strung together and alternating with spoken verses.

The English masque

The French court ballet exerted an influence on the English masque, which took its name and some of its early character from the medieval Italian *mascherate* (masquerades) in carnival entertainment. At a time of distinctive English literary achievement, the masque reached a high artistic level, performed mainly as an aristocratic entertainment. It combined instrumental and vocal music, mixed with dancing and acting, in the representation of mythological and allegorical subjects. At the same time, the first public theatres in London came into being. They date from 1576 (61 years before the first public Venetian opera house); the earliest public plays are known to have incorporated some form of music.

Cues for music recur throughout Shakespeare's plays, usually for simple songs or dances. Music between the acts of public plays was customary by 1600, with the audience often calling for the tunes they wanted played. Instrumental music was employed for supernatural effects and to heighten dramatic tension; it was usually performed behind, at the side of, or even under the stage. After the suppression of playhouses during the Civil War, the restoration of the English monarchy with King Charles II brought an even richer flowering of theatre music, led by Henry Purcell.

Besides those works of Purcell that are nearer to masque than drama, such as the Shakespeare adaptations for *The Fairy Queen* (1692) and *The Tempest* (1695), he composed suites of incidental music for more than 40 plays. These generally comprised overtures, "act-tunes" (interludes), dances, and songs. Rather than growing out of the verbal drama, however, they are often so arbitrarily interpolated into it that only the quality of the music can justify most of them. After Purcell's death, English theatrical music ceased to contribute significantly to the theatre, but Thomas Arne, who wrote numerous masques and ballad operas such as *Love in a Village* (1762), was very popular in the mid-18th century, and his simplicity of expression has a certain direct appeal.

The flourishing tradition of Spanish Renaissance drama precluded much opera from taking root in Spain, but the music for plays had generally less distinction than the English equivalent. The early zarzuela (not to be confused with the later Romantic version already mentioned) originated in the 17th century as a court entertainment. It was the Spanish counterpart to the court ballet and acquired a strong Italian influence on its musical character. Spanish music and musicians travelled to the Western Hemisphere with the early explorers, and by the late 17th century the Peruvian capital of Lima had become musically important. The composer José Diaz worked there and wrote much incidental music to the plays of Calderón de la Barca.

The Italian *intermedio*

Renaissance theatre in Italy bred the *intermedio,* which consisted of songs and instrumental music added before or after the acts of a play. The words of the songs were generally relevant to the action of the drama, and this development—together with more extended musical settings in pastoral plays—became the direct precursor of Italian opera. As a new form of "drama in music" which rapidly acquired serious artistic pretensions, the opera inevitably brought in its train a less aristocratic variety of musical theatre variously termed opera buffa (comic opera), vaudeville, ballad opera, singspiel (literally, song-play), or *tonadilla,* always performed in the vernacular of its audience and often in dialect.

These depicted current events instead of historical or mythological subjects, involved elements of parody and social satire, and usually depended on modest musical resources for economic reasons. They began as interludes performed between the acts of serious opera and comprise an essential link in the history of musical theatre. By about 1700 the scenes (usually two) had acquired a linked plot, and by 1740 they were performed apart from the opera as a genuinely popular entertainment. Eventually they responded to the demands of the rising middle classes by raising their own standards into the category of comic opera.

CLASSICAL DEVELOPMENTS

The Italian commedia dell'arte entertainment of strolling players in mainly improvised comedy had left its mark on French fairground theatre, although the performers were expelled from France in 1697 for having ventured their satire too close to court topics. Ten years later French satirical comedies were also banned, whereupon the resourceful performers found a new way round by employing monologue, mime, and music. They thereby developed a new form of popular entertainment to contrast with the aristocratic opéra-ballets, which were soon to be dominated by the spectacular productions with Jean-Philippe Rameau as composer, and in 1713 two theatrical managements in Paris were given license to perform "Le nouvel Opéra-comique."

Opéra comique was a contraction of *opéra rendu comique* ("opera made comic"), signifying parody and satire at the expense primarily of serious opera. The entertainment soon came to veer either toward *comédie vaudeville,* mostly made up of bawdy satire or simply songs of disparaging social comment, or to the alternative *comédie à ariette,* involving a generally more decorous musical parody at the expense of Italian styles. The *Guerre des Bouffons* ("war of the comedians") between partisans of French and Italian theatrical styles was eventually resolved by the emergence of the opéra bouffe (literally, "comic opera")—the French variety of operetta. It is usually dated to the Paris production in 1753 of *Les Troqueurs, Iroqueurs,* based on a fable by Jean de La Fontaine and having original music by a court violinist, Antoine Dauvergne.

Ballet was declining about this time from courtly heroics to simple diversion unrelated to any dramatic point. Apart from the opera-ballets of Rameau, little significant music was composed for the dance until the German composer Christoph Willibald Gluck, who initiated the major reform of serious opera during the century, first turned his attention to a move for balletic reform involving a more dramatic style. In 1761 Gluck composed the music for *Don Juan,* a ballet by Gasparo Angiolini, the Italian ballet master at Vienna, who maintained that dancing should be self-expressive without recourse to verbal explanations.

Gluck's contribution to ballet music

Gluck's vividly descriptive score contains 31 musical pieces, alternating between formal dances and narrative drama. It made the music a foreground element in the ballet instead of a background accompaniment and could have brought about—if its example had been followed up—a revitalization of ballet music almost as significant as the operatic reform Gluck launched in *Orfeo ed Euridice* a year later. In the ballet, the fight scene near the beginning and the dance of the Furies at the end (itself later incorporated into *Orfeo*) have a concentrated intensity of musical expression, and the graveyard scene has a degree of imaginative orchestration that is unsurpassed in any other music at that date.

For reasons that belong more properly to the history of ballet, Gluck's influence on its future course was less fruitful than in opera. Perhaps his example, nevertheless, encouraged the participation of such composers as Mozart with *Les Petits Riens* (1778; "Sweet Nothings") and Beethoven in *The Creatures of Prometheus* (1801). It was, otherwise, an era theatrically dominated by opera of various kinds, so that there was at first little call for music in relation to spoken drama. Haydn, however, composed some music (1796) for an early German translation of Alexander Bicknell's *The Patriot King, or Alfred and Elvida,* and Mozart contributed a suite of superior choral and orchestral music for *Thamos, König in Ägypten* (1773; *Thamos, King of Egypt*), which was never used for the play in his lifetime but which has survived where the play has long been forgotten.

Eighteenth-century opera nourished musical developments in the theatre chiefly through establishing regular orchestras of some quality. Outside of cities with more than one theatre, such as Vienna, Prague, Paris, and London, the numerous court theatres needed to keep a resident and costly orchestra reasonably occupied, with interest divided between opera and drama. It therefore became customary either to commission incidental music for existing plays whenever possible (especially the historical classics, as more and more of them were translated from one language to another) or to commission new plays that would incorporate ample provision for orchestral and sometimes choral music.

ROMANTIC EXPANSION

Examples of commissioned incidental music have previously been cited in Beethoven's music for *Egmont,* which belongs to the first category just mentioned, and Schubert's for *Rosamunde,* which is in the second. The practice spread as a matter of rivalry and prestige to cities without a court but which maintained a municipal theatre (for example, Hamburg and Leipzig) and to other countries with a thriving theatrical interest and ample funds. In Russia, for instance, Mikhail Glinka composed music to *Prince Kholmsky* (1840), an otherwise obscure drama by Count Kukolnik, and the Shakespeare repertory brought the collaboration of such composers as Mily Balakirev (*King Lear,* 1861) and Tchaikovsky (*Hamlet,* 1891).

France and England, having different systems of patronage, produced different results during the 19th century. English theatre music was confined for most of its course

to a taste for crude melodrama and burlesque at a low level, apart from a sporadic interest in mostly imported opera and ballet. Arthur Sullivan, however, provided incidental music for Shakespeare plays as well as cultivating, in his collaboration with the author W.S. Gilbert, a native variety of operetta derived from the French model. France fared somewhat better with the popularity of opéra bouffe, and the birth of romantic ballet in Paris also kindled a new kind of theatre interest, even though its musical quality was usually secondary.

Gilbert and Sullivan operetta

Music for Romantic ballet developed in two directions. From the time of the French composer Adolphe Adam's score for *Giselle* (1841), ballet composers made rudimentary attempts to express mood and scene, to create dramatic tension, and to characterize personality in music. The general level was somewhat raised by the French composer Léo Delibes in his music for *Coppélia* (1870) and more especially for *Sylvia* (1876); the latter was a score that Tchaikovsky came to know and admire. The second feature in many ballet scores of the period was the attempt to compose suitably flavoured music to match the new growth of interest in national and regional dances, which were regularly incorporated into the ballets.

Music in 19th-century ballet reached its peak of achievement with Tchaikovsky, whose instinct for the theatre was probably stronger than his talent for the subtleties of symphonic argument. He treated the art of ballet as worthy of real musical imagination and told a colleague who adversely likened some of his *Symphony No. 4* to ballet music: "I cannot understand why the term should be associated with something reprehensible. There is such a thing as good ballet music." Tchaikovsky demonstrated its possibilities in three original scores for ballet that enjoy continuing universal popularity in the theatre: *Swan Lake* (first performed 1877); *The Sleeping Beauty* (1890); and *The Nutcracker* (1892).

Swan Lake achieved lasting success only after the composer's death—a fact which accounts for the recurring problems of the relationship of music to choreography, because some of the original musical sequence was changed for the 1895 production at St. Petersburg (now Leningrad), from which most current versions of the ballet are descended. The two later scores benefitted from detailed choreographic specifications. According to Stravinsky, *The Sleeping Beauty* is "the convincing example of Tchaikovsky's great creative power," and *The Nutcracker* in its theatre context has a narrative vividness much beyond the limited charm of the concert suite that Tchaikovsky arranged from it.

Adolphe Adam's contribution to the development of ballet music had its parallel in the sphere of romantic operetta. By incorporating a measure of frivolous vaudeville into the otherwise conventional comedy of *Le Châlet* (1834), Adam stimulated a popular taste for what became the mainstream of operetta. Its source was in Paris, and it flowed in turn principally to Vienna, to London and thence to North America, submerging the German singspiel and its Scandinavian offshoots but leaving the Spanish zarzuela to cultivate its own regional idiom.

Adam's enterprise in opening a theatre in 1847 to stage his own works and those of other young composers disdained by the operatic establishment in Paris was brought to a premature end by the political uprising a year later, but Offenbach was poised to take advantage of the subsequent situation. He opened his Bouffes-Parisiens theatre in 1855, whence travelled such immediate hits as *Orpheus in the Underworld, La Belle Hélène, La Grande-Duchesse de Gérolstein*, and *La Périchole* over almost all of Europe. The Parisian operetta was principally continued to the end of the century by Charles Lecocq and André Messager.

Offenbach's influence in Europe

Offenbach meanwhile had paid several visits to Vienna from 1858, when Franz von Suppé was quick to turn the French model to local advantage, notably with *Die schöne Galatea* (1865; *The Beautiful Galatea*). The younger Johann Strauss was eventually persuaded to follow this trend by turning the Viennese craze for his waltzes, polkas, and other social dances to theatrical purpose. With the aid of an unusually good libretto, Strauss created the supreme example of Viennese operetta in *Die Fledermaus*. The Viennese tradition was continued in turn by Franz Lehár and Emmerich Kálmán.

Offenbach's influence extended southward to Bohemia, where the composer Bedřich Smetana compared his first song-and-dialogue version of *The Bartered Bride* (1866) to an Offenbach operetta, and Antonín Dvořák composed an outstanding but little-known example in *The Peasant a Rogue* (1878). Otherwise, no specialist or specially distinguished composer of operetta emerged in southeastern Europe, nor in Poland or Russia, where there were only occasional and tenuous contacts with forms of musical theatre other than full-scale opera and ballet for the moneyed classes.

The northward spread of the Offenbach model reached England, where it influenced the character of Sullivan's first operetta, *Cox and Box* (1867). It led in due course to the success of *H.M.S. Pinafore* (1878), in collaboration with Gilbert, and the subsequent line of "Savoy operettas" (their collective nickname derived from the London theatre where they were first performed by the D'Oyly Carte Opera Company, Ltd.). England made no other contributions of comparable musical interest to the operetta repertory until it was overtaken in due course by the trend to musical comedy in the 20th century.

English operetta represented by Gilbert and Sullivan nevertheless put down fresh roots in North America after the D'Oyly Carte company first travelled there in 1879, in the wake of a pirated version of *H.M.S. Pinafore*. The impact of Sullivan's music in New York and Boston was comparable to that of Offenbach in Vienna. Instead of stimulating an American equivalent, it first opened the way to 20 years or so of European imports to the American stage. The composers Reginald De Koven and Victor Herbert later established a short-lived local counterpart to European operetta, before it was overtaken by the indigenous idiom of American musical theatre noted earlier.

The language of ragtime and early jazz, with its rhythmic syncopation and varying degrees of harmonic innovation within a common musical vernacular, brought the first new element to the idiom of musical theatre (in musical comedy) since the emergence of national folk characteristics in 19th-century Europe. As the trends already described succeeded one another during the 20th century, in and out of fashion, and the musical theatre tried to reconcile the nostalgia for its past heritage with the need to experiment in search of a viable future, the immediate present can be seen to represent only one turn of a larger wheel across seven or eight centuries. The religious rock musical of the contemporary musical scene is but a variant of the mysteries and miracle plays that initiated all our modern forms of musical theatre when Western civilization first groped its way out of the Dark Ages.

BIBLIOGRAPHY. MARK LUBBOCK, *The Complete Book of Light Opera*, with an American section by DAVID EWEN (1962), gives synopses and background dates of numerous European and American operettas and musicals. GERVASE HUGHES, *Composers of Operetta* (1962), is a reliable critical and historical account of classical operetta. STANLEY GREEN, *The World of Musical Comedy*, rev. ed. (1969), gives a comprehensive account of the American musical in terms of its composers; and an informed discussion of its character and constituents is in LEHMAN ENGEL, *The American Musical Theatre* (1967). IVOR GUEST, *The Romantic Ballet in Paris* (1966), contains much little known background on music of its period; and NATALIA ROSLAVLEVA, *Era of the Russian Ballet Music* (1966), performs a similar but less well-documented service for its own subject. ROGER FISKE, *Ballet Music* (1958), is the only musically informed analysis to date of certain major ballet classics. HANNS EISLER, *Composing for the Films* (1947), remains a useful account of applied research. The wider historical aspects of theatrical music as a whole are included in the various volumes of the *New Oxford History of Music*, projected 11 vol. (1957–); and are comprehensively summarized in the excellent one-volume *Man and His Music* by ALEC HARMAN and WILFRID MELLERS (1962).

(N.Go.)

Music, Western

All ancient civilizations entered historical times with a flourishing musical culture. That the earliest writers explained it in terms of legend and myth is evidence of the remote beginnings of the art of sound. Among the speculations about its origin, the more plausible are that it began as a primitive form of communication, that it grew out of a device to expedite communal labour, or that it originated as a powerful adjunct to religious ceremonies. While such theories must necessarily remain speculative, it is clear, despite the prehistoric musical artifacts found in central Europe, that the cradle of Western music was the fertile crescent cupping the eastern end of the Mediterranean Sea. There the Mesopotamian, Egyptian, and Hebrew nations, among others, evolved political, social cultures that were absorbed by the conquering Greeks and, in turn, by the Romans, who transported a relatively sophisticated art form back to western Europe.

In all of these early cultures the social functions of music were essentially the same since their climate, geographic location, cultural pace, and mutual influences produced many more social similarities than differences. Magico-religious origins The primary function of music was apparently religious, ranging from heightening the effect of "magic" to ennobling liturgies. The other musical occasions depicted in both pictures and written accounts were equally functional: stirring incitements to military zeal, soothing accompaniments to communal or solitary labour, heightening aids to dramatic spectacles, and enlivening of social gatherings involving singing and dancing. In every case musical sounds were an adjunct either to bodily movement (dance, march, game, or work) or to song. Many centuries were to pass before pleasure in euphonious sound became an end in itself.

The establishment of Western musical traditions

ROOTS IN ANTIQUITY

Ancient Near East and Egypt. The inhabitants of the Mesopotamian region around the Tigris and Euphrates rivers (the Sumerians, the Babylonians, and the Assyrians) flourished from *c.* 3500 to *c.* 500 BC. Their pictures and the few surviving artifacts indicate that they had instruments of every basic type—idiophones, whose sound is made by resonating as a whole; aerophones, which resonate a column of blown air; chordophones, with strings to be plucked or struck; and membranophones, made of stretched skins over a resonating body. An undecipherable hymn engraved in stone, dating from *c.* 800 BC, is evidence that a primitive system of musical notation had been developed.

The Egyptians, entering historical times about 500 years later than the Mesopotamians, enjoyed all of the same types of activities and instruments, as may be deduced from numerous written references to music as well as seen on many artifacts, especially the pictures preserved on pottery utensils.

The musical culture of the Hebrew peoples, recorded from about 2000 BC and documented primarily in the Old Testament, was more directly influential in the West because of its adoption and adaptation into the Christian liturgy. Because of the prohibition of Jewish religious law against the making of "graven images," there are very few surviving artifacts or pictures. Among the established practices of the temple service still current in the synagogue are the extensive use of the shofar (a ritualistic ram's-horn trumpet) and the singing of passages from the Pentateuch (the first five books of the Old Testament), prayers, and songs of praise.

Ancient Greece. Of the eastern Mediterranean cultures, it was undoubtedly that of the Greeks that furnished the most direct link with musical development in western Europe, by way of the Romans, who défeated them, but adopted much of Greek culture intact. Entering historical times relatively late, *c.* 1000 BC, the Greeks soon dominated their neighbours and absorbed many elements of earlier cultures, which they modified and combined into an enlightened and sophisticated civilization. The two basic Greek religious cults—one devoted to Apollo, the other to Dionysus—became the prototypes for the two aesthetic poles, classical and romantic, that have contended throughout Western cultural history. The Apollonian and Dionysiac expression Apollonians were characterized by objectivity of expression, simplicity, and clarity, and their favoured instrument was the kithara, a type of lyre. The Dionysians, on the other hand, preferred the reed-blown aulos and were identified by their subjectivity, emotional abandon, and sensuality.

The prevailing doctrine of ethos, as explained by ancient Greek philosophers such as Plato and Aristotle, was based on the belief that music has a direct effect upon the soul and actions of mankind. As a result, the Greek political and social systems were intertwined with music, which had a primary role in the dramas of Aeschylus, Sophocles, Euripides, and Aristophanes. And the Grecian educational system was focussed upon *musica* and *gymnastica*, the former referring to all cultural and intellectual studies, as distinguished from those related to physical training.

To support its fundamental role in society, an intricate scientific rationale of music evolved, encompassing tuning, instruments, modes (melodic formulas based on certain scales), and rhythms. The 6th-century-BC philosopher and mathematician Pythagoras was the first to record the vibratory ratios that established the series of notes still used in Western music. From the total gamut of notes used were derived the various modes bearing the Origin of musical modes names of Grecian tribes—Dorian, Phrygian, Lydian, etc. The rhythmic system, deriving from poetry, was based on long–short relationships rather than strong–weak accentual metre. After Pythagoras, Aristoxenus was the major historian and theoretician of Greek music.

Ancient Rome. When the musical culture of the eastern Mediterranean was transplanted into the western Mediterranean by the returning Roman legions, it was inevitably modified by local tastes and traditions. In most cases, the resulting practices were more limited than their models. The diatonic (seven-note) scale, for example, became the standard, displacing the chromatic and enharmonic structures of the Grecian system. Of particular consequence was the new concept of metre as a series of equal durations, with emphasis being determined by accent (stress) rather than by duration.

An inventory of the musical heritage transplanted from the ancient East (particularly Greece) to Rome reveals the rich treasure inherited: an acoustical theory that accounted for the identification and classification of tones; a concept of tonal organization resulting in the system of modes; principles of rhythmic organization; basic principles of instrument construction; a system of notation that conveyed all necessary indications of pitch and duration; and a large repertory of melodies to serve as models for further composition.

THE MIDDLE AGES

Monophonic liturgical chant. With the decline of the Roman Empire, the institution destined to perpetuate and expand the musical heritage of antiquity was the Christian Church, but it was not a unified process. Many of the cultural centres of the Western church developed distinctive characteristics while sharing the common heritage of the Hebrew liturgy and Greek culture. In Milan, for example, metrical hymnody, as distinguished from the earlier practice of unmetred psalmody, was cultivated, particularly under the influence of the 4th-century Bishop Ambrose, who first attempted to codify the growing repertory of chants. This body of Milanese church music, therefore, came to be called Ambrosian chant. Somewhat later a unique style and repertory known as Mozarabic chant evolved in Spain, and in France the Gallican style prevailed.

But the mainstream of church music was the type of chant practiced in Rome. Beginning in the late 6th century, according to tradition, with Pope Gregory I, the vast Gregorian chant number of traditional melodies that became the foundation for the later development of Western art music were codified and organized. A systematic organization of tonal materials also was gradually accomplished, resulting in

the eight church modes. Each melody was assigned a specific function in the services of the liturgical year—some for the mass and some for the divine offices such as Matins, Vespers, and Compline. After a period of assimilation, the Gregorian chant repertory began a process of expansion in the 9th century, when the practice of troping originated. A trope is either a text or a melodic section added to a pre-existing melody or a combination of text and music incorporated into existing liturgical music. It is not surprising that church musicians, after years of singing traditional chants, should want to express themselves by adding words to vocalized melodies. Perhaps the motive was more functional: the added syllables would make the long textless passages easier to remember. Tuotilo (died 915), a monk of St. Gall in Switzerland, is credited with the invention of tropes. Notker Balbulus (died 912) is notable for his association with the sequence, a long hymn that originated as a trope added to the final syllable of the Alleluia of the mass.

Development of polyphony. At the same time that the Gregorian repertory was being expanded by the interpolation of tropes and sequences, it was being further enriched by a revolutionary concept destined to give a new direction to the art of sound for hundreds of years. This concept was polyphony, or the simultaneous sounding of two or more melodic lines. The practice emerged gradually during the Dark Ages, and the lack of definite knowledge regarding its origin has brought forward several plausible theories: it resulted from singers with different natural vocal ranges singing at their most comfortable pitch levels; it was a practice of organists adopted by singers; or it came about when the repetition of a melody at a different pitch level was sung simultaneously with the original statement of the melody. Whatever motivated this dramatic departure from traditional monophony (music consisting of a single voice part), it was an established practice when it was described in *Musica enchiriadis* (*c.* 900), a manual for singers and one of the major musical documents of the Middle Ages. To a given plainsong, or *vox principalis*, a second voice (*vox organalis*) could be added at the interval (distance between notes) of a fourth or fifth (four or five steps) below. Music so performed was known as organum. While it may be assumed that the first attempts at polyphony involved only parallel motion at a set interval, the *Musica enchiriadis* describes and gives examples of two-part singing in similar (but not exactly parallel) and contrary movement—evidence that a considerable process of evolution had already taken place.

The beginnings of polyphony

The next major source of information was the *Micrologus*, written in the early 11th century by the Italian monk and musical theorist Guido of Arezzo. This work documented principles that were crucial to the further development of polyphony. Rhythmic independence was added to melodic independence, and the added voice might sing two or more tones to one in the original plainsong. During the half century after Guido's death, developments came more rapidly as the plainsong chant became the lower rather than the upper voice. After the emancipation of the organal part, *vox organalis*, its ultimate freedom was reached in the organums of the monastery of Saint-Martial in Limoges, France, where the plainsong part was reduced to the role of sustaining each tone while the organal part indulged in free melismata (groups of notes sung to a single syllable), either improvised or composed. This new style was called *organum purum*.

The Notre-Dame school. Early in the 12th century the centre of musical activity shifted to the church of Notre-Dame in Paris, where the French composer Léonin recorded in the *Magnus Liber Organi* ("Great Book of Organum") a collection of two-part organums for the entire church year. A generation later his successor, Pérotin, edited and revised the *Magnus Liber*, incorporating the rhythmic patterns already well-known in secular music and adding more than one part to the cantus firmus (the "given" or pre-existing plainsong melody). When metre was applied to the original plainsong as well as to the *vox organalis*, the resulting form was called a clausula. Then, when words were provided for the added part or parts, a clausula became a motet. At first the words given to the motet were a commentary in Latin on the text of the original plainsong tenor (the voice part "holding" the cantus firmus; from Latin *tenere*, "to hold"). Later in the 13th century the added words were in French and secular in nature. Finally, each added part was given its own text, resulting in the classic Paris motet: a three-part composition consisting of a portion of plainchant (tenor) overlaid with two faster moving parts, each with its own secular text in French. At the same time another polyphonic form, the conductus, was flourishing. It differed from a motet in that its basic part was not plainsong and that all parts sang the same Latin text in note-against-note style. The conductus gradually disappeared with the rise of the motet, which apparently served both liturgical and secular functions.

The beginnings of the motet

Ars Nova. When the influential treatise *Ars Nova* ("New Art") by the composer Philippe de Vitry appeared early in the 14th century, the preceding epoch acquired its designation of Ars Antiqua (Old Art), for it was only in retrospect that the rapid developments of the century and a half from *c.* 1150 to *c.* 1300 could appear as antiquated. De Vitry recorded the innovations of his day, particularly in the areas of metre and harmony. While 13th-century music had been organized around the triple "modal" rhythms derived from secular music and a harmonic vocabulary based on "perfect" consonances (unison, fourth, fifth, octave), the New Art of the 14th century used duple as well as triple divisions of the basic pulse and brought about a taste for harmonious intervals of thirds and sixths.

The musical centre of 14th-century Italy was Florence, where a blind organist, Francisco Landini, and his predecessors and contemporaries Giovanni da Cascia, Jacopo da Bologna, and Lorenzo and Ghirardello da Firenze were the leading composers of several new forms: madrigals (contrapuntal compositions for several voices), ballatas (similar to the French virelai), and caccias (three-voice songs using melodic imitation).

Monophonic secular song. Secular music undoubtedly flourished during the early Middle Ages, but, aside from sporadic references, the earliest accounts of such music in the Western world described the music of the goliards, itinerant minor clerics and students who, from the 7th century on, roamed the land singing and playing topical songs dealing with love, war, famine, and other issues of the day. The emergence in France of a fully developed secular-musical tradition about the beginning of the 12th century is evidence that the art had been evolving continuously before that time. Partially motivated by the attitude of chivalry engendered by the Crusades, a new life-style began among the nobility of southern France. Calling themselves troubadours, they circulated among the leading courts of the region, devoting themselves to writing and singing poetry in the vernacular. The movement flourished in Provence during the 12th and 13th centuries. About the middle of the 12th century, noblemen of northern France, most notably Adam de La Halle, took up the pastime, calling themselves trouvères. In Germany a similar group known as Minnesingers, represented by Walther von der Vogelweide, began their activities about 1150 and continued for almost a century after their French counterparts had ceased composing. Late in the 13th century the burgher class in Germany began imitating the aristocratic Minnesingers. Calling themselves Meistersingers, they flourished for more than 500 years, organizing themselves into fraternities and following strict rules of poetry, music, and performance. The most famous of them, Hans Sachs, was immortalized in the 19th century in Richard Wagner's opera *Die Meistersinger von Nürnberg*. Relatively little is known of similar activities in Italy, Spain, and England. Closely associated with the entertainments of the aristocratic dilettantes were the professional musicians of the peasant class called jongleurs and minstrels in France, *Gaukler* in Germany, scops and gleemen in England.

Troubadours and Meistersingers

The musical style established by the troubadours—which was monophonic, of limited range, and sectional in

structure—was adopted by each of the succeeding groups. Of particular significance in view of its influence on polyphonic music was the metric system, based on six rhythmic modes. Supposedly derived from Greek poetic metres such as trochaic (long–short) and iambic (short–long), these modes brought about a prevailing triple metre in French music; German poetry produced duple as well as triple metre. A great variety of formal patterns evolved, in which musical and poetic structure were closely related. The most characteristic was the ballade, called *Bar* form in Germany, with an AAB structure. This type, along with the rondeau (song for solo voice with choral refrain) and the similar virelai (an analogue of the Italian ballata), was destined to become a favoured form of composers of polyphony such as Guillaume de Machaut, the universally acknowledged master of French music of the Ars Nova period. Machaut also continued the composition of motets, organizing them around recurrent rhythmic patterns (isorhythm), a major structural technique of the age. The beginnings of an independent instrumental repertory during the 13th century are represented by the estampie, a monophonic dance form almost identical in style to the vocal secular music.

THE RENAISSANCE PERIOD

The term Renaissance, in spite of its various connotations, is difficult to apply to music. Borrowed from the visual arts and literature, the term is meaningful primarily as a chronological designation. Some historians date the beginning of the musical Renaissance at about 1400, some with the rise of imitative counterpoint, about 1450. Others relate it to the musical association with Humanistic poetry at the beginning of the 16th century, and still others reserve the term for the conscious attempt to recreate and imitate supposedly classical models that took place about 1600.

The court of Burgundy. No one line of demarcation is completely satisfactory, but, adhering to commonly accepted usage, one may conveniently accept as the beginning of the musical Renaissance the flourishing and secularization of music at the beginning of the 15th century, particularly at the court of Burgundy. Certainly many manifestations of a cultural renaissance were evident at the time: interest in preserving artifacts and literature of classical antiquity, the waning authority and influence of the church, the waxing Humanism, the burgeoning of urban centres and universities, and the growing economic affluence of the states of western Europe.

Rivalry between church and state in musical patronage

As one manifestation of their cultivation of elegant living, the aristocracy of both church and state vied with one another in maintaining resident musicians who could serve both chapel and banqueting hall. The frequent interchange of these musicians accounts for the rapid dissemination of new musical techniques and tastes. Partly because of economic advantages, Burgundy and its capital, Dijon, became the centre of European activity in music as well as the intellectual and artistic focus of northern Europe during the first half of the 15th century. Comprising most of eastern France and the Low Countries, the courts of Philip the Good and Charles the Bold attracted the leading musicians of western Europe. Prime among them was Guillaume Dufay, who had spent some time in Rome and Florence before settling in Cambrai about 1440. An important contemporary of Dufay was Gilles Binchois, who served at Dijon from about 1430 until 1460. The alliance of Burgundy with England accounted for the presence on the Continent of the English composer John Dunstable, who had a profound influence on Dufay. While the contributions of the English to the mainstream of continental music are sparsely documented, the differences in style between Dufay and his predecessor Machaut are partially accounted for by the new techniques and, especially, the richer harmonies adopted by the Burgundian composers from their English allies.

New religious musical forms. The social circumstances of the age determined that composers would devote their efforts to the mass, the motet, and the chanson (secular French song). During the first half of the 15th century, the mass became established as a unified polyphonic setting of the five main parts of the Ordinary of the mass (Kyrie, Gloria, Credo, Sanctus, Agnus Dei), with each movement based on either the relevant portion of plainsong or, reflecting the dawning Renaissance, a secular song such as the popular "L'Homme armé" ("The Armed Man") and "Se la face ay pale." Still reflecting medieval practices, the pre-existing melody (or cantus firmus) was usually in the tenor (or lowest) part and in long, sustained tones, while the upper parts provided free elaboration. Dufay's nine complete settings of the mass, compared with Machaut's single setting, give a clear indication of the growing importance of the mass as a musical form. The motet became simply a setting of a Latin text from Scriptures or the liturgy in the prevailing polyphonic style of the time. It was no longer necessarily anchored to a plainsong tenor; the composer could give free reign to his invention, although some did, of course, resort to older techniques.

Importance of the mass

Secular music. It was in secular music that giant strides took place. While their chansons continued the tradition of rondeaux, virelais, and ballades, Dufay and his contemporaries added free forms divorced from the ordered patterns of the Ars Antiqua and Ars Nova periods.

Among the distinctive features of Burgundian musical style was the prevailing three-part texture, with melodic and rhythmic interest centred in the top part. Because it was so typical of secular songs, this texture is commonly referred to as "ballade style" whether it appears in mass, motet, or chanson. Its possible stylistic implication is that a solo voice sang the upper melody, accompanied by instruments playing the lower parts, although no documents remain to establish exactly how the music was performed. There was probably no standard performing medium: all parts may have been sung; some or all may have been doubled by instruments; or there may have been one vocal part supported by instrumental accompaniment.

The Franco-Flemish school. A watershed in the history of music occurred about the middle of the 15th century. The fall of Constantinople in 1453 and the end of the Hundred Years' War at about the same time increased commerce from the East and affluence in the West. Most significant musically was the pervasive influence of musicians from the Low Countries, whose domination of the musical scene during the last half of the 15th century is reflected in the period designations the Netherlands school and the Franco-Flemish school. These musicians travelled and resided throughout Europe in response to their great demand at princely courts, including those of the Medici family in Florence and the Sforzas in Milan. Further dissemination of knowledge resulted from the invention and development of printing.

Travelling musicians at courts

The leading composers, whose patrons were now members of the civil aristocracy as well as princes of the church, were Jean d'Okeghem, Jakob Obrecht, and, especially, Josquin des Prez. D'Okeghem, born and trained in Flanders, spent most of his life in the service of the kings of France and was recognized by his contemporaries as the "Prince of Music." Obrecht remained near his birthplace in the Netherlands, going occasionally to Italy in the retinue of Duca Ercole I (Duke Hercules I) of Ferrara. More typical of the peripatetic Netherlanders was the career of Josquin, the most influential and most celebrated composer of the period. After his training at St. Quentin, he served the Sforza family in Milan, the papal choir in Rome, Ercole I, and King Louis XII of France before returning to his native Flanders in 1516. These three composers and several of their contemporaries hastened the development of the musical techniques that became the basis of 16th-century practice and influenced succeeding musical developments.

Rather than the three parts typical of most Burgundian music, four parts became standard for vocal polyphony in the late 15th century. The fourth part was added below the tenor, increasing the total range and resulting in greater breadth of sound. The presence of the four parts also allowed for contrasts of texture such as the "duet style" so characteristic of Josquin, when the two upper parts might sing a passage alone and be echoed by the two

lower parts alone. The emergence of the technique of imitation (one voice repeating recognizably a figure heard first in another voice) as the chief form-generating principle brought about more equality of parts. At the same time "familiar style," in which all parts move together in chords, provided a means of textural contrast. The great variety of rhythmic techniques that evolved during the 14th and early 15th centuries made possible a wide range of expression—from quiet tranquillity for sacred music to lively and spirited secular music. Knowledge of the musical practices comes not only from the thousands of surviving compositions but from informative treatises such as the 12 by the composer Johannes Tinctoris (1436–1511), one of which, *Terminorum musicae diffinitorium* (*c.* 1475), is the earliest printed dictionary of musical terms.

Wider range of expression through rhythmic developments

The chief forms of vocal music continued to be the mass, the motet, and the chanson, to which must be added other national types that developed during the 15th century—the villancico (secular poetry set for voice and lute or for three or four voices) in Spain and the frottola (a simple, chordal setting in three or four parts of an Italian text) in Italy. The emergence of the frottola in northern Italy led to the development of the Renaissance madrigal, which impelled that country to musical supremacy in Europe.

Instrumental music. At the same time, an independent instrumental idiom was evolving. While instruments had been in common usage throughout the Middle Ages, their function was primarily to double or to substitute for voices in vocal polyphonic music or to provide music for dancing. Techniques unsuitable for voices were doubtless part of an instrumentalist's musical vocabulary, but most such music was improvised rather than being written. Although there are a few sources of instrumental music dating from the 13th and 14th centuries, the earliest relatively extensive documentation comes from the 15th century, particularly from German sources, such as the *Buxheimer Orgelbuch* and Konrad Paumann's *Fundamentum organisandi* (*Fundamentals of Organ Playing*). The compositions in both collections are of two basic types, arrangements of vocal works and keyboard pieces entitled *Praeambulum* (*Prelude*).

During the course of the 16th century, instrumental music burgeoned rapidly, along with the continually developing idiomatically instrumental techniques, such as strongly accented rhythms, rapid repeated tones and figures, angular melodic lines involving wide intervallic skips, wide ranges, long, sustained tones and phrases, and much melodic ornamentation.

Musical forms. Dance forms, a continuation of a tradition unbroken since the beginnings of recorded music history, were most characteristically composed in pairs, although single dances as well as embryonic suites of three or more dances appeared. The pairs usually consisted of pieces in contrasting tempo and metre that often were unified by sharing a common melody. Common dance pairs included the pavane and galliard, the allemande and courante, and the basse danse and tourdion.

Preludes continued as a major form of organ music and were joined by the fantasia, the *intonazione*, and the toccata in a category frequently referred to as "free forms" because of the inconsistency and unpredictability of their structure and musical content—sections in imitative counterpoint, sections of sustained chords, sections in virtuoso figuration. If a distinction must be made, it might be said in very general terms that the fantasia tended to be more contrapuntal while the toccata (or "touch piece") featured passages designed to demonstrate the performer's agility, although the designations were freely interchangeable. To the same category belong the descriptive pieces such as *The King's Hunt*, which featured naive musical representations of natural sounds.

Fantasias and toccatas

The ricercar and the canzona, generally referred to as fugal forms because of their relationship to the principle of the fugue (that of melodic imitation), arose out of the growing understanding of and dependence on imitation as a unifying structural technique. Although these designations were applied to a great variety of pieces—some identical in style to the fantasia or prelude—the classic ricercar of the 16th century was virtually an instrumental motet, slow and churchlike in character and consisting of a number of sections, each utilizing imitation. The canzona followed the same structural principle but was a lively counterpart to the chanson, with the sections sometimes in contrasting tempo and metre. Cantus firmus compositions were based upon pre-existing melody. During the 16th century most were designed for liturgical usage but were based upon both secular melodies and plainsong. In most cases the cantus firmus was sounded in long, sustained tones while the other part or parts added decorative contrapuntal lines. The organ mass, in which the choir and the organ alternated lines of the liturgical text, was a popular practice.

Variations also often used a pre-existing melody but differed from cantus firmus compositions in that the melody was much shorter and was repeated a number of times, each time with different accompanying parts. The two basic types during the Renaissance were the plain, or melodic, variations and the ground. In the former, the chosen melody usually appeared in the top part and was varied in each repetition with ornamentation and melodic figuration or with changing accompaniments. The ground, or ground bass, was a simple melodic pattern sounded in the lowest part, which served as a foundation for imaginative figuration in the upper parts.

Solo and ensemble instruments. The four major vehicles for instrumental music of the period were the lute, the organ, stringed keyboard instruments, and instrumental ensembles. Most popular by far was the lute, which could produce the major elements of instrumental style except for long, sustained tones. Noteworthy composers of lute music included Luis Milán in Spain, Arnold Schlick in Germany, and John Dowland in England. The organ, because of its close association with liturgical music, continued to be an important instrument, and its literature includes all of the formal types except dances. Among the leading organ composers were the Germans Paumann, Schlick, and Paul Hofhaimer, the Italians Claudio Merulo and Andrea and Giovanni Gabrieli, the Spaniard Antonio de Cabezón, and the Englishman John Bull.

The two basic classes of stringed keyboard instruments were the harpsichord (virginals, spinet, clavecin, clavicembalo), with quill-plucked strings, and the clavichord, with strings struck by thin metal tongues. Keyboard instruments were highly capable of idiomatically instrumental effects and flourished, particularly in England, from the last half of the 16th century onward, thanks to the composers William Byrd, John Bull, and Orlando Gibbons. A major manuscript source of the keyboard works of these masters is the famous *Fitzwilliam Virginal Book* of the 17th century.

Instrumental ensembles of the Renaissance were not standardized, although consorts (groups) of viols, of woodwind instruments such as recorders and shawms (loud oboes), or of brass-family instruments such as the cornet and sackbut (early trombone) were common. More common, however, were mixed consorts of various types of instruments, depending on the players available. All types of instrumental forms were performed by ensembles except for the prelude and the toccata, which were essentially keyboard works. Representative composers included the Gabrielis and Gibbons.

Vocal music in the 16th century. At the beginning of the 16th century the style of vocal music was generally uniform because of the pervading influence of Netherlanders during the preceding half century. That uniformity persisted well into the late Renaissance but was gradually superseded by emerging national differences, new forms, and the increasing importance of Italy as a musical centre during the last half of the 16th century.

The rapid accumulation of new musical techniques and resources produced a wide vocabulary of artistic expression, and the invention of music printing helped the rapid dispersal of new techniques. In an age in which music was an essential social grace, composers wrote more secular music, in which fewer technical restrictions were in force

and experimentation and novelty were applauded. Advances were particularly apparent in venturesome harmonies as chromaticism (the use of notes not belonging to the mode of the composition) sounded the death knell of the modal system.

Harmonic experiment

Liturgical practice dictated that the mass and the motet remain the chief forms of sacred vocal music. Compared with secular music, their style was conservative, but inevitably some of the newer secular techniques crept in and figured effectively in the music of the Counter-Reformation within the Roman Catholic Church.

Four distinct types of mass settings were established during the century. Two types were continuations of earlier practice: the tenor mass, in which the same cantus firmus served for all five portions of the Ordinary of the mass, and the plainsong mass, in which the cantus firmus (usually a corresponding section of plainsong) differed for each portion. Reflecting the more liberal attitudes of the Renaissance were the free mass, with no borrowed materials, and the parody mass, in which the entire polyphonic web was freely adapted from a motet or a secular composition. In all cases when a cantus firmus was used, the pre-existent melody might appear in its original form or in paraphrased version, with tones added, omitted, or altered. As a result of the upheaval in the church caused by the Reformation, new forms derived from established models appeared in Protestant worship: the German Lutheran chorale (hymn tune, arranged from plainsong or a secular melody), the chorale motet, English anthems (Anglican form of motet) and services, and the psalm tunes in Calvinist areas.

Italy. While not young in a chronological sense, the musical life of Italy was reborn at the beginning of the 16th century after a century of relative dormancy. The frottola remained the prevailing secular form in northern Italy for the first three decades of the century.

When the humanistic poets, seeking a more refined expression, and the Netherlanders and composers trained by them, applying a more sophisticated musical technique, turned their efforts to the frottola, the result was the madrigal. The name was borrowed from the 14th-century form, but there was no resemblance in poetic or musical structure. Compared to the frottola, the earliest Renaissance madrigals, dating from about 1530, were characterized by quiet and restrained expression. Usually written for three or four voices, they were mostly homophonic (melody supported by chords) with occasional bits of imitation. Among the early madrigal composers were several Flemish composers resident in Italy, among them Adriaan Willaert, Jacques Arcadelt, and Philippe Verdelot. About 1560 the normal number of parts increased to five or six, and the texture became more consistently polyphonic. At the same time, more attention was given to expressive settings of the text, notably in the madrigals of Cipriano de Rore, Philippe de Monte, and the Gabrielis. During the last two decades of the century and continuing until the middle of the 17th century, the musical style of the madrigal changed appreciably. The late madrigals were of a very dramatic nature, featuring colouristic effects, vivid word-painting, and extensive chromaticism. Their declamatory character dictated a return to a more homophonic style. Noteworthy among the many composers of the late madrigal were Luca Marenzio, Don Carlo Gesualdo, and Claudio Monteverdi.

Birth of the madrigal

During the course of the century simpler secular forms, such as the villanella, the canzonetta, and the balletto, appeared in Italy, largely as a reaction against the refinement, complication, and sophistication of the madrigal. They reverted to the chordal style of the frottola, often with intentionally parodistic lyrics. The balletto was particularly distinguished by a refrain of nonsense syllables such as "fa la la."

England. Most of the Italian forms, along with their designations, were adopted by Elizabethan England during the last half of the 16th century. Most leading English composers, from William Byrd and Thomas Morley to John Wilbye, Thomas Weelkes, and Orlando Gibbons, contributed to the vast treasury of English secular music. Morley is particularly important as the editor of the most significant collection of English madrigals, the *Triumphes of Oriana,* published in 1603 and dedicated to Queen Elizabeth I (Oriana). These pieces correspond in style roughly to the middle-period Italian madrigal. English counterparts of the canzonetta and balletto were the canzonet and ballett. A late-16th-century innovation in both Italy and England was the ayre (air), a simple, chordal setting especially suitable for a solo voice with a lute or a consort of instruments playing the other parts. John Dowland and Thomas Campion were notable composers of ayres.

France. The French counterpart of Italian and English madrigals was the polyphonic chanson, a continuation of the chief medieval and early Renaissance form of secular music. Revitalized by composers such as Josquin, Clément Janequin, and Claudin de Sermisy, the chanson developed several distinctive features: a clearly delineated sectional structure with some repetition of sections, much vivid programmatic writing, and occasional use of irregular metric organization. The irregular metric structure, called *musique mesurée,* was used for maintaining faithfully the accentuation of the poetry and reflects the traditional primacy of textual over musical considerations in French music.

The chanson

Germany. The lied, or song, continued its 15th-century role as the chief secular form in Germanic areas, but it did not develop to the same extent as the madrigal and the chanson. Throughout the Renaissance it was relatively conservative in its adherence to the cantus firmus principle and its tendency toward chordal over contrapuntal texture. Following Heinrich Isaac in the 15th century, the major 16th-century lieder composers were Ludwig Senfl, Hans Leo Hassler, and Johann Hermann Schein. To all national schools of the 16th century must be added the name of the Flemish composer Orlando di Lasso, who wrote in French, Italian, or German, depending on his current employment. The Spanish villancico was a flourishing popular form, but there was no Iberian equivalent to the madrigal, the chanson, or the lied.

The tonal era and after: 1600 to the present

The beginning of the 17th century was one of the most dramatic turning points in the history of music, even more so than the beginning of the Ars Nova and almost as revolutionary as the beginning of the 20th century. The winds of change had been felt several decades earlier, and the establishment of the new style required several decades after the turn of the century, but the year 1600 saw the performance of several works destined to change the course of music.

THE BAROQUE ERA

Originally used in a derogatory sense of referring to something bizarre, degenerate, and abnormal, the term Baroque gradually acquired a positive connotation for the grandiose, dramatic, energetic spirit in art that prevailed during the period from about 1600 to about 1750. The new spirit required a vastly expanded musical vocabulary, and a rapid evolution of new techniques occurred, particularly in vocal music. Two distinct musical styles were recognized. One, the *prima prattica* (or *stile antico*), was the universal style of the 16th century, the culmination of two centuries of adherence to Flemish models. The other, called *seconda prattica,* or *stile moderno,* referred to the new theatrical style emanating from Italy. The expanded vocabulary allowed for a clearer distinction between sacred and secular music as well as between vocal and instrumental idioms, and national differences became more pronounced. The tonal organization of music evolved also, as the medieval modes that had previously served as the basis of melody and harmony were gradually replaced, during the 17th century, by the system of tonality dominating Western music until about 1900: a system based on contrasting keys, or sets of interrelated notes and chords deriving from a major or minor scale. Viewing the period as a whole, two additional innovations most clearly distinguish it from the preceding Renaissance: concertato, or the contrast, combination, and alternation of voices and instruments, and basso

The spirit of the Baroque

continuo (thorough bass, figured bass), an accompaniment consisting of a low-pitched instrument, such as a violoncello or a bassoon, combined with a keyboard instrument or lute capable of harmonic elaboration.

Opera. Most typical of the emerging style were the dramatic productions of the Camerata, a group in Florence who were dedicated to recreating and imitating the musical ideals and practices of classical antiquity —in a sense, the musical manifestation of the Renaissance. Their guiding philosophy was the pre-eminence of textual over musical considerations; their belief was that the function of music was to heighten the dramatic impact of words. The musical result was monody: originally recitative (solo singing reflecting speech rhythms), later also arioso (more lyric than recitative) and aria (more elaborate song), accompanied by a basso continuo that could provide an innocuous background to a solo voice. Among the major figures in this revolutionary movement were Giulio Caccini and Jacopo Peri, both of whom composed operas based on the legend of Orpheus and Eurydice. Caccini also provided the name for the new movement with his publication of *Le nuove musiche*, a collection of solo songs with continuo accompaniment. The ideas and techniques conceived by the Camerata spread rapidly over Italy and, subsequently, all over Europe.

Early Italian operatic schools. During the 1620s and 1630s the centre of operatic activity shifted from Florence to Rome, where several distinctive features developed: a chorus was used extensively, dancing was incorporated into the dramatic spectacle, and an overture in the style of a canzona became the accepted norm. A flourishing operatic activity developed a decade later in Venice, where the first public opera house was opened in 1637. Public taste began to influence operatic composition, and, as a result, several innovations, such as the extensive use of popular tunes, spectacular staging, and short, fanfare-like overtures, were introduced. The audience's desire for tuneful songs also contributed to the clear distinction between recitative and aria, which began with the Venetian school. Foremost among contemporary composers was Monteverdi, who had known of the activities of the Florentine Camerata while serving as musical director to the Gonzaga family in nearby Mantua. He adopted the new style for his later madrigals and wrote two operas, *Orfeo* (1607) and *L'Arianna* (1608), before moving to Venice in 1613. Francesco Cavalli and Antonio Cesti became the leading Venetian operatic composers after Monteverdi's death in 1643.

17th-century developments in Rome

Neapolitan opera. The last major operatic centre to develop in Italy began its activities in the 1670s in Naples. Neapolitan opera seria, or serious opera, with characters from classical history or mythology, dominated Europe for a century. It was essentially a series of recitatives and arias, the latter mostly of the da capo type (ABA, the A section given improvised embellishment on its repetition) characterized by florid virtuosic singing. Other features were, first, the distinction between recitativo secco (dry recitative), accompanied by the continuo, and recitativo accompagnato, or stromentato, accompanied by the orchestra, and, second, the establishment of the Italian overture. Called a sinfonia, the overture in three parts (fast–slow–fast) evolved into the symphony during the 18th century. Alessandro Scarlatti was the most influential of the early Neapolitan operatic composers.

France. During the same period, opera was introduced at courtly functions outside Italy. After Luigi Rossi's *Orfeo* was performed in Paris in 1647, the Italian form was gradually merged with the major French dramatic form, the ballet; the importance of dancing in French operas thereafter is not surprising. Another distinguishing feature was the French overture (a slow movement, a fast movement, and, occasionally, a return to the opening slow section), which, like the Italian overture, later had an independent life. The masters of French opera during the Baroque period were Jean-Baptiste Lully and his successor Jean-Philippe Rameau. Because of the social and political upheaval of the Thirty Years' War, there was less operatic activity in Germany than in France, and the activity that did occur was more completely dominated by the Italian style. Hamburg, Munich, Dresden, and Vienna were the major centres, with Reinhard Keiser and Georg Philipp Telemann as the most prolific composers.

The joining of the French and Italian forms

England. The situation in England resembled that in France, since the English also had a flourishing musico-dramatic form, the masque, which gradually merged with Italian opera. Henry Purcell and John Blow were the chief composers of opera in English before Italian domination of serious opera became almost complete during the 18th century.

Cantata and oratorio. The leading Neapolitan opera composers also helped to establish the Baroque successor to the madrigal—the cantata—which originated as a secular form for solo voice with instrumental accompaniment. Giacomo Carissimi standardized the form as a short drama in verse consisting of two or more arias with their preceding recitatives. The cantata was introduced into France by one of Carissimi's students, Marc-Antoine Charpentier; Louis Nicolas Clérambault continued the tradition in the late Baroque period. With the fading stylistic distinction between sacred and secular music, the cantata was quickly converted to church purposes, particularly in Germany, where it became the chief decorative service music for the Lutheran Church. Dietrich Buxtehude and Johann Kuhnau were two of the leading composers of such church cantatas.

While the new concertato techniques were being applied to established forms of church music, such as the mass, service, motet, anthem, and chorale, new forms emerged that were clear departures from Renaissance styles and types. The oratorio and settings of the Passion story developed simultaneously with opera and on almost identical lines, consisting of recitatives, arias, vocal ensembles, instrumental interludes, and choruses. Emilio de' Cavalieri was the "founder" of the oratorio with his *La rappresentazione di anima e di corpo* (*The Representation of the Soul and the Body*). Produced in Rome in 1600, this work, unlike true oratorio, used actors and costumes. Carissimi and Alessandro Scarlatti were the chief Italian Baroque composers of oratorio, and Heinrich Schütz, a pupil of both Giovanni Gabrieli and Monteverdi in Venice, was the leading 17th-century German composer in this field.

Instrumental music. The new techniques of *Le nuove musiche* were to be heard in music for instruments, especially now that they participated in genres formerly written for unaccompanied voices (*e.g.*, the motet). The forms and mediums of instrumental music remained essentially the same but with considerably different emphasis. The lute, for example, lost status quickly with the rise of the harpsichord as the most common instrument for continuo accompaniment of dramatic productions. The organ, as the traditional church instrument, retained its position and assimilated the evolving forms.

Continuo instruments

Modification and expansion of older forms. Dance pairs of the Renaissance grew, about the middle of the 17th century, into dance suites consisting basically of four dances: allemande, courante, saraband, and gigue, with optional dances such as the gavotte, the bourrée, and the minuet sometimes inserted before the final movement. Variation forms—the chaconne (in which a set of harmonies or a bass theme is continuously repeated), the passacaglia (in which the theme is repeated but not necessarily in the bass), along with the ground bass and variations on well-known melodies—continued to be popular. Free forms also continued in the patterns of their Renaissance antecedents, while growing in dimension and inventiveness. The toccata, prelude, and fantasia were expanded into multisectional forms using the three basic instrumental textures—imitative counterpoint, chordal homophony, and virtuosic passage work—in combination, alternation, and contrast. The Renaissance fugal forms, chiefly the canzona and the ricercar, gradually evolved into the late Baroque fugue, and cantus firmus compositions continued to flourish as a result of their liturgical function.

The sonata and concerto. The major new categories of instrumental music during the Baroque period were the sonata and the concerto. Originally applied to instrumen-

tal ensemble pieces derived from the canzona, the term sonata became the designation for a form that was to dominate instrumental music from the mid-18th until the 20th century. In its keyboard manifestation, it was a binary (two-part) structure similar to a dance-suite movement. For small ensemble, it evolved into a series of independent movements (usually in a slow–fast–slow–fast arrangement) called a *sonata da chiesa* ("church sonata") or a dance suite called a *sonata da camera* ("chamber sonata"). Especially prominent was the trio sonata, for two violins (or flutes or oboes) and cello with continuo. Eventually, similar forms were adopted for orchestra (sinfonia or concerto), for orchestra with a small group of featured instruments (concerto grosso), or for a solo instrument with orchestra (solo concerto). The fundamental principle of the concerto was that of contrast of instrumental groups and musical textures.

Throughout the period, keyboard music flourished, notably in the hands of Jan Pieterszoon Sweelinck in the Netherlands, Johann Pachelbel and Johann Froberger in Germany, Girolamo Frescobaldi in Italy, and Domenico Scarlatti in Spain; in France the chief exponents included Rameau and François Couperin.

Instrumental ensemble music, both chamber and orchestral, was dominated by Italians, chiefly from Bologna, the Bolognese school producing such composers as Arcangelo Corelli, Antonio Vivaldi, and Giuseppe Tartini. Purcell in England and Couperin and Jean-Marie Leclair in France are representative of the many composers in other nations who were influenced by Italian models of instrumental ensemble music.

The late Baroque. The Baroque era reached its zenith in the work of Johann Sebastian Bach (1685–1750) and George Frideric Handel (1685–1759). Both were born in the same part of Germany; both were reared in the Lutheran Church; and both were primarily organists; but because of different environmental circumstances each became a master of different musical forms. Handel, because of his conditioning in Italy, was primarily a dramatic composer, writing opera, oratorio, and secular cantatas, mostly after he reached England. He also wrote quite extensively for orchestra and instrumental ensemble. Bach, by contrast, was influenced by his lifelong employment in the church and by his dedication as a teacher; his works thus include Passions, cantatas for church services, liturgical organ pieces, and harpsichord compositions, many instructional in purpose.

The primacy of Bach and Handel

In the works of both Handel and Bach changes in technique reached a culmination with the clear establishment of the tonal system, allowing for modulation from one key centre to another, primarily as a device for formal organization. Rich, chromatic harmonic language was both reason and result of such a change. The fusion of contrapuntal technique with homophonic style resulted in a distinctive hybrid texture that employed figured bass (homophony) as a foundation for two or more independent melodic lines (polyphony).

THE CLASSICAL PERIOD

The term classical

As in the case of the Renaissance, difficulties with terminology again arise with the label classical. Does it refer to a period of time, a distinctive musical style, an aesthetic attitude, an ideal standard, or an established norm? Again, the term was borrowed from the visual arts of the same epoch and is awkward when applied to music in that there were no known models from classical antiquity for composers to imitate. A full understanding of the term depends on a clear conception of the term romantic, for the two stand at opposite poles. Each represents a set of artistic ideals that has been in opposition to the other since both were recognized by early Grecian writers. As has been noted, the ancient Greek followers of Apollo established the ideal of classicism, whereas the cult of Dionysus produced the prototype of romanticism. A mixture of the two qualities has prevailed throughout recorded history, with first one and then the other in the ascendancy. Thus, there have been many "classic" and many "romantic" eras, but the labels have come to refer most specifically to the last half of the 18th century and the 19th century, respectively, because those periods represent most vividly the two tempers.

The social and political scene during the late 18th century was hardly a setting for a quiet, composed "classical" age in view of the prevailing revolutionary spirit and colonial rivalry. The revolutionary movement did have a direct effect on music in that "music for the masses" became a new ideal—music directly appealing to a large number of unsophisticated people who had previously been excluded from courtly entertainments.

Precursors of the Classical style. *The Rococo style galant.* As the pendulum swung from the predominantly romantic Baroque period toward the Classical period, there was an inevitable overlapping of the old and the new. While Bach was composing his intricate and erudite polyphony, his sons were reflecting a new ideal, the Rococo. Fostered by the court of the French king Louis XV, whose life-style was far less formal than that of his illustrious great grandfather, the Rococo ideal was artistic expression dedicated to elegance, frivolity, and gracefulness; a work of art must be delicate, playful, entertaining, and immediately appealing. The result was often artificial and unrealistic, but it succeeded in capturing the discreetly sentimental and hedonistic attitudes of the times. Powdered wigs, lace cuffs, and perfumed handkerchiefs for both sexes were other manifestations of the same playful spirit that produced music in the *style galant.*

The empfindsamer Stil. The German counterpart of the essentially French Rococo was the *empfindsamer Stil,* or "sentimental style," which flourished in the 1750s and 1760s. Its leading exponent was one of J.S. Bach's sons, Carl Philip Emanuel Bach, who served for a time at the court of Frederick the Great in Berlin. The distinguishing feature of this German reaction against Baroque profundity was its concern with emotional feeling in the music itself, on the part of the performers and, hopefully, in the reaction of the audience. The French obsession with lightness, gracefulness, and decoration was countered by the German determination to affect sensibilities that were often more attuned to tears than to laughter. A late and less reserved manifestation of *Empfindsamkeit* was the *Sturm und Drang* ("storm and stress") movement in the arts during the 1770s and 1780s. The inclination toward the more intense personal expression of that movement was a harbinger of the coming Romantic period.

Consolidation of the Classical style. The fundamental changes in musical style that distinguished Classical from Baroque were inspired by Rococo ideals and refined and stabilized by the Classicists, particularly Joseph Haydn, Wolfgang Amadeus Mozart, Christoph Willibald Gluck, and the young Ludwig van Beethoven.

Stylistic elements. For the first time in the history of music, instrumental music became more important than vocal music. The orchestra and chamber groups, such as the string quartet, trio, and quintet, and the piano trio became standardized and replaced the heterogeneous trio sonata and other ensembles of the Baroque period. The basic duple and triple organization of metre remained unchanged, but rhythmic patterns tending toward more regularity and simplicity became the rule, producing the "tyranny of the bar line" that was to prevail for more than a century.

Central role of instrumental music

Melody was inclined to be more motivistic, tuneful, and epigrammatic, in contrast to the extended, figurative style of many Baroque melodies. Harmony was second only to melody as a focal element. Harmonic patterns that clearly established the tonal centre were the rule of the day.

As a reaction against the intricate polyphony of the later Baroque period, homophonic texture dominated by melody became the norm, but the accompanying patterns were different from those of the early Baroque, when monody supported by sustained chords was the prevailing style. In the late 18th century, figurations such as the Alberti bass (form of accompanying figure consisting of broken chords) and rhythmically enlivened repeated chords formed the typical textural patterns. Counterpoint was retained in some forms, however, and regained status particularly in development sections of works in sonata form.

Formal structure, a definitive aspect of classical style, was characterized by simplicity and clarity. Sectional forms (created by contrast and repetition of thematic materials, tonalities, and textures), variations, and the new principle of development (fragmentation, expansion, and modification of themes) were the established norms. Phrases of musical material became shorter and more clearly demarcated as well as more balanced and regular. A new concept of dynamic contrast also contributed to formal clarity. Shading from loud to soft or vice versa provided a dramatic means of building toward an expressive climax. Orchestration and instrumentation were closely allied to dynamic variation, and much more colour contrast and variety appeared in orchestral music, even though the ensemble was more standardized than formerly.

Sonata form. The pattern that served as the structural basis for most instrumental music of the classical period was the sonata. A large-scale work in several movements, it evolved from several Baroque predecessors, chiefly the Italian overture, the *sonata da chiesa,* and the concerto grosso. Depending on the medium of performance for which it was intended, it would be called, for example, a symphony, a concerto, a string quartet, a sextet, a trio. The designation sonata was reserved for a solo instrument or for an instrument accompanied by harpsichord or piano. Originally in three movements, the sonata became standardized as a four-movement form when a minuet was incorporated in the following sequence: (1) a serious allegro, (2) a slow, lyrical movement (andante or adagio), (3) a minuet and trio, and (4) a brilliant, vivacious finale. The internal structure of the first movement was so uniform that it acquired the designation sonata-allegro form; that is, the form employed in the allegro movement of a sonata, consisting basically of exposition, development, and recapitulation. The slower second movement is less structurally predictable. It is frequently a sectional form (for example, ABA, AABA, ABCA) or a set of variations. It may, even though in a slow tempo, be a sonata-allegro form, illustrating again the inconsistency of musical terminology. The third movement, usually omitted in the concerto and sometimes in other forms, is either a graceful minuet or a scherzo, a lively rhythmic form derived from the minuet. The structural pattern of the minuet had been fixed when it was established as the official court dance by Louis XIV in the mid-17th century. The last movement is frequently a rondo form, in which the principal theme recurs regularly between subordinate themes.

Instrumental music. *The symphony.* The most important and influential manifestation of the sonata form was that played by an orchestra—the symphony. During the 17th century the term sinfonia had been used for various kinds of instrumental music. "Sonata" was equally ambiguous. Late in the century, the designation sinfonia began to be confined to the Italian opera overture—a three-movement arrangement, fast–slow–fast. By the mid-18th century, opera overtures were being played independently in concerts. The insertion of the minuet between the last two movements resulted in the prototype of the Classical symphony.

During the waning Baroque period, vigorous advocates of the burgeoning Rococo and *Empfindsamkeit* ideals were active in Milan, Vienna, and Mannheim. In Milan, Giovanni Battista Sammartini began writing his symphonies, some 25 of them, in the 1730s. While employing the continuo of his models, Corelli and Giuseppe Torelli, the bithematic plan for his opening movements foreshadowed the exposition of the Classical symphonies. At about the same time, young composers in Vienna were experimenting with the new genre, thus laying the foundation for the later Viennese masters. The most famous and probably the most influential group was active in Mannheim in the court orchestra of Karl Theodor, the elector of the Palatinate. Their activity began in the 1740s, when Johann Stamitz became leader of the orchestra. His experiments with dynamic techniques—crescendo (increasing in loudness), diminuendo (decreasing in loudness), sforzando (special emphasis)—with homophonic textures featuring the first violins in virtuoso passages and with tremolo and other dramatic effects, became the hallmarks of the Mannheim style and served as models for his son Karl Stamitz and for composers in Vienna. Thanks to the fortuitous presence of certain instrumentalists as well as to benevolent patronage, the basic ensemble of the modern symphony orchestra was gradually established: violins, violas, violoncellos, and double basses; two flutes, two oboes, and two bassoons; two French horns and two tympani. Trumpets were added for festive occasions.

The Mannheim school

The concerto. Unlike the symphony, which had its origins in other forms, the Classical concerto grew directly out of the Baroque solo concerto and resembles it in that it is based on exchange of musical material between solo instrument or instruments and orchestra. While directly derived from the ritornello principle of the Baroque concerto (that of a recurrent musical passage when the soloists are silent), the internal structure of the first movement assimilated the developmental principle of sonata-allegro form. Pietro Locatelli and Giuseppe Tartini are especially notable for their numerous late-Baroque violin concerti.

Chamber music. While music for small instrumental ensembles had flourished for over 200 years previously, the late 18th century witnessed the establishment of chamber music in the modern sense of the term: music in sonata form for a small group of instruments with one player for each part. Replacing the trio sonata of the Baroque period, the most popular classical ensemble was a group of four stringed instruments—two violins, a viola, and a violoncello. Both the group itself and a sonata written for the group were called a string quartet. Among other popular ensembles were the string trio (violin, viola, and violoncello; or two violins and a violoncello) and the piano trio (violin, violoncello, and piano).

The keyboard sonata. The solo keyboard sonata was one of the most vital forms of the period, partly because of the great increase in amateur performers resulting from the newly affluent middle class. The sonatas of Domenico Paradisi, of J.S. Bach's sons, and of Haydn and Mozart reflect the evolution from the one-movement, binary form of the Baroque period to the standard classical three-movement form. A four-movement form did not become popular until the time of Beethoven. A celebrated contemporary of Mozart, Muzio Clementi, composed more than 60 sonatas for the piano alone and half again as many for piano and violin or flute and strongly influenced the style of piano writing.

Clementi's 60 sonatas

Other instrumental forms. While the sonata was unquestionably the most important form of instrumental music during the period, several other types were cultivated. For orchestra and chamber ensemble, a suitelike work called variously divertimento, serenade, cassation, or notturno was popular for light entertainment, differing from the more serious symphonies, concerti, and sonatas (which were intended for attentive listening) in that the ensemble of instruments was inconsistent, unpredictable, and often unspecified. The number, types, and arrangements of movements were equally flexible, ranging from three to ten or more, some in dance forms and others in forms suitable for a sonata. While nonsonata forms for solo instruments (particularly keyboard) occasionally bear these designations, the most popular smaller solo forms were sets of variations, individual dances or marches, fantasies, and small pieces that would have been appropriate as movements of sonatas. For some reason, composition for the organ dwindled drastically after the death of J.S. Bach, in 1750.

Vocal music. *Opera.* There was less distinction between Baroque and Classical opera than between instrumental styles of the two periods because opera, with musical interest centred on a solo voice, had been largely melodic–homophonic since its inception. Another reason for the continuity of operatic style throughout the 18th century was the universal domination by the Neapolitan opera seria. Even in Paris, where the Lully–Rameau tradition maintained its vitality, there was an Italian opera theatre. While there was some effective reform of certain

aspects of Neapolitan style that had become decadent and some nationalistic reaction in the field of comic opera, nothing in the nature of serious opera challenged Neapolitan supremacy. As a result, the late 18th century was a period of great vitality in operatic composition.

Domination of opera seria

The distinguishing characteristics of Neapolitan opera seria reveal why it is little known and rarely heard today. It was a very conventionalized form, with artificial and overcomplex plots. There were usually six main characters representing three of each sex, with some of the male and female parts sung by castrati (emasculated male sopranos and contraltos). Each character was allotted a standardized number of arias in fairly standardized succession. Obviously, with such constant interruption of the action, dramatic truth received little if any consideration. The singers and the arias were the focus of the entire production, with little of musical interest in the parlando recitatives (*i.e.*, using speech rhythms), little use of chorus, and little function for the orchestra aside from providing a subordinate accompaniment.

Objections to the decadence and artificiality of the Neapolitan style, which had begun to appear as early as the 1720s, would have been fruitless had not a champion appeared to put suggestions and theories for reform into actual practice. Culminating the movement for reform was Christoph Willibald Gluck, who began his career in the 1740s by writing about 20 operas in the prevailing style. Then, beginning with *Orfeo ed Euridice* in 1762, he attempted to enhance both the dramatic and musical components of opera. Superfluous virtuosity and vocal display were drastically curtailed if not eliminated by providing music that reflected the emotional or dramatic situation. As a result of Gluck's reforms, opera moved toward a classical simplicity of style of which his and Mozart's works were the culmination.

Comic opera

A second challenge to established Neapolitan opera was emerging through comic opera in which the subject matter was light, sentimental, often topical, and satirical, reflecting both the social changes of the period and ridicule of serious opera. The music was engagingly tuneful, easy to perform and to comprehend. Comic opera had appeared during the 17th century but began its independent existence during the first half of the 18th century in Italy, where it was called the opera buffa. The French opéra comique evolved during the same period and was given new impetus by the *guerre des bouffons* ("war of the buffoons") of the early 1750s, when support of the Italian opera buffa company then performing in Paris exceeded that of the French heroic opera of Rameau. In England, ballad opera, beginning with *The Beggar's Opera* in 1728, followed a course of development similar in both period and style to that of the opéra comique. German singspiel grew out of translations and imitations of English ballad opera. Models that centred on Vienna adhered to the Italian style and culminated in Mozart's *The Abduction from the Seraglio* and *The Magic Flute*. Yet Mozart also brought the old Italian style to its zenith in *Le Nozze di Figaro (The Marriage of Figaro)*, *Così fan tutte (Thus Do They All)*, and *Don Giovanni*.

Other vocal music. Aside from opera, secular vocal music was composed for solo voice and chorus. But the production of solo songs and cantatas in other countries could not compare with the growing interest in the German lied, which flourished under C.P.E. Bach and later composers. The most extensive development of secular part-songs took place in England, where numerous catches and glees were written.

Large-scale sacred choral music of the period was strongly influenced by the prevailing operatic style. Except for the text, some passages from oratorios and passions are indistinguishable from an operatic excerpt. But the Handelian tradition combined with the Neapolitan style and culminated in Haydn's two noble oratorios, *The Creation* and *The Seasons*. Liturgical music, such as masses, motets, litanies, psalms, and canticles, also demonstrated that the same composers were writing for both church and theatre. In many instances the style was uniform for the two types, although the chorus naturally played a much greater role in church music.

THE ROMANTIC PERIOD

The beginning of the 19th century witnessed a change of both musical style and aesthetic attitude that has become identified as Romantic. The term romantic originated in German literature of the late 18th century, illustrating once again the overlapping of classical and romantic attitudes and ideals. The Franco-Swiss writer Mme de Staël articulated the new ideals of the movement in 1813 as original, modern, national, popular, derived from the soil, religion, and prevailing social institutions. Obviously, some of these proclaimed romantic ideals and purposes were the same as those of the 18th-century Classicists.

Establishment of the Romantic idiom. In defining classicism, it was suggested that the distinctive elements of musical romanticism embrace emotionalism, subjectivity, individualism, nationalism, and a preference for a certain type of subject matter. Emotionalism is reflected in the revelation of intensely personal feelings, indeed, the sentimentality that pervades 19th-century music. Subjectivity replaces the formalism of the Classical period, in that impulse and inspiration play a major role in the motivation of both composer and performer, and the listener's response is expected to be more sensory than intellectual. Closely related to subjectivity is the individualism reflected in the highly self-centred expression of composers of the period, as well as by the conviction that a composer's most personal thoughts and feelings are the ultimate artistic message. In contrast to the universality of musical style that prevailed during the 18th century, much 19th-century music is identifiable in terms of national origin. Nationalism—the consciousness of the distinctive features of a nation and the intent to reveal, emphasize, and glorify those features—played a prominent part in Romantic music, partly as a result of social and political developments. The subject matter favoured by Romantic composers is most apparent in vocal music, where words can convey the explicit theme, but instrumental music was also affected by the Romantic attraction to national identification and to remoteness, strangeness, and fantasy, particularly to the fantastic aspects of medieval tales and legends.

Personal aspect of romanticism

Stylistic traits. During the 19th century, musical techniques and materials were rapidly enriched by new resources, all devoted to the ideal of emotional or dramatic expressiveness. The orchestra, the piano, the solo voice with piano accompaniment, and the opera were the four predominating mediums; chamber and choral music occupied a less central position. Duple and triple divisions of the measure remained the basis of metre, but there were occasional experiments with metric irregularity, and rhythm was recognized as one of the most effective agents of expressiveness in music. Strong rhythmic energy, frequently produced by dotted patterns, provided a vigorous force that could be enhanced by faster and faster tempi. Flaccid patterns in slower tempi provided for the requisite pensive or sorrowful moods.

Melodic style was determined on one hand by the vocal ideal of song, with long, lyric lines. On the other hand, the new idiomatic possibilities of instruments were being exploited. In either case, expressiveness was the governing ideal. Harmonic and tonal elements were gradually expanded during the century, with more chromaticism, enriched sonorities (seventh and ninth chords), and more nonharmonic tones resulting in a more flexible tonal scheme. Tonic and dominant chords (those based on the first and fifth notes of the key), were no longer the secure poles of tonal movement; frequent and remote modulations (changes from one key to another) contributed to the restlessness of key centres. Because musical interest was centred in melody and harmony, texture remained prevailingly homophonic, though counterpoint played a prominent role in developmental sections. Fugues and other imitative forms occurred as a result of studied archaism or for special effect, but the composers' preoccupation with direct and immediate expression led them to neglect the traditional polyphonic forms, with their inherent traditions and restraints.

Increasing importance of modulation

The Romantic abhorrence of formalism has frequently been exaggerated for the purposes of distinguishing be-

tween Classical and Romantic attitudes. Established patterns such as the sonata-allegro and rondo forms were subjected to many modifications and extensions, but musical coherence demands a judicious balance of unity and variety, so most compositions of the 19th century are still fairly clear-cut sectional, variational, or developmental forms. The distinctive new features are largely in the area of emphasis and dimension—symphonies lasting over an hour in contrast to the 20- to 30-minute standard of the Classical period. Instrumental colour and variety, as another aspect of expressiveness, was made possible by a greatly enlarged orchestra and figured prominently in the new sound ideal.

Beethoven as a transitional figure. The Janus-like figure who marked the transition from the Classical to the Romantic style was Beethoven, the first composer whose personality and character made a purposeful impact on the types and style of music he composed. Inspired by the revolutionary forces prevailing at the time, he declared himself a free artistic agent, with neither allegiance nor responsibility to any patron. His early works reflected the 18th-century acceptance of providing music on demand, and he applied his craftsmanship to supplying compositions in hope of financial reward. But in his later works, from about 1820 on, he declared his personal independence and wrote only what his imagination and inspiration dictated, thus establishing individuality, subjectivity, and emotional expression as the standard for Romantic composers. Yet the body of music he produced reflects the tastes of the 18th rather than the 19th century, in that he was attracted more by the absolute forms of instrumental music than by the dramatic and lyrical forms cultivated by the Romanticists. Symphonies, chamber music (particularly string quartets), and piano pieces (including 32 sonatas) far outweigh his one opera, one oratorio, one major mass, and assorted songs and part-songs. His lack of interest in dramatic vocal music reflects the classical side of his nature, though the expressive changes apparent in his instrumental works are evidence of his being the springboard to the Romantic epoch.

Opera. The opera remained a flourishing medium throughout the 19th century, and Italian opera continued as the dominant type during the first half of the century in the hands of Gioacchino Rossini, Vincenzo Bellini, and Gaetano Donizetti. The reforms instigated by Gluck were discernible, but enough of the genre's indigenous Italianate character remained to distinguish it from other national types. The man who, more than any other, personifies Italian opera of the period is Giuseppe Verdi (1813–1901), whose works are still among the most performed. Late in the century, the tendency toward even more realistic and topical subject matter produced the *verismo* ("realism") school of Ruggiero Leoncavallo, Pietro Mascagni, and Giacomo Puccini.

Meanwhile, German opera developed into the epitome of romantic subject matter and expressiveness, beginning in 1821 with the performance of *Der Freischütz* (*The Freeshooter*), by Carl Maria von Weber. Plots based on tales from Teutonic mythology and medieval legend that emphasized the mystical aspects of nature were a distinctive feature of Germanic operas and distinguished them from the more mundane Italianate plots. Richard Wagner (1813–83) crystallized the German Romantic ideal into the music drama, in which all aspects of the production—drama, music, design, performance—were intended to fuse into a manifestation of pure artistic expression in which no one element predominated over the others, as singing still tended to do in Italian opera. There was no development in Germany after Wagner comparable with the post-Verdi *verismo* group in Italy. Wagner's innovations—once again a readjustment of dramatic versus musical forces in musical theatre—were the point of departure for most German opera since his time, from Richard Strauss to the present.

Wagner's music drama

In Paris, the operatic centre of the world from late in the 18th century until well into the 19th, native composers were quick to sense the Gluckian changes in Italian opera as well as the new directions in Germany. Beginning with Rossini's *Guillaume Tell* in 1829 and crystallizing in the operas of Giacomo Meyerbeer in the 1830s and 1840s, French grand opera emerged as the most opulent and grandiose musico-dramatic spectacle of the first half of the century. During the later 19th century, opéra comique and grand opera merged to produce the prevailing French lyric opera. At the same time, opéra comique branched off in another direction to produce operettas, which developed into the musical comedies of the 20th century. Indigenous opera appeared in other regions, especially in Russia, Bohemia, and Scandinavia, as a result of nationalistic fervour.

Orchestral music. Reaching both a culmination and a turning point in the nine symphonies of Beethoven, orchestral music developed in two directions during the 19th century. On the one hand were composers who, because of their training and temperament, adhered primarily to Classical forms and ideals of absolute music. On the other hand were the composers seeking new realms of dramatic content, colour, and expressiveness. Even for the more conservative group, both the forms and the orchestra itself were greatly expanded during the century, but the total output of works was much smaller than in the Classical period. Romantic musical vocabulary replaced the Classical language in symphonies, of course, and programmatic content (*i.e.*, an extramusical image or story) was a frequent element.

New orchestral forms. The more progressive composers cultivated new musical types that represented the tastes and ideals of the Romantic period—the concert overture, the symphonic poem (later called tone poem), the symphonic suite, and symphonic variations. The concert overture, a direct development of overtures to dramatic works, was an attempt to reconcile the old classical demands for form with Romantic desire for programmatic content. It was usually a sonata-allegro form with picturesque themes designed to suggest (with the help of the title) characters, locations, or dramatic situations. Felix Mendelssohn's *Hebrides* overture and Brahms's *Tragic Overture* (completed 1880) are representatives of the genre. The symphonic poem, foreshadowed in Hector Berlioz' *Symphonie fantastique* (completed 1830), was originated by Franz Liszt at midcentury as an orchestral work, usually in one movement, based on an extramusical idea such as a poem or a narrative. The futility of attempting to depict explicit events and attitudes in purely musical terms resulted in the demise of the form early in the 20th century after the many tone poems of Richard Strauss. The symphonic suite was one of three distinct types: (1) an outgrowth of 18th-century dance suites, divertimentos, or serenades, (2) the extension of the symphonic poem into a composite work of several movements of related programmatic nature, or (3) a group of selections from a dramatic work such as a ballet. Rimsky-Korsakov's *Scheherazade* represents the second type, and Tchaikovsky's *Nutcracker Suite* is typical of the third. While variations had appeared as movements of symphonies and concerti since the mid-18th century, they became an independent orchestral form during the last quarter of the 19th century. César Franck's *Variations symphoniques* (1885) is a good example of the type. Popular orchestral pieces, such as the waltzes of Johann Strauss, also flourished.

Programmatic and picturesque works

The mainstream of composers whose orchestral music reflected most clearly their allegiance to classical forms and models—though conditioned by Romanticism, of course—is represented by Beethoven, Franz Schubert, Robert Schumann, Johannes Brahms, and Anton Bruckner. The more overtly Romantic contingent was centred around Berlioz, Liszt, Gustav Mahler, and Richard Strauss.

The movement toward national expression. A third group, chiefly nationalists who were reacting against Germanic domination of instrumental music as well as reflecting the sociopolitical developments of the era, combined features of both conservative and progressive camps, to which they added national characteristics. While there were manifestations of the movement in countries such as Hungary, Poland, Spain, and England, the most productive and outstanding of those who sought

to reflect national distinctiveness were the Russian "Five" —César Cui, Mily Balakirev, Aleksandr Borodin, Modest Mussorgsky, and Nikolay Rimsky-Korsakov—the Bohemians Bedřich Smetana and Antonín Dvořák, and the Scandinavians Edvard Grieg, Carl Nielsen, and Jean Sibelius. French composers such as Camille Saint-Saëns, César Franck, and Vincent d'Indy were motivated by the same impulse of independence, but they could hardly be categorized as nationalists in the same sense as their eastern European colleagues, since there was less distinctive folk material from which to draw colourful materials and since they had been in the mainstream of musical development all along.

Piano music. One of the most popular media of the Romantic era, thanks to the rapid technical development of the instrument, was piano music. Another reason for the popularity of the piano was the growing demand for recreation and entertainment on the part of the newly affluent middle class. In tune with the taste of the times, small pieces of distinctive expressive character (hence, "character pieces") were the most popular type, either as single pieces or as parts of composite works. Stylized dances continued to be popular, but nationalistic types such as the polonaise and mazurka and the novel waltz replaced the staid minuets of the previous era. Sonatas continued to occupy serious composers, and sets of variations continued to flourish. The virtuosity of the violinist Niccolò Paganini and his contemporaries led to many studies, or études, designed to exhibit the performer's dexterity as well as the invention of the composer. Chopin, Schumann, Liszt, and Brahms were the major composers of piano music after Beethoven, but practically all composers of the time contributed to the literature.

Songs. The vocal counterpart of the keyboard character piece was the solo song with piano accompaniment. With the rise of the German romantic poetry of Goethe, Schiller, Heine, and others, about the beginning of the 19th century, the German lied ("song") flourished. After 1850, composers of other nations, especially France and Russia, also produced a song literature of universal appeal. A pioneer and certainly the most prolific composer of lieder was Schubert, who in his short life wrote more than 600 songs. His chief successors, in chronological order, were Karl Loewe, Mendelssohn, Schumann, Brahms, Hugo Wolf, and Richard Strauss.

Schubert's 600 lieder

Chamber and choral music. The great Viennese tradition of chamber music reached its zenith in the works of Beethoven and with the death of Schubert came temporarily to a close. The conciseness, unity, and balance that were basic to the Classic ideal were incompatible with the essence of musical Romanticism. When writing for instruments, the typical Romantic composer was inclined toward the colouristic effects and expressive possibilities of the orchestra. Chamber music continued to be written and performed, of course, but nowhere was it one of the primary interests of composers as it had been during the 18th century. Predictably, the more conservative composers, such as Mendelssohn, Schumann, and Brahms, were the chief composers of chamber music.

While the same musical vocabulary and style had served both church and opera house since the rise of dramatic music, the 19th century witnessed a separation of musical idioms according to function—sacred or secular. Music for use in church was generally conservative, especially after the "rediscovery" of Palestrina and systematic research into the reform of Gregorian chant. On the other hand, cantatas and popular part-songs produced for the many amateur choral societies incorporated as many of the new techniques as could be managed by the singers. There was some fusion of the two idioms in oratorios and in settings of liturgical texts for the concert hall or for special occasions. The requiem mass, with its vividly dramatic content, was attractive to Romantic composers, and Berlioz's and Verdi's settings remain as emotionally telling today as most operas of the period.

MODERN PERIOD

Diversity of styles. The striking changes in musical style that occurred about 1900 were a turning point in the history of Western music comparable to the dramatic transformation of the early 14th and early 17th centuries. But never before had the change been so rapid, and never before had there been such a diversity of resulting styles. The last decades of the 19th century witnessed what might be termed the diffusion of Romanticism, when significant departures from the current musical vocabulary appeared in the works of some nationalist composers and especially in the Impressionistic style represented in France by Claude Debussy and Maurice Ravel. The amorphous rhythmic patterns, the whole-tone scale, the concept of free relationship of adjacent harmonies, and the kaleidoscopic textures of musical Impressionism were a musical manifestation of the aesthetic movement current in painting and literature.

The experimental works of Arnold Schoenberg and Igor Stravinsky about 1910 heralded a new epoch in music. Schoenberg was the pioneer when his adoption of the ideals of the Expressionist movement—like Impressionism an aesthetic development shared by other art forms —resulted in his discarding traditional concepts of consonance and dissonance as well as tonality and led into the development of atonality and 12-tone technique (in which all 12 tones of the octave are serialized, or given an ordered relationship). Stravinsky's revolutionary style, variously labelled "dynamism," "barbarism," or "primitivism," concentrated on metric imbalance and percussive dissonance and introduced a decade of extreme experimentation that coincided with World War I, a period of major social and political upheaval.

Stravinsky's innovations and experiments in Neoclassicism

In contrast with Schoenberg's and Stravinsky's experiments during the second decade of the century, another line of demarcation appeared about 1920 with a general return to the aesthetic ideals of the late 18th century. Under the leadership of Stravinsky, Paul Hindemith, Béla Bartók, and Sergey Prokofiev, among others, most prominent composers entered a Neoclassical period characterized by restraint of emotional content; simplification of materials, structures, and textures; a greater attention to craftsmanship; and a revival of concern for linear counterpoint rather than instrumental or harmonic colour. Baroque emphasis on counterpoint and Classical formalism were now clothed in 20th-century melodic, harmonic, rhythmic, tonal, and orchestral idioms. The Expressionist followers of Schoenberg, most notably Alban Berg and Anton von Webern, remained aloof from the Neoclassical movement and continued in their preoccupation with serial techniques.

Neoclassicism continued as the dominant trend throughout the period from about 1920 until World War II, while the experimental techniques introduced during the revolutionary second decade of the century were gradually refined, modified, and assimilated into the accepted musical vocabulary. At the same time, experimentation continued alongside a tenacious conservatism that echoed Romantic ideals and styles. Nationalism also continued to flourish, reaching a level in some countries never achieved during the 19th century.

After World War II the two leading artistic attitudes tended to merge when the followers of Webern carried serial composition to such a rigorous extreme that its craftsmanship and intellectual orientation suggested Classicism rather than Expressionism. Shortly afterward, Stravinsky, the doyen of the Neoclassical group, began experimenting with serialism. Avant-garde music since that time has begun to employ the techniques made possible by technological developments in electronics.

Advent of electronic composition. Beginning about 1950, two leading groups began experimenting with electronic music, one in Cologne and the other in Paris. The product of the latter group was referred to as *musique concrète* in acknowledgement of the principle that preexisting, or "concrete," recorded sounds serve as the basis of all sonorities in the finished work. The basic sounds, which may be derived from any source—musical, natural, or mechanical—are modified electronically and arranged in any combination and succession suitable to the composer's purpose. The German group, led by Karlheinz Stockhausen, was concerned with a purer form of

the medium in that its basic sounds are electrically generated instead of being recorded from sources external to the electronic apparatus. The two approaches share one connecting link with music of the past: all sounds have pitch, intensity, duration, and quality. All other concepts of musical organization have been discarded, including the necessity of a performer. Electronic compositions exist on a tape (or disk), and can be made audible by a speaker system. The dehumanizing of music has been carried several steps further by the use of mathematics and even of computers to determine the nature of sound materials—either electronic or that produced by more conventional means—and their organization. At the other extreme is aleatoric music, in which the performer is allowed to choose the manner and order of presentation of materials specified or simply suggested by the composer.

Computer music

Popular music and jazz. Another result of advances in electronics has been the tremendous growth of popular music during the 20th century. New techniques have made possible high-fidelity reproduction of sound and its widespread and rapid dissemination through radio, phonograph, tape recorder, and television. In addition, some of the instruments used in popular music have incorporated electronic amplification as well as sound production. While there has been a popular music as long as mankind has turned to singing and dancing for diversion and recreation, much of it was folk music and existed only as an oral tradition. But popular music in the modern sense originated in the late 18th century, when ballads made popular in ballad opera and dance music received wide circulation. The same types flourished throughout the 19th century and into the 20th, when a new direction was prompted by the emergence of jazz among Negroes in the southern United States. After the original jazz forms came several stylistic modifications such as ragtime, swing, bebop, and rock 'n' roll. Early in the century, the novelty of jazz rhythms and dominance of brass, woodwind, and percussion instruments over strings attracted some serious composers who occasionally incorporated suitable jazz idioms into their works. Since about 1930, the influence has worked in both directions, and popular music has gradually adopted techniques that originated in serious music. Regardless of the interaction of popular and serious music, the popularity of the former is one of the most significant musical developments of the 20th century, especially in view of the widening gulf between the serious composer and the potential audience.

Interaction of serious and popular idioms

It is impossible to arrive at a complete and objective description of a revolutionary movement while it is in progress; only a period of time can provide the necessary perspective. It can be acknowledged, however, that music has never before passed through a more anarchic phase than in the 20th century. The tremendous number and diversity of stylistic distinctions has precluded a characteristic designation for the first half of the century, but one must be forthcoming, for musicians of the future will need the terms modern and contemporary for their own times.

Despite the disproportionate publicity given by communications media to the most radical experiments, the majority of leading composers continue along the moderate path established in the late 1920s and 1930s. And, if one can rely on the lessons of history, the mainstream of music will continue to absorb those new techniques that contribute to expressiveness and communication while discarding the merely novel and sensational, so that music history will remain an evolutionary rather than a revolutionary process.

Musical Composition

Both the process of "putting together" a piece of music and the finished product susceptible to repeated rendition are designated by the term musical composition. In Western civilization musical composition refers to the finished work primarily as fixed by a complex system of graphic notation, or, more recently, by sound recordings. This article will examine different cultural approaches to composition as well as changing concepts and specific procedures associated with the stylistic development of Western music.

THE PROCESS OF COMPOSITION

Varying societal conceptions. Whether referring to the process or to the completed work, composition implies the creation of a unique musical event that may or may not be based on original musical materials. At certain cultural levels and in many non-Western societies unique performance characteristics tend to assume greater significance than composition in itself. In oral traditions, related variants of common origin often take the place of unalterable musical entities, so that tune families rather than single autonomous tunes form the collective repertory. Where certain patterns of musical structure have gained broad recognition (as the ragas, or melody types, of India), musicians will as a rule rework such patterns extemporaneously, though in accordance with prevailing attitudes and conventions.

Oral tradition

European music was communicated orally well into the Middle Ages and received important stimuli from a variety of oral traditions even after musical notation had developed to a high degree of precision. Indeed, the lower population strata, especially in rural areas, never abandoned the relative freedom that comes from reliance on the ear alone, and the sophisticated music of the upper strata, throughout its rapid evolution, rarely severed its connection with folk music altogether. Ultimately, the process of composition, as seen by the American musicologist Alan P. Merriam, does "not seem to differ radically between literate and non-literate peoples save in the question of writing." As a conscious act of social communication it always "involves learning, is subject to public acceptance and rejection, and is therefore a part of the broad learning process which contributes, in turn, to the processes of stability and change." Whether explicitly or not, composition is thus subject to rules that represent the stylistic consensus of a specific segment of society at a given stage of cultural development. During the Middle Ages, when man's natural instincts were held in particularly low esteem, musical compositions were often judged primarily in terms of their adherence to the rules. Hence, the supreme authority in matters musical was the *musicus* as theorist; only he was considered sufficiently conversant with musical science, "the discipline which treats of numbers in their relation to those things which are found in sounds" (Cassiodorus, 6th century AD), to vouchsafe its continued existence as the sonorous embodiment of universal truths. And it was because the metaphysical properties of numbers were allegedly embedded in the rules of composition that music, on a par with arithmetic, geometry, and astronomy, attained and retained an honorable place as a constituent member of the quadrivium, the more exalted of the two divisions of the seven liberal arts. Characteristically, music was not classified with grammar, rhetoric, and logic, the "rhetorical arts"

gathered in the trivium. About 1300 musical composition as a mere craft was ranked by Johannes de Grocheo, a shrewd observer of the Parisian musical scene, with shoemaking and tanning.

Musical elements. At its most fundamental level the act of composition involves the ordering of pitched sounds in musical time and space. Pitch relationships are referred to as intervals; their specific occurrence in musical time is determined by rhythm, a concept that embraces all durational aspects of music. Rhythm in turn may or may not be regulated by metre. In metrically organized rhythm, recurring patterns of accented and unaccented "beats" furnish a durational substructure that necessarily affects all the other elements of composition, including the nature of melody, harmony, and texture. Metrical rhythm is nearly always present in dance music because its patterning is largely analogous to that of bodily motions and step figurations. But logogenic, or word-determined, music also often employs metrical patterns, corresponding as a rule to those of the poetic text. The first large corpus of logogenic compositions transmitted through the ages is that of medieval plainchant, consisting of monophonic settings (limited to a single melodic line) of liturgical texts for the entire year, based on a system of eight church modes, diatonic scales abstracted from the melodic motives utilized by medieval singers. Modality—whether referring to a melodic or a rhythmic framework—furnishes compositional frames of reference in a wide variety of essentially monophonic musical styles, especially in Asia. Asian influences upon early European music cannot be ruled out, whether by way of ancient Judaea, Greece, Byzantium, or the medieval Arab invasions. But unlike their Asian counterparts, Europeans at first limited modality to melody, through pitch arrangements. The rhythmic properties of plainchant have largely remained a matter of conjecture, for no systematic discussion of plainchant rhythm survives, and the notation used was noncommittal with respect to rhythm. By the same token, plainchant no doubt owed much of its amazing vitality to the absence of an all-encompassing notation, which made possible the flexibility of performance and regional variation inherent in a partly written, partly oral tradition.

Rhythm and metre

Music like medieval plainchant, in which the lengths of individual tones tend to be rather uniform, is often referred to as nonrhythmic or rhythmless. Such careless terminology denies the very essence of music as a temporal art, which implies by definition the omnipresence of rhythm as "order in musical time." Actually, the relative presence or lack of rhythmic differentiation in the duration of tones can act as a decisive stylistic determinant. Thus the rhythmic equanimity of the monophonic plainchant, at least in the interpretation set forth by the 19th-century Benedictine monks of Solesmes, France, and recognized as authoritative by the Roman Catholic Church, effectively symbolizes an atmosphere of faith and inner peace. By contrast, the strictly metrical organization of rhythm in most 18th-century music reflects the thinking of an age of reason, favouring mathematically definable, hence "natural," structures in its music.

Motive and melody

The smallest melodic-rhythmic unit (minimally two separately perceived sounds) is the motive. Pitched sounds are, however, not of the essence: drum motives are so effective rhythmically precisely because they lack pitch definition. By and large, rhythmic motives are used to endow pitch relationships with identifiable durational characteristics. And consequently rhythmic identity often serves to establish motivic connections between different intervals. A famous case in point is the opening short–short–short–long motif of Beethoven's *Symphony No. 5 in C Minor*, Opus 67, which serves as an effective element of structural cohesion in this large-scale work.

Types of melody owe their aesthetic associations in many instances to their motivic peculiarities. In Western music motivic contrast has been identified with emotional conflict since at least the mid-16th century, when composers of madrigals (Italian polyphonic secular songs) began to set dramatic texts. The opening of Mozart's *Symphony No. 35 in D Major*, K 385 (the *Haffner Symphony*) offers an excellent example. Analogous in its motivic structure to a section of the first act of Mozart's opera *Don Giovanni*, the opening of the symphony engenders emotional contrasts similar to those inherent in the opera's dramatic action when Donna Anna, under the double impact of attempted rape and her father's violent death at the Don's hands, impulsively rejects Don Ottavio's sympathy until, realizing that she has no one else to rely on for help, she reverses herself and induces him to swear revenge. Conversely, melodic lyricism correlates with a high degree of motivic affinity.

HISTORICAL APPROACHES TO COMPOSITION

The Middle Ages. The European written tradition, largely because it evolved under church auspices, de-emphasized rhythmic distinctiveness long after multipart music had superseded the monophonic plainchant. But multipart music might never have gone beyond the most primitive stages of counterpoint (from Latin, *punctus contra punctum*, "note against note") had it not been for the application of organized rhythm to musical structure in the late Middle Ages. This era witnessed the emergence of basic polyphonic concepts identified with European art music ever since. The precise measurement of musical time was simply an indispensable prerequisite for compositions in which separate, yet simultaneously sounded, melodic entities were combined in accordance with the medieval theorists' rules of consonance (specifying the proper intervals to be used between voice parts, especially at points of musical repose). Toward the end of the 1st millennium of the Christian Era church singers had grown accustomed to enhancing their chants through organum—*i.e.*, the simultaneous singing of the same melody at different pitch levels, specifically the "perfect" intervals of the octave, fifth, and fourth (distances of eight, five, or four notes of a diatonic scale). "Parallel" organum of this type was followed, in turn, by "free" organum, which allowed the synchronized voice parts to utilize contrary melodic motion.

The decisive relationship between text and melody in early European music led to stylistic distinctions that have survived the ages. Thus, "syllabic" denotes a setting where one syllable corresponds to one note; "melismatic" refers to a phrase or composition employing several distinct pitches for the vocalization of a single syllable. Late medieval composers made clever use of these distinctions, including an intermediate "neumatic" style (Greek *pneuma*, "breath") to create ever more extensive polyphonic pieces. By the 12th century musicians at Notre-Dame in Paris, led by Léonin, the first polyphonic composer known by name, cultivated a type of melismatic organum that featured a highly florid upper part above a slow moving cantus firmus taken from a suitable plainchant melody. The melismatic sections alternated with strictly measured, or "discant," sections. This very effective procedure possibly was inspired by Middle Eastern practices with which the crusaders must have been well acquainted. In Eastern music, the rhythmically measured portions following the virtuoso singer's florid "outpouring of the soul" are nearly always played or at least supported by instruments. In the 13th century the clausula, a short, textless composition in discant style, tended to be dancelike in its systematic sectionalization, strongly suggesting instrumental derivation, if not necessarily actual performance. The motet, a major genre of the medieval and Renaissance eras, was in its 13th-century form essentially a texted clausula, frequently employing two or three different texts in as many languages. This fact merely reinforces the suspicion that little distinction was made between vocal and instrumental composition in an era that so blithely based dancelike settings of erotic, in a few instances outright obscene, texts on a chant-derived cantus firmus. The point is not without its broader ramifications. For, brought up largely on 19th-century notions about the "purity" of church music, one easily overlooks the fact that even Bach and Mozart had few compunctions about the use of secular—in their cases mostly operatic—styles and specific tunes in church music. Over the centuries, the church has been the most

Rhythmic contrast as a structural device

important employer of composers and has offered far greater outlets for newly created music than any other social institution or category. Thus composers of sacred music have had to satisfy the aesthetic needs and expectations of its highly differentiated "public." The church in turn repeatedly permitted the adaptation of promising secular types of composition, even though instrumental music, because of its more lascivious associations, remained suspect well into the 17th century.

In accordance with medieval tendencies generally, Gothic polyphonic music was conceived in loosely connected separate layers. Thus, two-part motets could be converted into three-part motets, and Léonin's successor Pérotin expanded the organum to three and four parts. Inevitably, as their compositions gained in length and depth, musicians began to search for new integrative procedures. A system of six rhythmic modes (short, repeated rhythmic patterns) evolved rapidly. Pérotin used a single rhythmic mode for the multiple upper parts of his organums so that, separated from their cantus firmus, they resembled the conductus, a syllabic setting of a sacred text for two or three voices sharing the same basic rhythm. Finally, as organum faded into history conductus-type motets were composed outright. Most prominent among the devices used to achieve structural integration in the 13th century were *color*, or melodic repetition without regard to rhythmic organization; *talea*, or rhythmic repetition without regard to pitch organization; and ostinato, or repetition of a relatively brief melodic-rhythmic pattern. Exchanges of melodic phrases between two or more parts in turn led to canon, a form in which all voice parts are derived from one tune—either by strict imitation of the basic melody or by manipulations stipulated in often quite sophisticated verbal instructions (canon = law). For instance, the canon *Ma fin est mon commencement* (*My End Is My Beginning*), by Guillaume de Machaut, the leading French composer of the 14th century, demands the simultaneous performance of a melody and its retrograde version (the notes are sung in reverse order). French musicians of the 14th century were particularly partial to isorhythm, which refers to repetition of the rhythmic organization of all the voices in a given compositional segment. It enjoyed considerable popularity for more than a hundred years.

Melodic and rhythmic manipulation

Meanwhile, though somewhat eclipsed historically by the increasingly abstract nature of polyphony, the primacy of poetry was safeguarded in 13th-century music by the troubadours of southern France and their northern counterparts, the trouvères, as well as the German Minnesingers. These noble poet-composers created a rich tradition of purely monophonic secular song that furnished convenient points of departure for much of the secular polyphonic music in both 14th-century France and 15th-century Germany. By the beginning of the 15th century, European music had also begun to feel the impact of English music. The English emphasis on the rich sonorities of the third and sixth provided welcome relief from the aesthetic consequences of the earlier continental dedication to the "perfect" intervals of the octave, fourth, and fifth. Because the perfect intervals were also those formed by the lowest pitches of the harmonic overtone series (faint tones sounding above a fundamental tone, caused by a sound wave vibrating both as a whole and in parts), their "naturalness" had long been an unassailable theoretical axiom.

Impact of English music

Late 14th-century French secular music literally lost itself in rhythmic complexities without any substantive changes in the basic compositional approach, which continued to favour relatively brief three-part settings of lyrical poetry. But the ensuing 15th century eagerly embraced the simpler melodic and rhythmic ideas associated with the rich harmonies of the English style; often melodies were outright triadic in contour; *i.e.*, they outlined the intervals of the triad, an increasingly important chord composed of two linked thirds (*e.g.*, C–E–G). But the truly amazing stylistic development from the influential English composer John Dunstable (*c.* 1385–1453) to Josquin des Prez (*c.* 1445–1521), the Franco-Flemish composer who stands at the apex of his era, was equally indebted to the flowing cantilenas, or lyric melodies, that characterized the top parts of Italian trecento music. If the French music of the waning Middle Ages was structured essentially from the bottom up, with relatively angular melodic and rhythmic patterns above the two-dimensional substructure of tenor and countertenor, its Italian counterparts were quite often monodically conceived; *i.e.*, a highly singable tune was sparingly yet effectively supported by a single lower voice. Indeed, the passion for melody, if need be to the detriment of other musical elements, has been a constant of Italian music. It sparked the *nuove musiche*, or "new music," of about 1600 and is exemplified in innumerable works of composers as diverse as Claudio Monteverdi (1567–1643) and Luigi Dallapiccola (1904–). But it found its first major artistic expression in the city-states of northern Italy during the lifetimes of such 14th-century literary figures as Giovanni Boccaccio and Petrarch.

The Renaissance. During the latter part of the 15th century, French rhythmic sophistication, Italian cantilena, and English harmony finally found common ground in the style of Renaissance polyphony that, under the aegis of Flemish musicians, dominated Europe for nearly two centuries. Often referred to as modal because it retained the medieval system of melodic modes, Flemish polyphony was characterized by a highly developed sense of structure and textural integration. Although the older cantus firmus technique was never totally abandoned, Renaissance polyphony is identified above all with imitative part writing, inspired no doubt by earlier canonic procedures but devoid of their structural limitations. After a canonic or freely imitational beginning, each of the subunits of such a polyphonic piece proceeds unfettered by canonic restrictions, yet preserves the fundamental equality of the melodic lines in accordance with contrapuntal rules amply discussed by various 15th- and 16th-century theorists and ultimately codified by the Italian theorist Gioseffo Zarlino. Through the works of Giovanni da Palestrina, the model composer of the Catholic Counter-Reformation, Renaissance modal counterpoint has influenced the teaching of musical composition to this day, suggesting the near perfection with which it conveys some fundamental aspects of the historic European ideal of composition as the art of lasting musical structures.

Whereas imitative polyphony affected virtually all 16th-century music, modal counterpoint was paramount in sacred pieces, specifically the motet and mass, probably because of its close kinship with the traditional modality of liturgical plainchant. In contrast, the beginnings of functional harmony (chordal relationships governed by primary and secondary tonal centres) manifested themselves first in the polyphonic French chanson, its Italian counterpart, the madrigal, and related secular types. Under the influence of less sophisticated music, such as that of the Italian frottola, a popular vocal genre, these secular polyphonic genres favoured rather simple bass lines highlighting a limited number of related harmonies. Thus, undisturbed by the theoretical writings from the pens of church-employed musicians, secular musical practice in the later Renaissance laid the foundations for the harmonic notions that were to dominate three centuries of Western art music. The increasing emotionalism of texts taken from the leading Italian poet of the 16th century, Torquato Tasso, and his immediate successors, acted as a further stimulant, as Italian composers, searching for appropriate musical symbols, discovered the expressive possibilities of chordal progressions.

Changing conceptions of harmony

The Baroque era. Inevitably, the strong desire for heightened expression through harmony led at first to new, mostly chromatic, chord progressions (using notes foreign to the diatonic scale). Eventually it precipitated the total abandonment of traditional polyphony about 1600 in the monodic experiments of the Florentine Camerata, a group of aristocratic connoisseurs seeking to emulate the Greek drama of antiquity. The accompaniment for these passionate and heroic solo recitations is based on a simple basso continuo. Only the bass part was

written down; it was played by low, sustaining instruments bowed or blown, while plucked or keyboard instruments supplied the chords suggested by the bass and melody lines. The small figures used to indicate the proper harmonies gave the system the alternative name "figured bass." Monody had its historical antecedents in mid-16th-century solo lute songs and in the plentiful arrangements of polyphonic vocal compositions for single voices accompanied by plucked instruments and for solo keyboard instruments. But it was the attempt to resurrect the spirit of antique drama in the late Renaissance that created the textural revolution that has been equated with the beginnings of modern music: the monodic style with its polarity of bass and melody lines and emphasis on chords superseded the equal-voiced polyphonic texture of Renaissance music. Monteverdi, the undisputed master of the monodic style, recognized the possibility of two basic approaches to composition: the first or polyphonic "practice" and the second or monodic "practice." Thus, with penetrating analytical insight he formulated the basic stylistic dialectic that has since governed the course of Western music.

Aesthetic and technical reorientation

The emergence of an essentially nonpolyphonic style went hand-in-hand with the rise of a variety of specifically instrumental idioms. Not only did accompanied vocal music offer instrumentalists various opportunities for improvisation; the basically chordal style also facilitated the emergence of virtuosity in the modern sense of the term, especially among keyboard artists. But as the singer and composer Giulio Caccini demonstrated in the preface to his influential collection *Le nuove musiche* (*The New Music;* 1602), singers, too, put their newly found freedom to good improvisational and ornamentational use. In short, after two centuries dominated by the highly structured, rationalistic polyphony of the Renaissance, the performing musician reiterated his creative rights. Inevitably, under such forceful pressures, the teaching of composition, previously tied to the laws of modal counterpoint, quickly shifted to the harmonic challenges of the figured bass.

Because the bass-oriented music of the 17th century relied primarily on chord progressions as fixed by the bass notes, it was structurally quite open-ended; *i.e.*, the new technique suited any number of formal patterns. Even so, the incipient rationalism that was to reach its peak in the 18th century soon led to the consolidation of broadly accepted structural types. Indeed, the very concept of musical "form," as generally understood from the late 17th century on, was intimately tied to the growing importance of instrumental music, which, in the absence of a text, had nothing to rely upon save its own organically developed laws. At least for a while, vocal music, which had been so largely responsible for the monodic revolution, continued to adhere to the Monteverdian principle that the words must act as "the mistress of harmony." Both melody and harmony, therefore, reflected often minute affective textual differentiations. And as late as the early 18th century similar musico-rhetorical considerations led to *Affektenlehre*, the theory of musical affects (emotions, feelings), developed primarily in Germany. Following this theory, German musicians dealt with composition systematically in terms of a specific but broadly adopted expressive vocabulary of melodic, rhythmic, and harmonic figures. Meanwhile, the Italians laid the foundations for such lasting categories of instrumental music as the symphony, the sonata, and the concerto. In each instance the structural outline was harmonically determined through juxtapositions of principal key areas acting as focal centres of tonality. As for tempo, the earliest 17th-century solo sonatas had relied on drastic short-range changes in accordance with a general predilection for "instant sensations." Subsequently, as musical composition fell in line with the prevailing rationalistic trend, tempo served above all as a means of differentiation between the various movements, or self-contained sections that constituted the large-scale works of the Italian string school and of French and German instrumental composers as well. Texture, too, was used to provide contrast, particularly within a given movement, as in the concerto grosso with its alternation between small and large groups of players (concertino and tutti).

Emotional expressiveness

Interrelated with the spectacular rise and amazing vitality of instrumental music was its unprecedented variety. By the early 18th century, composers drew freely upon everything from contrapuntal forms like the fugue (an adaptation of the imitative techniques of the Renaissance motet within the context of functional harmony) to stylized popular dances, such as those that make up the suites and partitas of J.S. Bach. The figured bass era took full advantage of the possibilities of variety and contrast through judicious manipulations of all elements of composition. Whereas accompanied solo music pitted bass against treble (the latter often split up into two parts, as in the trio sonata), composers generally liked to juxtapose figured bass and polyphonic textures. Melodically, the far-flung phrases of Italian bel canto, the florid singing style characteristic of opera seria (17th- and 18th-century tragic opera), had little in common with the concise, symmetrically balanced phrases found in music of popular inspiration, whether in opera buffa (Italian comic opera) or the many types of dances. As for the latter, their impact on sophisticated 18th-century music is evident not only in many dance-inspired arias and concerto movements but is also in certain polyphonic compositions. Both the chaconne and passacaglia, related polyphonic types, were based on dancelike ostinato patterns, often with specific harmonic implications. Perhaps the most famous example is Bach's "Chaconne" for solo violin, which concludes the *Partita in D Minor*.

Major structural developments of the Baroque

Even though the Baroque preoccupation with style worked somewhat to the detriment of structural definition, certain closed forms did gradually emerge. The da capo aria distinguished clearly between an initial section (A), a contrasting section (B), and the repeat (da capo) of the initial section, as a rule with improvised vocal embellishment. In instrumental music, the French opera overture began with a slow, stately introduction followed by a fast, often fugal movement, whereas its Italian counterpart had a tripartite fast–slow–fast scheme. Dance-based suite movements were binary in outline: the first of the two sections, each separately repeated, moved to the dominant key (a fifth above the tonic or principal key) or to the relative major (a minor third above the tonic) in the case of a piece in a minor key; the second section, after some modulatory activity (*i.e.*, passing through several key areas), returned to the central key. Even more decisive in its far-reaching historical consequences was the structural organization of a number of the keyboard "sonatas" of the composer Domenico Scarlatti. These works consisted of single, essentially binary movements, the first section of which differentiated not only between two key areas but two contrasting thematic ideas as well.

The Classical period. The Classical era in music is compositionally defined by the balanced eclecticism of the late 18th- and early 19th-century Viennese "school" of Haydn, Mozart, Beethoven, and Schubert, who completely absorbed and individually fused or transformed the vast array of 18th-century textures and formal types. Expansion of the tripartite Italian overture had produced the basic three-movement scheme of the symphony even before the 18th century reached midpoint. Shortly thereafter, the minuet, borrowed from the dance suite, was inserted with increasing frequency as a fourth movement, between the slow movement and the fast finale. The French opera overture in turn lent its slow introduction where needed for structural variety. Texturally, homophony (chordal texture) and polyphony soon assumed rather specific roles, with polyphonic writing usually reserved for the central or development section of the classical first-movement form. The organic fusion of a number of stylistic traits previously associated with strong and immediate contrast is exemplified by the obbligato accompaniment, the texture most typical of Viennese classicism. Here the relative equality of all the melodic parts in a given composition is ensured without denying the melodic supremacy of the treble and the harmonically decisive role of the bass. The evolution of

Integration of homophony and polyphony

this characteristic texture can be traced in the string quartets of Haydn. At first, following earlier 18th-century custom, Haydn wrote strictly treble-dominated compositions with a simplified bass (as compared with the more varied basso continuo); then, with the six *Sun Quartets* (Opus 20), dating from the early 1770s, he defied precedent and concluded each work with a fugue in the "learned style" of Handel. Finally, in his *Russian Quartets,* Opus 33, written, in his own words, "in a new manner," Haydn achieved the fusion of elements of both the learned and the treble-dominated styles. The result was a harmonically oriented, yet polyphonically animated, texture that was to affect both instrumental and vocal ensemble music for generations. It was also at this point, when compositional procedures reached a degree of stability and universality unmatched since Renaissance polyphony, that composition began to be taken seriously as a separate musicianly discipline. Johann Joseph Fux's famous *Gradus ad Parnassum* (*Steps to Parnassus*), published first in Latin in 1725 and subsequently in every important modern language, was still basically a didactic treatise on counterpoint abstracted from 16th-century practice. As such it served its purpose throughout the 18th century, while harmony continued to be taught as the art of accompaniment—*i.e.*, the improvised realization of a figured bass. But eventually the general fascination with comprehensive knowledge, sparked by the French *Encyclopédie,* inspired at first sporadic, then ever more numerous volumes dealing progressively with all aspects of composition. During the ensuing 19th century the rapid institutionalization of musical education in the image of the National Conservatory of Music in Paris, created while the French Revolution was still raging, added further to the academic systematization of all musical studies along lines that have essentially remained in force. Thus the teaching of musical composition reflects to this day the biases of the 19th century, specifically its concern with functional harmony as the principal generative force in music—a doctrine first proclaimed in the 1720s in the name of nature (as being consistent with the harmonic overtone series) by the composer and theorist Jean-Philippe Rameau.

Composition as an academic discipline

The Romantic era. With the onset of the Romantic era in the wake of the French Revolution, composers began to view their own role in society as well as the social function of their work, and hence also its aesthetic prerequisites, in a radically different light. With respect to social function, Beethoven was actually the first musician of stature to achieve emancipation in the sense that his work reflected, with relatively few exceptions, purely personal artistic concerns. He simply took it for granted that patrons would supply funds sufficient for him to pursue his creative career unfettered by financial worries. This attitude represents a total reversal of the basic assumptions of the preceding century, when composers were hired by and large to satisfy the musical needs of specific individuals or institutions.

The view of the composer as artist also changed. If during the Middle Ages the craft of musical composition had been evaluated largely in terms of its strict adherence to established rules, instinctiveness and spontaneity had remained suspect well into the Italian Renaissance. For a 15th-century composer–theorist like Johannes Tinctoris, the value of a musical composition depended on learned judgment as well as spontaneous reaction. Thus his admiration for certain composers of his time stemmed both from the happiness and from the enlightenment that he found in examining their music. But the Swiss theorist Henricus Glareanus, writing 70 years later, explicitly preferred natural talent to the most exquisite craftsmanship. The Renaissance was the first epoch in European intellectual history to recognize that the greatness of a composer rests upon his inherent talent and unique personal style, and that genius supersedes both experience and the observance of theoretical precepts. Likewise, it was the first era in which the process of composition was viewed as linked to powerful internal impulses. The rising tide of academicism notwithstanding, this basic attitude on the whole dominated the European scene more or less consistently from then on. According to E.T.A. Hoffmann, the early 19th-century poet, critic, and composer, "effective composition is nothing but the art of capturing with a higher strength, and fixing in the hieroglyphs of tones, what was received in the mind's unconscious *ecstasis.*" And Romantic composers from Schumann and Chopin to Hugo Wolf and Gustav Mahler did in fact produce much of their very best creative work in precisely such a state of exaltation, in a few tragic instances (*e.g.*, Schumann and Wolf) to the ultimate detriment of their sanity.

The composer as genius

The aesthetic effects of this drastic change in conception of the composer's task and potential were immediate and far reaching. For one, every large-scale composition assumed artistic significance of a type previously accorded only a whole series of works, sometimes a composer's entire output. And concomitantly, many leading composers of the 19th century wrote in considerably smaller quantities than their predecessors. But in exchange they revelled in idiomatic and structural peculiarities even in works that nominally fell into the same formal category. Thus although "characteristic" symphonies alluding to nonmusical ideas occurred occasionally in the late 18th century, virtually every symphonic composition postdating Beethoven's *Symphony No. 3 in E Flat Major,* Opus *55* (*Eroica;* completed 1804), could be so designated. "Characteristic" works like Beethoven's *Symphony No. 6 in F Major,* Opus 68 (*Pastoral;* 1808), or his overture to Goethe's drama *Egmont* are but one step removed from the kind of characteristic scenes that make up the *Symphonie fantastique* of the French composer Hector Berlioz or, for that matter, Felix Mendelssohn's *Hebrides* (also known as *Fingal's Cave*), an overture unrelated to any particular drama, spoken or sung. Franz Liszt, in the free-wheeling forms of his symphonic poems, simply pursued the individualistic line to its ultimate consequences, severing whatever tenuous ties to traditional structures the works of his immediate predecessors had still maintained. The Romantic composer viewed himself basically as a poet who manipulated musical sounds instead of words. But if the composers catered to poetry, writing Lieder (German songs) and attempting to retell stories in instrumental works, the poets looked with awe and envy upon the composers' use of a language so utterly dissociated from material existence. "All art aspires to the condition of music," said Wordsworth. It is thus hardly surprising that opera, whose extramusical connotations had in the past been responsible for some of the most daring stylistic innovations, rapidly incurred the disfavour of progressive composers. Although some, like Berlioz, Mendelssohn, and Schumann, tried their hands at an occasional opera, others, including Chopin, Liszt, and Brahms, felt no inclination whatever to compose for the stage. Instead, each developed personal idioms capable of a depth of expression that words could not match. Mendelssohn spoke indeed for many when he remarked that, as far as he was concerned, music was more precise in meaning than words.

Nonmusical allusions

As in the late Renaissance, harmony once again furnished the primary expressive means. In defining musical structure, too, harmonic and modulatory procedures predominated at the expense of the contrapuntal interplay of motives. Numerous Romantic composers excelled in concise forms of strong melodic-harmonic import, variously entitled Impromptu, Nocturne, Song Without Words, Ballade, Capriccio, Prelude, Etude, etc. The form of these works was nearly always tripartite, with a literal or modified repeat of the first part following a melodically and harmonically contrasting middle section. Works of larger scope often consisted of a series of relatively autonomous subunits tied together either by the same tune presented in different guises (as in variation sets) or by fairly literal recurrences of an initial musical idea (the rondo principle). Compositions of the Classical sonata-allegro type, to which motivic-contrapuntal development was essential, inevitably suffered from the Romantic love for pure, harmonically defined melody. Thus Tchaikovsky frankly admitted in 1878 that, although he could not complain of poverty of imagination or lack of inventive power, his lack of structural skill had frequently caused

Interrelation of aesthetic, technique, and form

his "seams" to show: "there was no organic union between my individual episodes." Composers such as Tchaikovsky were indeed particularly successful with chainlike formations like the serenade or the ballet suite, which comprised a well-calculated number of carefully wrought smaller entities.

In the context of functional harmony, the Classical motivic-contrapuntal approach had no doubt been exploited in the last sonatas and string quartets of Beethoven to the very limits of its potential to define musical structure. The heroic image of Beethoven as one who had overcome every possible personal and artistic difficulty to achieve the highest aims of the art assumed well-nigh traumatic proportions among 19th-century musicians. Not only did composers ill equipped both by training and artistic temperament try to emulate him, but theorists from Adolf Bernhard Marx to Vincent d'Indy based treatises on his works. Thus, unwittingly the Classical Beethovenian inheritance turned into something of an aesthetic liability for Romantic composers swayed by the image of Beethoven and unable or unwilling to face the fact that their particular talents were totally unsuited for any further capitalization of his basic compositional procedures. Confronted with the task of writing in the Beethovenian manner, a great master like Schumann, who had created the near-perfect, totally Romantic suite *Carnaval*, Opus 9 (1835), was clearly out of his element: the development of his *Symphony No. 1 in B Flat Major*, Opus 38 (*Spring;* 1841), offers a prime example of the "rhythmic paralysis" that affected so many large-scale 19th-century works. That this symphony managed nevertheless to maintain itself in the concert repertory, on the other hand, demonstrates the extent to which the best among the German composers compensated for obvious weaknesses in handling motivic development by sustaining above all constant harmonic interest. For their part, the French, always coloristically inclined, turned instrumentation into a principal compositional resource, so that in an unadorned piano transcription Berlioz' *Symphonie fantastique* retains little more than its basic contours. That by the end of the century virtuoso instrumentation had become universal practice is attested by any work of Richard Strauss or Gustav Mahler.

Characteristically, the most unique compositional achievement of the 19th century, that of Richard Wagner, was also the most eclectic. Wagner represents the apotheosis of Romanticism in music precisely because he fused into musico-poetic structures of unprecedented proportions virtually every musical resource that went before him. Seen in this light it may be more than mere coincidence that *Tristan und Isolde*, perhaps Wagner's most perfect music drama, begins with the same four notes that make up the motivic substance of Beethoven's string quartets Opuses 130–133. Unlike most instrumental composers after Beethoven, the dramatist Wagner fully assimilated the motivic-contrapuntal process, even though his texture is principally determined by strong harmonic tensions and by a masterful use of instrumental colour in the vein of Berlioz and French grand opera. Just as he integrated diverse compositional techniques Wagner also achieved a balance of musical and poetic elements so perfect that critics, both favourable and unfavourable, have never ceased to be puzzled by its aesthetic implications. How consciously Wagner proceeded is attested not only by his numerous theoretical writings but also by compositional sketches pointing in some instances to several stages of mutual adjustments involving music and text.

Wagner's fusion of counterpoint with late Romantic harmony

Compositional approaches of the 20th century. Wagner's highly expressive harmonic bequest could not but drive chromaticism eventually beyond the retaining confines of the idea of a central key, for the extensive use of chromatic chords tends to blur the listener's ability to perceive the basic harmonic relationships that define a key. In their nontonal compositional procedures, Arnold Schoenberg and his 20th-century Viennese school abandoned the concept of key, using all notes freely without relating them to the system of functional harmony. They thus represent not so much a reaction to as a logical extension of Wagnerian principles. Wagner's compelling artistic personality certainly spelled near-magic powers over many of his younger contemporaries and successors, overshadowing even Beethoven. But others, too, contributed to "the music of the future." As Schoenberg was to point out in one of his remarkable essays, even Brahms, who looked upon himself as a conservative in the best sense of the term, was, historically speaking, a true "progressive," especially in his propensity for irregular phrasing and complex motivic manipulations.

The growth of political nationalism in the "peripheral" countries of Europe also had significant repercussions in musical composition. In the last half of the 19th century distinctive folk-music elements, previously totally unheeded by Europe's elitist musical cultures, found enthusiastic response in sophisticated circles, exerting an "exotic" attraction similar to that which had accounted earlier in the century for the Romantic infatuation with Eastern civilizations. Thus at a time when the exhaustion of Europe's "civilized" compositional resources appeared imminent, the "untutored" harmonies of the Russian composer Modest Mussorgsky—steeped in the spirit of Russian folk music and based on chord progressions alien to the standard harmonic usage of his day—helped breathe new life into a harmonic language about to succumb to redundant overdoses of functional chromaticism. Mussorgsky thus paved the way for the later whole-tone and pentatonic (five-tone scale) experiments of Claude Debussy (1862–1918) and Béla Bartók (1881–1945).

What was being questioned publicly in many quarters at the dawn of the 20th century was the evolutionistic view of Western art music as man's ultimate achievement in the realm of sound and its logical consequent that 19th-century harmony represented in turn music's most advanced stage of development. This increasing skepticism, given by the nature of late 19th-century music itself, was strongly reinforced by the growing awareness of historical compositional techniques that resulted from the mushrooming discoveries of musicological scholarship. Before long, all manner of pre-19th-century textures and structural principles were seized upon to counteract the type of self-defeating post-Wagnerianism—so tragically exemplified in several of the most ambitious works of Max Reger. The 20th-century search for fresh, flexible techniques extended far beyond the nontonal Viennese school of Schoenberg. In historical perspective, Anton Webern's fascination with 15th-century canonic techniques, Paul Hindemith's predilection for both modal and early-18th-century polyphony, Igor Stravinsky's emulation of Domenico Scarlatti, and, for that matter, Kurt Weill's reinterpretation of John Gay's *Beggar's Opera* (1728), represent but various individual and culturally conditioned manifestations of the same determination: to put the burden of history to positive use in a concerted effort to revitalize an art that seemed moribund by the time World War I changed the socio-economic and political physiognomy of Europe.

Re-application of older techniques

Historically, Schoenberg's formulation of the laws of composition with 12 tones—involving the consistent melodic and harmonic use of a specifically arranged sequence of the 12 notes of the chromatic scale—sprang in the early 1920s from the same obsession with textural and structural clarity that marked the postwar Neoclassic syndrome as a whole. Schoenberg himself may have considered his most fundamental contribution to musical history to be "the emancipation of dissonance"—a relativistic conception of intervals and chords that disregarded the careful regulation of dissonance characteristic of functional harmony. Actually, the 12-tone procedures he developed so consistently served to restore, to an extent far beyond that which Gustav Mahler had been able to achieve within the traditional harmonic framework, the primacy of motivic-contrapuntal development as a musical resource. Thus it was that the profusion of simultaneous melodies that animates Mahler's *Symphony No. 4 in G Major* (completed 1900) found its ultimate potential realized in Schoenberg's most uncompromising polyphonic work, the *Wind Quintet* (1924).

Possibly the most successful attempt to regenerate Beethovenian procedures without the total abandonment of functional tonality is represented by the string quartets and certain other instrumental compositions of Béla Bartók. Drawing upon the rhythmic-melodic properties of Hungarian and Romanian folk music, Bartók produced a unique type of functionally extended harmony determined largely by the contrapuntal interaction of motives. Others, such as Charles Ives in the United States and, under the impact of South American popular music, the Frenchman Darius Milhaud, transcended traditional tonality by writing polytonally (in two or three keys simultaneously).

Whatever their specific approach, progressive 20th-century composers everywhere clearly gave precedence to melodic-rhythmic energies. Even instrumental colour was pressed into the service of melodic definition. Years before World War I Schoenberg had advocated in practice (*Five Orchestral Pieces*) and in theory (*Harmonielehre,* 1911; *Theory of Harmony,* 1947 [the English edition omits the pertinent chapter]) the idea of tone-colour melody, or *Klangfarbenmelodie.* But it was his pupil Webern who in his mature works divided the individual components of melodic phrases over several instruments as an imaginatively coloristic reinforcement of the complex polyphony that characterized his style. After World War II Webern's procedures were adopted enthusiastically by composers on both sides of the Atlantic. Living in increasingly automated societies, the post-Webern composers soon discovered total serialism, a manner of composition in which all musical parameters follow numerical rules laid down in the course of what has been called the precompositional process. Whereas Schoenberg's row technique merely fixed the sequence of the 12 pitches of the chromatic scale in accordance with the motivic context of a given piece, Webern had indeed begun to serialize rhythm and to some extent instrumentation, possibly under the influence of medieval isorhythmic techniques. But total serialization, as practiced by the post-Webernians, left little, if anything, to spontaneous inspiration, and the 1950s thus witnessed the closing of a creative circle initiated during the early Middle Ages when spontaneous inspiration was manifestly suspect. Perhaps inevitably, such a hermetically closed system of composition provoked reactions that moved the aesthetic pendulum violently to the extreme opposite position. Spur-of-the-moment action became the watchword in music as well as in life generally. Aleatoric (chance-music) composition in its more radical manifestations provides only minimal guidelines for performers who are told to improvise freely within certain temporal or spatial limitations, or both.

Serialization of all elements

Thus, as the 20th century enters its last quarter, Western man has returned, insofar as is possible, to the pretypographical stage when musical tradition was essentially oral. More than that, the relatively recent replacement of "the public," once essentially the cultural elite, by a whole host of publics to whom mutually exclusive types of composers cater with great solicitude, suggests that the private musical life of Western man in the immediate past is in the process of being transplanted by experiences serving, among other things, the identification of special group interests and needs. At the same time, novelty rather than originality has become the order of the day. Musical compositions, electronically recorded—more recently also electronically produced—and distributed as salable items by mass-oriented corporations, have attained the status of physical objects that are easily discarded and replaced. Still, there are those who try to transform the burdens of history into significant new forms of composition. A new eclecticism is in the making, destined perhaps to preserve a long tradition that has been among Western man's proudest achievements.

BIBLIOGRAPHY. Because most writings on musical composition were conceived as didactic treatises for would-be composers, their content has virtually no bearing on a better understanding of crucial aesthetic attitudes and mental processes. Instead, depending on the era from which they hail as well as the specific outlook of their authors, such treatises deal for the most part with contrapuntal rules, harmonic laws, and the like. While numerous books of this type appeared through the ages, it was only with the creation of the educational institutions known as conservatories of music, following the lead of the National Conservatory of France established in the last years of the 18th century, that composition became a discipline formally taught and hence requiring comprehensive textbooks including the theory of form and instrumentation. This profitable need was satisfied by the voluminous activities of 19th-century writers from J.J. Momigny and Anton Reicha to Vincent d'Indy in France and from Heinrich Christoph Koch to Hugo Riemann in Germany. Few of these books were translated into English, and they are of primary interest to the specialist. The following is a selection of easily accessible monographs and documentary collections with emphasis on firsthand testimonies of the creative artists themselves.

JACQUES BARZUN (ed.), *Pleasures of Music* (1951), a collection of writings about music, including many from the pens of men of literature; LEONARD BERNSTEIN, *The Joy of Music* (1959), contains Bernstein's seven "Omnibus" television scripts, including his excellent comments on sketch materials relating to Beethoven's *Fifth Symphony* and its ultimate realization; FREDERICK DORIAN, *The Musical Workshop* (1947), a discussion of various aspects of musical composition, including comments on creative procedures; HANNS EISLER, *Composing for the Films* (1947), rare insights into the problems of cinematographic music from a composer who, during his Hollywood years, tried to turn music into an integral aspect of film art; MAX GRAF, *From Beethoven to Shostakovich* (1947, reprinted 1969), a popular study of psychological processes involved in composition; MICHAEL HAMBURGER (ed. and trans.), *Beethoven: Letters, Journals and Conversations* (1960), a concise but well-chosen selection of Beethoven's own words concerning both specific compositions and the problems of the composer in general; LEJAREN A. HILLER, JR., and LEONARD M. ISAACSON, *Experimental Music* (1959), the first and still basic monograph dealing with the philosophy, procedures, and techniques of composition with an electronic computer; PAUL HINDEMITH, *A Composer's World* (1961), a leading 20th-century composer looks at various facets of the composer's world, including questions of musical perception, inspiration, technique, performance, and education; IRVING KOLODIN (ed.), *The Composer as Listener: A Guide to Music* (1958), excerpts from pertinent writings, including letters mostly by important composers of the 19th and early 20th centuries; EDWARD E. LOWINSKY, "Musical Genius: Evolution and Origins of a Concept," *Musical Quarterly,* 50:321–340, 476–495 (1964), excellent documentation of the evolution of a concept that has been associated through the ages more consistently with music than any other form of artistic production; ALAN P. MERRIAM, *The Anthropology of Music* (1964), a comprehensive treatment of music in relation to culture, drawing upon fieldwork on every continent and at all social levels (see especially ch. 9, "The Process of Composition"); SAM MORGENSTERN (ed.), *Composers on Music: An Anthology of Composers' Writings from Palestrina to Copland* (1956), an excellent collection, mostly of letters, dealing with general and specific aspects of the composer's work; ERNEST NEWMAN, *The Unconscious Beethoven,* rev. ed. (1970), a fascinating, if not unproblematic, study of the successive stages of Beethoven's work as revealed in his sketches, by one of Britain's most famous critics; GERTRUDE NORMAN and MIRIAM LUBELL SHRIFTE (eds.), *Letters of Composers: An Anthology, 1603–1945* (1946), one of the most comprehensive of several collections of composers' letters available in paperback; JOSEF RUFER, *Die Komposition mit zwölf Tönen* (1952, 2nd ed. 1966; Eng. trans., *Composition with Twelve Notes Related to One Another,* 1965), a cogent introduction to dodecaphonic aesthetics and technique by a dedicated Schoenberg disciple; WILLIAM RUSSO, *Jazz Composition and Orchestration* (1968), one of the very few serious treatments of a type of composition that has gained respectability only in recent years; ARNOLD SCHOENBERG, *Style and Idea* (1950), a discussion of Schoenberg's artistic motivation and procedures as well as those of the composers he admired most, including Brahms and Mahler; ROGER SESSIONS, *The Musical Experience of Composer, Performer, Listener* (1962), a discussion of fundamental musical problems by America's senior living composer; WILLIAM OLIVER STRUNK (ed.), *Source Readings in Music History from Classical Antiquity Through the Romantic Era* (1950), an indispensable collection of relevant excerpts from the writings of philosophers, musical theorists, and composers from Plato to Richard Wagner; D.F. TOVEY, *The Mainstream of Music, and Other Essays* (1961), a paperback reprint of some of the finest essays by the great British critic who discusses basic compositional issues.

(A.L.R.)

Musical Criticism

Musical criticism, properly considered, is a branch of philosophy—more exactly, of aesthetics. It is chiefly concerned with making value judgments, either about composition or about performance, or both.

Unfortunately, it is difficult to show that a value judgment can stand for anything that is even remotely true about music, as opposed to standing for something that is merely a personal whim on the part of the critic, since there is, as yet, no such thing as an organized body of knowledge called "musical criticism." The entire history of musical criticism can be summed up as a vain struggle to forge itself into a suitable tool for coming to grips with the art of music. Criticism always seems to founder on the same small handful of basic problems. These problems are essentially philosophical. They appear to be insoluble. They are aggravated not only by the esoteric nature of music, but also by the psychological mystery surrounding the very act of criticism.

Attempts at rationalization

There have been three major attempts to place musical criticism on a rational footing. These were by Sir Henry Hadow in *Music and Musical Criticism: A Discourse on Method* (1892), M.D. Calvocoressi in *The Principles and Methods of Musical Criticism* (1923), and Ernest Newman in *A Musical Critic's Holiday* (1925). Newman, in particular, was obsessed by a lifelong search for what he called the principles of "scientific" criticism. He maintained that musical criticism, if it were to succeed, must be raised from the level of a hit-or-miss affair to that of scientific certainty. Hadow and Calvocoressi were no less scientific in outlook, although they did not use the term. All three musicians were concerned that criticism lacked bite; their aim, subsequently, was to give it some teeth. Are there any "standards" in criticism? If so, can they be defined? Are they objective or subjective? If the latter, can they possibly be true? These questions are fundamental. They disclose the full range of the philosophy of criticism. The present article will review these basic issues and propose a direction in which they are likely to be resolved.

THE PRACTICE OF MUSICAL CRITICISM

The function of criticism. Musical criticism has a primary aim: the evaluation of music. How does the critic set about this difficult task? The scientific school of criticism holds that he applies certain standards to the work in question. His evaluation, that is to say, is the result of testing music against his critical yardsticks, and observing how far short it falls. According to this view, a value judgment is like a prize to be won by careful, objective, intelligent effort. This is an attractive notion, particularly among critics. It fosters the view that the critic is in a position of authority, and that he possesses the means to arbitrate over the creative artist. Unfortunately for criticism, there is nothing to suggest that this is anything but an illusion.

The scientific school

If one reflects on the way in which one listens to music, a basic fact is apparent. Music's value is inherent; it resides in the work of art itself. A value judgment is something that comes across as part of musical communication. Paradoxically, a value judgment appears to be necessary before the critical process can start. The consequences of this observation are far-reaching. Rather than critics with standards, there appear to be only works with standards, which critics observe. It is not necessary to prove that Mozart's *Jupiter Symphony* is a masterpiece in order to be certain that it *is* a masterpiece. Its mastery is self-evident. Critics did not bestow value on Mozart; they perceived it in him.

The intuitive nature of value judgments

Music as an autonomous communication. Music is autonomous. It refers to nothing outside itself. This sets it apart from the other arts, which rely upon the outside world for their images. A hat, a man, or an apple tree may all turn up in a painting, a sculpture, or a play. Indeed, they may be part of the very language of visual art, and therefore essential to its understanding. Music has no such aids toward comprehension. It is completely lacking in conceptual crutches. It develops according to its own laws. It is a purely musical truth that is comprehended on a purely musical level. The purity of musical communication is what the German philosopher Schopenhauer was admiring when he said that all art aspires toward the condition of music.

The inexplicability of musical experience

The totally musical nature of musical experience raises a difficulty for the critic. Such experience is virtually impossible for him to describe. Consequently, the critic can hardly be called "the man in the middle," a role frequently assigned to him. Music is not like a foreign language that requires an expert to translate it for a lay audience. It is a universal tongue. It either speaks to each listener directly or it does not speak to him at all. If it speaks, the critic's words are already redundant. If it does not speak, a problem exists that his words cannot solve.

Two important consequences flow from these views. They are among the axioms of criticism. First: since music is autonomous, all knowledge about it must spring from experience of it; practice, in short, precedes theory. Second: because of the purely private and personal nature of musical communication, a work's mastery can only be demonstrated to those listeners who already know about it, who have already experienced it—and they hardly require the demonstration. To those listeners who have not experienced it, a work's mastery is not demonstrable. If it were demonstrable, it goes without saying that critical differences would cease to exist: there would be nothing to prevent those who had experienced it from converting those who had not. Yet critical differences remain.

Objectivity versus subjectivity. A difficulty confronting all critics concerns the subjectivity of their observations. Since music is perceived subjectively, so the argument runs, does this not reduce criticism to mere personal opinion? And if this is so, what makes one critic's opinions any truer than another's? This objection can be disposed of, first, on the broadest philosophical level. Since all things perceivable are perceived subjectively, the charge of subjectivity must either be levelled against every other human endeavour, or it must be withdrawn from criticism. Second, and more to the point, what would be said of a performer who proclaimed to all the world his objectivity, his non-involvement with music? As for the composer, he would be thought strange indeed if he managed to avoid subjective entanglement with his creations. Why is it considered virtuous for performers and composers to enjoy an inner participation with music, and not critics? Quite clearly, there is a contradiction here.

The crucial question facing every critic is how he is to demonstrate the truth of his reaction. Yet all critics cannot be right; many are diametrically opposed to one another. It is no wonder that musical criticism has been described as stuck at the litmus-paper stage: critics take a dip into music and one sees what colour they turn. Plainly, criticism remains indistinguishable from mere speculation until the critic develops the means of confirming the truth of his views. If he wishes to develop such means, it is to the theory of criticism that he must turn.

A definition of criticism

Meanwhile, a definition of musical criticism emerges: Criticism is the rationalization of intuitive musical understanding.

THE THEORY OF MUSICAL CRITICISM

If the practice of criticism, as has been noted, can be reduced to one thing—expressing value judgments—the theory of criticism is essentially one thing, too—explaining them. It is not enough for critics to assert that one work is a masterpiece, another a mediocrity. An attempt must be made to explain why, and this may lead to a central discovery. A masterpiece is not a matter of chance, nor is a mediocrity. Both are symptomatic of deep, far-reaching principles.

Principle of unity. When Rudolph Reti, the Viennese critic, was a young man studying music at the Vienna Conservatory, he once stood up in the middle of a composition class and put the following question to his professor: "Why can't we take the themes of one work and

substitute the themes of another?" Reti did not receive a very convincing reply, and was therefore stimulated to think about the problem for himself. Forty years later, he worked out an answer in his book *The Thematic Process in Music* (1951). Briefly, it was that masterpieces diversify a unity. They grow from an all-embracing idea. Their contrasting themes hang together because each of them represents a different aspect of a single basic thought. This observation was not new. The Austrian composer Arnold Schoenberg had made it years earlier. So, too, had Heinrich Schenker, who used it as the basis for a major theory of aesthetics in his monumental *Das Meisterwerk in der Musik* ("The Masterpiece in Music," 3 vol.; 1926–29). Reti sharpened the concept. He made the critics think again about what, precisely, they mean when they talk about the integrity of a musical structure.

Diversity in unity

Reti's thesis can be vividly demonstrated by taking an existing masterpiece and substituting random themes from another. Even if such themes preserve a semblance of continuity (matching the key, metre, and mood of the themes they displace), they lose the deep sense of unity communicated by the original.

Not all musicians accept this theory. They argue that many composers, notably Bach, have put together works by borrowing materials from other sources. They fail to realize, however, that the act of borrowing is so highly selective that it, too, must be regarded as part of the creative process. The question then becomes: Why was that particular theme or movement borrowed?

Medium and idea. Another question is why a composition expresses itself through its particular medium? Why that medium rather than another?

If a masterpiece is transferred from the instrumental medium for which it was conceived to some other, alien medium, it undergoes a curious distortion. Such distortion offers the clearest proof that a musical law is operating in the original: an identity of the idea with its medium. A master's inner inspiration adapts to his outer terms of reference. Individual instruments lay down individual limitations. If a composer ignores this fact, he can never be certain that his creative aims will ever coincide with the musical results.

Collision of idea and medium

Occasionally, a great composer deliberately engineers a collision between the idea and the medium for a special musical purpose. The fugue in Beethoven's *Hammerclavier Sonata*, for example, is one of the most physically awkward works to play in the entire piano repertory. It has been composed against, rather than for, the instrument. Some bars are strictly unplayable, and Beethoven knew it; they contribute to the sense of struggle that is an essential part of musical communication, which is present even in the greatest performance. The orchestration of this fugue by the Austrian composer and conductor Felix Weingartner does a major service to musical aesthetics by providing an alternative musical experience of the same work; but by rendering the difficult easy, his orchestral version robs the music of its basic characteristics. It is a splendid illustration of the way in which, in Beethoven's original, a creative aim has been identified with a physical limitation.

Thematic chronology. A further question is why the chronology of the themes of a masterpiece cannot be changed. Why does one thematic chronology sound good, another bad? If the movements of a great sonata or a symphony are switched around, the result will be musically inferior. If the themes of one movement are mixed with those from the same work's companion movements, the result may even be an artistic disaster.

The creative principle of contrast distribution

An illuminating exercise in criticism is to "reconstruct" a masterpiece, so that its thematic running order is altered; that is, to transfer the first movement's second subject to the position occupied by the finale's second subject, and vice versa. Any musician can carry out this simple experiment for himself. Nothing is better calculated to reveal to him the presence of a creative principle of contrast distribution in the original. Given the thousands of different directions in which the material of a work could be unfolded, a master chooses the "right" one, the one that maintains structural tension—and, hence, musical interest. The themes of a masterpiece cannot assume one another's functions. They are born to fulfill specific roles. They develop out of each other because they create a musical need for each other.

Principle of economy. Composers through the ages have hinted at a law of economy toward which all great music strives. Brahms, in a characteristic piece of understatement, once said of composing that "the essential thing is that every note should be in its place." Beethoven expressed the same truth another way. Once, after he had heard the "Funeral March" from the opera *Achille* by the Italian composer Ferdinand Paer, he observed: "I must compose that!" To "fix" the idea, to define it, to pin it down—both composers felt that this was of the essence. Notes are redundant that do not stand for precisely those musical thoughts they are supposed to express. To have more notes, or less, than are actually required to communicate musical meaning must render such meaning correspondingly obscure. This law may be divided into three subsidiary principles.

Idea and utterance. First is the principle of identity between the idea and its utterance. There is a concrete musical difference between what a composer intends (the idea) and what he actually says (the utterance). Some musicians contend that the distinction is merely theoretical, that in practice it cannot be made. Fortunately, composers have left ample evidence to the contrary. Consider the act of revision. Revision is an acknowledgment by the composer himself that what he actually wrote was not, on reflection, what he actually meant. Revision is self-criticism. The very word implies that a composer has a *re*-vision of the work, that he returns to the utterance and modifies it in order to be truer to the idea. Revision can sometimes result in criticism on a grand, creative level. Composers occasionally revise the work of other composers with such effective results that the original composition may be eclipsed by the new version, the "criticism," often succeeding where the original work failed. Bach's arrangement for four harpischords (in A minor) of Vivaldi's *Violin Concerto in B Minor*, for example, is more than an adaptation from one medium to another. It is an act of musical criticism *par excellence*. Vivaldi created the idea. But it was left to Bach to give it complete utterance.

Revision as self-criticism

Form and content. Why does music unfold a particular structure? Why that kind of structure rather than another? The textbooks on form remain silent. Yet this is a profound question. It is surely of paramount interest to know why music unrolls in one direction rather than another. Inspired music appears to carry within itself its own blueprint, according to which it propels itself across precise distances and in precise directions. If it is prematurely halted, diverted, or too long continued—all hallmarks of creative immaturity—it loses the sense of punctuality, the feeling of arriving "on time," the knowledge of being in the right place at the right moment, which characterizes each stage of an emerging structure masterfully handled.

The importance of structure

Some musicians have observed that the distinction between form and content is a false one. They rightly argue that no one hears one without the other, that the one is an organic result of the other. Therefore, why not abolish the distinction? They are right in regard to good forms, forms that arise inevitably from the musical material, in which case there is indeed no distinction to abolish. But bad forms, those that are not true to their content, produce a symptomatic division between the inner direction the music was born to follow and the outer direction it was made to follow.

Audibility. The objective of all compositions is to make a total aural impact. There have been some famous miscalculations, intrinsically inaudible passages, which even the most illustrious performance could not render audible. A striking case of inaudibility occurs toward the end of Grieg's *Piano Concerto in A Minor*, in which the "big tune" of the finale returns in full orchestral splendour and obliterates the part of the solo pianist. In the concert hall, it is an extraordinary sight to see the soloist

racing up and down the keyboard, fortissimo, without producing any sound. The observation is beyond all question, and may be checked every time the work is played in public.

In 1937 Schoenberg completed an orchestration of Brahms's *Piano Quartet in G Minor,* Opus 25. As a young man, he had regularly participated in performances of the *Quartet.* Time and again, he was bothered by its intermittent inaudibility: the piano tended to swamp the strings. Schoenberg's orchestration, as he himself claimed, attempted to put matters right. It remains an exercise in musical audibility—one master helping another to communicate. It constitutes an act of criticism on the highest creative level.

Other principles could be formulated to show that a theory of criticism is also a theory of composition. A search for these principles is really a search for the ultimate justification of the feelings of value inspired by great music.

CRITICISM AND PERFORMANCE

Interpretation. Since music does not exist until it is brought to life by the player, two basic requirements are demanded of the critic: a knowledge of the work, and a knowledge of the instrument. Many critics talk loosely about "the work" and "the performance" as though they were separate aspects of musical experience. They are, in fact, different aspects of a total musical experience, and it can be misleading to split them. Much bad criticism results from trying to do so. The Polish-American pianist Leopold Godowsky used to survey his audience before commencing his recitals in an endeavour to discover how many "detectives" there were in the house. Being such a superb pianist he attracted all those critics exclusively interested in keyboard gymnastics. On the other hand, those interested exclusively in the composition may be equally biassed. In this age of authenticity, when the *ur*-text is the thing, many a promising career has been blighted through what, in the profession, is called a "departure from the text." It is not always appreciated that at least a part of the total musical experience is created by the performer, who has a twofold artistic duty: first, to the fundamental character of the work he interprets; and second, to his own artistic conscience, which tells him how the work should unfold. The two are not necessarily mutually exclusive.

The performer's duty

Critics and performers. The criticism of performance is the most public, and publicized, aspect of a critic's function. It is also the least important. Unfortunately, what particular critics think of particular artists accounts for most contemporary music criticism. This is due rather to arbitrary factors than to the critics' sense of priority. Most newspapers insist that a musical event be reported the following day. The critic, consequently, is forced to telephone his review to his newspaper immediately after the concert, limiting himself to a strictly prescribed number of words. Under these conditions, it is not surprising that most criticism consists of predictable accounts of what was played, who played it, and how it was played. Nevertheless, performing artists are obliged to rely on these critical notices if they are to secure further work, even though neither critics nor artists like it. The box-office economics of concert giving are so delicate that bad publicity, or no publicity, can wreck artists and management alike.

THE DEVELOPMENT OF MUSICAL CRITICISM

Beginnings. The criticism of music first gained serious hold in the 17th and 18th centuries. Among the first writer-musicians to make systematic contributions to criticism were Jean-Jacques Rousseau in France, Johann Mattheson in Germany, and Charles Avison and Charles Burney in England. Their work coincided with the emergence of periodicals and newspapers all over Europe. The first journal devoted entirely to music criticism was *Critica Musica,* founded by Johann Mattheson in 1722. Mattheson had a number of successors, notably the Leipzig composer Johann Adolph Scheibe, who brought out his weekly *Der critische Musicus* between the years 1737 and 1740, and whose chief claim to notoriety was his scurrilous attack on Bach. Generally speaking, the criticism of the time was characterized by an obsessive interest in the rules of music and it tended to judge practice in the light of theory—a fatal philosophy. Mattheson, for instance, castigated Bach for ignoring certain rules of word setting in his cantatas.

Mattheson's contribution to musical criticism

At the turn of the century, the age of academicism dissolved into the age of description. Schumann, Liszt, and Berlioz, the leaders of the Romantic era, frequently saw in music the embodiment of some poetic or literary idea. They composed program symphonies, symphonic poems, and lesser pieces bearing such titles as "novellette," "ballade," and "romance." Their literary outlook naturally influenced criticism, the more so as they themselves frequently wrote it. In his pamphlet *On John Field's Nocturnes* (1859) Liszt wrote, in the purple prose of the time, of their "balmy freshness, seeming to exhale copious perfumes; soothing as the slow, measured rocking of a boat or the swinging of a hammock, amid whose smoothly placid oscillations we seem to hear the dying murmur of melting caresses." Most of the Romantics were guilty of this type of descriptive criticism. Its weakness is that unless the music is already known, the criticism is meaningless; and once the music is known, the criticism is redundant, since the music itself says it all far more effectively.

Schumann and Hanslick

The most influential critic of the age was Schumann. In 1834 he founded the periodical *Neue Zeitschrift für Musik* ("New Journal for Music") and remained its editor in chief for ten years. Its pages are full of the most perceptive insights into music and music makers. The first major article Schumann wrote was a laudatory essay on the young Chopin, "Hats off, gentlemen, a genius" (1834), and the last, called "New Paths" (1853), introduced to the world the young Brahms.

During the second half of the 19th century, the critical scene was dominated by the Viennese critic Eduard Hanslick, who is rightly regarded as the father of modern musical criticism. He was a prolific writer, and his book *Vom Musikalisch-Schönen* (1854; *The Beautiful in Music*) is a milestone in the history of criticism. It took an anti-Romantic stand, stressing the autonomy of music and its basic independence of the other arts, and it encouraged a more analytical, less descriptive approach toward criticism. The book was continually reprinted until 1895, appearing in many languages.

Inspired by Hanslick's example, critics in the 20th century rejected the age of description for the age of analysis. Scientific materialism created a climate of rationalism from which music did not remain immune. Critics spoke of "structure," "thematicism," "tonality"—a far cry from Liszt's "dying murmur of melting caresses." A group of musician-thinkers arose who questioned the very basis of musical aesthetics. They included Hugo Riemann, Heinrich Schenker, Hadow, Sir Donald Tovey, Newman, and, above all, Schoenberg, whose theoretical writings show him to be one of the most radical thinkers of the age. Criticism itself was criticized, its basic weakness clearly diagnosed. The search was on to discover the criteria for the evaluation of music. This quest has dominated the work of serious critics ever since. What will become of it is difficult to say, since the language of music itself is now rapidly changing. Under the leadership of such composers as John Cage (1912–) and Karlheinz Stockhausen (1928–), aleatoric techniques have been introduced in which nothing can be predicted, nothing can be repeated, everything is random, and every possible link with the past has been broken. This is a challenge to the theory of criticism that has so far not been taken up.

BIBLIOGRAPHY. The foundation for most of the subsequent developments in musical criticism was laid by SIR HENRY HADOW in his influential essay, "Music and Musical Criticism—A Discourse on Method," *Studies in Modern Music* (1892). This essay cleared the ground for two major inquiries into musical criticism: M.D. CLAVOCORESSI. *The Principles and Methods of Musical Criticism* (1923); and ERNEST NEWMAN, *A Musical Critic's Holiday* (1925). All these books consider the problem of criteria that now dominates the field of musical

æsthetics. Further contributions to the problem have been made by PAUL HINDEMITH in *A Composer's World* (1952); and by ARNOLD SCHOENBERG in *Style and Idea* (1950), containing a key essay, "Criteria for the Evaluation of Music." A later book that challenges the philosophical premises on which criticism is based is ALAN WALKER, *An Anatomy of Musical Criticism* (1966), an attempt to relate æsthetics to psychology. Important supplementary reading exists in the related field of musical analysis. The more significant books include: SIR DONALD TOVEY, *Essays in Musical Analysis,* 6 vol. (1935–39); HEINRICH SCHENKER, *Das Meisterwerk in der Musik,* 3 vol. (1926–29); DERYCK COOKE, *The Language of Music* (1959); and the analytical essay, "Mozart's Chamber Music" by HANS KELLER, in *The Mozart Companion,* ed. by H.C.R. LANDON and DONALD MITCHELL (1956).

(A.W.)

Musical Form

The term used to refer to the structure or shape of a musical composition—that is, the arrangement of individual elements so as to constitute a whole—is musical form. In music the word form is regularly used in two senses: first, to denote a standard type, genre, or species (*e.g.*, symphony, sonata); and, second, to denote the procedures in a particular work. The two meanings are often not kept separate in writing on music. The situation is complicated by the fact that nomenclature for the various musical formal types is determined in different ways—by, for instance, the medium of performance (string quartet, trio sonata), the technique of composition (fugue, variation), or function (prelude, overture, offertory).

PRINCIPLES OF MUSICAL FORM

Music exists in time; as an aesthetician, Susanne K. Langer, put it in *Feeling and Form,* "music is time made audible." The proper perception of a musical work depends in the main on the ability to associate what is happening in the present with what has happened in the past and with what one expects will happen in the future. The frustration or fulfillment, or both, of such expectations and the resulting tensions and releases are basic to the conception of most musical works.

Musical form depends, therefore, on the disposition of certain structural units successively in time. The basic principles can be discerned from a brief consideration of melody, which may be defined as an organized succession of musical tones. This succession of tones consists of component parts, structural units, the principal of which is the phrase—a complete musical utterance, roughly corresponding to what can be sung or played in one breath or played with a single stroke of the bow. A melody, then, ordinarily consists of a succession of phrases, in which there may occur repetition (the same phrase repeated), contrast (a completely different phrase), or variation (the phrase altered, but in such a way that its identity remains perceptible). The relation between these component phrases is important for form. There may, for instance, be a complementary grouping of phrases as antecedent and consequent or "question and answer." The phrases may or may not be equal in length. Some writers, pressing the analogy between music and language, also distinguish larger groupings of phrases: into periods, sentences, paragraphs, and the like. Most musical forms are thus not only additive but also hierarchical: phrases are conjoined to produce a melody, which in turn may be a constituent part of a larger work. A melodic entity that functions as an element in a larger whole is called a theme.

Melody

Coherence may be produced by the use of a motive or figure, *i.e.*, short elements consisting ordinarily of two to four notes. But whereas the motive is usually characterized by a striking interval or rhythmic arrangement, the figure consists of entirely conventional elements (a scale segment, notes of a chord, etc.). Finally, coherence may also be achieved by the consistent use of a rhythmic pattern.

A few examples will serve to illustrate these points. The various phrases have been identified by slurs (phrase marks) and by lowercase letters (the exponential numbers designate variations), whereas larger groupings are designated by capital letters. In the hymn tune "Bethany," by Lowell Mason, shown below, the eight phrases may be grouped in pairs to produce the scheme:

a b a b^1 c c^1 a b^1
A A^1 B A^1

This four-phase arrangement with statement, repetition (here with variation at the cadence), contrast, and restatement is extremely common in the traditional and art music of the West.

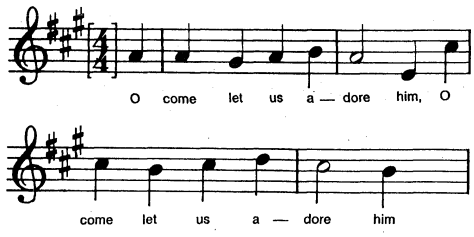
Other schemes based on repetition and contrast abound. The famous "Largo" from Antonín Dvořák's *New World Symphony,* Opus 95, goes like this:

Here the scheme is:

a a^1 b b a a^2
A B A^1

This common arrangement is known as three-part form. Coherence is provided by the use of a rhythmic motive, (marked "x" in the second example).

A common device is melodic sequence, in which the phrase is repeated but in transposition (at a different pitch level), as in the refrain of the Christmas carol "O Come All Ye Faithful."



Different from the above procedures is an English traditional song, "How Should I Your True Love Know":

The phrase structure here is a b c d, so that there is no repetitive plan. Such a melody is said to be through-composed. In some through-composed melodies a rhythmic pattern may appear throughout to promote coherence.

Function of pitch

Other elements contribute to formal organization in music. Among those having solely to do with pitch are range or register—whether most of the activity is high, low, or in the middle, or combinations of these, and whether the range of pitches used is large or small; types of melodic motion, whether conjunct (*i.e.*, by step along the scale) or disjunct (by leaps); and the use of different types of scales or modes. Factors included in music's temporal aspect include tempo, whether fast or slow, as well as duration; *i.e.*, whether individual notes are long or short (the gradually increasing use of constantly shorter note values, for instance, is associated with acceleration and accumulation, thus with increasing intensity). Among the harmonic aspects, there is key, or tonality (set of interrelated notes and chords, based on a major or minor scale), whereby the reassertion of a key following the intervention of other keys may produce an effect akin to the restatement of a phrase after a contrasting one has been heard; in this respect, cadences (sections giving the impression of conclusion) are of crucial importance in defining key. Still other factors include the use of dynamics (loud and soft); timbre, or tone colour, especially in the employment of unusual instruments or combinations of instruments; texture, whether monophonic (consisting of a single melodic line) or polyphonic (many-voiced), be it contrapuntal (having simultaneous independent melodic lines) or homophonic (one voice leading melodically, supported by chordal procedures); and, in vocal music, whether the text is set syllabically (one note to a syllable) or melismatically (many notes to a syllable).

FORMAL TYPES

Four basic types of musical forms are distinguished in ethnomusicology: iterative, the same phrase repeated over and over; reverting, with the restatement of a phrase after a contrasting one; strophic, a larger melodic entity repeated over and over to different strophes (stanzas) of a poetic text; and progressive, in which new melodic material is continuously presented (thus synonymous with through-composed). The following discussion deals first with Western and then with non-Western music.

Iterative and reverting types. Iterative types, not common in Western music, may be found in the recitation tones of Gregorian chant, in which, for example, each line of a psalm is sung to the same melodic formula. Far more common, however, are reverting types. In the Middle Ages there existed the fixed forms used in songs, such as the French ballade (a a b), virelai (A b b a A), and rondeau (A B a A a b A B), the Italian ballata (A b b a A) and the German bar form (a a b), where the patterns of repetition and contrast correspond to poetic forms. (In the representations of the reverting types in songs, lowercase letters refer to the same music set to different words, while capital letters indicate that both text and music are the same.) Since the Baroque period (*c.* 1600–*c.* 1750) there has been binary, or two-part form, such as a b. A variety of binary form particularly prominent in the dances of the 18th century is the rounded binary form, the two sections of which are a and b a (*i.e.*, with a final return to original material in the second section), each of which is repeated, part one being heard twice before part two begins: ||: a :|| ||: b a :|| (||: and :|| indicate the enclosed material is to be repeated).

Binary. The rounded binary form took on great importance in the late 18th century, when it was expanded and elaborated into what is known as sonata form (also called sonata-allegro or first movement form), which may be represented thus: ||: exposition :|| ||: development recapitulation :||, whereby the kinship to the ||: a :|| ||:b a:|| structure of rounded binary form is clear. Ordinarily, in the exposition the principal musical themes are stated; in the development they are subjected to a process of working out and variation; and, finally, in the recapitulation they are restated. Sometimes the scheme is enlarged by adding a slow introduction before the exposition or a coda (concluding passage) at the end, or both. This formal principle, usually treated with a certain freedom, has been of basic importance in Western instrumental music since the mid-18th century.

Sonata form

Ternary. Another basic reverting type is ternary (three-part) form, a b a, also known as "song form" because of its frequent use in that genre, as well as in character pieces for piano. The form dominates the aria in late Baroque opera (the da capo aria, in which the final statement of a is not written out, but the performers simply follow the written instruction da capo, meaning "from the beginning," and repeat the first part). The da capo principle also appears in the instrumental minuet and scherzo with trio.

Rondo. On a larger scale are refrain schemes, in which contrasting episodes appear between statements of the refrain. In instrumental music this is found most often in a five-part arrangement, the rondo, frequently a b a c a b a; but many departures from the form occur, most common being the replacement of c by a development passage, usually based on the rondo theme. This important variant, known as the sonata-rondo, is particularly associated with Joseph Haydn. The refrain principle also appears in the rondeau of 18th-century French harpsichord music, in which there is no set limit to the number of episodes. The third movements of concertos, with the reversions of the tutti or ritornello (passage for full orchestra) and the intervening episodes for the solo instrument or instruments, are also of this type, as occasionally are large operatic arias.

Strophic types. The strophic type is seen in hymns and traditional ballads, in which different poetic strophes are set to the same melody. Thus, while the melody of a single stanza may accord with one of the reverting types, the hymn or ballad as a whole is strophic; this also applies to the fixed forms of medieval music and to many other types of song, simple and complex.

Theme and variation

The instrumental equivalent of the strophic type is variation (or theme and variation) form, in which a musical theme, often a complete melody with a harmonic accom-

paniment, is stated and then repeated a number of times, but with variations. A clear example of the relation between variation and strophic form is the chorale-partita of the Baroque era, a keyboard piece based on a hymn, with each varied statement of the hymn tune corresponding to a strophe of the hymn text. But the structure is more common in independent instrumental compositions, often of considerable dimensions (*e.g.*, Beethoven's *Diabelli Variations* for piano). In the Baroque a common type was the ostinato, or variations on a ground, in which the composition was built on a recurring melodic or harmonic pattern, generally in the bass, the accompanying parts being varied with each statement of the pattern, as in Bach's *Passacaglia and Fugue in C Minor* for organ or his "Chaconne" from the *Partita in D Minor* for unaccompanied violin. This procedure is also found in early operatic arias in the strophic variation form, in which each statement of the ostinato corresponds to a strophe of the aria's text. In the 19th century Brahms made impressive use of the ostinato (finales of the *Variations on a Theme by Haydn* and the *Symphony No. 4 in E Minor*).

Progressive types. The progressive type is common in songs and instrumental pieces of the 19th and 20th centuries but is also found in earlier music (*e.g.*, in the melodies used for the Gloria and Credo of the mass in Gregorian chant) and in the prose, or sequence (*c.* 9th–*c.* 12th centuries), the phrases of which are arranged in pairs (a a b b c c d d, etc.), and its instrumental equivalent, the estampie. Polyphonic forms using a cantus firmus or basic melody (often a plainchant excerpt) also belong to the progressive type and include the liturgical organum, the early motet, and the conductus from the medieval era, as well as many chorale-preludes for organ of the Baroque. If, however, the cantus firmus itself is in one of the reverting forms, then the polyphonic setting will frequently follow suit.

The most important forms of Renaissance polyphony also belong to the progressive type, since the characteristic procedure was to give each line of the text its own musical phrase, as in the Renaissance motet and other types of secular polyphonic music. The same applies to the instrumental contrapuntal forms of the late Renaissance and Baroque: the ricercar, canzona, invention, and fugue. Other progressive types include intonations, preludes, toccatas and fantasias for lute and keyboard of the 16th, 17th and early 18th centuries, in which the thematic material consists primarily of figurative elements (scale passages, arpeggiated chords, trills, turns, and the like); in larger works of this kind—by Bach for instance—passages in fugal style are often also present. Finally, there is simple binary form (a b), often found in early dances and in large operatic arias of the Classical period (Mozart and Beethoven).

WESTERN COMPOUND FORMS

Early history. With the larger forms of instrumental music there are extended musical pieces, usually called movements, which in their succession and totality make up a larger whole. An important unifying factor is key: a single key often dominates the work, others being used for contrast. This idea goes back at least to the Baroque, when two formal types were established: the first is the *sonata da camera,* or chamber sonata, consisting of a series of dances in the same key (also known as partita and, later, suite). By J.S. Bach's time (1685–1750) a set arrangement of dances was common: allemande (moderate slow triple time), courante or corrente (fast triple time), saraband (slow triple time), and gigue (fast triple time), usually with some other dance inserted between the saraband and the gigue. The other type is the *sonata da chiesa,* or church sonata, which consists of four movements, again all in the same key, in a slow–fast–slow–fast succession. The distinction between the two types is explicit in Bach's sonatas and partitas for unaccompanied violin: the sonatas are in the "church" form, whereas the partitas are suites. Other large forms of Baroque music are the two types of overture: the French, in two parts, the first slow and stately, the second fast and fugal; and the Italian, in three movements in the succession fast–slow–fast, the middle movement usually in a different key. The instrumental concerto after 1700 usually employed the same scheme as the Italian overture.

The sonata. Around 1750 a combination of these types produced the forms most common in the standard repertory of concert music. The sonata became a piece for either a keyboard instrument or a solo instrument accompanied by keyboard. It ordinarily consisted either of three movements in the arrangement fast–slow–fast or of four, with a minuet inserted between the slow movement and the finale; but there are examples of two-movement sonatas, notably by Beethoven, and even of one-movement sonatas (*e.g.*, by Domenico Scarlatti, the Italian-born composer to the Spanish court). Usually all movements except the slow one (and sometimes the trio, as well) are in the same key. The first movement typically is cast in the sonata form, the slow movement in one of the reverting schemes (often ternary), and the finale either in sonata or rondo form; but variation form may appear in any of these movements.

This large form is also used in chamber music, particularly the string quartet, and in the large form of orchestral music, the symphony, both of which ordinarily have four movements. Notable exceptions to this are the late quartets of Beethoven as well as those of the 20th-century composer Béla Bartók, the latter in two instances using what is called the "arch form," a large reverting arrangement, A B C B A, each element being a separate movement; needless to say, there are innumerable other exceptions. The concerto, on the other hand, adheres more to the older three-movement form. The various kinds of late 18th-century entertainment music (cassation, divertimento, nocturne, serenade, and the like) may employ any of a number of arrangements, ranging from three movements all the way to six or more.

Exceptions to sonata form

Cyclic form. Some authorities believe that from the 18th century on such sonata-form compositions have been organized by the use of a few musical thematic motives, often submitted to considerable variation throughout. Compositions organized in such a way are said to be in cyclic form. While this becomes important in the 19th century, the extent to which it characterizes the Classical period is a matter of some controversy at present.

Fantasias and program music. Simultaneously a much freer form was cultivated, beginning in the late 18th century, the fantasia, primarily for keyboard, notably in the hands of Carl Philipp Emanuel Bach. Consisting of an indefinite number of highly contrasting sections, surprise and expression were of prime significance.

The fantasia, along with the overture to a play or opera, was the precursor of the large forms of orchestral program music of the 19th century, in which an extramusical content (usually a narrative of some kind), called the program, is expressed in the composition. There are two main types: the program symphony, associated with Hector Berlioz, in which the norms of symphonic form are for the most part preserved, and the symphonic poem, associated with Franz Liszt and Richard Strauss, in which the composer allows the extramusical subject matter to determine the structure of the composition. Some 19th-century concert overtures by German composers such as Felix Mendelssohn and Robert Schumann belong to this type of composition. Important here is the association of musical themes with aspects of the program, the themes being used throughout the work, often in varied forms.

The symphonic poem

Another arrangement is called the suite, which no longer consists exclusively of dances but also of instrumental pieces of all kinds. Usually some common element runs throughout: a cyclic theme may be used, as in Schumann's *Carnaval* or the Russian composer Modest Mussorgsky's *Pictures from an Exhibition,* or the music may originally have been intended for use with a play (Mendelssohn's music to *A Midsummer Night's Dream* or the Norwegian Edvard Grieg's for Henrik Ibsen's *Peer Gynt*).

Opera and oratorio. Among the large forms of vocal music, opera and oratorio are the most significant. Both are extended works in which a narrative is set to music.

While an opera is performed in a theatre, an oratorio is a concert piece. Both may be either sacred or secular. A special type of oratorio is the Passion, the setting of New Testament accounts of Christ's crucifixion. The cantata may be regarded as a smaller form of oratorio.

Operas and oratorios ordinarily consist of several musical genres: recitative (imitating the manner of speech), aria, ensemble and choral pieces, often with instrumental interludes and an overture (most overtures of the late 18th and 19th centuries being cast in sonata form). Opera often includes ballets and large sectional finales at the ends of acts. With respect to the oratorio, Handel greatly increased the role of the chorus in his work with this genre (especially *Israel in Egypt*), an example seized upon by his successors. Oratorios also differ from operas in that they frequently make use of a *testo* (narrator), who relates the events of the action, usually set in recitative style. Stravinsky's *Oedipus Rex* (1927) combines the two traditions.

Wagner's new operatic form

Whereas operas are usually composed as a series of enclosed musical forms, the German composer Richard Wagner devised a special kind, known as music drama, in which the music is continuous and in which the distinction between recitative, aria, and ensemble is largely eliminated. Instead, Wagner used a flexible melodic line which he referred to as "tone speech." Wagner also greatly increased the role of the orchestra, stressing the technique of thematic development and transformation borrowed from instrumental music and further associating each theme with an aspect of the operatic plot, such themes being known as leitmotivs ("leading motifs").

The mass. Another large vocal form is the mass, the earliest polyphonic settings of which date from the 14th century. At first the mass was set in cantus firmus style, each movement built on the appropriate Gregorian chant melody, as in the mass of the French composer Guillaume de Machaut. In the 15th century a Burgundian composer, Guillaume Dufay, and his contemporaries developed the cyclic mass, in which a single cantus firmus was employed throughout. This idea was extended in the parody mass, built by elaborating thematic material taken from an existing polyphonic work, usually a motet or chanson; most 16th-century masses are of this kind. In the Baroque mass, each segment of the text is treated as an independent composition (aria, duet, chorus), similar to the procedure in a cantata or oratorio, except that no recitatives are used. J.S. Bach's *Mass in B Minor* is of this type.

In the 16th and 17th centuries, Monteverdi and others grouped madrigals into a kind of cycle around a particular subject; should a dramatic text be involved, the form is known as a madrigal comedy. In the 19th century and after, similarly grouped songs with piano accompaniment are known as a song cycle (*e.g.*, those by Beethoven, Schubert, and Schumann).

Twentieth-century modifications. In the 20th century many composers have continued to use the traditional forms, although in other respects their work makes significant departures from what had been established. Others have virtually discarded them. Radically new elements have been introduced to serve as structural units: instead of the traditional phrases and motives, composers have come to employ what they call "sound events," combinations of textures, types of timbre, aggregates of different simultaneously sounding pitches, and the like. An early example is afforded by the notion of the melody of timbres—the *Klangfarbenmelodie* of Arnold Schoenberg and Anton von Webern. The broadest possible range is included in the conception of a sound event: not merely tones but also noises; in fact, sounds of all kinds. These sound events have been arranged in a complex manner. An important principle of organization has been serialism, originally applied only to pitch, so that the pitch content of the work is decided by reiterations of a series (set or row) of pitches that has been determined in advance (*e.g.*, in the twelve-tone compositions of Schoenberg and Webern). Since 1945 the serial principle has been extended to other aspects of music as well: durations, dynamics, and types of attack and tempi, as in the music of the French composer Olivier Messiaen and the German Karlheinz Stockhausen. Other composers, including Stockhausen and the Greek Yannis Xenakis, have used numerical relationships to determine the structure of compositions mathematically. Still others have conceived of form as a dynamic interaction between contrasting and continually evolving sound events—the French composer Edgard Varèse and the American Elliott Carter. Simultaneously, there are works, such as those of the American John Cage, in which the form is not predetermined by the composer but left to chance, such pieces being called indeterminate or aleatoric. These statements apply to electronic music as well.

"Sound events"

NON-WESTERN FORMS

Elements of structure. In many non-Western civilized cultures, such as those of India and Near Eastern Islāmic countries, music for the most part is not written down in advance of the performance but improvised upon framework-like patterns. In effect a composition exists only in its performance. Problems are presented by the different scales and intervals, rhythmic patterns, timbres, inflections, and the like. Or, again, a type of polyphony known as heterophony may result from the discrepancies that occur when several different singers or players simultaneously vary the same melodic line. In Japanese *gagaku* music, in which improvisation is not a factor, the beats often vary in duration, producing what is known as "elastic rhythms," akin to the Western tempo rubato. Much non-Western music is functional: each piece has a specific purpose and is associated with certain events, actions, or situations, which often determine the musical structure.

Important elements of form in non-Western music are melody types and rhythmic patterns. By melody type is meant a melodic formula using a recognized scale, stressing particular tones and using specific configurations of intervals, which can provide the basis for a larger piece. In a given society or culture there ordinarily exists a large repertory of these melody types from which the musician, following convention, selects those for use in his rendition. The use of rhythmic patterns for form is seen, for instance, in colotomic structure, in which the composition is marked off in temporal entities by the differing but regularly recurring entrances of particular musical instruments in a set order.

Rhythmic patterns used for form

In the music of nonliterate cultures, simple iterative and strophic structures predominate. These are characterized by short phrases and the frequent use of alternation between a soloist and the group (the "call-and-response" pattern). Such pieces, often associated with dancing, usually belong to specific rituals of one kind or another.

In literate cultures comprehensive theoretical music systems often exist, with elaborate musical forms. Nonetheless, the conception of propriety, that each musical piece has a certain function, is dominant. While strophic forms continue to be important, as in the Indian *gat,* the *umui* religious chants of the Ryukyu Islands (both of which also use variation), and in the popular music of most cultures, there are also such large musical forms as those related to the Indian *rāgas*, the Arabic *maqāmāt* (melody types), and the music of the *gamelan* (gong and percussion ensembles) of Java and Bali.

Specific formal patterns. The term *rāga,* meaning colour or passion, refers not only to a scale but also to the melody type. It has given rise to several musical forms, among them the ancient northern *dhurpad* and the shorter type known as *khyāl* in the North and *kīrtana* in the South. These may be vocal, instrumental, or both, the main performer or performers being accompanied by a drone played by a bass lute and by the reiteration of an extended rhythmic pattern (the *tāla*) by a drum. While much variety is possible, a typical formal arrangement includes a prelude which states the *rāga* (scale and melody type) in its simplest form and continues with a number of contrasting sections that differ in the degree of elaboration of the *rāga*, the register exploited, and the rapidity of the notes and figuration, usually reaching a climax near the end, in which daring variations on the *rāga* in the uppermost register are played or sung in very

rapid tempo; the performance may conclude with a return to the character of the prelude. Interludes or linking passages, related to the prelude, are often present, so that an irregular reverting scheme results.

The Arabic *maqām*, roughly equivalent to the *rāga*, provides the basis, among others, for the *bashraf*, a reverting type not unlike the Western rondo, and the *nawba*, an extended multisectional performance with some resemblance to the suite. In Java and Bali particularly noteworthy is the *gending* (musical composition) for the *gamelan*, which may take one of several progressive sectional forms in which the colotomic principle is important: the large *gending agen*, usually bi-partite, a slow movement followed by a fast one, and the shorter *gending gangsaran*, used as preludes and interludes.

Musical Instruments

A device that produces musical sounds is a musical instrument, whether it is used for ritual or ceremonial purposes, for entertainment, or for private enjoyment. The fact that a number of instruments produce sounds of no definite pitch does not exclude them from this definition, since rhythm is an essential element in all music. The beat of a drum can be as important in a composition as a melody played by violins. Many instruments seem to have developed from the imaginative use of objects originally designed for other purposes. The drum has its origin in the pot and the pitcher; the rattle was used to mark the steps of a dance and also as a charm against evil spirits. Composers of recent times have used other objects not normally associated with music. Stage properties such as the wind machine and the thunder machine have been called for in works of a dramatic character. Iron chains, typewriters, and milk bottles are not unknown in 20th-century music. None of these, however, has established itself in normal use; and to extend the definition of musical instruments to include such objects would involve admitting any solid body that can make a sound when struck.

The material of which an instrument is made does not necessarily affect the sound that it produces. In the case of instruments that are struck with some kind of beater, the difference may be very marked. Wood and metal when struck produce quite different sounds. On the other hand, a flute made of metal does not produce a substantially different sound from one made of wood, as in this case the vibrations are in the column of air in the instrument. Oboes have been made of ivory, clarinets of ebonite. The characteristic tone of wind instruments depends on other factors, notably the length and shape of the tube and the means by which the air column is set in motion. The length of the tube not only determines the pitch but also affects the tone: the piccolo, being half the size of the flute, has a shriller tone; the bass clarinet, being larger than the clarinet, produces a darker sound. The shape of the tube determines the presence or absence of the "upper partials" (harmonic or nonharmonic overtones), which give colour to the single note. In the oboe the tube, or bore, is conical, expanding gradually from the reed mouthpiece to the bell; this means that a strong and uninterrupted series of upper partials is present, and this and the fact that the air column is set in motion by the vibrations of the reed give the instrument its characteristic tone. In the clarinet, on the other hand, the bore is cylindrical, and the tube is stopped at one end by the mouthpiece, with the result that up to a point only the odd-numbered upper partials are present. Hence, the clarinet has a mellower, less reedy tone than the oboe.

The volume of sound produced by an instrument depends on resonance, whether created by a vibrating air column or by a solid body vibrating in sympathy. In bowed string instruments the hollow box over which the strings are stretched vibrates in sympathy when the bow is drawn across the strings. Similarly, the volume of tone produced on the piano depends on the vibrations of the soundboard, without which the mere impact of the hammers on the strings would produce very little effect.

Cultural aspects. The use of instruments purely for entertainment is a development of civilized societies. In primitive societies instruments were used as an adjunct to dancing and labour, and they also had magical properties that could serve in religion and medicine. These functions naturally overlapped. Bells or flutes could be used to attract the opposite sex and also to ward off evil spirits. It is also significant that most instruments were assigned to men. As an element in magic, instruments could be used equally to repel evil or to invoke a deity. The use of instruments for religious ceremonies has continued down to the present day, though at various times they have been suspect because of their secular associations. The many references to instruments in the Old Testament are evidence of the fact that they played an important part in Jewish worship until for doctrinal reasons they were excluded. It is also clear that the early Christians in the eastern Mediterranean used instruments in their services, since the practice was severely condemned by ecclesiastics, who insisted that the references to instruments in the Psalms were to be interpreted symbolically. As a result of this official attitude the music of the Christian Church became for several centuries restricted to voices. The organ, which seems to have been developed in Alexandria in the 3rd century BC, was a purely secular instrument in the Greco-Roman world. It remained so at Byzantium after the official acceptance of Christianity: it was used for ceremonial occasions such as banquets and chariot races but not for church services. The use of the organ in church in western Europe appears to date from the 8th century AD, when the Frankish monarch Pepin III installed at Compiègne an instrument he had received as a present from Byzantium.

The invention of the organ

Belief in the magical properties of instruments is found in many societies. The Jewish shofar (a ram's horn), which is still blown on Rosh Hashana (New Year) and Yom Kippur (Day of Atonement), must not be seen by the congregation. Similar secrecy is found among primitive peoples. The power of the shofar is illustrated by the story of Joshua at the siege of Jericho: when the priests blew their shofars seven times the walls of the city fell flat. In India, according to legend, when the deity Kṛṣṇa played the flute, the rivers stopped flowing and the birds came down to listen. The birds are said to have done the same in 14th-century Italy when the composer Francesco Landini played his organetto, or portative organ. In China, instruments were identified with the points of the compass, with the seasons, and with natural phenomena. The Melanesian bamboo flute was a charm for rebirth. Many primitive instruments were phallic symbols.

Most of the instruments used in the West in medieval times came from the Near East. Trumpets, long associated with military operations, had a ceremonial function in the establishment of kings and nobles and were, in fact, regarded as a sign of nobility. In the later Middle Ages and for long afterward, they were associated with kettledrums (known originally as nakers, after their Arab name, *naqqārah*), which were often played on horseback, as they still are in some mounted regiments. Trumpet fanfares, heard on ceremonial occasions in the modern world, are a survival of medieval practice. In the 17th century, trumpets and kettledrums were introduced into opera and orchestral music of a festal character. In the same way, horns, originally hunting instruments, became normal members of the orchestra in the 18th century.

Technological developments. The earliest instruments appear to have been natural objects capable of producing sound; for example, the conch (marine shell) and the bone pipe. The conch and the primitive trumpet at first served only as a means of amplifying the human voice.

The discovery that tubes possessed acoustic properties that enabled them, by vibration of the lips, to sound more than one note was a later development. From using natural objects, it was an obvious step to construct instruments that would serve a similar purpose, using wood or terra-cotta or any other available material.

Development of string instruments

Another development of natural resources was the discovery that a stretched string could produce a musical note. This resulted in the construction of the musical bow, the ancestor of all plucked string instruments. Its shape is similar to that of the hunter's bow, but it seems to have had an independent origin. Since the sound of the simple string is feeble, it is reinforced by means of a resonator—either a pot placed on the ground beneath the instrument or a gourd attached to it or the player's mouth. The string can either be struck with a stick or be plucked with the fingers. In the former case it could be regarded as the forerunner of the Persian dulcimer, in which numerous strings are struck with a stick, and ultimately of the piano.

The construction of all but the simplest instruments requires skill and craftsmanship: the piercing of a tube to a uniform or expanding width, the flaring of the bell of a wind instrument to increase sonority, the measurement of the bars of a xylophone or glockenspiel, the curvature of the back of a lute, the internal and external structure of the body of a violin. All of these involve accurate workmanship from experts in wood and metal and, from present-day designers, a knowledge of the mathematics of sound. The latter is particularly true in the case of woodwind instruments, where the holes must be accurately pierced in order to produce a scale that is in tune. Of all instruments, the organ demands the fullest cooperation from workers in different skills: in the construction of pipes in metal and wood, in fashioning them to the right length, in securing uniformity of tone throughout a single row, and in adjusting the great variety of sounds so that they blend happily together; in the provision of leather pallets to allow the passage of air; in providing direct and immediate contact between the keyboard and the pipes; and in constructing a blowing apparatus that will be adequate for the pressure required.

Woods used for making instruments

The first step in the building of any instrument is the selection of material. Wood, whether cocus, rosewood, or maple (to mention three that are favoured for woodwind instruments) or pine, used for string instruments, needs to be seasoned. This applies equally to the reeds of oboes, clarinets, and bassoons, which are cut from the plant *Arundo donax,* now grown for this purpose, particularly in the south of France. Climate is also an important consideration. The moist, damp climate of tropical countries has often proved disastrous to instruments built for use in Europe.

Our knowledge of medieval instruments is derived almost entirely from pictorial illustrations, and the men who made them remain anonymous. Their skill, like that of the cabinetmaker and the silversmith, was developed by long practice, and the principles that determine both tone and intonation were discovered by trial and error. The growth of instrumental playing in the 16th century stimulated the production of instruments to be used not merely for ceremonial and official entertainment but also for social occasions and private pleasure. From this time we begin to know the names of makers, many of whom established family businesses that lasted for several generations. These include, for example, Andrea Amati (16th century), violin maker in Cremona; Hans Ruckers (late 16th century), harpsichord maker in Antwerp; and Johann Haas (1649–1723), trumpet maker in Nürnberg.

Modern technology has in many cases simplified or improved the construction of instruments. In the past, for example, the tubes of horns and trumpets were made from a sheet of brass cut to the right width, which was rolled into shape, leaving the edges to be joined by brazing. In modern manufacture the tube is drawn in one piece, and there is no seam. Evolution of design has been particularly notable in the construction of wind instruments: in the case of woodwind instruments, not only in the fixing of the metal keys and the mechanism that controls them but also in the piercing of holes in such a way that they are both acoustically correct and under the direct control of the fingers. This achievement, which dates from the first half of the 19th century, was due mainly to the pioneering work of Theobald Böhm (1794–1881). His system, designed for the flute, was also applied to the clarinet, and some of its mechanical principles were adapted for the oboe and bassoon. The early 19th century also saw a revolution in the manufacture of brass instruments: the addition of pieces of tubing of different lengths through which the air could be directed by the depression of valves (or pistons), enabling an instrument to produce all 12 notes of the chromatic scale, in place of its earlier limitation to the notes of the natural harmonic (overtone) series.

Modern changes in design

The discovery of plastics in the 20th century has also influenced the manufacturers of instruments; for example, plastic has been used instead of quill or leather for the plectra that pluck the strings of the harpsichord, and plastic recorders have been built. Mechanization has made possible the mass production of instruments of all kinds. Insofar as this makes it possible for people to acquire an instrument at a moderate price, mass production is a good thing, and in education it has been beneficial to schools working on a small budget. A natural development has been the provision of kits consisting of the separate parts of an instrument, which can then be assembled by the purchaser. It remains true, however, that the production of an instrument of the finest quality still demands the highest degree of individual skill. A violin glued together from mass-produced parts cannot be the equal of one that has been meticulously constructed from the first by an individual craftsman who will not be satisfied with his work until every detail of it has been tested.

Importance of craftsmen

Technology has been of service to music by providing composers with instruments they have asked for, by eliminating the defects of instruments and facilitating the work of performers, and by making instruments more widely available to the community in general. Richard Wagner suggested the heckelphone, a double-reed instrument akin to the oboe, and ordered a special type of tuba for use in his music drama tetralogy *Der Ring des Nibelungen.* Not all the improvements in construction have been wholly advantageous. It is easier to play in tune on a modern woodwind instrument, but the older examples, being less cluttered with metal fittings, had a purer tone. Similarly, the modern horn, which is virtually two instruments in one, is inferior in tone quality to its 18th-century predecessor. Only the trombone and the string instruments have remained, apart from minor modifications, unchanged in structure over the centuries, though the substitution of wire strings for gut has materially altered the tone of the violin.

The older makers of instruments were craftsmen who took delight in the appearance of their work. Pictures were painted on the inside of harpsichord lids; delicate inlay and carved heads adorned string instruments. Rings of ivory concealed the joints in woodwind instruments; the bells of trumpets were richly chased. Sometimes there was extravagance—for instance, making the bell of a wind instrument in the shape of a dragon's head. Modern taste in most cases rejects ornamentation. The coats of arms painted on military bass drums are there principally to indicate their regimental function. But overall design and finish are as important as they have always been. If instruments were not meant for use, those that are produced today would deserve, on aesthetic grounds, to find a place in museums, side by side with the musical treasures of the past that lead a beautiful but generally silent existence there.

Classification of instruments. Instruments have been classified in various ways, some of which overlap. The Chinese divide them according to the material of which they are made—as stone, wood, silk, and metal. Although applicable to Chinese instruments, this system will not do as a classification of instruments in general. To take a simple example, a saxophone is made of metal, but its method of tone production associates it with the clarinet,

which is, at least in origin, a wooden instrument. Writers in the Greco-Roman world distinguished three main types of instruments: wind, string, and percussion. This classification was retained in the Middle Ages and persisted for several centuries: it is the one preferred by some writers, with the addition of electronic instruments, at the present day. Some 16th-century writers excluded certain instruments from this classification; the musical theorist Ludovico Zacconi (1555–1627) went so far as to exclude all percussion instruments and established a fourfold division of his own—wind, keyed, bowed, and plucked. A different fourfold classification was accepted by the Hindus at least as early as the 1st century BC: they recognized string instruments, wind instruments, percussion instruments of wood or metal, and percussion instruments with skin heads (that is to say, drums). This ancient system—based on the material producing sound—was adopted by the Belgian instrument maker and acoustician Victor-Charles Mahillon (1841–1924), who named his four main classes autophones, or instruments made of a sonorous material that vibrates to produce sound (*e.g.* bells, rattles); membranophones, in which a stretched skin is caused to vibrate (*e.g.* drums); aerophones, in which the sound is produced by a vibrating column of air (wind instruments); and chordophones, or string instruments. In their highly influential studies of musical instruments, the Austrian musicologist Erich von Hornbostel (1877–1935) and his German colleague Curt Sachs (1881–1959) accepted and expanded Mahillon's basic division, creating the classification now used in most systematic studies of instruments. The name idiophones was substituted for autophones, and each class was subdivided according to a method similar to that used by botanists. A fifth class, electrophones, in which vibration is produced by oscillating electric circuits, was added later. The Table gives examples of instruments that come within the various categories.

Systems based on the material sounded

Classification and Examples of Some Musical Instruments

Idiophones	
Struck	against each other: cymbals, castanets
	with a beater: triangle, glockenspiel, xylophone, slit drums
Shaken	rattle, jingles
Scraped	scraper
Plucked	jew's harp, music box
Rubbed	musical glasses
Membranophones	
Struck	tambourine, side drum, bass drum, timpani
Rubbed	friction drum
Blown	mirliton (or kazoo)
Chordophones	
Plucked	without keyboard: harp, lute, violin, zither, lyre
	with keyboard: harpsichord
Struck	without keyboard: dulcimer
	with keyboard: clavichord, piano
Rubbed (with a bow)	viol and violin families
Aerophones	
Flues	without keyboard: recorder, flute
	with keyboard: organ
Reeds	without keyboard: single reed—clarinet, saxophone
	double reed—shawm, crumhorn, oboe, bassoon, sarrusophone
	with keyboard: harmonium, American organ (melodion)
Lipped	horn, cornet, trumpet, trombone, tuba, serpent
Electrophones	
Monophonic	producing a single line of melody: theremin, trautonium, Ondes Martenot
Polyphonic	producing harmony and simultaneous melodic lines: Hammond organ

The classification shown in the Table is convenient, but it is not completely logical. Some instruments may belong to more than one class or more than one subdivision. The tambourine is a membranophone in so far as it has a skin head which is struck; but, if it is only shaken so that its jingles sound, it should be classed as an idiophone, for in this operation the skin head is irrelevant. Flue pipes are the foundation of organ tone, but the instrument also has a number of reed pipes, so that the organ belongs equally to the first and second order of aerophones. The violin is undoubtedly a chordophone, but if the strings are struck with the wooden part of the bow it belongs to the second order of this class, not the third. Modern composers not infrequently require players to slap their instruments instead of playing them in the normal way. A slapped guitar or a slapped trombone is technically an idiophone. The classification according to the source of vibrations also ignores common elements in means of production. It is normal practice to speak of keyboard instruments as a group, including piano, harpsichord, organ, and so on; but in the Hornbostel–Sachs classification these are either chordophones or aerophones, and, if the keyed glockenspiel is included, there is an idiophone as well.

History and evolution. Men have speculated about the origin of instruments since antiquity. Older writers were generally content to rely on Greek mythology or Old Testament legends. In the 19th century there was an attempt at a more scientific approach, partly as a result of theories of evolution put forward by Darwin and Herbert Spencer. The British writer John Frederick Rowbotham argued that there was originally a drum stage, followed by a pipe stage, and finally a lyre stage. The Austrian writer Richard Wallaschek, on the other hand, maintained that, although rhythm was the primal element, the pipe came first, followed by song, and the drum last. Sachs, instead of relying on anthropological evidence, based his chronology on archaeological excavation and the geographical distribution of the instruments found in them. Following this method, he established three main strata. The first, of wide distribution, consists mainly of noisemakers, such as the rattle and the bull-roarer. The second, found in several continents but not universally, includes drums, trumpets, and plucked strings. The third, occurring only in certain areas, includes more advanced instruments, such as the xylophone and the flute. That percussion instruments should appear at an early stage is not surprising. From stamping out a rhythm with his feet, primitive man learned to do the same with an implement: these implements became more elaborate as time went on and were followed by further experiments in extracting sound from sonorous objects.

The development of musical instruments among ancient high civilizations appears to have been most substantial in Asia and North Africa. By contrast, instrumental performance remained confined to winds and percussion in Central and South America. It is not always easy to say whether instruments are indigenous to a particular area, since their cultivation may well have spread from one country to another through trade or migration. The harp was used from early times in Mesopotamia, Egypt, and India but was not imported into China before the end of the 4th century AD. In Greece it was regarded as a foreign instrument: the standard plucked instrument was the lyre, known in its fully developed form as the kithara (or cithara). Apart from the trumpet, the only wind instrument in normal use in Greece was the aulos, a double-reed instrument akin to the modern oboe. The Egyptians used wind instruments not only with double reeds but also with single reeds and thus may be said to have anticipated the clarinet. Peculiar to China was the *sheng*, or mouth organ; the Chinese also used as an artistic instrument the panpipes (*hsiao*), which in Greece had merely a rustic function.

Early use of the harp

The most notable development in western Europe was the practice, originating apparently in the 15th century, of building instruments in families, from the smallest to the largest size. A typical family was that of the shawms, which were powerful double-reed instruments. A distinction was made between *haut* (loud) and *bas* (soft) instruments, the former being suitable for performance out of doors and the latter for more intimate occasions. Hence, the shawm came to be known as the *hautbois* (loud wood), and this name was transferred to its more deli-

cately toned descendant, the 17th-century oboe: the Italian name was a phonetic transliteration of the original French. By the beginning of the 17th century the German musical writer and composer Michael Praetorius, in his *Syntagma Musicum* ("Musical Treatise"), was able to give a detailed account of families of instruments of all kinds—recorders, flutes, shawms, trombones, viols, and violins.

Origin of viols and violins

Stringed instruments. The idea of playing a string instrument with a bow appears, from the available evidence, to have originated in Persia in the 9th century AD. The medieval fiddle, like its Eastern prototype, was originally a folk instrument and existed in various forms: by the 16th century these had settled down into two distinct types—the viol, known in Italy as viola da gamba (leg fiddle), and the violin, or viola da braccio (arm fiddle). The two types differ in several respects. The viol has a flat back and sloping shoulders, the violin a rounded back and rounded shoulders. The viol has six or seven strings, the violin four. The viol, unlike the violin, has frets—pieces of gut wound at intervals around the fingerboard—which make every stopped note (*i.e.*, the string being pressed by the finger to produce a higher pitch) sound like an open (unstopped) string. The violin, being the smallest member of the family, came to be known by the diminutive violino: the tenor of the family was called simply viola (in France *alto*; in Germany *Bratsche,* a corruption of Italian *braccio,* "arm"), while the bass acquired the name violoncello, a diminutive of violone ("big fiddle").

The clavichord, harpsichord, and piano

Keyboard instruments. Of all instruments, the organ showed the most remarkable development from the early Middle Ages to the 17th century. Originally, sound was admitted to the pipes by withdrawing sliders or depressing levers. Both of these methods were clumsy: they gave way to a reduction in the size of the levers, which eventually could be depressed by the fingers, while the larger pipes were controlled by pedals. A further development was to separate the various rows of pipes, so that each row could be brought into action or suppressed by means of a draw stop. Once a manageable keyboard had been produced, it could be applied to the portable organ, carried by the player, which was already in use by the 12th century. Scientific experiments with the monochord, a stretched string that could be divided into various lengths by means of a metal tangent, were followed by the construction of an instrument with a whole range of strings and a keyboard similar to that of the organ—the clavichord. A similar adaptation of the plucking of string instruments led to the harpsichord, the ingenious mechanism of which had been perfected by the 16th century. It is curious that a similar method was not applied to the dulcimer, which was struck with hammers, until the early 18th century, when the Italian maker Bartolomeo Cristofori constructed the first pianoforte, so-called because, unlike the harpsichord, it could vary the tone from soft (*piano*) to loud (*forte*).

The effect of the orchestra. The establishment of orchestras, as opposed to chamber groups, in the early 17th century favoured the violin family at the expense of the viols. The latter gradually dropped out of use, with the exception of the bass viol, which was still used in the first half of the 18th century as a solo instrument and as the bass of an accompaniment. It was not until the end of the 19th century that the viols were revived, in order to play the music written for them in the past. Other instruments besides the viols fell into temporary oblivion. The medieval crumhorn, a double-reed instrument with the reed inside a pierced cap, barely survived the 16th century. Another old instrument, the cornett, consisting of a wooden tube with finger holes and played with a cup-shaped mouthpiece, dropped out of use in the 17th century, except in Germany, where it was still played by *Stadtpfeifer,* or "town musicians," in the 18th century. Both Bach and Handel wrote for this instrument, but its tone was too weak for later orchestral music, and it had to wait until the 20th century for a full-scale revival.

Wind instruments. The practice of constructing instruments in families continued from the 17th century onward. English composers wrote for the tenor hautbois, which in various forms was known as oboe da caccia ("hunting oboe," possibly from its curved shape) or cor anglais ("English horn"). There was also an intermediate instrument called oboe d'amore. The bass, or baritone, oboe originated in the 18th century but was not perfected until the 19th. The clarinet (the name means "little trumpet") emerged at the end of the 17th century and, like the oboe, developed into a family extending to a contrabass clarinet in the 19th century and later a subcontrabass. It established itself only gradually in the orchestra in the course of the 18th century.

The work of Sax

The improvement of brass instruments by the addition of valves in the early 19th century led to the creation of others. A pioneer in this field was the Belgian instrument maker Antoine Joseph Sax, who in 1845 built a family of valve instruments called saxhorns, using the bugle as the basis for his invention. Similar instruments were soon being manufactured all over Europe. They were widely adopted in military and brass bands, but only the bass, under the name bass tuba, became a normal member of the orchestra, replacing the older ophicleide and serpent. Sax also invented the saxophone, a single-reed instrument like the clarinet but with a conical tube. This, too, was made in various sizes, which came to be used both in military bands and in jazz ensembles. The saxophone never became a normal member of the orchestra, but the alto and the tenor have been used by composers, largely as solo instruments, and occasionally a complete quartet of four different sizes has appeared in an orchestral work.

Electrically powered instruments. The development of electricity led not only to its use for mechanical purposes—for example, to control the key action and wind flow in the organ—but also as a means of amplification (*e.g.,* in the vibraphone) and as a source of vibrations that can be converted into sound. In the Hammond organ (1935), the player, by selecting the appropriate harmonics that comprise their timbres (tone colours), can produce a tolerable imitation of a variety of orchestral instruments and of certain organ stops, though the tone is not likely to be confused with the sound produced by pipes. A number of keyboard instruments working on similar or related principles have been produced in the course of the 20th century. The use of electronic equipment such as sound synthesizers and tapes to produce and combine sound unrelated to the musical scale lies outside the scope of this article.

Musical Notation

Broadly defined, musical notation is a visual record of heard or imagined musical sound, or a set of visual instructions for performance of music. It usually takes written or printed form and is a conscious, comparatively

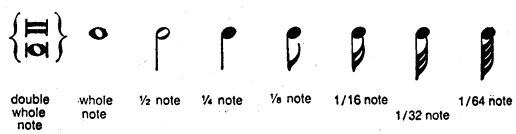
laborious process. Its use is occasioned by one of two motives: as an aid to memory or as communication. By extension of the former, it helps the shaping of a composition to a level of sophistication that is impossible in a purely oral tradition. By extension of the latter, it serves as a means of preserving music (although incompletely and imperfectly) over long periods of time, facilitates performance by others; and presents music in a form suitable for study and analysis.

The primary elements of musical sound are pitch, or the location of musical sound on the scale (hence interval, or distance, between notes); duration (hence rhythm, metre, tempo); timbre or tone colour; and volume (hence stress, attack). In practice, no notation can handle all of these elements with precision. Most cope with a selection of them in varying degrees of refinement. Some handle only a single pattern—*e.g.*, a melody, a rhythm; others handle several simultaneous patterns.

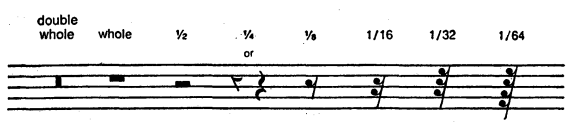
WESTERN STAFF NOTATION

The position of staff notation as the first notational system to be described in this article acknowledges its international acceptance in the 20th century. As an indirect result of colonization, of missionary activity, and of ethnomusicological research—not because of any innate superiority—it has become a common language among many musical cultures.

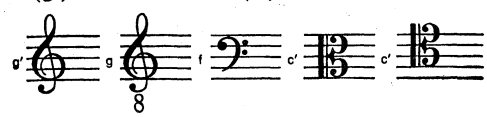
General principles. *Pitch and duration.* Staff notation, as it has developed, is essentially a graph. Its vertical axis is pitch, its horizontal axis, time; and note heads are dots plotting the graph's curve. The five horizontal lines of a musical staff function like horizontal rulings of graph paper, bar lines like vertical rulings. In practice, the system is far more complex and sophisticated than this. The vertical axis of pitch operates to represent melodic contour in music for a single instrument or voice; but when several staves are combined to form a score, the principle breaks down, each staff being a self-contained vertical system. Representation of time (duration) by horizontal spacing is used only in a very limited way. It is in reality made almost redundant because the symbol for a note gives the necessary information itself: not its absolute duration but its duration in relation to the notes around it. These symbols are as follows; each has half the duration of its neighbour to the left:



A system of "rests" measures silence in the same way:



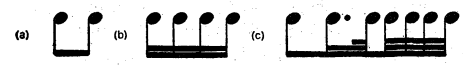
A dot placed to the right of a note head increases by half the duration of that note. Such symbols when placed on a staff may indicate relative pitch and relative duration. In the grid, lines represent alternate notes of the scale and the spaces the intervening notes. Pitch and duration may be fixed by supplying two further indications: a clef and a tempo mark. The clef assigns a definite pitch to a given line of the staff; the first clef fixes the second line up as the G(g′) above middle C(c′):



Tempo and duration. The tempo mark is a sign that lies outside the staff. It appears above and may be a precise fixing of one duration ("♩ = 120 MM" means that the quarter note lasts $^1/_{120}$ of a minute, or one-half second), or it may be an approximate verbal indication setting tempo by reference to accepted conventions (allegro, or quickly; moderato, or moderate speed; etc.).

Staff notation is well adapted to two fundamental aspects of Western music: harmony and rhythm. For harmony, note symbols can easily be placed vertically together on a single stem, and these notes need not be all of the same duration; or more than one stem may be used to indicate multiple melodic lines in the musical texture. For rhythm, the existence of an underlying regular pulse, or stress, must be indicated. This is achieved by two devices: the bar line and the time signature. The bar line primarily indicates a point of main stress. Bar lines are usually equally spaced as to duration, though there are numerous exceptions. A time signature indicates, first, the duration of the space between two bar lines (a measure, or bar); and, second, the subsidiary stress patterns within that space. A supplementary system for indicating stress is the device of linking successive notes together by "beaming." Two eighth notes may be linked together as shown in (a); four sixteenth notes (b); or a mixed group of values (c):

The function of a time signature



The implication of such grouping is generally that the first note carries a stress of some sort. Beaming thus may be used either to reinforce the stress patterns of the time signature (the metre) or to contradict it and set up a cross rhythm.

Accidentals. Staff notation rests firmly on the Western system of scales, within which all notes are assumed to be natural unless either accidentals precede them or a key signature is in use. An accidental (♭, or flat; ♯, or sharp) is a temporary raising or lowering of pitch by a semitone; a key signature is the use of the same signs on a more permanent basis, valid to the end of a piece or until countermanded by a new signature. Another accidental, the natural (♮), cancels out a previously indicated flat or sharp and may be used to alter one note or in a key signature to emphasize a key change. Any combination of sharps or flats is theoretically possible in a key signature, but the actual combinations are usually governed by the Western system of keys, or groups of interrelated notes and chords.

Auxiliary signs. Timbre and volume are specified through a variety of additional signs: symbols such as > (stress) and  (increase in volume), verbal instructions (frequently in Italian) such as forte (loud) and col legno (with the wood of the bow) placed above or below the staff wherever space permits. Additional symbols may also provide information about pitch and duration: the dot for staccato, the hold sign (𝄐), the phrase mark, indications of amount of vibrato, and so forth. Other verbal instructions indicate the general manner of performance (pesante, "heavy"; cantabile, "songlike"; etc.) or expression (con dolore, "with suffering"; giocoso, "playfully"; etc.). Further, there are for each type of instrument certain technical signs, as for bowing, breathing, tonguing, or use of mutes.

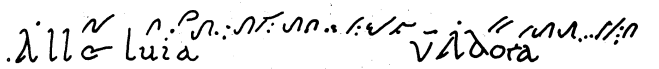
Other auxiliary signs are in the nature of shorthand. Most important are certain symbols indicating performance of notes not shown on the staff. An ornament sign placed over a note may call for several additional notes to be played within the value of that note. It may even delay the sounding of the main note. The precise meaning of such an ornament will vary from one style of music to another and must be interpreted according to the set of conventions governing a particular style.

Types of musical "shorthand"

Comparable to the use of "shorthand" signs for ornaments is the system of placing arabic numerals beneath a bass line in keyboard music of the 17th and 18th centuries. A numeral, or "figure," signifies a harmonic (*i.e.*, a vertical) interval; thus a "6" indicates a note six degrees of the scale above a given bass note (A above C, for example). It is in itself an imprecise measurement, specifying neither whether the interval is major or minor nor in which octave register that upper note should be played. But the figures are governed by the same prevailing key signature as notes on the staff and can, like notes, carry their own accidentals. They are thus not an independent type of notation but a hybrid representation of interval/

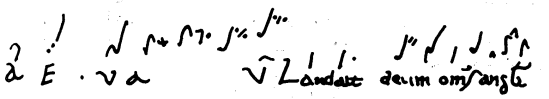
pitch that works in conjunction with staff notation. Its purpose is to indicate the harmonies implied by a bass line (even absence of figuring has a meaning) while at the same time leaving the player free to choose the precise notes that he plays. The systems of letters and figures used by jazz musicians have this same imprecision; they are less dependent upon conjunction with staff notation but lack clear rhythmic significance unless allied to staff notation in at least a simplified form. They operate by defining a harmony in relation to the tonic chord (the chord built on the key note, or tonic), rather than by interval or pitch.

Evoluton of staff notation. *Neumes.* Staff notation has its roots in the neumatic notations of plainchant and secular song of the 9th–12th centuries. Neumes were graphic signs indicating essentially the rise and fall of the voice. Their origin lies probably 1,000 years earlier in signs devised by Greek and Roman grammarians to guide declamation, such as / *acutus* (high voice), \ *gravis* (low), and ∧ *circumflexus* (falling). The musical adaptations of these signs took many different regional forms. Unlike note symbols in staff notation, neumes, with two exceptions, comprised two, three, four, or more notes each and indicated their approximate relative pitches. Each comprised the notes belonging to a single syllable of text, though in florid chant the notes of a single syllable might be split up into several neumes:



Neumes were by intention only a memory aid to singers who knew words and melody by heart. Between the 10th and 12th centuries, however, there occurred significant developments toward a notation that could be sight-read. "Heighted" or "diastematic" neumes were ones that had been carefully spaced on the page in relation to each other, so that an entire line of them formed a continuous graph of pitch over the words of text:

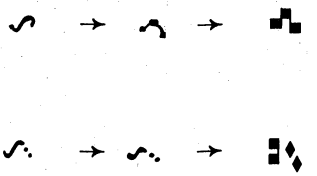
Sight-reading developments



Eventually, precision of pitch was further achieved by using horizontal scratched lines as a grid on which to space the neumes, so that degrees of the scale fell alternately on a line or in a space, and by colouring one line red to signify the pitch "F" and possibly another yellow to signify "C"—or simply by placing a letter "F" or "C" at the beginning of the appropriate scratched line. Together, the two devices fixed the relative pitches of all notes by indicating where the semitones of the scale occurred (that is, immediately below the marked lines: E–F or B ♮–C). In the 11th century two signs from a quite different system of notation (alphabetical notation; see below) were incorporated as accidentals before the pitch "B": b, the ancestor of ♭; ♮, the ancester of ♮ and ♯, and also of the German "h," which refers to b ♮. These two signs were progressively applied to other pitches in the following centuries. By the 13th century a four-line staff ruled entirely in black or red had become established, using stylized forms of the letters *f*, *c*, and *g* (ancestors of the modern 𝄢, 𝄡, and 𝄞) as clefs. For polyphonic music (having several simultaneous voice parts) a five-line staff became standard by the 14th century, but keyboard music in some countries used six- or seven-line staves as late as the mid-17th century.

Adoption of the five-line staff

During the 12th century, in northern and northeastern France the thin, curved lines of neumes were drawn more thickly at the points corresponding to the separate notes within them. In time, a firmly rectilinear notation of heavy horizonal pen strokes, diamond-shaped dots, and hairline vertical strokes emerged, whose groups of notes are called "ligatures":



This was the notation of the troubadours' and trouvères' songs; also of plainsong from the 13th century to the present day. It was also used in 12th-century polyphony for the upper voices, which were without text. Freed from syllabic considerations, the grouping of notes into ligatures took on rhythmic significance, specific groupings representing short, repeated patterns called rhythmic modes:

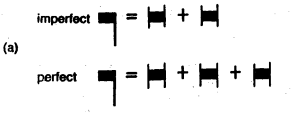
A ligature did not yet have a single, unvarying meaning. Its rhythmic pattern depended upon context.

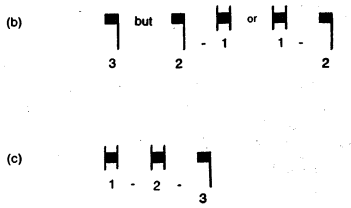
Mensural notation. The freeing of ligatures from considerations of context occurred during the early 13th century. Time values for ligatures, single notes, and rests were codified around 1260 by the influential theorist Franco of Cologne. The notes then in use included the duple long, later called maxima (▬); long (▮); breve (■); and semibreve (◆). In French music a shorter note value was created: the minim (▮).

These note symbols provided the basis for notation from the late 13th to the late 15th centuries. This system, called mensural notation, was based on several fundamental principles that determined the value of a note relative to that of its neighbours. In the terminology of mensural notation a given note might be either perfect—*i.e.*, divided into three notes of the next lesser time value; or imperfect—*i.e.*, divided into two notes of the next lesser value. Thus, as in part (a) of the example below, a long might be perfect, containing three breves; or imperfect, containing two breves. To determine which note symbols were perfect and imperfect for a given piece, special symbols were devised: ⊙, ◯, ⊙, ◯, ◯, ¢, 3/2, 3/1, 4/3, etc. (Of these 𝐂 and ¢ survive, together with fractions such as 3/2, as modern time signatures.)

Specific rules provided for lengthening or shortening the value of notes in certain instances. To "imperfect" a long meant to shorten it by one-third of its value; this occurred when the long was preceded or followed by a breve or by notes equalling a breve in value, as shown in part (b) of the example below (for purposes of illustration, numbers have been placed under the notes showing their time value relative to the shortest note). Part (c) of the example shows another common alteration of time value: in a composition in which the long is perfect, a breve (brevis) preceding it may be doubled in value under certain conditions. The time-value relationships between breve and long similarly applied to the other pairs of notes: maxima and long (longa); breve and semibreve (semibrevis); and semibreve and minim (minima).

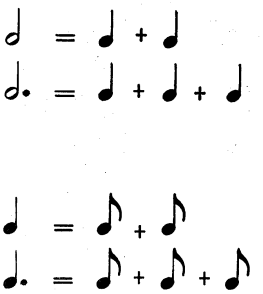
As the system of mensural notation evolved, another device, coloration, came into use. If a composer wished to





render a potentially perfect note imperfect, he could write it in red or as a hollow note (as 𝅗𝅥, 𝅗𝅥, or ◇); these two devices had, however, various other, less common meanings. About 1400, hollow note shapes were adopted where full black notes had hitherto been used, and full black served as coloration. The notes then current and their corresponding rests were as follows:

Transition to modern staff notation. In 16th-century manuscripts and, rather later, in printed music, the diamond-headed notes became rounded. Ligatures were used less and less often in the later 15th century. The principles of perfection and imperfection gave way to the modern relationship of 2 to 1 between adjacent note values, with the dot adding an extra half value to give a 3 to 1 relationship.



Shorter note values were also introduced, and the old, longer ones became obsolete. Yet, because of a paradoxical survival from 15th-century practice, slow music has tended to be written in short values (for example, Beethoven's slow movements) and fast music in long values.

Introduction of the bar line

The bar line as a measure of metre arose first in 15th-century tablatures (notation showing playing position rather than pitch, as for lute). Barring entered staff notation in the 17th century, but regularly spaced barring became a practice only in the 18th century. Separate tempo indications, arising first in the 17th century, were verbally expressed; for example, adagio, largo, presto. The range of these terms greatly increased during the 18th and 19th centuries, and the metronome mark, an absolute indication of tempo, has never superseded them since its arrival in Beethoven's day. The bulk of the shorthand devices emerged during the 17th century, figured bass early in the century, the majority of ornamental signs later. Indications for loud and soft arose early in the century, expressed as words (forte, mezzoforte, piano) and later as abbreviations (*f, mf, p*). Graphic signs for dynamic and attack (staccato dot, crescendo mark, for example, and also phrase marking) appeared in the 18th century. A great proliferation of dynamic instructions and signs occurred in the late 19th and early 20th centuries.

Twentieth-century notation. Two developments in musical style in the 20th century have placed great strain upon staff notation: integral serialism—in which the music is controlled by a mathematical system—and indeterminacy, or chance music. In the former, every note in a texture may have its individual dynamic marking and type of attack (for example, in Olivier Messiaen's *Mode de valeurs et d'intensités* and in parts of *Structures I* and *II* of Pierre Boulez). There may also be extensive use of unconventional playing techniques. Since staff notation indicates volume, attack, and technical effects in a comparatively clumsy manner, the written page becomes cluttered and unclear. In indeterminate and aleatoric music (the latter type allowing the performer a limited degree of freedom), the notation must offer choices to the performer or be deliberately imprecise. Staff notation is for these purposes often too specific. In addition, electronic music, composed with such devices as graphs, mathematical symbols, and diagrams, is not easily translated into a readable "score" for publication.

Notation that offers the performer a choice

New systems. Notation, in face of this, has moved in two directions: toward adaptation of staff notation and toward the devising of new notational systems. Music using microtonal intervals (less than a semitone) has tended to adapt by modifying the standard accidental signs:

—meaning one-third sharp, two-thirds sharp, and so on (*e.g.*, in Krzysztof Penderecki's *Anaklasis*). So-called space time notation is a further adaptation that reasserts the graphic nature of staff notation. It abandons symbolic indication of note values and replaces it by the spacing out of note heads horizontally on the staff, accompanied by an instruction such as "1 inch = 1 second." The principle may then be amplified by using different note heads (𝅝, □, ◇, etc.) to signify short, medium, and long sustaining of a note, thus obviating the use of rests, and by beaming together notes to be performed in one breath or bow (*e.g.*, Witold Lutosławski's *Trois poèmes d'Henri Michaux* and John Cage's *Music of Changes*).

Indeterminacy. Indeterminate music requires constant experimentation with notation. A composer may offer directions for one element of the music—as rhythm or pitch contour—and leave the performer to improvise the remaining elements. Or he may simply describe the general character of a passage by resorting to a specially designed symbol, a verbal description, or even an impressionistic drawing (as in Earle Brown's *Hodograph*). At the extreme, John Cage supplies "materials" (lines, dots, shapes) and leaves the performer to attach musical significance to them. For electronic music, published scores have so far adopted either strict graph form (Karlheinz Stockhausen, *Electronic Study II*) or pictorial form, using patterned drawings to represent different timbres (as in Henri Pousseur's *Electre* and Stockhausen's *Kontakte*).

Cage's "materials"

Adaptation to non-European music. Notations evolve with the musical styles they serve, and they reflect the underlying aesthetics of their own cultures. Thus staff notation is ill-equipped to cope with non-Western scales and tunings, with music to which the idea of the "note" (a stable, sustained pitch) is foreign, or with music whose subtlety lies as much in delicate gradations of volume or timbre as in pitch and rhythm. Ethnomusicologists have developed a range of supplementary symbols—*e.g.*, for notes of uncertain pitch, glissandi (slides), slight length-

ening of a value, half-voiced notes, and other sounds. They have also experimented with staves of fewer or more lines. The Western system of proportional note values (for example, quarter note = half of a half note) does not easily cope with fine fluctuations of value; instead, constant changes of metronome tempo mark may be necessary. Among the most complex uses of staff notation in ethnomusicology are the transcriptions of Serbo-Croatian and Romanian folk song by the Hungarian composer Béla Bartók. Other transcribers have used graph paper to draw a curve of pitch against time. Many significant mechanical methods of transcription have been devised. The two most notable are the melograph, invented by the ethnomusicologist Charles Seeger, which traces a pitch/time graph immediately above a volume/time graph, and a device developed by Dahlbeck, which produces two similar graphs by means of a cathode-ray tube. These methods can reveal a level of interpretation by the performer that aural transcription into staff notation fails to bring out.

OTHER SYSTEMS OF NOTATION

Written notations are to be found in the musical cultures of the Far East, Southeast Asia, South Asia, the Middle East, and the West. The earliest examples survive from Ancient Egypt and Greece. The written symbols of notation may be classified into two broad categories: phonetic symbols—words, syllables, abbreviations of these, letters, and numbers; and graphic signs—accentual signs for the rise and fall of the voice (developing into neumelike "ecphonetic" signs), curves, lines, dots, and other symbols, perhaps originally depicting hand signs, and neumes. Symbols in both categories may denote simple sounds or stand for groups of successive sounds. In the West they are read in lines from left to right, whereas in the Orient many are read from right to left or read vertically, in columns.

Major categories of notational systems

A second fundamental distinction is that between representational notations, which depict the sound of the music—leaving the player to produce that sound as he wishes—and tablatures, which instruct a player as to the technical means of producing a sound. Phonetic symbols play an important role in both types of notation, while graphic signs contribute mainly to representational notations. A prime example of non-Western representational notation is the *kraton* notation used in music for the Javanese gamelan orchestra, its grid using the "graph" principle found also in Western staff notation but oriented at a 90° angle relative to the latter.

Verbal and syllabic notations. In oral traditions of music, solmization (the naming of each degree of a basic scale with a word or syllable) plays an important role. The modern European sol-fa method ("do," "re," "mi," etc., representing the notes of the rising major scale at any pitch transposition) is such a system. The Indian

Javanese *kraton* notation.

syllables *ṣa, ṛi, ga, ma, pa, dha, ni* are similar, as are the Balinese *ding, dong, deng, dung, dang,* the ancient five-note Chinese scale *kung, shang, chiao, chih, yü,* and the Korean *tŭng, tung, tang, tong, ting.* Slightly different are the 12 chromatic Chinese *lü* syllables: each pitch bears the name of a bell—as *huang chung* ("yellow bell"), *ling chung* ("forest bell")—and its name is reduced to a syllable—*huang, ling, t'ai,* etc. Though primarily for reciting or singing as a melody is being learned, these syllables can be used to write down the notes of a melodic line (each appearing as a single ideogram in the Chinese examples) and thus form a simple syllabic pitch notation. Of the five Balinese syllables, only their vowels are used in written form—*i, o, e, u, a*—so that a letter notation results; this is still essentially an abbreviated syllabic notation, not an alphabetical notation.

Words and syllables are not only applied to pitch. In Western plainchant, abbreviated words were used to indicate duration (for example, *c* = *cito* or *celeriter* =

Notation for duration

"short" value) and direction of melodic movement (*l* = *levare,* and *s* = *sursum* = "upward"). In the notation of early Ethiopian church music a single letter or a pair of letters (short for a passage of text) signified a group of notes, even a complete melodic phrase. The drum syllables of North Indian music are a solmization of timbre (as *na, ta, dhin*) and often also of rhythmic patterns (as *tirikita, dhagina*) and can be written down to make a notation.

Alphabetical notations. Alphabets are historically a phenomenon of the Middle East, Europe, and the Indian subcontinent. Their ordering of letters provides a convenient reference system for the notes of musical scales in ascending or descending order. Alphabetical notations are among the most ancient musical scripts. Two Greek notations were of this type, the earlier using an archaic alphabet and the later using the Classical Greek alphabet. Many comparable notations arose in the Middle Ages, and the modern note names, A to G, are an outgrowth of these. The clefs of staff notations are a formalized survival. The system of pitch notation devised by the 19th-century German philosopher and scientist Hermann Helmholtz was derived from the Greek system, using dashes for octave register but employing Roman letters: $A_{,,}$, $B_{,,}$, $C_{,}$–$B_{,}$, C–B, c–b, c′ (middle C)–b′, c″–b″, c‴–b‴, etc.

Numerical notations. The notation of pitches by numbers is rare. A modern Javanese system allots numbers 1–7 to the pitches of the seven-note *pelog* scale, and a similar five-note system exists in Bali. Modern Japanese notation for the samisen (a type of lute) uses 1–7 for the diatonic scale, 7 being the lowest note; and modern China has a similar system for publishing popular songs. An Arabic notation of the 16th century used the first seven Persian numbers to signify pitches of a seven-note scale. Numbers lend themselves more directly to expression of duration, of metre, or of the division of a basic time unit into a number of equal parts (for example, the Western triplet $\overset{3}{\frown}$ and its extensions in the works of Chopin $\overset{11}{\frown}$ $\overset{21}{\frown}$; and the Western time signatures). Arabic alphabetical notation of the 13th and 14th centuries used arabic figures, placed beneath the pitch letters, to indicate durations of individual notes.

Graphic notations. The character of neumes and of accentual signs has already been described under Western staff notation. The Vedic chant of southern India uses a form of accentual notation: a dot beneath or above a syllable of text indicates a lower or upper reciting pitch. Analogous systems, involving dots and dashes, formed a notation for ancient Jewish cantillation and for early Syrian Christian chanting. Such signs are really only an extension of punctuation. A more developed form ("ecphonetic" notation) was used for recitation of Byzantine liturgical chants. In addition to simple signs for vocal inflection, it had also more elaborate, compound signs, such as

capable of signifying degrees of loudness and changes of voice production. The Western phrase mark and crescendo and decrescendo symbols are graphic signs of this type.

The dividing line between compound ecphonetic signs and neumes is slender. Neumes are concerned not with inflection of the voice between high, medium, and low but with groups of sung pitches rising and falling over a quite narrow range: a neume may represent a given pattern of intervals whether it lies high or low in the voice's compass. Neumes made up of curves, hooks, lines, and dots are found in Tibetan Buddhist chant books; in vocal notations for Japanese Buddhist chant, Nō plays, and *gagaku*

(court music); and, in simplified form, they are used in Chinese notation in conjunction with pitch syllables.

Tablatures. A tablature notates music as a series of playing positions. Hence a tablature for a plucked stringed instrument guides the player's fingers to the string he must pluck and to the fret at which the string should be stopped. Similarly, a tablature for a wind instrument guides a player's fingers to cover certain holes, and a tablature for percussion directs a player as to which drum to strike, which hand and stick to use, and what type of stroke to execute. Each single instruction in a tablature corresponds to one action by the performer. The order of his actions is automatically prescribed, and more precise rhythmic indication can be given quite easily as the length of time between successive actions—rests are unnecessary. Thus, a tablature for a plucked instrument (for example, a lute, guitar, or zither), requires signs for: each string, each fret, and possibly also each right-hand plucking finger, direction of stroke, and ancillary techniques such as harmonics, vibrato, and left-hand plucking. To indicate these, the tablature may use letters, numbers, and graphic signs. Thus 16th-century French lute tablatures indicate the strings (more properly the "courses") graphically as parallel horizontal lines, frets as letters, and right-hand fingering by dots:

From Francis Pilkington, Brian Jeffrey (ed.), *Complete Works for Solo Lute* (1970); by permission of Oxford University Press, London

Italian lute tablatures use numbers in place of letters.

The tablature for the Japanese koto zither is simpler in that its 13 strings are not stopped. The pitch of each string is indicated at the beginning of a tablature, and thereafter the strings are represented by numbers combined with graphic signs for special technical effects. The tablature for the Chinese ch'in, a zither whose strings are stopped, uses a combination of numbers (for strings and for stopping points) and ideograms (for other technical details). These are grouped close together in composite symbols. One composite symbol may contain an ideo-

Tablature for the Chinese ch'in.

gram for the left-hand finger; a number for the stopping-point; another number for the string itself; an ideogram for the right-hand finger; and possibly an ideogram indicating loudness, legato, glissando, etc. German 16th-century lute tablature achieved economy of space by indicating string and fret as a single letter (as, k = first string stopped at third fret). No grid of lines was necessary.

Musical Performance

Musical performance is that step in the musical process during which musical ideas are realized and transmitted to a listener. In Western music, performance is most commonly viewed as an interpretive art, though it is not always merely that. A performer to some degree determines aspects of any music he plays. Issues of tempo, phrasing, dynamics and, in some types of music, pitches and instrumentation are subject to a performer's discretion. In this article, the various aspects and traditions of musical performance in Western and non-Western civilization are treated and their development traced.

Because the pleasure men derive from sounds has always been closely related to the pleasure they derive from making the sounds themselves, it is difficult to conceive of the origin of music as separate from an act of musical performance. Models for the establishment of rhythm may be found in heartbeat and breathing, and in the inflections of speech and cries of grief, pleasure, and desire are found the source of what became song.

The earliest visual manifestations of musical performance are found in rock paintings and excavated objects. While the interrelationship of music and ritual is clear, there is evidence that music was performed for dancing, in various work activities, and primitive games as well. Flutelike instruments of many sizes, made from bones and wood, and elaborate percussion instruments figure prominently in all primitive cultures, in which these instruments often were assigned symbolic significance associated with forces of the supernatural.

Singing is most probably the oldest musical activity. Even in the most primitive cultures the singer has had a special, defined position. In primitive singing there are three classes of sound: the first is called logogenic, in which words form the basis for the wavering musical incantation; the second, called pathogenic, consists of harsh, forceful, percussive, nonverbal sounds emitted to express strong feeling; in the third category, called melogenic, the sounds of the two previous categories combine to form a contour of pitches which pursue a course seemingly dictated by the weight of tensions inherent in the sequence of pitches and hence melodic in effect.

Primitive societies evolved several means to relieve the monotony of one person's singing. A principle device is called antiphony, which involved two groups that sang in alternation or a leader who sang and was answered by a group of singers. In the latter may be seen the origin of responsorial singing, which continues today and which may be the point of origin for several types of musical-phrase structures. Polyphony was also anticipated in primitive musical performance. It appeared through haphazard rather than intentional manifestations, such as the singing of the same melody with the parts starting on different pitches or at different times.

Primitive antiphony

WESTERN MUSICAL PERFORMANCE

The performer as interpreter. Music as an interpretive art is a relatively recent phenomenon. In primitive societies, music plays a ritual role based on an oral tradition, and each performer in a sense interprets the tradition, but, more importantly, he renews it and transforms it through his own performance.

The development of the performer's role as interpreter coincided with the development of musical notation. Because composers for so many centuries were in a position to supervise the performances of their music, certain aspects of performance were not notated. Notation has grown increasingly complex as the dissemination of printed music has become more widespread. Ultimately, the degree of judgment a performer may exercise is determined by the period in which the music was composed. For music of certain periods, even though their notational systems are incomplete and give few indications of how the music should sound beyond pitch and rhythm, musical scholarship has amassed much information concerning proper instrumentation, ornamentation, improvisation, and other traditional performing practices that determine to a large degree the sound and stylistic character of the music. A performer as interpreter operates within a range of limitations imposed upon him by his understanding of the printed page, whatever knowledge may be available concerning the tradition that surrounds the music he is playing, and the extent to which his personal tastes coincide with this information. Certain aspects of the musical taste of the past sometimes cease to be expressive and gradually disappear from usage. Just as often, with the passage of time, performers tend to reassess the literature of previous ages and find renewed interest in practices that an earlier generation may have set aside. In any case, the performer as interpreter speaks to and with the tastes of his own time. And his task, no different from that of the performer in primitive music, is to renew, to refine, and to enrich the materials and traditions he inherits.

Mediums of performance. The mediums for musical performance are extraordinarily various. Western technology has had a tremendous impact on the development of musical instruments and has thereby greatly expanded the means whereby music is made. Performance may be vocal, instrumental, or electronic. Vocal performance is the oldest and the primary influence for the development of all subsequent musical gestures and materials. Instrumental music began with the development of percussion instruments and crude horns; string instruments came later. Electronic music is a 20th-century development involving the reproduction of traditional performance mediums through electronic means, at the same time that it is also evolving composition and performance of its own. At first it reproduced natural sounds by electronic means;

Vocal, instrumental, and electronic performance

later, composers and technicians began to invent electronic sounds and to discover new sound relationships.

Solos. In all musical mediums the solo performance is the most spectacular. The power of music to compel attention and to stir emotions lends to the solo performer an especially fascinating aura. This is the domain of the virtuoso, that musical performing phenomenon of prodigious technical mastery, invention, and charisma. Most solo literature includes another instrument or group of instruments, and the literature varies from one medium to another according to the expressive range and technical capabilities of the solo instrument.

The largest solo literature for a single instrument is for keyboard instruments. Vocal solo literature is very important and extensive, and the string instruments also have a distinguished solo repertory. The wind, brass, and percussion solo literature is more restricted.

Ensembles. In vocal and instrumental chamber ensemble performance, the performing groups are divided into duets, trios, quartets, quintets, sextets, septets, and octets, which exist for every medium and combination. Of particular importance is a string quartet consisting of two violins, viola, and violoncello. Dating from the 18th century, this instrumental ensemble is analogous to the vocal ensemble consisting of soprano, alto, tenor, and bass.

Beginning of symphonic music

Symphonic music dates from the 17th century. With the rise of the middle class and its aspirations for culture, music as an art required performing situations which would accommodate more people. Larger halls required ensembles acoustically suited to the expanded performing area. The primary result of this development was the symphony orchestra with its multiple string, wind, brass, and percussion instruments.

Ensemble performance places a special responsibility on the concentration of the performer, who must attend not only to his own playing but also to that of all the others in the ensemble. All aspects of the performance depend on this mutual awareness. The leader of most small ensembles is one of the performers, the first violinist, a keyboard player, or one of the singers who indicates tempi, entrances, and musical character and supervises rehearsals. As ensembles grew in size and complexity and their problems of coordination increased, the leader set aside his instrument and devoted his efforts to the beating of time and the communication through clear hand signals of his indications for entrances, tempo changes, dynamic accents, and the shaping of phrases. The conductor often occupies a position analogous to that of a soloist in the attention of an audience, though the conductor himself makes no musical sound. As they are chiefly responsible for the music orchestras play, both in terms of choice and execution, conductors have had considerable impact on the development of music.

Opera. Opera, the marriage of music and drama, is the most complex performance situation. It entails much more than a single performer or group of performers, their instruments, and a hall in which to play. Text, decor, costumes, histrionic projection, preparation time, as well as singers, instrumentalists, and a bevy of extramusical technicians must all be brought together and coordinated into the final production.

Artistic temperament. Many forces interact in developing those traits that distinguish various performing traditions and individual performers. Personality and temperament fundamentally affect the manner in which a performer works, as does his cultural milieu. There are performers who use music as a vehicle for display and others for whom performance is only a means to illuminate the music. Nor does performance necessarily mean public performance. For some people musical performance is essentially private, requiring no confirmation in the form of audience approval. The musical pleasure of such people rests solely on performing, either alone or with other musicians. Much chamber music is played under these private circumstances, and much music has been written for such situations. This used to be the primary realm of the musical amateur, that skilled but nonprofessional music lover, whose ranks are diminishing in the era of the phonograph.

The type of performing situation at the opposite end of the spectrum is one directed to securing audience attention and affections. The need for audience approval has led to innovations as well as some decadence in its impact on the musical scene: innovation, if the performer is led to discover imaginative and fresh means of attracting public acclaim; decadence, if the devices for audience attraction become cheap and thinly spectacular, when the performer may distract the audience from more deserving work and debase their taste.

Intuition versus intellect

Intuition and intellect figure prominently in the temperament of a musical performer. Intuition is the capacity to do the musically "right" thing without instruction or special consideration of the alternatives. Intellect is the means whereby a musician enlarges the range of his instincts through the pursuit of new information, reflection, and analysis of the musical material at hand. Each element informs and completes the other.

Many musicians depend heavily on intuition in solving performance problems. Their solutions are often imaginative and fresh and their performances exciting. Others pursue a methodical path as they examine minutely relevant musical details. They analyze thoroughly the scores they perform, comparing manuscript facsimiles and various printed editions, and attempt to discover new musical relationships, new ways of delineating these relationships in performance, and, in short, new ideas as to how the music might best be played and how it should sound. Art, poetry, biographies, cultural history, and any material relating to the period of the piece of music being studied for performance may be sources of musical insight for the performer.

National characteristics. At various times in history, national origin has been considered an important delineating characteristic in musical performance. This is partly the result of certain consistent emphases and features in the music written by composers of different nationalities. The Italian interest in the voice has evolved a special singing (bel canto) quality in their music, which has carried over into their music for instruments (the string instruments especially), and into the general texture of Italian music, which has always given melody special prominence.

The English have had a highly developed and sophisticated musical performance tradition. Amateur improvisation figured importantly in its early history. While this has perhaps tended toward a conservative musical atmosphere, it has also produced a high standard for performance. The French have maintained a strong sense of national identity in their performing arts. In music their concerns for orderly design, delicate expressiveness, simplicity, naturalness, and beauty of sound extend back for centuries. In German music, articulate philosophical and structural considerations have played important roles in developing nationalistic traits in their tradition of musical performance.

The rich folklorist traditions of Spain, Hungary, and Russia have influenced rhythm, melody, and sonority in Western musical performing traditions. The Russian schools of string and piano technique have greatly advanced the performance resources of these instruments in the past 100 years. The United States, younger and more heterogeneous, has had a shorter musical history but an abundance of great symphony orchestras and solo artists, who are in demand because of their precise execution, versatility, and breadth of repertory.

Historical stylistic developments. In antiquity the Sumerians, Egyptians, Greeks, and Romans evolved the first aesthetic theories and musical systems relevant to the music of the modern Western world. Unfortunately, few actual musical examples survive because of primitive notational practices and the gradual erosion of oral traditions. What is known is derived from the writings of the period and iconography—depictions of performing musicians, instruments, and musical events in sculpture, and in wall and vase paintings.

In the Middle Ages traditions of musical performance were kept alive by the church and in the music sung and played by wandering minstrels.

In the Renaissance, polyphony (combining several simultaneous voice parts) and the early precursors of modern tonality (organization of music around a focal tone) were developed. The smooth flow of Renaissance liturgical counterpoint (polyphony) and the perky rhythms of secular Renaissance dance music remain as models of taste and musical technique even into the 20th century.

Developments in the Baroque

The performer emerged as a central figure in the focus of musical attention and purpose during the Baroque period. The heightening of the role of the individual performing artist and the invention of increasingly dramatic gestures to demonstrate performers' skills combined with a steady refinement in the construction of musical instruments. The reduction of musical materials to two modes (scale and melody patterns), in this case the major and minor scales, and the initial efforts to compose with large musical forms (opera, oratorio, sonata, and concerto) took place in this period. It is notable that in the Baroque era the equal-temperament system for tuning the strings or pipes of keyboard instruments evolved—a development that has had profound effect on the nature of musical language.

In the Rococo or Classical period that followed, the elaborate contrapuntal texture of Baroque music gave way to music of subtle dynamic differentiation often based on simple folk materials (rhythms and melodies). The relationships between tonal materials and large musical forms achieved their highest state in the sonata and in opera.

The Romantic age was a period of refinement and intensification of Rococo principles with heavy literary overtones. It was the true age of the star virtuoso; that is, the age in which the role, person, and effect of the virtuoso was most dramatized and glamourized. The symphony orchestra in this period achieved its maximum development. Italian opera under Verdi found its noblest expression and German opera with Wagner expanded into the *Gesamtkunstwerk* ("complete art work").

Modern music dates from an era beginning roughly around World War I. Concert life has remained more or less what the 19th century established; the virtuoso conductor and performer dominate the musical establishment. More chamber, symphony, and opera programs are performed in more parts of the world than ever before, but musical progress has ceased to occur in established organizations and is found instead in the combo: jazz, rock, improvisational, experimental, live electronic, and multimedia groups that have sprung up in the 20th century.

HISTORY OF WESTERN MUSICAL PERFORMANCE

Antiquity. The civilizations of antiquity expanded the role assigned to music in primitive cultures. The Sumerians established the foundations for the tradition of liturgical music. Some of the prayers which they sang have survived. From various artifacts of this civilization something is known about Sumerian musical instruments and some of the situations in which music was played. Such instruments as the lyre, harp, sistra, pipes, timbrels, and various drums figured importantly. Particular instruments were identified as accompaniment with specific types of religious poetry, and indeed the development of different poetic genres seems to have been considerably influenced by the nature of these instruments. While its primary purpose was religious, music also had something of a secular role in Sumerian culture and was played in processions, at banquets, and during primitive sporting events. Music as a profession first developed in Sumerian culture. Both men and women participated as singers and instrumentalists and held priestlike positions with specific functions and ranks of authority.

The musical culture of ancient Egypt, which apparently emerged from the same primitive sources as Sumer, resembles that earlier culture in many aspects: the close relationship between music and religion, the presence of a musical profession, some secular musical activity, and similar musical instruments. Of special interest in Egyptian music is the development of chironomy, the use of hand signals to indicate to instrumentalists what they should play. The singer in this manner guided instrumentalists through melodies with which the singer was seemingly more familiar than the players.

In these ancient cultures there was no notational system or codified theory of musical practice. Different musical traditions were exchanged in the process of trade, migration, military conquest, and intermarriage to form that common body of practices which is the basis of Western music.

Importance of Greek music

Of the early civilizations, Greece provided the musical culture of greatest significance for the development of Western music. The system of scales and modes, as well as a large part of the general philosophy concerning the nature and effect of musical sounds, has been inherited from the Greeks. It was also the Greeks who developed the theory of ethos, which defines the character of psychological and emotional responses to different musical stimuli. Building on the ancient religions and magical accoutrements of music, the Greeks assigned specific mental and emotional states to specific pitch arrangements and instrumental combinations. Music infused with this motivating power stood at the centre of the social order.

Though a major part of Western musical terminology, basic music theory and philosophy, basic notational practices, and the foundations of acoustical physics derive from the ancient Greeks, very little of their music has survived. The great ethical significance of music in Greek society caused performing mastery to be an essential aspect of education. Everyone was taught to sing and to play instruments. For a major part of the period all music was a setting of words with instrumental accompaniment, for the most part doubling the voice at the interval of octaves, fourths, or fifths. It was only in the later part of the period, after the age of Pericles (late 5th century BC), that instruments began to play independently of singers.

Music, in the later stages of the Hellenistic period, became an increasingly important part of public spectacles. As musical performance became increasingly secularized and became the property of the masses, the upper classes withdrew to esoteric considerations of the art and reflections on its past. It was perhaps at this point that music was divided into two fairly artificial categories: the contemplation of music's nature and history and practical musical performance.

Assuming the artistic mantle of ancient Greece, the Romans disseminated Greek music throughout the known world. The essential role of music in the Roman Empire remained unchanged. Rome's principle contribution consisted in serving as a catalyst for the mixing of Hebraic and Hellenic traditions of musical performance, which, preserved by the Christian Church for a thousand years, emerged again in the Renaissance into the first flowering of modern musical practices in the West.

North Africa and the Near East. Although not in the mainstream of Western musical performance, Islāmic (North African and Near Eastern) classical music closely approaches the orchestral tradition of European music in one respect: large choruses and orchestras—consisting of tambourines, pot drums, recorder-flutes, *ʿūds* (plucked lutes), bowed lutes, and dulcimers—are assembled to perform "suites" consisting of a series of instrumental solos and orchestral selections interspersed with unison choral songs or solo recitatives based on classical poetry. But while these suites are perfectly suited to performance in formal concert halls, they may also be heard in much less regulated settings, such as cafés. Here the listener is free either to concentrate intellectually on the progress and development of the musical ideas or to converse and eat, relaxing in the beauty of the general musical design. The more "oriental" side of Islāmic musical performance is more improvisatory, either in solo performance on a recorder-flute, fiddle, *ʿūd*, or dulcimer or by any of these in combination with the voice—the instrumentalist then elaborating on the singer's improvisation. Here, too, the relationship of audience to performer is much less formal than in the performance of European music.

"Oriental" side of Islāmic musical performance

The Middle Ages. The tradition of sung prayers and psalms extends into the shadows of early civilization.

Such sacred singing was often accompanied by instruments, and its rhythmic character was marked. In the synagogue, however, the sung prayers were often unaccompanied. Ritual dance was excluded from the synagogue as the rhythmic character of sacred music surrendered its more sensual aspects. Even in the prayers themselves, rhythmic verse gave way to prose. The exclusion of women, the elevation of unison singing, and the exclusion of instruments served to establish a clear differentiation between musical performance in the synagogue and that of the street.

The musical performance tradition of the Christian Church grew out of the liturgical tradition of Judaism. The melodic formulas for the singing of psalms and the sung recitation of other scriptural passages are clearly based on Hebraic models.

Music in the Roman Catholic liturgy was performed mainly for the mass. Originally, the music was performed by the priest and the congregation, until, in time, there emerged from the congregation a special group of singers, called the choir, who assumed the musical role of answering and contrasting the solo singing of the priest. Women participated actively in musical performances in the ancient Christian Church until 578, when older Hebraic practices excluding them were restored. From that time until the 20th century, Roman Catholic Church choirs were composed solely of men and boys.

First codification of church music

The first codification of early church music was reputedly made by Pope Gregory I during his reign (590 to 604). Gregory's collection was selected from chants already in use. His codification assigned these chants to particular services in the liturgical calendar. In general it reinforced the simple, spiritual, aesthetic quality of liturgical music. The music in this collection serves as a model of melodic design even in the 20th century and is regarded as one of the monuments of Western musical literature. This school of unison liturgical singing is called Gregorian chant. Specific details concerning the manner in which chant was performed have been lost. There are speculations that the quality of sound the singers employed was somewhat thinner and more nasal than that used by contemporary singers. The authentic rhythmic style of chant cannot be ascertained. There is a theory, however, that the basic rhythmic units had the same durational value and were grouped in irregularly alternating groups of twos and threes. Pitch levels and tempos apparently varied somewhat according to the occasion. There are preserved manuscript notations reminding singers to be careful and modest in their work, indicating that temptations of inattention and excessive vocal display existed for even the earliest liturgical musicians.

While modern musical traditions in the West are based to a large extent on the principles of antiquity preserved in the notated music of the early church, a secular musical practice did exist, but because of the pervasive influence of the church, the dividing line between sacred and secular aspects was thin throughout a good part of the medieval period.

Several types of later secular song have survived. The musical notations are for the most part inadequate to give an accurate impression of the music, but it is known that it retained the essential monophonic character of liturgical music. One curious type of secular song, conductus, originated in the church itself. This song did not use traditional liturgical melodies or texts but was composed to be sung in the liturgical dramas or for processions. For this reason it dealt occasionally with subjects not religious in character. The goliard songs dating from the 11th century are among the oldest examples of secular music. They were the often bawdy Latin songs of itinerant theological students who roamed rather disreputably from school to school in the period preceding the founding of the great university centres in the 13th century.

Several other groups of medieval performers developed literary and musical genres based on vernacular texts: the jongleurs, a group of travelling entertainers in western Europe who sang, did tricks, and danced to earn their living; the troubadours in the south of France and the trouvères in the north; and the minnesingers, a class of artist-knights who wrote and sang love songs tinged with religious fervour.

Instruments, such as the *vielle*, harp, psaltery, flute, shawm, bagpipe, and drums were all used during the Middle Ages to accompany dances and singing. Trumpets and horns were used by nobility, and organs, both portative (movable) and positive (stationary), appeared in the larger churches. In general, little is known of secular instrumental music before the 13th century. It is doubtful that it had a role of any importance apart from accompaniment. Yet the possibility of accompanied liturgical music has not been eliminated by modern scholars.

Medieval polyphony

The medieval musical development with the farthest reaching consequences for musical performance was that of polyphony, a development directly related, as indicated above, to the experience of performing liturgical chant. For performers and performance, perhaps the most important developments in the wake of polyphony were refinements of rhythmic notation necessary to keep independent melodic lines synchronous. At first the obvious visual method of vertical alignment was used; later, as upper voices became more elaborate in comparison with the (chant-derived) lower ones, and writing in score thus wasted space, more symbolic methods of notating rhythm developed, most importantly in and around the new cathedral of Notre-Dame in Paris.

In the 14th century, partly because of the declining political strength of the church, the setting for new developments in music shifted from the sacred field to the secular, from the church to the court. This shift led in turn to a new emphasis on instrumental music and performance. Already the lower voices began to be performed on instruments—both because their long notes made them difficult to sing and because their texts (of only a few syllables) became senseless outside their original liturgical positions. Now, as secular princes became increasingly important patrons of composers and performers—a situation which would continue well into the 18th century—secular and instrumental music flourished. The polyphonic music of the church merged with the poetic art of the troubadours, and the two most important composers of the age were the blind Florentine organist Francesco Landini and the French poet Guillaume de Machaut, canon of Reims.

Most of the music of these composers seems to have been intended for combined vocal–instrumental performance, although this is seldom expressly indicated in the manuscripts. Medieval composers probably had no rigid expectations about performance media. Until the 17th century, and even through the 19th in the case of domestic performance, choice of instruments was likely to be dependent as much on available performers as on anything else. Many sources do, however, indicate that medieval musicians tended to separate instruments into two groups, loud and soft (*haut* and *bas*, or, very generally, wind and string), and to prefer contrasting sonorities within those groups, for maximum differentiation of the individual parts. Outdoor or ceremonial music would be performed with loud instruments (shawm, bombard, trombone, organ); room music, with soft ones (lute, viol, recorder, harp). Paintings and manuscript illuminations of the period show that much secular performance included both a wide variety of bells, drums, and other percussion instruments, and instruments with drones—bagpipes, fiddles, double recorders, hurdy-gurdies. The parts for these instruments are never found in the musical sources and must be reconstructed for modern performance.

Notation of medieval music

The notation of medieval music often is misleading for the modern performer. Accidentals (sharps and flats, called then *musica ficta*) were often omitted as being understood. Further, it seems likely that variation, embellishment, and improvisation were very important elements of medieval performance. It is known that sections of some 15th-century two-part vocal music were enhanced by an extempore third part, in a technique called fauxbourdon; the notation of the 15th-century *basse danse* consisted of only a single line of unmeasured long notes, evidently used by the performing group of three

instrumentalists for improvisation, much as a modern jazz combo's chart.

The Renaissance. The very concept of improvisation as a mere subcategory within performance practice could arise only after the invention of music printing, which had at first little discernible effect on performance. Extemporized ornamentation of polyphonic music continued and increased during the 16th century, in instrumental, vocal, and combined performance, both secular and sacred. Later in the century, liturgical music again became less extravagant in the wake of the Council of Trent (1545–63), which ordered that masses be sung "clearly and at the right speed" and that singing "be constituted not to give empty pleasure to the ear, but in such a way that the words may be clearly understood by all." Music printing was at first too expensive to alter seriously the social structure of musical performance; the traditions of ostentation and exclusiveness embodied in music written by Guillaume Dufay for the early 15th-century Burgundian court were continued in the magnificent musical establishments of the Italian Renaissance princes and popes. Detailed records exist of the elaborate musical festivities arranged for weddings and baptisms of the powerful Florentine family, the Medici. Printing increased the dissemination as well as the survival of these works but, like the earlier Burgundian chanson, and unlike the contemporary Parisian chanson, which was cast in a more popular mould, they were nonetheless primarily intended for a select group of discriminating performers.

Printing, both of music and of books, does document the ever increasing development and sophistication of instrumental music during the 16th century. Printed descriptions of instruments date from the 16th century. Their discussions of tuning and technique supplied the needs of professional and nonprofessional musicians alike. There was a growing tendency to construct instruments in families (whole consorts of homogeneous timbre, high, middle, and low), a tendency perhaps related to recent expansion at both ends of the musical scale: with more space available, contrapuntal parts no longer crossed so frequently and no longer needed the differentiation provided by the markedly contrasting timbres of the medieval "broken consort."

The 17th and 18th centuries. After printing, the next significant influence on music performance was the gradual emergence of the audience, for the relationship between participants in the musical experience—between performer and listener—became polarized. The first evidence for this shift was the rise of the professional vocal virtuoso about the last quarter of the 16th century, and this development soon had a profound influence on musical style. Italian composer–singers, such as Giulio Caccini and Jacopo Peri, reacted quickly to their audiences' desire for more expressive and passionate vocalism, and the music they wrote for themselves eventually was imitated and refined by other composers, such as the Italian Claudio Monteverdi, whose nine successive books of madrigals document the changes in style from music composed for four to six essentially equal voices to music in which the interest lay primarily at the extremes of the texture. The technical underpinning for this new monodic style was the basso continuo, or thorough bass, played by one or more polyphonic solo instruments "realizing" a "figured bass": that is to say, improvising chords above a single line of music provided with numbers and other symbols to indicate the other notes of the chords. In the 17th century a wide variety of continuo instruments was used, including lute, theorbo, harp, harpsichord, and organ. By the 18th century the practice was more standardized: the bass line would be realized on a keyboard instrument and reinforced by a monophonic bass instrument, such as a lute, viola da gamba, violoncello, or bassoon. The continuo player not only completed the harmony but could also control rhythm and tempo to suit the particular conditions of a performance.

Rise of the vocal virtuoso

The development of monody was itself a necessary precondition for that most expensive of all performance institutions, opera. Beginning in Florence at the very end of the 16th century, opera soon spread over Italy: through Rome, where its initially pastoral nature matured into full-blown spectacle, to Venice, where the first public opera theatre opened in 1637. There, although audiences were still aristocratic, opera was dependent upon the sale of admissions rather than royal patronage, and musical performance began to find an entirely new method of economic support.

In the realm of purely instrumental music, the new economy of performance was slower to emerge, but there were many other new developments. By far the most popular Renaissance instrument had been the versatile lute; it served all levels from the merchant's daughter learning the simplest dance melody to the virtuosos. In the 17th century the lute began to yield to keyboard instruments, but the intimate music of the French *clavecinistes* (harpsichordists) was still a clear outgrowth of the precious and evanescent performance style of the lutanist Denis Gaultier (1597/1603–1672). Later, keyboard ornamentation began to be codified in tables of agrément-symbols published with each new collection of music. In Italy composers also were attempting to provide performers with more explicit directions. Contemporary keyboard fingering systems, which used the thumb much less than modern ones, also served contemporary preference for subtlety and unevenness of rhythm. As the century progressed and national styles drew farther apart, there evolved a specifically French tradition of *inégalité:* performing certain evenly written notes unequally, with alternately longer and shorter values.

Predominance of keyboard instruments

A more lasting French development was the first instance of instrumental music consistently performed by more than one player to a part. In 1656, Jean-Baptiste Lully made his orchestra, the Petits Violons ("Little Violins"), abandon the old tradition of free embellishment and drilled them in a disciplined and rhythmically pointed precision which was widely imitated. Simultaneously, the violin and its family, because of their passionate brilliance and versatility, replaced viols as the standard ensemble instruments—especially quickly in Italy, where performance was less sophisticated, less mannered, and less restrained than in France.

In the 18th century national performance styles tended again to merge, except in the case of opera. French opera, which had reached its first height under Lully and had counted among its star performers Louis XIV himself, continued to emphasize ballet and correct declamation more than pure vocalism. In other areas, standardization and codification were the trend. The place of improvised embellishment and variation was further circumscribed, limited in general to such recognized spots as repeated sections in binary and da capo forms, slow movements of sonatas and concertos, and cadences. Instrumental tutors by famous performers were important and widespread.

Foundation of public concerts

The foundation of public concerts increased, and orchestras all over Europe followed the pattern set by the famous ensemble maintained by the Elector of the Palatine at Mannheim, with its standard size (about 25) and new style of performance with dramatic dynamic effects and orchestral devices (*e.g.*, crescendos, tremolos, grand pauses). The Mannheim composers also hastened the decline of the improvised thorough bass by writing out harmonic filler parts for the violas; conducting from the keyboard nevertheless remained standard practice into the 19th century. Meanwhile, entrepreneurial speculation was finally supplanting aristocratic patronage as the economic base for concert activity. Haydn, who had already spent one full career in Austria, in the service of the House of Esterházy, in 1791 began another and more lucrative one in association with the concert manager Johann Peter Salomon—conducting his London symphonies from the piano.

The 19th century. The heyday of the concert artist began before Haydn's first journey to London, and it still shows few signs of ending. It reached its zenith and was the primary factor in all music performance in the 19th century. Mozart and Beethoven were famous concert pianists before they were famous composers, and succeeding generations saw a large number of piano virtuosos travelling over Europe and, later, North and South America.

Some were composers of works for themselves; others were more important as interpreters of other composers' works. The tradition of the star singer was of course much older, and it continued; one new development was that of the claquer, paid by the star for his applause. The independent conductor, as distinct from the first violinist or the continuo player, emerged from the body of the orchestra during the first half of the 19th century, and his development toward the lionized figures of the 20th century was swift. Parallel with this rise came the establishment of many of today's major orchestras: New York Philharmonic (1842), Vienna Philharmonic (1842), Boston Symphony (1881), Berlin Philharmonic (1882), Amsterdam Concertgebouw (1883), Chicago Symphony (1891), London Symphony (1904).

Establishment of major orchestras

The result of the enormous widening of concert activity and of the increasingly international reputations of performers was an even further standardization of performance practice. Eighteenth-century concern with appropriateness and taste in embellishment yielded to emphasis on clarity and evenness of touch, purity of intonation, and accuracy of execution. As composers' scores became increasingly precise, the performers' interpretative decisions were increasingly limited to matters of technique, tempo, rhythmic and dynamic nuance, and personality—a subjectivism justified by the cult of Romantic genius prevalent in 19th-century artistic life. Real improvisation in music would not re-emerge until the 20th century—in jazz. The addition of such mechanical aids and improvements as chin rests and end pins to string instruments (which permitted a wider and more constant vibrato without tiring); valves and extra keys to brass and woodwind instruments (making scales more even and intonation more secure); and double-escapement action, iron frames, and cross-stringing to the piano (which facilitated crisper and surer attack and made both tone and tuning last longer) all had profound influence not only on performance techniques but also on the very sound of the instruments. The most successful new instrumental and vocal teaching methods emphasized virtuosity, brilliance, evenness, and wide range, reflecting a desire to make music more effective for large audiences.

Technical advances in instruments

The rise of the concert artist was seconded by the appearance of the professional music critic, whose influence on performance has been, and is, difficult to assess. At first critics tended to be primarily practicing musicians; later this was less the case. A more tangible residue of 19th-century music performance and one that illustrates how little its basic social structures have changed since then is the large number of concert halls and opera theatres which were built and are still used today.

One final development, the import of which would not be fully realized until the present century, was that of historicism: the active revival of old music. This incipient recognition of the validity of other styles of composition and performance is dated conventionally from the German composer Felix Mendelssohn's 1829 performance of parts of Bach's *St. Matthew Passion*, but it was preceded in a sense by the Concerts of Antient Music (1776–1848) in London. The stated policy of this musical group was not to perform music less than 20 years old (but they often updated the compositions with added brass parts). The revival of interest in the music of Palestrina and Bach, while at first expressed only in terms of 19th-century Romanticism, would pave the way for 20th-century advances and retrenchments in both style and performance.

The 20th century. The major performing institutions of the 19th century have continued into the 20th century with only minimum structural change, except for a rather belated movement toward unionization of personnel; this development has of course improved the performers' lot greatly, while increasing the costs of performance. Unquestionably, the major new influence on 20th-century music performance has been electronics. Broadcasting and recording have widened even further the potential audience for concert artists, at the same time as they have tended to decrease the physical necessity for large new public performance arenas. Electronic instruments have appeared, both amplified versions of older ones (guitar, piano, and even some woodwinds) and instruments with fundamentally electronic means of tone production (electronic pianos and organs, the theremin and Ondes Martenot, and sound synthesizers). Other new compositional and performance possibilities have also developed, for example, film, tape, stereophonism, and computers. Even before the phonograph (invented *c.* 1875) had begun to be regarded as more than a toy, serious research into the authentic performance of older music had produced an awareness of possibilities which pointed the way out of the seeming dead end of late Romantic gigantism and subjectivism. From the very beginning of the century, the chamber concerts given by Arnold Dolmetsch and his family, on reconstructions of old gambas and recorders, attracted attention to small ensembles and different sonorities and encouraged the activities of other artists.

Appearance of electronic instruments

The true end of the Romantic era and the beginning of the modern era can be dated from the second decade of the 20th century, the time of the composition of two masterpieces which more than any others mark the departure from 19th-century performance ideas: the German composer Arnold Schoenberg's *Pierrot Lunaire* (1912) and the Russian composer Igor Stravinsky's *Histoire du soldat* (*The Soldier's Tale*, 1918). These are chamber works, but their instrumental makeup is a unique mixture of instruments that do not necessarily blend and which seem further to repudiate the orchestra as a performing medium. *Pierrot* is a series of songs which repudiate the 19th-century lied: the voice does not sing but produces a kind of pitched speech (*Sprechstimme*). *Histoire* repudiates both orchestra and opera as previously understood: it is specifically (and inexpensively) designed for performance on a portable stage by three dancers, a narrator, and seven instrumentalists. For these works a new kind of performer is required, and these works in turn have helped to train the new performer—who might be called the group-virtuoso. Teams or groups of such performers have sprung up everywhere. Often they are centred on a living composer or the university where he teaches, where they function as partners to his composition, realizing the work rather than interpreting it. The performer is very much involved in the creative act, the product of which reflects his particular skills and personality, and the dynamics of the working situation. In the second half of the 20th century the important musical action is no longer in the recital nor in opera or symphony; it is in the combo, experimental or folk, live electronic or improvisational, or multimedia.

Prospects. The prospects for musical performance remain as rich and unpredictable as ever. Technology continues to alter the situation considerably through the invention of new sound resources and the creation of new performing situations.

The established performance situation is moving from the formal, ritualized event of the past to a more informal and spontaneous type of gathering. The interaction of various media is leading to new art forms and circumstances. Many artists are attempting to create performance situations that will actively involve as participants all those in attendance. The roles of composer, performer, and listener are consolidated in a single participant, who in interaction with others arrives at an art work, which all have invented, realized and perceived, and which can never take place again.

Increasing spontaneity of performance situations

On the other hand, the growing use of technology may intensify the problem of evaluating the meaning and effect of electronically produced and assembled performances that, in their totality, never took place at all and possibly never could.

The electronic media may continue to improve until soon anyone may be able to select chamber, concert, opera, and other new types of performance from anywhere in the world, experiencing them through nearly lifelike reproduction facilities. Vast numbers of people may study performance skills via two-way transmission with great artists. The number of actual public performing events may decrease as private musical performance increases. Already there is the phenomenon of the wide-

spread dissemination of great performers' recordings, which has forced the standards of quality for a live performance to almost inhuman heights and has increased interest in the performance of older as well as contemporary music.

HISTORY OF NON-WESTERN MUSICAL PERFORMANCE

South Asia. Although the classical South Asian or Indian musician usually performs in a concert situation quite analogous to that of a typical Western artist, his audience responds to him quite differently: he is not judged on how faithfully he reproduces the music the composer imagined but on how well he creates his own music within certain wide bounds set by the composer and by the general practice of Indian music. Since Indian musical performance is based on improvisation, Indian musical pedagogy is therefore a more personal procedure, in which an aspiring musician will "apprentice" himself to a guru, with whom he thereafter identifies himself; in the West this kind of organization is reflected in the rise of the group-virtuoso discussed above. Similarly, Western development away from large performing groups such as the full orchestra reflects—or at least parallels —the more intimate character of Indian music, the basic texture of which usually involves a quite small group of performers: one player to provide rhythm on a drum such as the double-headed, pitched *ṭablah;* one to provide a basic drone, often on the lute-like tambura; and a central performer on the sitar (technically also a plucked lute but one with melodic capability, unlike the tambura). The players often engage in a kind of competition not unlike that of Western jazz groups. If there is singing, the style of performance is low and soft, in contrast to that of Indonesian classical vocalism.

Intimate character of Indian music

Southeast Asia. The gamelan is at the center of the art-music tradition of Indonesia. It may range in size from a few to over 75 instruments. The basic melodic instrument is the *saron* (bronze xylophone), accompanied by various gongs, a kind of violin, a recorder-flute and/or a zither; the group is led by a drummer. As in medieval Western music, there are two kinds of gamelan playing, one emphasizing the bronze instruments (comparable to medieval *haut,* or loud, consorts) and the other the wind and string instruments (*bas,* or soft, groups). A similar differentiation exists in Indochinese music, in the contrast between the percussion-dominated *pi phat* band of Thailand and the string-dominated *mahori* bands of Thailand and Cambodia. Gamelan playing, particularly of the softer type, often accompanies solo and unison choral singing of classical poetry (music is connected with most of Indonesian literature). Southeast Asian vocal performance—like that of a great deal of non-Western art music—is characterized by tense, high, often nasal voice production; this is one of many alternatives being explored by the more experimental 20th-century Western composers and performers.

China and Japan. The most extensively developed and most important Chinese and Japanese traditions of musical performance are closely tied to theatrical styles and traditions. Perhaps the most spectacular of non-Western performance traditions is Chinese opera, in which singers, acrobats, costumes, scenery, and instruments are combined in the creation of a highly varied work of art. Peking opera uses two basic kinds of instrumentation: for military scenes a battery of drums, gongs, and cymbals with a kind of oboe playing the melody; for the more frequent domestic scenes a wider variety based on a drum (*pan ku*) with a peculiarly sharp, cracking sound for keeping time, and a number of two-stringed, bowed lutes played with the bow passing between the strings. Plucked lutes and flutes also appear at times. All of the melody instruments play heterophonically with the singers, whose vocal style, as in the West, is highly artificial. Heroines are usually portrayed (sometimes by female impersonators) in a high, thin voice; heroes use a raucous, rasping tone quite foreign to traditionally oriented Western ears—but, again, not unlike some of the vocal techniques required by 20th-century Western avant-garde composers.

A performance tradition peculiarly Japanese is the emphasis on the visual aspects of making music: custom directs that *gagaku* (court orchestra) instruments must be played as gracefully as possible.

BIBLIOGRAPHY. While any of the standard histories of music or of specific musical style-periods will consider performance at least implicitly, the best direct and concise account of the whole problem is THURSTON DART, *The Interpretation of Music* (1954). Other general views of the subject are FREDERICK DORIAN, *The History of Music in Performance: The Art of Musical Interpretation from the Renaissance to Our Day* (1942); and ROBERT DONINGTON, *The Interpretation of Early Music,* 2nd ed. (1965), which, like Dart, includes a bibliography of sources. What bibliographic aids to individual performers exist are given in "Dictionaries and Encyclopedias of Musical Instruments, Makers, and Performers," in VINCENT H. DUCKLES, *Music References and Research Materials: An Annotated Bibliography,* 2nd ed., pp. 40–50 (1967). Certainly the most extensive bibliography ever published on the subject is MARY VINQUIST and NEAL ZASLAW (eds.), *Performance Practice: A Bibliography* (1971).

Some book-length studies of particular aspects of musical performance are listed below: P. ALDRICH, *Rhythm in Seventeenth-Century Italian Monody* (1966); F.T. ARNOLD, *The Art of Accompaniment from a Thorough-Bass As Practised in the XVIIth and XVIIIth Centuries* (1931); J.M. BARBOUR, *Tuning and Temperament* (1951); D.D. BOYDEN, *The History of Violin Playing, from Its Origins to 1761 and Its Relationship to the Violin and Violin Music* (1965); WALTER EMERY, *Bach's Ornaments* (1953); R.E.M. HARDING, *Origins of Musical Time and Expression* (1938); WILFRID H. MELLERS, "Theory and Practice," in *François Couperin and the French Classical Tradition* (1950); FRITZ ROTHSCHILD, *The Lost Tradition in Music: Rhythm and Tempo in J.S. Bach's Time* (1953); and *Musical Performance in the Times of Mozart and Beethoven: The Lost Tradition in Music, Part II* (1961); DENIS W. STEVENS (ed.), *The Art of Ornamentation in the Renaissance and Baroque* (1967), a stereophonic record; HENRY PLEASANTS, *The Great Singers: From the Dawn of Opera to Our Own Time* (1966); and WILLIAM P. MALM, *Music Cultures of the Pacific, the Near East, and Asia* (1967).

(L.Fo./J.Th./B.A.C.)

Musical Rhythm

In its most general sense rhythm (Greek *rhythmos,* derived from *rhein,* "to flow") is an ordered alternation of contrasting elements. Though this article is confined to rhythm in music, the notion of rhythm occurs in other arts (*e.g.,* poetry, painting, sculpture, and architecture) as well as in nature (*e.g.,* biological rhythms).

Attempts to define rhythm in music have produced much disagreement, partly because rhythm has often been identified with one or more of its constituent, but not wholly separate, elements, such as accent, metre, tempo. As in the closely related subjects of verse and metre, opinions differ widely, at least among poets and linguists, on the nature and movement of rhythm. Theories requiring "periodicity" as the *sine qua non* of rhythm are opposed by theories that include in it even nonrecurrent configurations of movement, as in prose or plainsong.

Elements of rhythm. Unlike a painting or a piece of sculpture, which are compositions in space, a musical work is a composition dependent upon time. Rhythm is music's pattern in time. Whatever other elements a given piece of music may have (*e.g.,* patterns in pitch or timbre), rhythm is the one indispensable element of all music. Rhythm can exist without melody, as in the drumbeats of primitive music, but melody cannot exist without rhythm. In music that has both harmony and melody, the rhythmic structure cannot be separated from them. Plato's observation that rhythm is "an order of movement" provides a convenient analytical starting point.

Beat. The unit division of musical time is called a beat. Just as one is aware of the body's steady pulse, or heartbeat, so in composing, performing, or listening to music one is aware of a periodic succession of beats.

Tempo. The pace of the fundamental beat is called tempo (Italian "time"). The expressions slow tempo and quick tempo suggest the existence of a tempo that is neither slow nor fast. This "moderate" tempo is often assumed to be that of a natural walking pace (76 to 80

paces per minute) or of a heartbeat (72 per minute). The expression of tempo as a given number of beats to the minute resulted from the work of Johann Mälzel, who in 1816 perfected the metronome. The tempo of a piece of music indicated by a composer is, however, neither absolute nor final. In performance it is likely to vary according to the performer's interpretative ideas or to such considerations as the size and reverberation of the hall, the size of the ensemble, and, to a lesser extent, the sonority of the instruments. A change within such limits does not affect the rhythmic structure of a work.

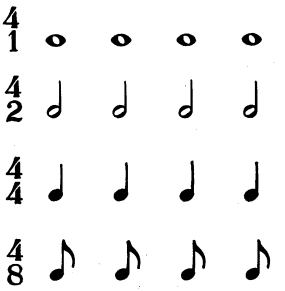
Rubato. The tempo of a work is never inflexibly mathematical. It is impossible to adhere in a musical manner to the metronomic beat for any length of time. In a loosely knit passage a tautening of tempo may be required; in a crowded passage a slackening may be needed. Such modifications of tempo, known as *tempo rubato*—*i.e.*, "robbed time"—are part of the music's character. Rubato needs the framework of an inflexible beat from which it can depart and to which it must return.

Time. The mind apparently seeks some organizing principle in the perception of music, and if a grouping of sounds is not objectively present it imposes one of its own. Experiments show that the mind instinctively groups regular and identical sounds into twos and threes, stressing every second or third beat, and thus creates from an otherwise monotonous series a succession of strong and weak beats.

In music such grouping is achieved by actual stress; *i.e.*, by periodically making one note stronger than the others. When the stress occurs at regular intervals, the beats fall into natural time measures. Although in European music the concept of time measures reaches back to a remote age, only since the 15th century have they been indicated by means of bar lines. Thus, the terms measure and bar are often used interchangeably.

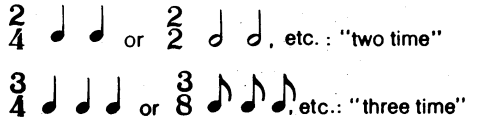
Time signatures

The time measure is indicated at the opening of a piece by a time signature; *e.g.*, $\frac{2}{4}$, $\frac{4}{8}$, $\frac{3}{4}$, $\frac{6}{8}$. The length of each beat in a measure may be a time unit of short or long duration:



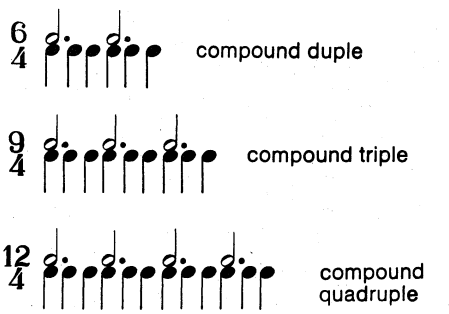
The signature $\frac{4}{1}$ (above) means that the whole note (1) is the unit in each measure, and there are four (4) of them to each measure. In the second illustration, $\frac{4}{2}$, the half note (2) is the unit of measurement, with four of them (4) to each measure, etc.

The two basic types of time measure have either two or three beats and admit of many different notations.



"Four time," or "common time," is really a species of duple time allied to "two time," as it can hardly be thought of without a subsidiary stress at the half measure; *i.e.*, on the third beat; thus:

Duple, triple, and quadruple time measures—*i.e.*, those in which there are two, three, and four beats to a measure—are known as simple time. The division of each of the component beats into three produces compound time:



More complex times, such as the quintuple, $\frac{5}{4}$, usually fall into groups of 3+2, as in "Mars" from Gustav Holst's suite *The Planets* and in the second movement of Tchaikovsky's *Sixth Symphony*. Rimsky-Korsakov, in *Sadko*, and Stravinsky, in *Le Sacre du printemps*, use 11 as a unit. Ravel's piano trio opens with a signature of $\frac{8}{8}$ with the internal organization 3+2+3. Folk song and folk dance, particularly from eastern Europe, influenced the use of asymmetrical time measures, as in the "Bulgarian Rhythm" pieces in $\frac{7}{8}$ and $\frac{5}{8}$ in Bartók's *Mikrokosmos*.

Metre. The combinations of long (—) and short (∪) syllables are known in prosody as feet. The system of notating the musical equivalents of feet derives from the application of prosody to music. The foundations for European music were laid in ancient Greece, where classical music and poetry were regarded as parts of a single art. These principles were adopted by the Romans and were transmitted, by way of Latin poetry, to medieval Europe. The feet of classical poetry and their equivalents in music are shown in Table 1. And in late antiquity St. Augustine (354–430), in *De musica*, added more.

Prosody applied to music

Table 1: Classical Poetic Metre

	metrical foot	poetic syllables	musical notation	groups of beats	equivalent time signatures
duple	dactyl	— ∪ ∪	♩ ♫	2 + 2	$\frac{2}{4}$
	anapest	∪ ∪ —	♫ | ♩	2 + 2	$\frac{2}{4}$
triple	trochee	— ∪	♩ ♪	2 + 1	$\frac{3}{8}$
	iamb	∪ —	♪ | ♩	1 + 2	$\frac{3}{8}$

Rhythmic modes. Until the 12th century, church music was virtually limited to unadorned plainsong. The early composers found that polyphony required a rhythmical organization to keep the parts together; so rhythmic modes or metres were adopted (see Table 2).

Table 2: Classification of Rhythmic Modes

poetry	metrical foot	musical notation
— ∪	trochee	♩ ♪
∪ —	iamb	♪ ♩
— ∪ ∪	dactyl	♩. | ♪ ♩
∪ ∪ —	anapest	♪ ♩ | ♩.
— —	spondee	♩. | ♩.
∪ ∪ ∪	tribrach	♫

Compared with a hypothetical flow of beats equal in stress, metre adds significance to what was merely a forward flow in time—though the continuation of a metrical pattern may itself become monotonous. Thus, metre, though "rhythmic" by comparison with pulse, is not the whole of rhythm.

The 13th-century musicians often varied the rhythmic modes by combining several of them simultaneously in different parts of polyphonic composition.

Polyphonic metre. Theoretically, metre appears to be without stress accent, and certainly much polyphonic music of a later period, such as the masses of Palestrina, has an almost stressless flow. Yet despite the absence of strong and weak accents, these works reveal a subtle rhythmical organization. At a later period metre and time measure cannot be wholly separated. In their "purest" forms they may be extremes, but in music predominantly of one type, the other element is rarely wholly absent, though on an instrument such as the organ, actual dynamic stress is impossible. After all, metres like the spondee, , and the dispondee,  , need an accent on the first beat to keep their identity. Notwithstanding the opposite tendencies of metrical organization and stress accent, however, some metre is obviously subject to stress, so that metre and time measure become very closely linked, as in the scherzo of Beethoven's *Ninth Symphony*, where a measure has a strong first beat and at the same time follows a metre.

Organic rhythm. In broad terms, the time framework of music comprises tempo, time measure, metre, and period; and its rhythmical life hangs on rubato, musical motif (which may already include cross accent), and metrical variation, as well as on asymmetry and balance of phrase.

Rational and irrational features

Whereas the former are more or less mechanical factors, measured and rational, the latter are organically inspired and numerically irrational—the very life of the music.

Prose rhythms and plainsong. Rhythm is, therefore, not any one of these rational or formal features, nor is it composed solely of a combination of these factors. Yet rhythm requires the background of a rational framework in order that it may be fully perceived, but this framework need not embrace all the rational factors described above. Thus plainsong, as it is known in modern times, makes no use at all of measure or of regular metre but is supremely rhythmical in conception; its "free" rhythms are felt. Whereas so much music has for its framework a regular repetition of underlying accent, whether stress or durational, the framework of plainsong is irregular. Its rhythm belongs to the Latin tongue and springs from the correct accentuation of the text and the dynamic quality inherent in the word grouping.

Rhythm and melody. Thus far, music's structure in time has been examined separately from its structure in tone, but no such separation is really possible. Melody and rhythm are intimately connected. Moreover, various styles of music tend to standardize their melodic cadences and, with them, their time divisions (*e.g.*, Mozart's melodic rhythm is much more regular than Prokofiev's).

Rhythm and harmony. In music employing harmony, the rhythmic structure is inseparable from harmonic considerations. The time pattern controlling the change of harmonies is called harmonic rhythm. In 17th- and 18th-century music, harmony tends to limit rhythmic subtleties and flexibility of the melodic elements (as well as determining the basic type of melody), in regard to stress accents. It is, therefore, no accident that the polyphonic music of Indonesia and Southeast Asia, like much European music, exhibits certain four-square melodic tendencies. By contrast, the music of India and the Perso-Arab world employs a melody instrument or voice performing in a given metre offset by a drum playing cross rhythms or (in the Arab world) a quite different metre; with no harmony (except a drone) to impede its flow, the rhythm can reach a structure of great subtlety and complexity.

Diversity from conceptual differences

Rhythm, structure, and style. In European music the great variety of styles derives its relation to melody from different concepts of rhythm. They include the strict rhythmic modes of the 13th century; the free oratorical speech-rhythms of the Renaissance; the almost stressless flow of Renaissance polyphony; the strong body rhythms of the Baroque; the freedom of the late Romantics; and the primitivistic rhythms of the 20th-century with composite and ever changing time signatures

Thus, study of musical history shows a varying attitude toward rhythm, sometimes closer to strict rule, sometimes to "freedom," as the temper of the times and the relative influence of poetry, dance, and folk music decree. Plato's definition of rhythm as "an order of movement" might, therefore, be expanded. As a determining factor in the vitality of music, rhythm may be described as "an inspired, organic order of movement," communicating intelligibly to the senses. From the analytical viewpoint, it operates in the rational framework described, which it varies in terms of rubato, motif, etc. Ultimately, rhythm is the organic process of music in time; it is music's direction in time. The quality of rhythm is the quality of life; however vitally the composer conceives his music, he must depend upon the performer to recreate it rhythmically.

BIBLIOGRAPHY. CURT SACHS, *Rhythm and Tempo* (1953), the most comprehensive work on rhythm in music, ranges over many non-Western cultures as well as over the successive periods of Western musical history. Detailed rhythmical analyses of Western music since the 17th century appear in GROSVENOR W. COOPER and LEONARD B. MEYER, *The Rhythmic Structure of Music* (1960). Studies of special periods are available in CHARLES F. ABDY WILLIAMS, *The Aristoxenian Theory of Musical Rhythm* (1911); W.F. JACKSON KNIGHT, *St. Augustine's De Musica: A Synopsis* (1949); WILLIAM G. WAITE, *The Rhythm of Twelfth-Century Polyphony, Its Theory and Practice* (1954); PHILIP F. RADCLIFFE, "The Relation of Rhythm and Tonality in the Sixteenth Century," *Proc. R. Musical Assn.*, 57:73–97 (1931); and HENRY D. COWELL, *New Musical Resources* (1930, reprinted 1969). Particular applications of rhythm have been studied in CHARLES F. ABDY WILLIAMS, *The Rhythm of Song* (1925); and WILLIAM THOMSON, *The Rhythm of Speech* (1923). Aesthetic aspects are considered in MARGARET GLYN, *The Rhythmic Conception of Music* (1907); and MATHIS LUSSY, *Le Rythme musical*, 3rd ed. rev. (1897; abridged Eng. trans., *A Short Treatise on Musical Rhythm*, 1909). EMILE JACQUES-DALCROZE, *Le Rythme, la musique et l'éducation* (1920; Eng. trans., *Rhythm, Music and Education*, 1921), is the pioneer work in its aspect of the field; musical rhythm has been put in wider perspectives by ELSIE FOGERTY in *Rhythm* (1937).

(P.C–H.)

Music Theory

A theory of music comprises acoustics, aesthetics, and stylistic practice. The musical theories of a culture reflect not only its attitude to the arts but also its religious, philosophic, and scientific biases. China, India, Greece, and Islām developed musical theories long before the modern era, and western Europe has, since medieval times, contributed extensively to this multiple heritage.

Acoustics connects with instrument design and musical-scale derivation and also with number theory and metaphysical symbolism. Aesthetics derives from the practice of artists and also from religious and philosophic theories of universal and social order. Although musical practice generates theories of composition and performance, fundamentally it springs from the religious, philosophic, and scientific thought of the culture that engendered it.

Chinese music theory, based acoustically on a system of relations of the numbers 2 and 3, connects symbolically with metaphysical theories of the interaction of Yin (2) and Yang (3), the two principal contrasting elements of the Chinese cosmos; and, by dint of a theory claiming causal effects on human behaviour for musical sounds, it also connects with ethical, social, and political teachings.

Indian music, based acoustically on numbers 2, 3, and 5, yields many seven- to nine-tone scales (called *rāgas*), each with associated melodic patterns and each causing a specific emotional effect (called *rasa*). Varying interval tensions are produced against a fixed drone by the tones of the scale. The fixed pitches of the drone symbolize the *ātman* (soul; the individual's participation in the universal Brahman), and the changing pitches of the *rāga* represent life experiences. Indian music, therefore, is connected by tradition with meditation and self-transcendence. Other non-Western music is similarly based upon such religious and philosophical foundations.

Western European music is characterized by counterpoint and harmony and by its constant stylistic evolution.

Counterpoint refers to the simultaneous unfolding of several melodic lines. The combinations of tones that result are harmonies, classified as consonant (bearing harmonic repose) and dissonant (bearing harmonic tension) and arranged since the 17th century in hierarchical families called tonalities (relationships between tones). Since the Renaissance, Western music has increasingly emphasized perceptual factors other than pitch and rhythm, until, in the 20th century, types of music have emerged in which pitch and rhythm no longer predominate. The evolution of style is currently expressed in a wide diversity of kinds of music without a common practice. Also radically dissimilar are the acoustical and organizational properties in the music of contemporary composers. Hence, a theory of contemporary Western music would need to be unusually comprehensive.

ORIGINS AND HISTORY OF WESTERN EUROPEAN MUSIC THEORY

The origins of western European music lie in the music of the medieval Roman Catholic Church. The liturgical plainchant adopted by the Roman Church was codified by Pope Gregory I in the 6th century and was based upon a system of seven-tone modes (scale formations) handed down in Greek tradition from Pythagoras. The tuning of these modes was based, like traditional Chinese music, on relationships of the numbers 2 and 3, symbols of the worldly and the divine. Gregorian chant was monophonic (a single melodic line without accompaniment) until near the end of the 1st millennium AD, when a polyphonic practice (*i.e.*, combining several voice parts simultaneously), called organum, was introduced. From this early counterpoint, at first almost entirely a matter of parallel motion in fourths (*e.g.*, F above C), fifths (*e.g.*, G above C), and octaves, the unique polyphonic tradition of western European music gradually evolved.

Harmony of the universe

The Roman scholar and philosopher Boethius, writing in the 5th century, distinguished three kinds of "music," *musica mundana, musica humana,* and *musica instrumentalis.* Of these, only the last refers to sounded music, the first two indicating, respectively, the arithmetically expressed harmony of the universe (a Pythagorean idea) and the harmony of the soul. By the correspondence between these harmonies, music was believed to symbolize man's place in the universe, and the potent psychological impact of music was to some extent explained. This conception survived for a long time, especially in the tabulation of intervals (distances between notes) in terms of their relative consonance and dissonance, measured as fractions of string length on a monochord needed to produce the intervals. Considerations of this kind were especially crucial in polyphonic music, as were also the methods of rhythmic integration. Thus, medieval and Renaissance treatises usually concerned problems of consonance and dissonance, techniques for integrating polyphonic voices, and methods of notating pitch and rhythm. The most important of these for the subsequent development of music was the 14th-century treatise of a French musical theorist, Philippe de Vitry, *Ars nova,* which provided a new rhythmic notation liberating music from the rigidity of earlier methods. During the 13th and 14th centuries the tuning system shifted gradually away from the Pythagorean toward a triadic system later called "just intonation," as intervals of a third (*e.g.*, C–E) and a sixth (C–A) came to be recognized as consonances.

At the end of the Renaissance, as instrumental and operatic music began to replace choral music, the practice of accompanying instruments and voices with an improvised keyboard part, called a "figured bass," led to the organization of compositions around harmonic progressions. This had two important effects: to simplify the traditional system of modes into major and minor tonality and to make urgent the need to temper the tuning of the scale so as to provide a wide scope for modulation (change of key within a work) with a limited gamut of pitches.

Rameau and others. The French composer and theorist Jean-Philippe Rameau went far to establish tonality as a distinct technique of composition. He conceived each triad (a chord formed by two superimposed thirds, such as C–E and E–G) as representing the acoustic proportion 4:5:6 and considered a given triad to keep its identity regardless of the distribution of its three notes. Each triad thereby has a "root" position, a "first inversion," and a "second inversion," depending upon which of its tones is in the bass. Thus, the triad C–E–G can assume the forms E–G–C and G–C–E.

Another aspect of theory that gradually acquired importance during the 18th and 19th centuries was the codification of stylistic and compositional techniques. Such was *Gradus ad Parnassum* (1725), a treatise on counterpoint by the Austrian theorist Johann Joseph Fux, which had a long-standing effect upon pedagogy.

In the 19th century the emphasis in this area shifted to techniques for musical analysis. The theories of phrasing and functional harmony of the German musicologist Hugo Riemann gave tonal and rhythmic practices of the "common-practice period" increased coherence.

Then, an Austrian theorist, Heinrich Schenker, gave the process of tonality its most thoroughgoing formulation. In Schenker's view, pitch (the location of sound in the tonal scale), as both melody and harmony, is the controlling factor in tonal music. Rhythm and dynamics function secondarily to articulate the structures created by pitch design. All tonal compositions can be reduced to a melody, a bass line, and a harmonic progression. In Schenker's view, all modulation should be regarded as "tonicization" of various subordinate progressions within one overall key. Schenker's ideas, designed to apply to common-practice-period music, have been applied to earlier and more recent music with notable success, allowing for some generalizations of his basic concepts.

Modern theorists. Some 20th-century theorists have devoted themselves to the codification and teaching of compositional or theoretical techniques. A small number have provided bases in theory for the music of their times.

Schoenberg's theories

Arnold Schoenberg's 12-tone serial theory provides an alternative method of pitch organization to tonality, in which the traditional rules of tonality and harmony are replaced by new rules and principles. This system has been used widely by many 20th-century composers. Serial techniques have been applied to factors other than pitch, notably among the "post-Webern school" of composers (Anton von Webern was a pupil of Schoenberg).

The theoretic work of the German composer Paul Hindemith was directed toward the continuation of the tradition of tonality into post-triadic music. Using the concept of consonance–dissonance as expounded by a 19th-century German acoustician, Hermann von Helmholtz, Hindemith provided a method of classifying harmonies by computing the frequencies of vibration interferences produced by their constituent frequencies. His most original contribution was his use of consonance–dissonance as a controlling factor in phrase design.

The most influential of the concepts of the German composer Karlheinz Stockhausen is the breaking down of the field of musical perception into controlling and dependent factors. Beginning with the concept of total organization of all parameters by the composer (*e.g.*, pitch, rhythm, dynamics, tone colour, stress, and all other facets of sound), Stockhausen proceeded to a fluid concept of musical control, allowing for much indeterminacy.

The theories of the U.S. composer John Cage are largely aesthetic, with philosophical and religious (specifically, Zen Buddhist) overtones. Insisting that all sounds and also silence itself are materials for music, he developed a theory that places duration at the centre of musical organization. This was followed by an interest in chance and indeterminancy as valid modes of composition.

The theories of the Greek composer Yannis Xenakis concern the use of probability theory and statistical distribution in composition. His interest in applying mathematical models led him to use computers extensively.

APPLICATION OF MATHEMATICS TO MUSIC

By far the oldest and most widespread application of mathematics to music is the derivation of pitch scales and rhythmic proportions by means of whole number fractions referring either to frequency or to tempo ratios. The

Chinese, the Indian, the Islāmic, and the ancient Greek pitch systems were derived in this way. The medieval western European pitch system was similarly based upon modes derived from Pythagorean traditions. Only with the introduction of temperament (the system of tuning in which the intervals deviate from the "pure") in Europe during the Baroque era was this kind of system abandoned. Equal temperament was proposed at about the same time in China but was rejected. In spite of the adoption of equal temperament in the West in the 18th century, it was not until the 20th century that compositional techniques of pitch organization, such as serialism, which are not based on proportional tuning, made their appearance. Not only pitch scales but also laws of harmony, in particular the classification of intervals in terms of consonance and dissonance, derive from proportional tuning. Furthermore, the modern metrical system of rhythmic notation, from its inception in the 14th century, is based upon the same mathematical procedure.

Triadic tuning. The lists of intervals in their order of consonance, given by most medieval and Renaissance theorists after the 9th-century French monk-musician Hucbald, reflect the kind of tuning system favoured by the musicians of the time. The shift from Pythagorean to triadic tuning is reflected in the greater consonance allowed to thirds and sixths by later theorists. That the acceptance of new consonances was accompanied by a shift in methods of tuning can be verified by the monochord experiments detailed by theorists. From these it is clear, for instance, that the precise size and, hence, tuning of the major third dealt with by earlier theorists differed from that which later came to be preferred. Early medieval theorists, following the Pythagorean system, derived the proper tuning of the third (as well as that of the entire diatonic scale) by tuning a series of fifths: as C–G, G–D, D–A, A–E, the resulting notes C and E then forming a major third. This process yielded a sound-frequency ratio of $^{81}/_{64}$ as the relation of top to bottom pitch. Later theorists adopted a major third the frequency ratio of which was the simpler $^{5}/_{4}$, a proportion found in the harmonic series or component vibration pattern of vibrating strings and air columns. For its relation to the natural harmonic series, this later third was known as a "just" third. It differed in size only minutely from the earlier third, by a ratio of $^{81}/_{80}$ ($^{5}/_{4} = {}^{80}/_{64}$; *cf.* $^{81}/_{64}$ for the Pythagorean third), but its sound was generally regarded as more consonant. Although $^{5}/_{4}$ involves a higher prime number (81 is factorable into $3 \times 3 \times 3 \times 3$) than previously allowed in a consonance, the ear superseded previous theory (but was given legitimacy by invoking the physics of vibrating strings).

Importance of sixths and thirds

This example may shed some light upon how one musical system succeeds another. The simplest pentatonic scale, one used the world over, is obtained by tuning four successive fifths. If, in the interest of filling in the two largest intervals of this scale, two more fifths are added to the succession, the result is a seven-tone diatonic scale—*i.e.*, one consisting of five whole and two half steps. The Pythagorean thirds and sixths of this scale are dissonant. If, in order to obtain smoother thirds and sixths, the system of just intonation is adopted, an alternative tuning of the seven-tone scale becomes available. These scales received letter or syllable names in India and in Europe.

The diatonic scale

Although two chromatic inflection symbols (♯ and ♭) were introduced to take care of additional fifths or thirds added to the scale, as in forming the 12-tone chromatic scale from a combination of the major and minor seven-tone diatonic scales, no such pair of symbols was introduced to distinguish in notation between Pythagorean and just thirds and sixths. Such a pair of symbols (+ and −) would refer to the syntonic comma ($^{81}/_{80}$, or about one-tenth of a tone), an interval too small to be easily perceptible in general usage, while ♯ and ♭ refer to a much larger interval (about a half tone).

Modern practice. While the common practice period took for granted the permanence of both the tuning system of 12-tone equal temperament and the harmonic and melodic tradition of triadic tonality, the 20th century has called both of these practices into question. The condition of harmonic practice at the end of the 19th century resembled, in some ways, the condition of polyphony in the 13th century, when the use of thirds and sixths began to become widespread. During the last half of the 19th century, extended tertian chords (*i.e.*, derived by the superimposition of thirds) such as sevenths, ninths, 11ths, and 13ths (comprising three, four, five, and six superimposed thirds) became increasingly prevalent. In both cases, dissonances resulting from combinations of consonances became so prevalent as to demand acceptance as consonances. In the earlier case, a simpler tuning system was replaced by a more complex one; in the recent one, many composers abandoned harmonic organization according to the principle of consonance–dissonance. This coincided with a rejection of the tradition of tonality. In order to provide an alternative system of ordering pitch in atonal music, Schoenberg, the first to grapple with this problem, developed the tradition of thematic unity into an all-pervasive, 12-tone serialism. Serialism proved useful not only for pitch but for almost any materials capable of manipulation by the composer. As John Cage pointed out, the ultimate application of atonal thinking is the abandonment of tone as a controlling factor.

At the same time, there have been efforts to devise a new pitch system in place of the old one. The most prevalent of these new systems have been those based upon tempered subdivisions of the 12-tone equal-tempered scale. In other cases, a new pitch system has been based upon some kind of just intonation. The best known such system is that of a U.S. composer, Harry Partch, whose 43-tone scale is based upon sound frequency ratios expressible as fractions utilizing the prime numbers two, three, five, seven, and eleven. A less-complex system than Partch's is that devised by the Dutch theorist Adriaan Fokker, associated with a 31-tone tempered scale.

Much music since 1950 has dealt principally with schemes of organization based on less-precise kinds of design. For this reason, the period since 1950 has seen extensive experiment with notational methods designed to communicate these less specific modes of order. Such problems as the use of chance and indeterminacy in composition and performance or the use of statistical ordering procedures raise basic questions regarding the kind and degree of the order in music. It is because of the widespread concern about these and related matters that aspects of communications theory such as information theory and systems analysis are finding a role in mid-20th-century music theory.

Use of the chance factor

As the world's cultures become aware of each other's traditions through improved communications, the need increases for theoretical tools and concepts sufficiently versatile and nonrestrictive to show the relationship between very diverse kinds of thinking. The exploration of the nature of human intelligence affords one of the most fruitful sources for concepts useful in this endeavour. For this reason, many aesthetic theorists have sought to express their concepts mathematically, in the form of algorithms capable of producing or recognizing specific kinds of systematic order via computers. (An algorithm is a procedure by which one class of problems can be solved and in which the initial state is connected with the final state by an uninterrupted succession of intermediate states, each of which is generated by its predecessor.) The necessity to be absolutely specific about every detail of a computer program is an excellent way of discovering in any discipline exactly what assumptions have been made besides those that are explicitly recognized. Aesthetic behaviour is an especially revealing facet of human activity, connecting as it does sensory-motor, intellectual, and emotional modes of behaviour. Music especially involves activities organized by means as various as improvisation and mathematics.

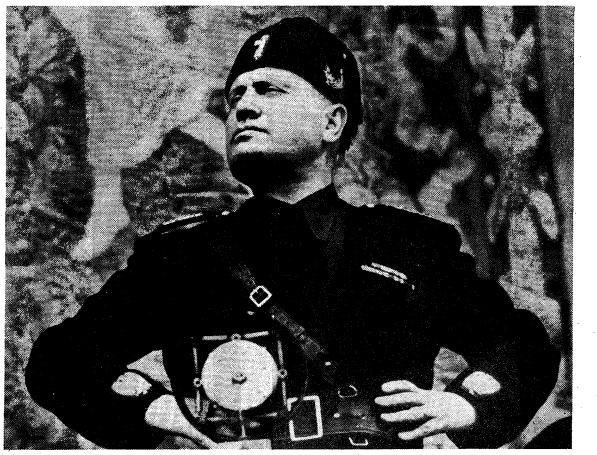
pear to be compatible activities satisfying analogous requirements; and "From Musical Ideas to Computers and Back," in HARRY B. LINCOLN (ed.), *The Computer and Music*, pp. 23–36 (1970), about the conditions under which systems of digital and analog computers would assist a composer in creating and generating music of contemporary relevance and significance; JOHN CAGE, *Silence: Lectures and Writings* (1961), *A Year From Monday: New Lectures and Writings* (1967), and *Notations* (1969), publications of one of the most influential 20th-century composers; ALAIN DANIELOU, *An Introduction to the Study of Musical Scales* (1943), deals with the problem of scales and modes on an intercultural basis, particularly in relating those of India to those of ancient Greece; HERMANN HELMHOLTZ, *Die Lehre von den Tonempfindungen als physiologische Grundlage für die Theorie der Musik*, 3rd ed. (1870; Eng. trans., *On the Sensations of Tone As a Physiological Basis for the Theory of Music*, 1875), still an indispensable treatise for one interested in the acoustics, and to some extent, the physical aspects of music; PAUL HINDEMITH, *Unterweisung im tonsatz*, 2 vol. (1937–39; Eng. trans., *The Craft of Musical Composition*, 2 vol., 1941–42; 4th ed. reprinted 1970), presents the composer's personal approach to writing and analyzing music, and contains analyses of a number of 20th-century compositions; LEONARD B. MEYER, *Emotion and Meaning in Music* (1956), an investigation of the nature of emotional and intellectual meaning in music, the responses to musical stimuli, and the social and psychological conditions under which communication takes place in a musical experience; ABRAHAM MOLES, *Théorie de l'information et perception esthétique* (1958; Eng. trans., *Information Theory and Esthetic Perception*, 1966), the earliest and most thorough attempt to apply to sequences of musical events the mathematical theories of information developed by Shannon, Weaver, and others for linguistic codes; HARRY PARTCH, *Genesis of a Music* (1949), a personal exposition of one of the 20th-century's most individualistic aesthetics, as remarkable for its philosophy as for its detailed theories of tuning and instrumentation; LEON PLANTINGA, "Philippe de Vitry's *Ars Nova*: A Translation," *Journal of Music Theory*, 5:204–223 (1961), an epochal treatise of the early 14th century that presents a notation capable of expressing more precisely a greater variety of rhythmic relationships than theretofore possible in writing; GEORGE PERLE, *Serial Composition and Atonality: An Introduction to the Music of Schoenberg, Berg, and Webern*, 2nd ed. rev. (1968), a lucid introduction to early twelve-tone practice that emphasizes motivic manipulation and the atonal origins of serialism (many examples and analyses are included); HUGO RIEMANN, *System der musikalischen rhythmik und metrik* (1903); and *Die Natur der Harmonik* (1882; Eng. trans., *The Nature of Harmony*, 1886), views all music from the point of view of Riemann's own musical and intellectual heritage—19th-century Germany; HEINRICH SCHENKER, *Neue musikalische Theorien und Phantasien*, vol. 1 (1906; Eng. trans., *Harmony*, 1954), one of the most influential theoretical treatises of the first half of the 20th century that involves reducing harmony and melody to their skeletal and functional frameworks; ARNOLD SCHOENBERG, *Style and Idea* (1950), a collection of essays on various aspects of music that gives insights into the author's thinking about music, both technically and emotionally; KARLHEINZ STOCKHAUSEN, "How Time Passes," *Die Reihe*, no. 3, pp. 10–40 (1959), an attempt to apply serial concepts to the notation of time and to take time and its ordering to be the basis for composition (difficult and occasionally obscure, but influential and controversial); OLIVER STRUNK (ed.), *Source Readings in Music History from Classical Antiquity Through the Romantic Era* (1950), contains basic readings, in English translation, of many relevant areas of music theory, especially of Medieval and Renaissance theory.

(B.B.J.)

Mussolini, Benito

The first of Europe's Fascist dictators and the authoritarian head of the Italian state for more than 20 years, Mussolini first seized power in a coup d'etat in 1922 as the leader of a nationalist, anti-Communist political party, whose policy was based on force and supported by black-shirted military squads. Having established a totalitarian dictatorship, he imposed order upon the country and carried out extensive schemes of social reform and public works. But, impelled by territorial ambitions, he invaded Abyssinia in 1935, occupied Albania in 1939, and declared war on the Allies in 1940, leading Italy to exhaustion and defeat and his regime to extinction.

Early life. Mussolini was born near the small town of Predappio in the Romagna district of central Italy on July 29, 1883, the first child of the local blacksmith. In later years he expressed pride in his humble origins and often spoke of himself as a "man of the people." Although the Mussolini family was, in fact, less humble than he alleged—his father, a part-time Socialist journalist as well as a blacksmith, was the son of a lieutenant in the National Guard, and his mother was a schoolteacher—the Mussolinis were certainly poor. They lived in two crowded rooms on the second floor of a small, decrepit *palazzo*; and, because the blacksmith spent much of his time discussing politics in taverns and most of his money on his mistress, the meals that were eaten by his three children were often meagre.



Mussolini.
H. Roger-Viollet

Schooling and early jobs. Benito was a quarrelsome, restless child, who was disobedient, unruly, and aggressive. He was a bully at school and moody and introspective at home. "One day," he told his mother, "I shall make the whole earth tremble." Because the teachers at the village school could not control him, he was sent to board with the strict Salesian Fathers at Faenza, where he proved himself more troublesome than ever, stabbing a fellow pupil with a penknife and attacking one of the Fathers who had attempted to beat him. He was expelled and sent to the Giosuè Carducci School at Forlimpopoli, from which he was also expelled after assaulting another pupil with his penknife.

Turbulent youth

Although a violent and intractable child, he was also intelligent; and he passed his final examinations without difficulty. He obtained, also without difficulty, a teaching diploma and for a time worked as a schoolmaster. But he soon realized that he was totally unsuited for such work—too restless, too ambitious, too impatient. "I was a Bohemian in those days," he wrote, "I made my own rules and I did not keep even them." At the age of 19, a short, pale young man with a powerful jaw and enormous, dark, piercing eyes, he left Italy for Switzerland with a nickel medallion of Karl Marx in his otherwise empty pockets.

For the next few months, according to his own account, he lived from day to day, carelessly and recklessly; jumping from job to job, working as a building labourer and in a butcher's shop, as a delivery man and a factory hand; sleeping in public lavatories, under bridges, with any women who would have him and threatening to rape those who would not.

Recognition as a journalist and orator. At the same time, however, he was gaining a reputation as a young man of strange magnetism and remarkable rhetorical talents. He read widely and voraciously, if not deeply, plunging into Kant and Spinoza, Kropotkin and Nietzsche, Hegel, Kautsky, and Sorel, picking out what appealed to him and discarding the rest, forming no coherent political philosophy of his own yet impressing his companions as a potential revolutionary of uncommon personality and striking presence. While earning a reputation as a political journalist and public speaker, he undertook propaganda for a building trade union, proposing a general strike and advocating violence as a

means of enforcing the workers' demands. Repeatedly, he called for a day of vengeance; more than once he was arrested and imprisoned. When he returned to Italy in 1904, even the Roman newspapers had started to mention his name.

For some time after his return little was heard of him. He once more became a schoolmaster, this time in the Venetian Alps, north of Udine, where he lived, so he confessed, a life of "moral deterioration," neglecting his unwelcome duties, drinking too much, making flamboyant speeches to the fountain in the village square, contracting syphilis. But soon tiring of so wasteful a life, he returned to trade-union work, to journalism, and to extreme politics, which led yet again to arrest and imprisonment.

Marriage to Rachele Guidi

During a period of freedom in 1909 he fell in love with 16-year-old Rachele Guidi, the younger of the two daughters of his father's widowed mistress; she went to live with him in a damp, cramped apartment in Forlì and later married him. Soon after the marriage, Mussolini was imprisoned for the fifth time; but by then Comrade Mussolini had become recognized, both as journalist and orator, as one of the most gifted, and dangerous, of Italy's younger Socialists.

After writing in a wide variety of Socialist papers, he founded a newspaper of his own, *La Lotta di Classe* ("The Class Struggle"), all four pages of which he wrote himself. So successful was this paper that in 1912 he was appointed editor of the official Socialist newspaper, *Avanti!*, whose circulation he soon doubled; and as its anti-militarist, anti-nationalist, and anti-imperialist editor, he thunderously opposed Italy's intervention in World War I.

Soon, however, he changed his mind about intervention. Swayed by Karl Marx's aphorism that social revolution usually follows war, and persuaded that "the defeat of France would be a death-blow to liberty in Europe," he began writing articles and making speeches as violently in favour of war as previously he had condemned it. He resigned from *Avanti!* and, financed by a publisher who favoured war against Austria, he assumed the editorship of *Il Popolo d'Italia*, in which he unequivocably stated his new philosophy: "From today onwards we are all Italians and nothing but Italians. Now that steel has met steel, one single cry comes from our hearts—*Viva l'Italia!*" It was the birth cry of Fascism. To shouts of "Traitor!" "Cutthroat!" "Scoundrel!" Mussolini was expelled from the Socialist Party. He went to fight in the war.

Rise to power. Wounded while serving with the Bersaglieri (a corps of sharpshooters), he returned home a convinced anti-Socialist and a man with a sense of destiny. As early as February 1918, he was advocating the emergence of a dictator—"a man who is ruthless and energetic enough to make a clean sweep." Three months later, in a widely reported speech at Bologna, he hinted that he himself might prove to be such a man.

Advocation of a dictatorship

The birth of Fascism. The following year the nucleus of a party prepared to support his ambitious idea was formed in Milan. In an office in Piazza San Sepolcro about 200 assorted republicans and anarchists, syndicalists and discontented Socialists, restless revolutionaries and discharged soldiers met to discuss the establishment of a new force in Italian politics. Mussolini called this force a Fasci di Combattimento, a group of fighters bound together by ties as close as those that secured the *fascinae* of the lictors—the symbols of ancient Roman authority. So Fascism was created and its symbol devised; and in Mussolini Fascism had found its natural *duce* (leader).

In rally after rally, surrounded by supporters wearing black shirts, which the labourers of the Romagna had adopted as the uniform of the anarchists, Mussolini caught the imagination of the crowds. His physique was impressive; his style of oratory, staccato and tautophonic, was superb; his voice was described by an English admirer as the most beautiful she had ever heard. His attitudes were highly theatrical, his opinions were contradictory, his facts were often wrong, and his attacks were frequently malicious and misdirected; but his words were so dramatic, his metaphors so apt and striking, his vigorous, repetitive gestures so extraordinarily effective, that he rarely failed to impose his mood upon his audience.

Throughout the immediate postwar years, the Fascist *squadristi* marched through the towns and villages of Italy, singing patriotic songs, shouting nationalist slogans, waving skull-embroidered flags, attacking Socialists and Communists and all who sympathized with them, gathering more and more recruits. They provoked and intensified an anarchic situation in Italy, trying to prepare the people for the authoritarianism of the dictator that Mussolini prescribed as a cure for the nation's ills.

The march on Rome. In the summer of 1922 Mussolini's opportunity presented itself. To the dismay of the Italian people as a whole, a general strike was called. Mussolini declared that unless the government prevented the strike, the Fascists would. "Either the government will be given to us," he threatened at a gathering of 40,000 Fascists in Naples, "or we will seize it by marching on Rome. It is a matter of days, of hours. . . . I guarantee, I swear to you that the orders . . . will come." Responding to his oratory the assembled Fascists excitedly took up the cry, shouting in unison "Roma! Roma! Roma!" All appeared eager to march.

Later that day, Mussolini and other leading Fascists decided that in four days' time—following Fascist-provoked riots and the occupation of police and radio stations, prefectures, and post offices—the Fascist militia would advance upon Rome in converging columns led by four leading party members later to be known as the Quadrumviri. Mussolini himself was not one of the four. Indeed, in the opinion of one of them—Italo Balbo, a young hero of the *squadristi*—Mussolini's character was not suited to the determined leadership of a coup d'état. So hesitant, capricious, and vacillating did Mussolini prove to be at this critical period, Balbo said afterward, that he had to be firmly told that the Fascists were going to Rome, either with or without him.

In fact, even at this late stage Mussolini was still hoping for a political compromise, and he was still in touch with other parties outside the Fascist camp. He returned to Milan, determined to remain there until he could be sure that the crisis was about to be resolved, prevaricating when more zealous Fascists urged him to move to Rome and to seize the power so nearly within his grasp. He refused to move before King Victor Emmanuel III summoned him in writing. Meanwhile, all over Italy the Fascists prepared for action, and the march on Rome began. Although the march was a far less orderly affair than Fascist propaganda later suggested, it was sufficiently threatening to bring down the government. And the King, prepared to accept the Fascist alternative, dispatched the telegram for which Mussolini had been waiting.

Appointment as prime minister

Dictatorship. Mussolini's obvious pride in his achievement at becoming (October 31, 1922) the youngest prime minister in Italian history was not misplaced. He had certainly been aided by a favourable combination of circumstances, both political and economic; but his remarkable and sudden success owed quite as much to his own personality, to native instinct and shrewd calculation, to astute opportunism, and to his unique gifts as an agitator.

In the first speech he made in the Chamber after the march on Rome, Mussolini declared, "I could have transformed this grey hall into an armed camp of Blackshirts, a bivouac for corpses. I could have nailed up the doors of Parliament."

Yet, although he had achieved power by force, initially he exercised it with restraint. Anxious to demonstrate that he was not merely the leader of Fascism but also the head of the government of a united Italy, he presented to the King a list of ministers, a majority of whom were not members of his party. He made it clear, however, that he intended to govern authoritatively and personally. He demanded and obtained full dictatorial powers for a year; and in that year he pushed through a law that enabled the Fascists to secure a majority in the Chamber. The elections in 1924, though undoubtedly fraudulent, firmly secured his personal power; it was a power that he was to keep for more than 20 years.

The popular leader. Indeed, in the early days of his rule, the Italian people welcomed his authority. They were tired of strikes and riots, responsive to the flamboyant techniques and medieval trappings of Fascism, and ready to submit to dictatorship, provided the national economy was stabilized and their country restored to its dignity. Mussolini seemed to them the one man capable of bringing order out of chaos. Soon order had been restored, the conditions of the workers had begun to improve, and ambitious programs of public works had been inaugurated; and it was he who was given the credit for Fascism's apparent success. After his regime had survived the shock of the murder by Fascists of the distinguished Socialist leader, Giacomo Matteotti, Mussolini was accepted throughout Italy at his own evaluation as Italy's man of destiny.

World-wide acclaim

It was not only Italians who fell under the sway of his massive, proudly jutting jaw and black, wide-open eyes and who thrilled to the sight of him as he stood gazing down impassively upon his admirers from the balcony outside his office in the Palazzo Venezia in Rome, his hands upon his hips, his legs splayed apart, awaiting the moment when he would enthrall them with expressive gestures and deep, emotive voice. He was hailed as a genius and a superman by public figures all over Europe and in the United States, compared to Caesar, to Napoleon, and to Cromwell. The American Cardinal O'Connell of Boston said that Mussolini was a genius given to Italy by God; Winston Churchill declared that he himself would have donned the Fascist black shirt, had he been an Italian.

Mussolini's achievements were considered scarcely less than miraculous. He had transformed and reinvigorated his divided and demoralized country; he had carried out his social reforms and public works without losing the support of the industrialists and landowners; he had even succeeded in coming to terms with the papacy.

He was undoubtedly more popular in Italy than anyone had ever been before, despite his sure destruction of civil liberties. After Mussolini had survived an attempt upon his life by an unbalanced Irishwoman, the secretary of the Fascist Party announced to wildly cheering crowds, "God has put his finger on the Duce! He is Italy's greatest son, the rightful heir of Caesar!" And the crowds roared their approval and devotion.

The private man. Yet beneath the public figure, there was a different Mussolini—far less decisive, less magnanimous, less omniscient. For all his undoubted gifts, he remained essentially a journalist rather than a statesman; and his true genius lay in his ability to manipulate the masses by the written and spoken word. As the years progressed his intimates recognized that behind the bluster, the cunning, and the charm, the Duce was coarse and childish, unstable and irresolute, suspicious, deceitful, and pathologically egotistic. From Turin to Naples, walls were covered with the words that set out the fundamental tenet of Fascist doctrine: "*Il Duce ha sempre ragione*" ("The Duce is always right"). But those who knew him best knew that in truth the Duce was often wrong. He knew little of how to run a government and had no patience with difficult work; he was even known to have carelessly written "Approved" on two conflicting memorandums emanating from two different ministries before going upstairs to one or another of his mistresses. The light was left burning in his office far into the night; but there was no one there.

Foreign policies. Nevertheless, throughout the 1920s and the early 1930s Mussolini remained a hero to his own people and profoundly respected in the outside world. He might, indeed, have remained so until his death had not his callous xenophobia and arrogance, his misapprehension of Italy's fundamental necessities, and his dreams of empire led him to look about for foreign conquest.

His eye rested first upon Abyssinia, which, after ten months of preparations, rumours, threats, and hesitations, Italy invaded in October 1935. Europe expressed its horror; but, having done so, did no more. Sanctions were imposed by the League of Nations; yet care was taken to ensure that the list of prohibited exports should not include any, such as oil, that might provoke a European war. Had he been faced with oil sanctions, Mussolini said, he would have had to withdraw from Abyssinia within a week. But he was faced with no such problem; and on the night of May 9, 1936, he was able to announce to an enormous, expectant crowd of about 400,000 people standing shoulder to shoulder around Piazza Venezia, that "in the 14th year of the Fascist era" a great event had been accomplished: Italy had its empire.

Alliance with Hitler

Italy had also found a new ally. Intent upon his own ambitions in Austria, Hitler had actively encouraged Mussolini's African adventure, and, under Hitler's guidance, Germany had been the one powerful country in western Europe that had not turned against Mussolini. The way was now open for the Pact of Steel—a Rome–Berlin Axis and a brutal friendship between Hitler and Mussolini that was to ruin them both.

Hitler had long admired Mussolini, but the admiration had not been returned. The Duce had viewed Hitler with a kind of amused contempt. "He's quite mad," he had said after meeting him for the first time, "a silly little clown." As for Hitler's National Socialism, Mussolini saw it as merely the "revolt of the German tribes of the old primeval forest." But as Hitler piled triumph upon triumph, and succeeded in one aggressive gamble after another, Mussolini became increasingly respectful of German might and jealous of his rival.

Role in World War II. The outbreak of World War II in 1939 faced Mussolini, therefore, with a cruel dilemma. Although he had for years been the victim of his own propaganda, although he had grown accustomed to subordinates telling him what he wanted to be told, he recognized in his more thoughtful moments that the country was ill-prepared for war. The Abyssinian campaign, followed by Italian intervention on Francisco Franco's side in the Spanish Civil War (1936–39), and the Italian occupation of Albania (April 1939) had placed a great strain on the country's already inadequate military resources. Mussolini boasted proudly of the "8,000,000 bayonets" that could be mobilized to fight the enemy at any moment; but because he had been in charge of all three service ministries since 1925—apart from a short break between 1929 and 1933—he was well aware of the falsity of Italian military pretensions, the lack of modern tanks, artillery, and aircraft, and the weakness of the navy. Moreover, Abyssinia and the other recently acquired Italian possessions in North Africa needed a long period of peace for their stability; so did Albania. In Italy, peace was equally needed to move factories, plant, and machinery to the impoverished south from the congested industrial centres of the north and to improve Italian holdings of foreign currency.

Yet, while Mussolini understood that peace was essential to Italy's well-being, that a long war might prove disastrous, and that he must not "march blindly with the Germans," he was beset by fears that the Germans "might do good business cheaply" and that by not intervening he would lose his "part of the booty." His foreign secretary and son-in-law, Count Galeazzo Ciano, recorded that during a long, inconclusive discussion at the Palazzo Venezia, Mussolini at first agreed that Italy must not go to war, "then he said that honour compelled him to march with Germany."

Italian intervention. Mussolini watched the progress of Hitler's war with bitterness and alarm, becoming more and more bellicose with each fresh German victory, while frequently expressing hope that the Germans would be slowed down, would meet with some reverse that would satisfy his personal envy and give Italy a breathing space. When Germany marched westward, however, and France seemed on the verge of collapse, Mussolini felt he could delay no longer. To Marshal Pietro Badoglio, the army chief of staff, who urged caution and delay, he declared,

> You, Marshal, are not calm enough to judge the situation. I can tell you that everything will be over by September and that I only need a few thousand dead so that I can sit at the peace conference as a man who has fought.

So, on June 10, 1940, the fateful declaration of war was made.

From the beginning, the war went badly for Italy.

France surrendered before there had been the opportunity for even a token victory; and Mussolini left for a meeting with Hitler, sadly aware, as Ciano put it, that his opinion had "only a consultative value." Indeed, from then on Mussolini was obliged to face the fact that he was very much the junior partner in the Axis alliance.

Mussolini's subordination to Hitler

Thenceforth, every time he met Hitler throughout the war, the failure of Italian arms was uppermost in his mind; and he was forced to listen, while Hitler talked at interminable length about past German victories and future German plans. To make his meetings with Hitler more intolerable, the Germans kept the details of their plans concealed, presenting their allies with a *fait accompli* for fear lest prior discussion would destroy surprise. "All Italians chatter like gypsies," the German propaganda minister Josef Goebbels had warned; and Hitler had heeded the warning. "Our aims," Hitler had decided before the war began, "must remain hidden from Italy." And thus such moves as the occupation of Romania and the later invasion of the Soviet Union were undertaken by Germany without any prior warning being given to Mussolini.

It was to "pay back Hitler in his own coin," as Mussolini openly admitted, that he decided to attack Greece through Albania without advising the Germans of his plans. Hitler had always intended that Mussolini should concentrate his efforts upon ejecting the British from Egypt and the Middle East; exasperated by the slowness of his commanders in North Africa, however, the Duce turned upon Greece instead. The result was an extensive and ignominious defeat, and the Germans were forced unwillingly to extricate him from its consequences. Hitler also had to come to his ally's help in North Africa; and the Germans began to take precautions against the likelihood of an Italian collapse. When the Allies successfully invaded Sicily in July 1943, it was obvious that collapse was imminent.

Fall from power. For some time Italian Fascists and non-Fascists alike had been preparing Mussolini's downfall. On July 24, at a meeting of the Fascist Grand Council—the supreme constitutional authority of the state, which had not met once since the war began—a resolution was passed by an overwhelming majority in effect dismissing Mussolini from office. Disregarding the vote as a matter of little concern and refusing to admit that his minions could harm him, Mussolini appeared at his office the next morning as though nothing had happened. That afternoon, however, he was arrested by royal command on the steps of the Villa Savoia after an audience with the King.

Last years. Imprisoned first on the Island of Ponza, then on a remoter island off the coast of Sardinia, he was eventually transported to a hotel high on the Gran Sasso d'Italia in the Abruzzi Mountains, from which his rescue by the Germans was deemed impossible. Nevertheless, by crash-landing gliders on the slopes behind the hotel, German commandos effected his rescue and flew the Duce to Munich.

Rather than allow the Germans to occupy and govern Italy entirely in their own interests, Mussolini agreed to Hitler's suggestion that he establish a new republican Fascist government in the north and execute those members of the Grand Council, including his son-in-law, Ciano, who had dared to vote against him. But the Repubblica Sociale Italiana thus established at Salò was, as Mussolini himself grimly admitted to visitors, no more than a puppet government at the mercy of the German command. And there, living in dreams and "thinking only of history and how he would appear in it," as one of his ministers said, Mussolini awaited the inevitable end.

As German defenses in Italy collapsed and the Allies advanced rapidly northward, the Italian Communists of the partisan leadership determined upon Mussolini's execution. Rejecting the advice of various advisers, including the elder of his two surviving sons—his second son had been killed in the war—Mussolini refused to consider flying out of the country, and he made for the Valtellina, intending to make a final stand in the mountains; but only a handful of men could be found to follow him. He tried to cross the frontier disguised as a German soldier in a convoy of trucks retreating toward Innsbruck. But he was recognized and, together with his mistress Claretta Petacci, who had insisted on remaining with him to the end, he was shot and killed near Azzano on April 28, 1945.

Capture and execution

Mussolini's death was greeted by the great mass of the Italian people without regret. He had lived beyond his time and had dragged his country into a disastrous war, which it was unwilling and unready to fight. His achievements were forgotten; and it was not until many years later, when Fascism could be viewed objectively as a short episode in Italy's long history, that they could be truly assessed.

BIBLIOGRAPHY. All biographies of Mussolini will eventually be superseded by that of RENZO DE FELICE, whose first three volumes deal exhaustively with his career up till 1929. These are *Mussolini il rivoluzionario, 1883–1920* (1965); *Mussolini il fascista, 1921–1925* (1966); and *Mussolini il fascista, 1925–1929* (1968). At present the most comprehensive biography is GIORGIO PINI and DUILIO SUSMEL, *Mussolini, l'uomo e l'opera*, 4 vol. (1953–55). The best biography in English is IVONE KIRKPATRICK, *Mussolini* (1964). LAURA FERMI, *Mussolini* (1961), is particularly valuable for the years of power; and CHRISTOPHER HIBBERT, *Il Duce: The Life of Benito Mussolini* (1961), for the final phase. ROY MACGREGOR-HASTIE, *The Day of the Lion* (1964), is an original and controversial study of Mussolini's hold upon the Italian people. GAUDENS MEGARO, *Mussolini in the Making* (1938), provides a detailed account of his origins and early years; and PAOLO MONELLI, *Mussolini, piccolo borghese* (1950; Eng. trans., *Mussolini: An Intimate Life*, 1953), gives the best portrait of the man. There are some details not elsewhere available in RICHARD COLLIER, *Duce! The Rise and Fall of Benito Mussolini* (1971).

(C.Hi.)

Mussorgsky, Modest

A leading composer of the 19th century, Mussorgsky was one of the first to use Russian folk music as a basis for his compositions. He is chiefly noted for the realism of his music as expressed in his songs and operas, the best known of which is *Boris Godunov*. His importance and influence on later composers is out of proportion to his relatively small total output. Few composers, however, were less derivative, more bold and original in their musical language.

The Bettmann Archive

Mussorgsky, portrait by Ilya Repin, 1881. In the Gosudarstvennaya Tretyakovskaya Galeriya, Moscow.

Modest Petrovich Mussorgsky was born on March 21, (March 9, old style), 1839, at Karevo in the province of Pskov. He was the son of a landowner but had peasant blood, his father's grandmother having been a serf. According to his autobiographical sketch, written in 1881, Mussorgsky claimed that he learned about Russian fairy tales from his nurse. "This early familiarity with the spirit

of the people, with the way they lived, lent the first and greatest impetus to my musical improvisations. . . ." His mother, herself an excellent pianist, gave Modest his first piano lessons, and at seven he could play some of Franz Liszt's simpler pieces.

In August 1849 his father took Modest and also his other musical son, Filaret, to St. Petersburg (now Leningrad), where Modest attended the Peter-Paul School in preparation for a military career. At the same time, mindful of Modest's musical bent, their father entrusted the two boys to Anton Gerke, future professor of music at the St. Petersburg Conservatory.

In 1852, after a short period at another preparatory school, Mussorgsky entered the School for Cadets of the Guard. There, in his first year he composed his *Podpraporshchik* (*Porte-Enseigne Polka*), published at his father's expense. Although not the most industrious of students, he gave proof of tremendous curiosity and wide-ranging interests. His lifelong enthusiasm for literature, history, painting, philosophy, science, astronomy, and theology was already evident, to say nothing of music, as attested by his frequent and lengthy visits with his religion instructor, Father Krupsky, who taught him "the very essence of church music—the music of the Greek, Catholic, Protestant and Lutheran churches."

First published work

In 1856, by now a lieutenant, Mussorgsky joined the Preobrazhensky Guards, one of Russia's most aristocratic regiments, where he made the acquaintance of several music-loving officers who were habitués of the Italian theatre. During this same period he came to know Aleksandr Borodin, a fellow officer who was to become another important Russian composer. Borodin has provided a very vivid picture of the musician:

> There was something absolutely boyish about Mussorgsky; he looked like a real second-lieutenant of the picture books . . . a touch of foppery, unmistakable but kept well within bounds. His courtesy and good breeding were exemplary. All the women fell in love with him. . . . That same evening we were invited to dine with the head surgeon of the hospital. . . . Mussorgsky sat down to the piano and played . . . very gently and graciously, with occasional affected movements of the hands, while his listeners murmured, "charming! delicious!"

During the winter of 1856 a regimental comrade introduced Mussorgsky into the home of the Russian composer Aleksandr Dargomyzhsky. At one of the musicales there, Mussorgsky discovered the music of the seminal Russian composer Mikhail Glinka, and this quickened his own Russophile inclinations. Three years later, in June 1859, he saw the Moscow Kremlin for the first time, an important experience that represented his first "physical" communion with Russian history. Later he was to say: "To bring the past into the present—that is my task!" Through Dargomyzhsky, Mussorgsky met another composer, Mily Balakirev, who became his teacher. Since the death of their father (in 1853), the Mussorgsky brothers had seen their poorly administered patrimony decrease substantially. Now, with the freeing of the serfs, it vanished. Mussorgsky, having decided to devote himself to music, had quit the army three years earlier and, since 1863, had been working as a civil servant in the Ministry of Communications. His distressing financial troubles date from that time, and he had to seek the help of moneylenders. Mussorgsky achieved artistic maturity in 1866 with a series of remarkable songs about ordinary people; an even larger series appeared the following year. In 1868 he reached the height of his conceptual powers in composition with the first song of his incomparable cycle *Detskaya* (*The Nursery*) and a setting of the first act of Nikolay Gogol's *Zhenitba* (*The Marriage*).

Composition of *Boris Godunov*

In 1869 he settled on his great work *Boris Godunov*, to his own libretto based on a book by Aleksandr Pushkin. The first version, completed on December 27, 1869, was rejected by the advisory committee of the imperial theatres. In no way discouraged, the composer returned to the task and on August 4, 1872, put the finishing touches to the second version, adding the roles of Marina and Rangoni as well as several new episodes. The first production of *Boris* took place on February 8, 1874, at St. Petersburg.

In spite of the work's success, Mussorgsky was not happy. His solitude and bitter ordeal now commenced. Having once loved a cousin who died prematurely and having remained faithful to this memory, the composer never married. In 1865, after the death of his mother, he lived with his brother, then shared a small flat with the Russian composer Nikolay Rimsky-Korsakov until 1872, when his colleague married. Left very much alone, Mussorgsky began to drink to excess, although the composition of *Khovanshchina* perhaps offered some distraction (left unfinished at his death, this opera was completed by Rimsky-Korsakov). After long months of solitude, he found a companion in the person of a distant relative, Arseny Golenishchev Kutuzov. This impoverished 25-year-old poet inspired his two cycles of melancholy melodies, *Bez solntsa* (*Sunless*) and *Pesni i plyaski smerti* (*Songs and Dances of Death*). At that time Mussorgsky was haunted by the spectre of death—he himself had only seven more years to live. One after another his friends died, the first being the painter Viktor Gartman, who inspired the piano suite *Kartinki s vystavki* (*Pictures from an Exhibition;* orchestrated in 1922 by the French composer Maurice Ravel). In August 1875 Mussorgsky wrote to his great friend the critic Vladimir Stasov: "Arseni took our latch key with him to the country and I was unable to get into our flat, so I went to live with my venerable friend Naumov in whose home I have just finished the first act of *Khovanshchina*." Actually, Arseny had not taken the key; the landlady had put the penniless Mussorgsky's suitcase on the doorstep and locked him out.

Decline and final years

This marked the beginning, in the company of Naumov, of Mussorgsky's downfall and of a solitude made all the more painful by the total neglect of his friends, who, Balakirev included, treated him like an outcast. Nonetheless, the composer, clinging to life, began his opera *Sorochinskaya yarmarka* (unfinished; *Sorochintsy Fair*), inspired by Gogol's tale. As the accompanist of an aging singer, Darya Leonova, Mussorgsky departed on a lengthy concert tour of southern Russia and the Crimea. On his return he tried teaching at a small school of music in St. Petersburg.

On February 24, 1881, three successive attacks laid him low. His friends had him transported to a hospital where for a time his health improved sufficiently for one of the leading Russian artists of the day, Ilya Repin, to paint his portrait. But on March 28 (March 16, O.S.), the nurse attending him heard him cry out: "All is over! . . . How unfortunate I am!" His final agony lasted less than 15 minutes.

Boris Godunov and to a lesser degree *Khovanschina* display Mussorgsky's dramatic technique of setting sharply characterized individuals against the background of country and people. His original orchestration for *Boris*, as opposed to Rimsky-Korsakov's more colourful gloss on it usually heard in the opera house, is as stark and economical as his unorthodox harmony. The songs he composed, many to his own texts, describe scenes of Russian life with great vividness and insight; they also realistically reproduce the inflections of the spoken Russian language.

MAJOR WORKS

OPERAS: *Zhenitba* (1st act only, composed 1868; *The Marriage*); *Boris Godunov* (St. Petersburg, 1874); *Khovanshchina* (completed by Rimsky-Korsakov, St. Petersburg, 1886); *Sorochinskaya yarmarka* (unfinished, composed 1874–80, produced at Moscow, 1913, *Sorchintsy Fair*).

ORCHESTRAL: *Ivanova noch na Lysoy gore* (1867; *St. John's Night on the Bare Mountain*); triumphal march, *Vzyatiye Karsa* (1880; *The Capture of Kars*).

PIANO: *Intermezzo in modo classico* (1861); scherzino, Shveja (1871; *The Seamstress*); suite, *Kartinki s vystavki* (1874; *Pictures from an Exhibition*), later orchestrated by Maurice Ravel.

SONGS: More than 60, including "Noch" (1864; "Night"); "The Seminarist" (1866); "Yevreyskaya pesnya" (1867; "Hebrew Song"); "Po griby" (1867; "Gathering Mushrooms"); "Koziol" (1867; "The He-Goat: A Worldly Story");

"Klassik" (1867; "The Classicist"); "Ozoznik" (1867; "The Ragamuffin"); *Detskaya* (song cycle, 1868–1872; *The Nursery*); *Bez Solntsa* (song cycle, 1874; *Sunless*); *Pesni i plyaski smerti* (song cycle, 1875–77; *Songs and Dances of Death*); "Pesn' Mefistofelja v pogzebke Averbacha" (1879; "Mephistopheles' Song of the Flea").

BIBLIOGRAPHY. The most exhaustive works on Mussorgsky have been published in Russian. An excellent recent study is Георгии Никитич Хубов, *Мусоргский* (1969). Although it has some political overtones, it is very complete, reproducing both an extensive Russian bibliography and a complete list of the major works. Also recommended are ROBERT GODET, *En Marge de "Boris Godounov"* (1926); VLADIMIR FEDOROV, *Moussorgski* (1935); OSKAR VON RIESEMANN, *Modest Petròwitsch Mussorgski* (1923; Eng. trans., 1929); MICHEL HOFMANN, *Le Vrai Visage de Moussorgski* (1952) and *La Vie de Moussorgski* (1964); JAY LEYDA and SERGEI BERTENSSON (eds.), *The Moussorgski Reader* (1947); and MICHEL D. CALVOCORESSI, *Mussorgsky* (1962). A complete edition of Mussorgsky's works was begun in Moscow in 1928; interrupted during the war, publication is once again in progress. Certain volumes have been done in collaboration with Oxford University Press and University Editions.

(M.-R.Ho.)

Mutation

Mutation is a process by which the hereditary constitution of a cell is altered; ultimately, it results in a genetically changed organism or population of cells. Thus, a heritable change of albinism (lack of pigmentation) may appear in an individual of an inbred colony of black rats, or a heritable change to a new seed colour may appear in a true-breeding variety of bean. In bacteria, mutation may result in the emergence of strains that are resistant to the antibiotic drugs by which the original strain was killed. The term mutation was coined in this sense early in the 20th century by the Dutch botanist Hugo de Vries, one of the rediscoverers of the work of the 19th-century Austrian biologist Gregor Mendel. The term has been retained, although it is now known that the changes observed by de Vries were not mutations in the present sense. Mutations in the modern conception, far from always having striking effects, are responsible for the slight changes that play a major role in evolution. See EVOLUTION; HEREDITY; POLYMORPHISM, BIOLOGICAL.

The nature of mutation. Heritable differences in cell constituents other than the nucleus, such as plastids or mitochondria, may have arisen through mutational processes; but the present article deals only with mutations that occur within the cell nucleus. These take place in the genes, which consist of deoxyribonucleic acid (DNA) or, rarely, of ribonucleic acid (RNA). In the chromosomes of all but the most primitive organisms, DNA is combined with protein. DNA is a long molecule with a backbone of two sugar–phosphate chains to which are attached sequences formed of two purine bases, adenine (A) and guanine (G), and two pyrimidine bases, thymine (T) and cytosine (C). The base sequences in the two chains of DNA are complementary to each other; that is, adenine is always paired with thymine and guanine with cytosine. These base pairs are the smallest elements of the genetic code, and their sequence spells the information for the inherited biochemical functions of a cell as well as for the formation of identical genes at each chromosome replication. Mutations arise from substitutions of one base for another or from changes in the sequence of bases. Base substitutions are of two types: transitions, in which a purine is replaced by a purine (*e.g.*, A by G) or a pyrimidine by a pyrimidine (*e.g.*, C by T); and transversions, in which a purine is replaced by a pyrimidine (*e.g.*, A by C) or vice versa (C by A). Changes in the sequence of bases result mainly from insertion or deletion of one or a few bases. In genes specifying a protein such as an enzyme (biological catalyst) or hemoglobin (an oxygen-carrying protein in blood), the code is read in triplets of bases from one end of the gene to the other. A base substitution results in the presence of one wrong protein component (amino acid) in the protein structure. What effect this has on the functioning of the protein depends on the type and position of the wrong amino acid. Certain base substitutions result in "nonsense" triplets that code, not for an amino acid, but for premature termination of the protein structure. Such mutations result in complete loss of function, as do most insertion and deletion mutations, which change the "reading frame," or order of bases, of the gene; as a result, every amino acid coded from the mutated site to the end of the gene is incorrect. Deletions, duplications, inversions, or transpositions of whole genes or sequences of genes may result in hereditary changes that are often difficult or impossible to distinguish from gene mutations.

Origin of mutation

That mutated genes or chromosome regions form replicas of themselves just as do normal genes and chromosomes once was an intriguing aspect of mutation, but is now realized to be a consequence of the complementarity of DNA. After a mutation has occurred, therefore, it can be reversed only by a second mutation, which either restores the function of the original gene (true reverse mutation) or, by a compensatory change in the biochemical pattern of the cell, restores some degree of function even in the presence of the original (forward) mutation (suppressor mutation). Because reverse mutations must fulfill more specific requirements than forward mutations, the former are usually much rarer than the latter (see GENE; NUCLEIC ACID; and PROTEIN).

In haploid cells (which contain only one set of chromosomes) mutation immediately yields a mutant type. Thus, one mutated yeast cell can grow into many mutant cells that, for example, can ferment a sugar that the original strain could not ferment. In cells with several haploid nuclei (*e.g.*, those of many micro-organisms) or in diploid cells (which contain two chromosome sets; *e.g.*, those of most higher organisms), recessive mutations—*i.e.*, mutations to genes the effects of which are suppressed by nonmutated partner genes—remain hidden until one of the various mechanisms of hereditary transmission has produced a cell with only mutated partner genes.

In higher organisms germinal mutation in reproductive cells is distinguished from somatic mutation in other cells. Somatic mutations form the basis for such changes as a branch with white currants on a red currant bush. Germinal mutations have no effect on the individual in which they occur but may become manifest in subsequent generations. The gametes (mature reproductive cells) are haploid, but diploidy is restored at fertilization by fusion of two gametes. A dominant mutation in either gamete gives rise to mutant offspring; a recessive mutation does so only when the other gamete happens to contain the same mutated gene. This is unlikely for rare mutations, and a recessive mutation may remain hidden for many generations. A special case is sex-linked mutations,

From *Journal of Heredity* (1929)

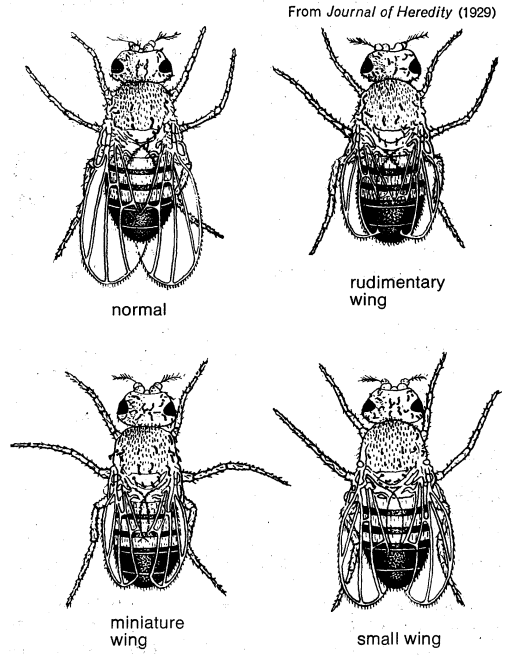


Figure 1: Mutations in the fruit fly *Drosophila*.

which, even if recessive, are always capable of expression in the sex with only one X-chromosome—the male in mammals including man. Thus, a sex-linked mutation to hemophilia expresses itself in the first male who receives the mutated gene through a gamete.

Origin of mutations. *Spontaneous mutation.* In nature, mutations occur spontaneously and unpredictably in single cells out of large populations (one in 100,000 to one in 10,000,000) of, for example, bacteria or spermatozoa.

Mutation frequency

Such a frequency seems to indicate that spontaneous mutations are exceedingly rare events in a slow-breeding species such as man. This rarity is true only when individual genes are considered. A set of human chromosomes contains at least 10,000 genes, and, if each of these mutates at a rate of one in 100,000, one out of every ten spermatozoa or ova (eggs) will carry a newly mutated gene. Because a child may receive a mutated gene from either parent, approximately every fifth child will be born with a newly mutated gene. (This is only a rough estimate, but it is not likely to be too high.) This situation does not mean that every fifth child will show some visible abnormality; the majority of mutations either are recessive or have very slight effects that are likely to be taken for normal variations in development.

The origin of spontaneous mutations is imperfectly understood. Only a fraction of them are caused by cosmic or natural mineral radiation; the remainder probably result from chemical processes in the cell nucleus or from temperature oscillations very close to a gene.

Radiation-induced mutation. The first worker to produce mutations by artificial means was the U.S. scientist H.J. Muller (1927), who exposed fruit flies (*Drosophila*) to X-rays and analyzed their progeny by ingenious methods that allowed quantitative assessment of mutation frequencies. Since then many physical and chemical agents have been shown to be mutagenic (able to cause mutation). The physical ones include all ionizing radiations (*e.g.*, X-rays), ultraviolet light, and, in cells sensitized by certain dyes, visible light. Radioactive phosphorus produces mutations not only through emitted radiation but through incorporation into the chromosomes.

The frequency of X-ray-induced mutations increases linearly with dose; *i.e.*, the output is directly proportional to the input. This finding has been interpreted to mean that every mutation is the result of one ionization event inside a gene or very close to it (target theory). The direct proportionality between X-ray dose and mutation frequency, which has been confirmed for various organisms and for doses as low as eight roentgens (units of radiation), is important in estimating genetical radiation damage. The target theory has been modified to include indirect radiation effects mediated by ionized (charged) components of water, organic substances, and peroxides. The theory is essentially unaltered by these modifications, which help to explain the influences of the physiological state of the cell and environmental conditions such as humidity and, most importantly, oxygen. Oxygen and various chemicals make cells more sensitive to the genetical action of radiation; other chemicals protect against radiation. Some chemicals act by affecting the utilization of oxygen; others, by scavenging mutagenic substances; and still others, by influencing short-lived repair processes that intervene between the original lesion in a chromosome or gene and the actual chromosome break or mutation. In actively metabolizing cells—*e.g.*, oocytes (female reproductive cells) and spermatogonia (immature male reproductive cells), but apparently not in spermatozoa (mature male reproductive cells)—the efficiency of repair seems to depend on radiation intensity; in such cells chronic irradiation produces fewer mutations than does the same dose given as acute radiation. It seems that in these cells very low radiation doses may be less effective than expected from the linear dose-effect relation.

Production and repair of dimers

While the nature of the X-ray-induced lesions in DNA has not yet been established with certainty, ultraviolet light is known to produce dimers—*i.e.*, chemically bonded pairs—between neighbouring pyrimidines, particularly thymines, on the same DNA strand. The dimers can be repaired in various ways before giving rise to mutational changes in DNA; shortwave visible light, for example, opens the chemical bonds between dimers and restores the original state (photorepair). In the dark, and in cells containing certain repair enzymes, the dimers are removed and replaced by new bases (excision repair). DNA containing dimers also may be repaired at the time of the next DNA replication by a process of reorganization involving recombination between two strands (recombination repair); this process probably results in mutant DNA.

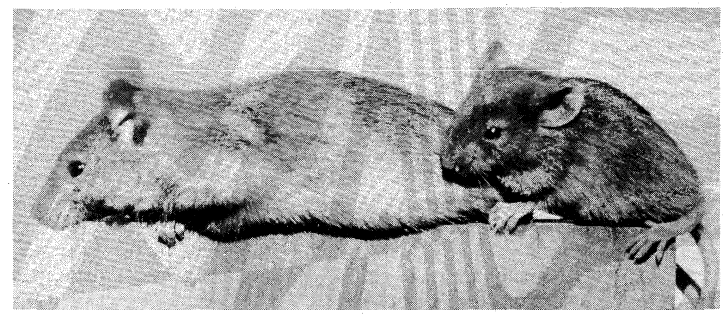

Figure 2: Two-and-a-half-month-old mouse on right, dwarfed as a result of mutation-induced pituitary deficiency, contrasted with normal littermate.
Clyde E. Keeler

In micro-organisms, mutations have been produced by exposing cells to ultraviolet-irradiated growth medium containing mutagenic peroxides. Very high doses of X-rays produce mutagenic chemicals in media used for growing bacteria and plant roots. The mutagenic effect of irradiated medium on *Drosophila*, however, is marginal. Whether radiation-sterilized food can be mutagenic for man is difficult to decide from this evidence.

Mutagenic chemicals. Chemical substances that induce mutation occur in widely divergent chemical groups and range from simple compounds such as formaldehyde to complex ones such as alkaloids. Hypotheses about the way in which chemicals produce mutations have been based mainly on studies of their reactions with DNA isolated from the cell; in some cases these hypotheses have been confirmed or supplemented by experiments with living cells containing DNA. Peroxides form a link between mutagenesis by radiation and by chemicals. Nitrous acid deaminates; *i.e.*, it removes the amino group (NH_2) from purine and pyrimidine bases. Purines such as caffeine, which has produced mutations in bacteria and fungi but not in mice, may act through their influence on nucleic-acid metabolism. Structurally similar compounds (analogues) of the naturally occurring bases in DNA—*e.g.*, 5-bromouracil or 2-aminopurine—produce mutations by first being incorporated in place of a normal base; at one of the following replications of DNA, this reaction may lead to replacement of one of the two normal purines or pyrimidines by the other—*e.g.*, of adenine by guanine. Alkylating agents such as mustard gas, epoxides, and ethylene imines remove guanine from nucleic acid in chemical tests and may do so when producing mutations. Alternatively, they may lead to replication errors via ionization of guanine. Their mutagenic ability is strongly correlated with carcinogenesis, which supports the mutation theory of cancer (see CANCER). Many chemical mutagens tend to produce delayed mutations in the descendants of treated chromosomes or instabilities that continue to give mutations over several or many generations. Some chemicals select specific chromosome regions for their action; others produce "hot spots" by attacking preferentially a few bases in a given gene. The compound hydroxylamine, for example, acts almost exclusively on cytosine; nitrosoguanidine (N-methyl-N-nitro-N-nitrosoguanidine) acts preferentially at the point of DNA replication.

Chemical mutagens have been a tool for "decoding" the information in DNA. In bacteriophage (viruses that attack bacteria), analysis of the frequencies with which certain chemicals produce mutations in opposite directions—from normal to mutant gene and back to normal—has been used to allot specific base pairs to certain

mutational sites, and results obtained with acridine dyes have helped to elucidate the triplet nature of the genetic code and the process of its translation.

Significance of mutation. Natural selection has used mutations to build well-integrated organisms. New mutations are likely to upset this balance and are therefore mostly harmful or lethal. Harmful genes are eliminated from a population by the failure of individuals carrying the mutation to reproduce. Over a long period harmful genes may do more damage than fully lethal ones, for, although a lethal gene kills the first individual in which it becomes active, a harmful gene may be carried through a series of more or less severely affected individuals before it finally kills one of them. Beneficial mutations are so rare that they can be utilized economically only in species with very high reproductive rates. Thus, better strains of *Penicillium* and other industrial fungi and of agricultural plants have been raised from artificially produced mutants. Because this work has been done at the expense of discarding thousands of inferior mutants, the method is obviously not suitable for farm animals. Nor can it be expected that an increase in mutation frequency, as a result of exposure to ionizing radiation from X-ray machines, artificial atomic disintegration, and radioactive isotopes, can have any but harmful effects on the hereditary constitution of the human race. Among chemical mutagens, only the most drastic and penetrating ones—*e.g.*, mustard gas—can be assumed to produce mutations in all cells. Most chemicals are likely to affect different cell types and organisms to different degrees; several have, in fact, been shown to do so. It is exceedingly difficult, therefore, to estimate the genetical hazards to man from chemicals in his environment on the basis of experiments with lower forms or even with other mammals. Organizations have been founded to coordinate this research and to evaluate its results.

The selective production of desirable mutations would be of obvious practical importance, but the repetitive nature of the genetic material makes it most unlikely that specific mutagens for individual genes—as distinct from individual bases—will be found. Before a chemical change in DNA becomes a mutated cell or organism with new properties, however, a series of biochemical events has to occur in the affected cell, and these may be modified by environmental or physiological conditions. Evidence is accumulating that manipulation of these secondary steps in the mutation process may specifically favour the appearance of certain mutations and inhibit that of others.

Mycota

The Mycota, or fungi, are plantlike organisms that lack chlorophyll and are devoid of such organized plant structures as stems, roots, and leaves. Nonetheless, they are among the most successful organisms on earth and are of the greatest importance to man. They include yeasts, rusts, smuts, mildews, molds, mushrooms, and others. The bacteria, formerly considered to be fungi of a very elementary and ambiguous kind (and still so considered by some biologists), are dealt with separately (see BACTERIA). Slime molds, straddling the animal and plant worlds, are touched on in this article but are treated fully elsewhere (see SLIME MOLD).

The mushrooms, by no means the most numerous or economically significant of the fungi, are the most conspicuous members of the group; thus the Latin word for mushroom, *fungus* (plural *fungi*), has come to stand for the whole group. Similarly, the study of fungi is known as mycology—a broad application of the Greek word for mushroom, *mykēs*. Fungi other than mushrooms are sometimes collectively called molds, although this term is better restricted to fungi of the sort represented by bread mold.

IMPORTANCE TO MAN

In 1928 a green mold accidentally grew in a culture dish of *Staphylococcus* bacteria that the bacteriologist Alexander Fleming was studying in a London hospital. The fungus colony that developed inhibited the growth of the bacteria. Such unavoidable contamination certainly had occurred many times before in laboratories throughout the world, but the people who may have seen such cultures probably regarded them as contaminated plates to be discarded as soon as possible. Fleming, however, carefully recorded his observation and in 1929 published a scientific report announcing the discovery of penicillin, the first of a series of antibiotics—many of them derived from fungi—that have revolutionized medical practice.

Ergotism

In 1951 a strange disease broke out in the small French village of Pont-Saint-Esprit. People became convinced that some evil spirit had entered their bodies, and several persons died. Doctors were baffled by the mysterious malady until it was recognized as a form of "St. Anthony's fire"—ergotism—that had resulted from eating bread made from contaminated flour. Ergotism was prevalent in northern Europe in the Middle Ages, particularly in regions of high rye-bread consumption; modern grain-cleaning and milling methods have practically eliminated the disease.

The cause of ergotism is ergot—a fungus. More precisely, ergot is a sclerotium (plural sclerotia), a special part of a fungus that develops on grasses and especially on rye. The wind carries the fungal spores to the flowers of the rye, where the spores germinate, infect and destroy the ovaries of the plant, and replace them with masses of microscopic threads cemented together into a hard fungal structure shaped like a rye kernel but considerably larger and darker. This is ergot—and it contains a number of poisonous organic compounds called alkaloids. A mature head of rye may carry several ergots in addition to noninfected kernels. When the grain is harvested, much of the ergot falls to the ground, but some remains on the plants and is mixed with the grain. If the ergot is not removed before milling, the ergotized flour is used to make bread and consumed; St. Anthony's fire—for which no cure is known—is the result. Nor is this the whole story. The ergot that falls to the ground may be the source of more trouble. Cattle put to graze in the rye fields after harvest are likely to consume enough ergot to bring on abortion of fetuses or death. In the spring, when the rye is in bloom, the ergot remaining on the ground produces tiny, black, mushroomlike bodies that expel large numbers of spores that start a new series of infections.

Among the many interesting chemicals in ergot is lysergic acid, the active principle of the psychedelic drug lysergic acid diethylamide (LSD). Here, then, is a single fungus that can reduce crop yields, cause abortion in cattle, sicken and sometimes kill people, and be used as a source of LSD. On the credit side, ergot provides medical science with drugs useful in inducing labour in pregnant women and in controlling hemorrhage after birth—drugs for which no good substitutes have yet been discovered.

The systematic study of fungi began 250 years ago, but
